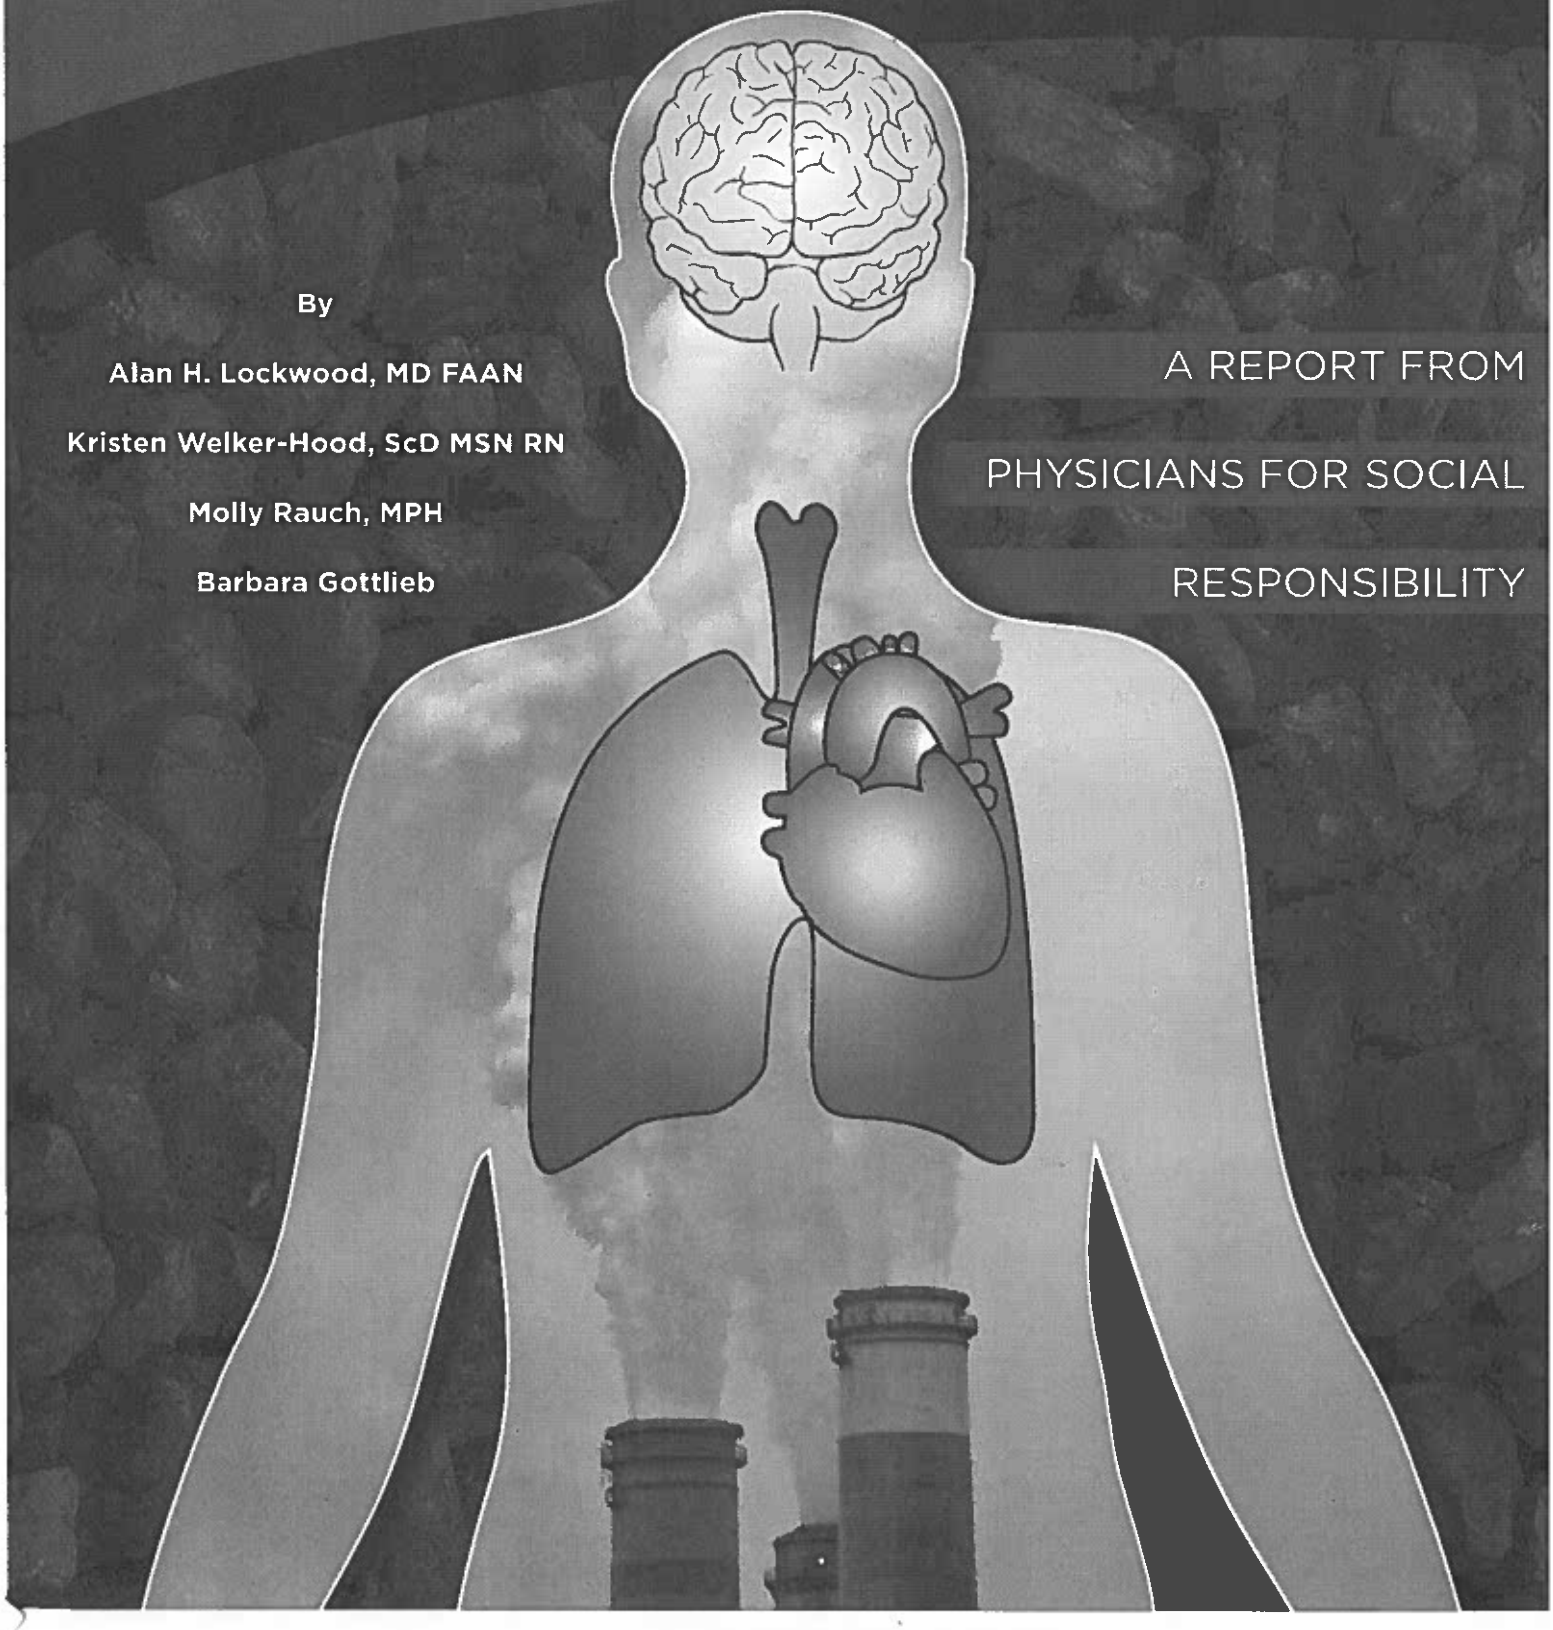
Checklist for Online Medicare, Retirement, & Spouses Applications

The information below will help you gather the information you may need to create a *my* Social Security account and complete the online Medicare, Retirement, and Spouse's applications. We recommend you print this page to use while gathering your information.

Create a *my* Social Security Account



You are required to login to your existing *my* Social Security account, or attempt to create one. To create an account, we will ask you a series of identity questions for verification. You may want to have certain items on hand to be prepared for additional security questions, such as, but not limited to: **mobile phone (for the purpose of receiving texts and emails), credit card, W-2, and tax forms.**

File for Benefits Online – The Information You Need	*Medicare Only*	*Retirement & Spouses*
Date and Place of Birth If you were born outside the United States or its territories: • Name of your birth country at the time of your birth (it may have a different name now) • Permanent Resident Card number (if you are not a U.S citizen)	X	X
MEDICAID Number (State Health Insurance) - Start and End Dates	X	
Current Heath Insurance • Employment start and end dates for the current employer (of you or your spouse) who provides your health insurance coverage through a Group Health Plan • Start and end dates for the Group Health Insurance provided by you (or your spouse's) current employer	X	
Marriage and Divorce • Name of current spouse • Name of prior spouse (if the marriage lasted more than 10 years or ended in death) • Spouse(s) date of birth and SSN (optional) • Beginning and ending dates of marriage(s) • Place of marriage(s) (city, state or country, if married outside the U.S.)		X
Names and Dates of Birth of Children Who: • Became disabled prior to age 22, or • Are under age 18 and are unmarried, or • Are aged 18 to 19 and still attending secondary school full time		X
U.S. Military Service • Type of duty and branch • Service period dates		X
Employer Details for Current Year and Prior 2 Years (not self-employment) • View your Social Security Statement online at ***www.socialsecurity.gov/myaccount*** • Employer name • Employment start and end dates		X
Self-Employment Details for Current Year and Prior 2 Years • View your Social Security Statement online at ***www.socialsecurity.gov/myaccount*** • Business type • Total net income		X
Direct Deposit - Domestic bank (USA) • Account type and number • Bank routing number **Direct Deposit** - International bank (non-USA) • International Direct Deposit (IDD) bank country • Bank name, bank code, and currency • Account type and number, branch/transit number		X

ABOUT PHYSICIANS FOR SOCIAL RESPONSIBILITY

PSR has a long and respected history of physician-led activism to protect the public's health. Founded in 1961 by a group of physicians concerned about the impact of nuclear proliferation, PSR shared the 1985 Nobel Peace Prize with International Physicians for the Prevention of Nuclear War for building public pressure to end the nuclear arms race. Today, PSR's members, staff, and state and local chapters form a nationwide network of key contacts and trained medical spokespeople who can effectively target threats to global survival. Since 1991, when PSR formally expanded its work by creating its environment and health program, PSR has addressed the issues of global warming and the toxic degradation of our environment. PSR presses for policies to curb global warming, ensure clean air, generate a sustainable energy future, prevent human exposures to toxic substances, and minimize toxic pollution of air, food, and drinking water.

7. POLICY RECOMMENDATIONS 43

Executive Summary

Coal pollutants affect all major body organ systems and contribute to four of the five leading causes of mortality in the U.S.: heart disease, cancer, stroke, and chronic lower respiratory diseases. This conclusion emerges from our reassessment of the widely recognized health threats from coal. Each step of the coal lifecycle—mining, transportation, washing, combustion, and disposing of post-combustion wastes—impacts human health. Coal combustion in particular contributes to diseases affecting large portions of the U.S. population, including asthma, lung cancer, heart disease, and stroke, compounding the major public health challenges of our time. It interferes with lung development, increases the risk of heart attacks, and compromises intellectual capacity.

Oxidative stress and inflammation are indicated as possible mechanisms in the exacerbation and development of many of the diseases under review. In addition, the report addresses another, less widely recognized health threat from coal: the contribution of coal combustion to global warming, and the current and predicted health effects of global warming.

ISTOCKPHOTO.COM

THE LIFE CYCLE OF COAL

Electricity provides many health benefits worldwide and is a significant contributor to economic development, a higher standard of living, and an increased life expectancy.[1] But burning coal to generate electricity harms human health and compounds many of the major public health problems facing the industrialized world. Detrimental health effects are associated with every aspect of coal's life cycle, including mining, hauling,

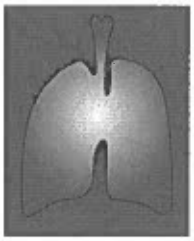
R04292

preparation at the power plant, combustion, and the disposal of post-combustion wastes. In addition, the discharge of carbon dioxide into the atmosphere associated with burning coal is a major contributor to global warming and its adverse effects on health worldwide.

Coal mining leads U.S. industries in fatal injuries[2] and is associated with chronic health problems among miners, such as black lung disease, which causes permanent scarring of the lung tissues.[3] In addition to the miners themselves, communities near coal mines may be adversely affected by mining operations due to the effects of blasting, the collapse of abandoned mines, and the dispersal of dust from coal trucks. Surface mining also destroys forests and groundcover, leading to flood-related injury and mortality, as well as soil erosion and the contamination of water supplies. Mountaintop removal mining involves blasting down to the level of the coal seam—often hundreds of feet below the surface—and depositing the resulting rubble in adjoining valleys. This surface mining technique, used widely across southern Appalachia, damages freshwater aquatic ecosystems and the surrounding environment by burying streams and headwaters.[4]

Coal combustion emissions damage the respiratory, cardiovascular, and nervous systems and contribute to four of the top five leading causes of death in the U.S.

After removal of coal from a mine, threats to public health persist. When mines are abandoned, rainwater reacts with exposed rock to cause the oxidation of metal sulfide minerals. This reaction releases iron, aluminum, cadmium, and copper into the surrounding water system[5] and can contaminate drinking water.[6]



Coal washing, which removes soil and rock impurities before coal is transported to power plants, uses polymer chemicals and large quantities of water and creates a liquid waste called slurry. Slurry ponds can leak or fail, leading to injury and death, and slurry injected underground into old mine shafts can release arsenic, barium, lead, and manganese into nearby wells, contaminating local water supplies. Once coal is mined and washed, it must be transported to power plants. Railroad engines and trucks together release over 600,000 tons of nitrogen oxide and 50,000 tons of particulate matter into the air every year in the process of hauling coal, largely through diesel exhaust.[7] Coal trains and trucks also release coal dust into the air, exposing nearby communities to dust inhalation.[8]

The storage of post-combustion wastes from coal plants also threatens human health. There are 584 coal ash dump sites in the U.S.,[9] and toxic residues have migrated into water supplies and threatened human health at dozens of these sites.[10]

The combustion phase of coal's lifecycle exacts the greatest toll on human health. Coal combustion releases a combination of toxic chemicals into the environment and contributes significantly to global warming. Coal combustion releases sulfur dioxide, particulate matter (PM), nitrogen oxides, mercury, and dozens of other substances known to be hazardous to human health. Coal combustion contributes to smog through the release of oxides of nitrogen, which react with volatile organic compounds in the presence of sunlight to produce ground-level ozone, the primary ingredient in smog.

Table ES.1 (pages x–xi) describes the major health effects linked to coal combustion emissions. These health effects damage the respiratory, cardiovascular, and nervous systems and contribute to four of the top five leading causes of death in the U.S.: heart disease, cancer, stroke, and chronic lower respiratory diseases. Although it is difficult to ascertain the proportion of this disease burden that is attributable to coal pollutants, even very modest contributions to these major causes of death are likely to have large effects at the population level, given high incidence rates. Coal combustion is also responsible for more than 30% of total U.S. carbon dioxide pollution, contributing significantly to global warming and its associated health impacts.

RESPIRATORY EFFECTS OF COAL POLLUTION

Pollutants produced by coal combustion act on the respiratory system to cause a variety of adverse health effects. Air pollutants—among them nitrous oxide (NO_2) and very small particles, known as $PM_{2.5}$—adversely affect lung development, reducing forced expiratory volume (FEV) among children.[11] This reduction of FEV, an indication of lung function, often precedes the subsequent development of other pulmonary diseases.

Air pollution triggers attacks of asthma, a respiratory disease affecting more than 9% of all children in the U.S. Children are particularly susceptible to the development of pollution-related asthma attacks. This may be due to their distinct breathing patterns, as well as how much time they spend outside. It may also be due to the immaturity of their enzyme and immune systems, which assist in detoxifying pollutants, combined with incomplete pulmonary development.[12] These factors appear to act in concert to make children highly susceptible to airborne pollutants such as those emitted by coal-fired power plants.[13]

Asthma exacerbations have been linked specifically to exposure to ozone, a gas produced when NO_2 reacts with volatile organic compounds in the presence of sunlight and heat.[14] The risk to children of experiencing ozone-related asthma exacerbations is greatest among those with severe asthma. That risk exists even when ambient ozone levels fall within the limits set by the EPA to protect public health.

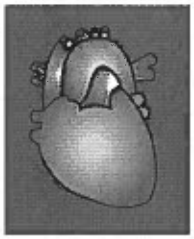
Coal pollutants trigger asthma attacks in combination with individual genetic characteristics.[15] This gene-environment interaction means that some individuals are more susceptible to the respiratory health effects of coal pollution. The genetic polymorphisms that appear to make people more susceptible include those that control inflammation and those that deal with oxidative stress, or the presence of highly reactive molecules, known as free radicals, in cells. (See text box.)

OXIDATIVE STRESS

Oxygen free radicals in biological systems are a normal cellular constituent and play critical roles in the control of many cellular functions. (Free radicals are atoms or molecules that contain at least one unpaired electron in an atomic or molecular orbit and are therefore unstable and highly reactive.)

The concentration of oxygen free radicals can be increased through exposure to environmental substances such as air pollution, tobacco smoke, pesticides, and solvents. When their concentration is excessive, these highly reactive molecules damage lipids, proteins, DNA, cell membranes, and other cellular components. "Oxidative stress" is the term used to describe that physiological state.

Oxidative stress is an important contributing factor in a variety of diseases, including atherosclerosis, hypertension, rheumatoid arthritis, diabetes mellitus, and neurodegenerative disorders such as Alzheimer's disease and Parkinson's disease, as well as normal aging. It is one of several mechanisms implicated in the pathogenesis of diseases caused or made worse by coal pollutants, such as cardiovascular and pulmonary disease.



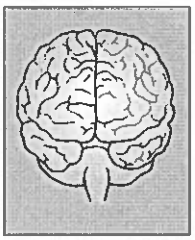
Valko M, Leibfritz D, Moncol J, Cronin MTD, Mazur M, Telser J. Free radicals and antioxidants in normal physiological functions and human disease. Int J Biochem and Cell Biology 2007; 39: 44–84.

Coal pollutants play a role in the development of chronic obstructive pulmonary disease (COPD), a lung disease characterized by permanent narrowing of airways. Coal pollutants may also cause COPD exacerbations, in part through an immunologic response—i.e., inflammation.[16,17,18] PM exposure disposes the development of inflammation on the cellular level, which in turn can lead to exacerbations of COPD. COPD is the fourth leading cause of mortality in the U.S.

R04294

Exposures to ozone and PM are also correlated with the development of[19] and mortality from[20, 21, 22] lung cancer, the leading cancer killer in both men and women.

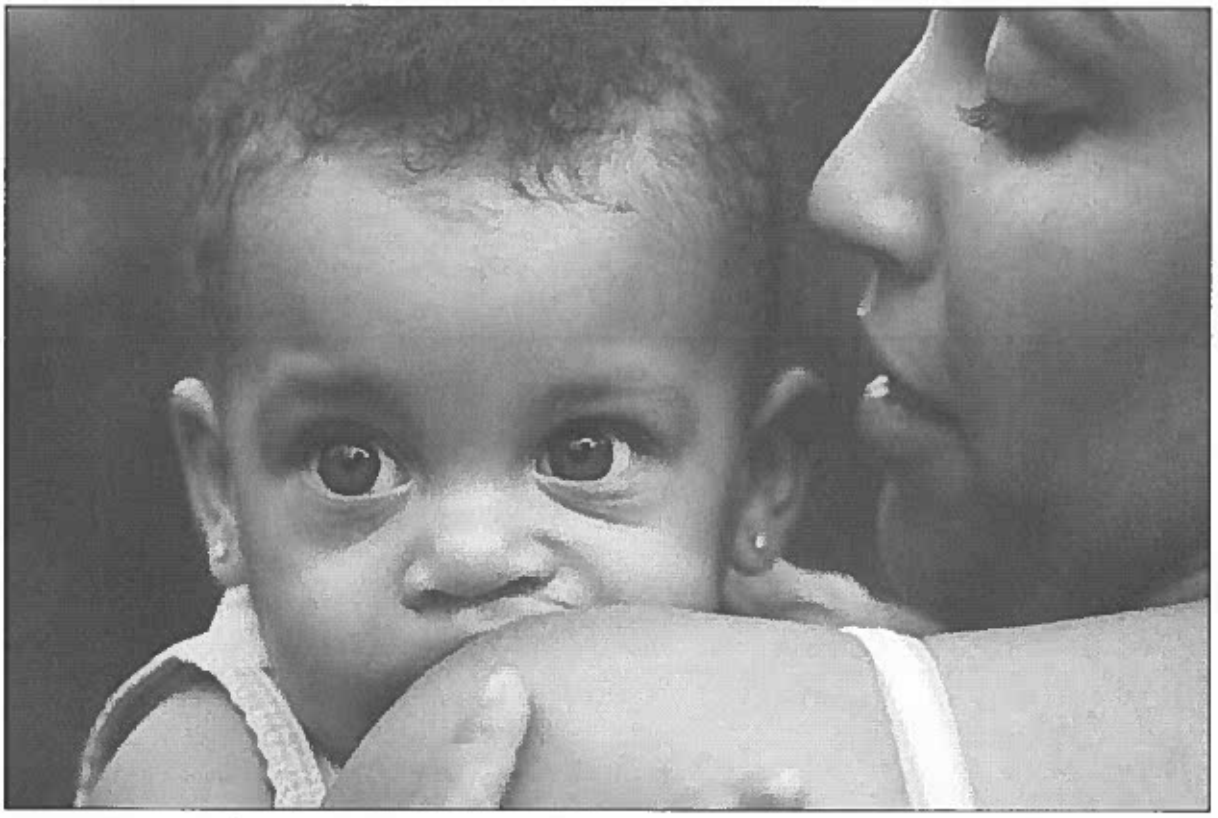
CARDIOVASCULAR EFFECTS OF COAL POLLUTION



Pollutants produced by coal combustion damage the cardiovascular system. Coronary heart disease (CHD) is a leading cause of death in U.S., and air pollution is known to negatively impact cardiovascular health.[23] The mechanisms by which air pollution causes cardiovascular disease have not been definitively identified but are thought to be the same as those for respiratory disease: pulmonary inflammation and oxidative stress. Studies in both animals and humans support this theory, showing that pollutants produced by coal combustion lead to cardiovascular disease, such as arterial occlusion (artery blockages, leading to heart attacks) and infarct formation (tissue death due to oxygen deprivation, leading to permanent heart damage).

Recent research suggests that nitrogen oxides and $PM_{2.5}$, along with other pollutants, are associated with hospital admissions for potentially fatal cardiac rhythm disturbances.[24] The concentration of $PM_{2.5}$ in ambient air also increases the probability of hospital admission for acute myocardial infarction,[25] as well as admissions for ischemic heart diseases, disturbances of heart rhythm, and congestive heart failure.[26] Additionally, cities with high NO_2 concentrations had death rates four times higher than those with low NO_2 concentrations.[27] These studies show important immediate effects of coal pollutants on indicators of acute cardiovascular illness.

There are cardiovascular effects from long-term exposure as well. Exposure to chronic air pollution over many years increases cardiovascular mortality.[28] This relationship remains significant even while controlling for other risk factors, such as smoking. Conversely, long-term improvements in air pollution reduce mortality rates. Reductions in $PM_{2.5}$ concentration in 51 metropolitan areas were correlated with significant increases in life expectancy,[29] suggesting that air quality improvements mandated by the Clean Air Act have measurably improved the health of the U.S. population. Reducing exposure to the pollutants emitted by coal combustion is therefore an important aspect of improving cardiovascular health for the population at large.



NERVOUS SYSTEM EFFECTS OF COAL POLLUTION

In addition to the respiratory and cardiovascular systems, the nervous system is also a target for coal pollution's health effects. The same mechanisms that are thought to mediate the effect of air pollutants on coronary arteries also apply to the arteries that nourish the brain. These include stimulation of the inflammatory response and oxidative stress, which in turn can lead to stroke and other cerebral vascular disease.

Several studies have shown a correlation between coal-related air pollutants and stroke. In Medicare patients, ambient levels of $PM_{2.5}$ have been correlated with hospital admission rates for cerebrovascular disease,[30] and PM_{10} has been correlated with hospital admission for ischemic stroke.[31] (Eighty-seven percent of all strokes are ischemic.) $PM_{2.5}$ has also been associated with an increase in the risk of—and death from—a cerebrovascular event among post-menopausal women.[32] Even though a relatively small portion of all strokes appear to be related to the ambient concentration of PM, the fact that nearly 800,000 people in the U.S. have a stroke each year makes even a small increase in risk a health impact of great importance.[33]

Coal pollutants also act on the nervous system to cause loss of intellectual capacity, primarily through mercury. Coal contains trace amounts

ISTOCKPHOTO.COM

of mercury that, when burned, enter the environment. Mercury increases in concentration as it travels up the food chain, reaching high levels in large predatory fish. Humans, in turn, are exposed to coal-related mercury primarily through fish consumption. Coal-fired power plants are responsible for approximately one-third of all mercury emissions attributable to human activity.[34]

A nationwide study of blood samples in 1999–2000 showed that 15.7% of women of childbearing age have blood mercury levels that would cause them to give birth to children with mercury levels exceeding the EPA's maximum acceptable dose for mercury.[35] This dose was established to limit the number of children with mercury-related neurological and developmental impairments. Researchers have estimated that between 317,000 and 631,000 children are born in the U.S. each year with blood mercury levels high enough to impair performance on neurodevelopmental tests and cause lifelong loss of intelligence.[36]

A continued reliance on coal combustion for electricity will contribute to the predicted health consequences of global warming.

GLOBAL WARMING AND COAL POLLUTION

Coal damages the respiratory, cardiovascular, and nervous systems through pollutants acting directly on the body. But coal combustion also has indirect health effects, through its contribution to greenhouse gas emissions. Global warming is already negatively impacting public health and is predicted to have widespread and severe health consequences in the future. Because coal-fired power plants account for more than one third of CO_2 emissions in the U.S.,[37] coal is a major contributor to the predicted health impacts of global warming.

The effects of global warming already in evi-

Table ES.1: Coal's contributions to major health effects

	Disease or condition	Symptoms or result	Most-vulnerable populations	Total disease burden (coal is a suspected contributing factor in an unknown number of cases)	Coal pollutants implicated
RESPIRATORY	Asthma exacerbations	Coughing, wheezing, shortness of breath, and breathlessness with a range of severity from mild to requiring hospitalization	Children, adults	Number of visits to office-based physicians for asthma: 10.6 million in 2006. Number of hospitalizations with asthma listed first as diagnosis: 440,000.[38] School days missed per year attributable to asthma: 11.8 million.[39]	NO_2 Ozone Particulate Matter (PM)[40,41,42]
RESPIRATORY	Asthma development	New cases of asthma, resulting in coughing, wheezing, shortness of breath, and breathlessness with a range of severity from mild to requiring hospitalization	Children	Children with asthma: 6.7 million (9.1%). Adults with asthma: 16.2 million (7.3%).[43]	Suspected but not confirmed:[44,45,46] NO_2 Ozone $PM_{2.5}$
RESPIRATORY	Chronic Obstructive Pulmonary Disease (COPD)	Emphysema with chronic obstructive bronchitis; permanent narrowing of airways; breathlessness; chronic cough	Smokers, adults	Adults with COPD diagnosis in 2006: 12.1 million.[47] Deaths in 2005: 126,000.[48] Fourth leading cause of mortality in U.S.	NO_2 PM[49,50,51]
RESPIRATORY	Stunted lung development	Reductions in lung capacity; risk factor for development of asthma and other respiratory diseases	Children	Unknown	NO_2 $PM_{2.5}$[52]
RESPIRATORY	Infant mortality (relevant organ system uncertain; may be respiratory)	Death among infants age < 1 year	Infants	Deaths in 2005: 28,384. Almost 25% may have had respiratory causes: 2,234 deaths attributed to Sudden Infant Death Syndrome (SIDS), and 4,698 deaths attributed to short gestation and low birth weight.[53]	NO_2 PM[54,55]
RESPIRATORY	Lung cancer	Shortness of breath, wheezing, chronic cough, coughing up blood, pain, weight loss[56]	Smokers, adults	Deaths in 2005: 159,217. Leading cause of cancer mortality in U.S. among both men and women.[57]	PM[58,59,60]
CARDIOVASCULAR	Cardiac arrhythmias	Abnormal rate or rhythm of the heart; palpitation or fluttering; may cause fatigue, dizziness, lightheadedness, fainting, rapid heartbeat, shortness of breath, and chest pain[61]	Adults, hypertensives, diabetics, those with cardiovascular disease	Unknown	NO_2 $PM_{2.5}$[62]
CARDIOVASCULAR	Acute myocardial infarction	Chest pain or discomfort; heart attack	Adults, diabetics, hypertensives	Deaths in 2006: 141,462.[63] Cases in 2006: 7.9 million.[64]	$PM_{2.5}$[65]
CARDIOVASCULAR	Congestive heart failure	Shortness of breath, fatigue, edema (swelling) due to impaired ability of heart to pump blood; can result from narrowed arteries, past heart attack, and high blood pressure; can lead to death[66]	Adults, hypertensives, diabetics, those with cardiovascular disease	Deaths in 2006: 60,337.[67] Number of people living with heart failure: 5.7 million. New cases diagnosed each year: 670,000.[68]	$PM_{2.5}$[69]

R04297

Table ES.1: Coal's contributions to major health effects, *continued*

	Disease or condition	Symptoms or result	Most-vulnerable populations	Total disease burden (coal is a suspected contributing factor in an unknown number of cases)	Coal pollutants implicated
NEUROLOGICAL	Ischemic stroke	Artery supplying blood to the brain becomes blocked due to blood clot or narrowing;[70] may cause sudden numbness or weakness, especially on one side of body, confusion, trouble speaking, trouble seeing, trouble walking, dizziness, severe headache;[71] effects can be transitory or persistent	Elderly, hypertensives, diabetics	Deaths in 2005: 143,579. Number of strokes occurring each year: 795,000. NOTE: 87% of all strokes are ischemic; statistics are for all strokes.[72]	NO_2 $PM_{2.5}$ PM_{10} SO_2[73,74,75,76]
	Developmental delay	Reduced IQ; mental retardation; clinical impairment on neurodevelopmental scales; permanent loss of intelligence	Fetuses, infants, children	Babies born each year with cord blood concentrations of mercury >5.8 µg/L, the level above which mercury exposure has been shown to reduce IQ: 637,233 (15.7% of all babies born).[77]	Mercury[78]

dence include increases in global average land and ocean surface temperatures; increases in snow melt and receding glaciers; increases in the mean sea level; and changes in precipitation.[79] These global climate changes are already affecting human health. The World Health Organization estimated global warming to be responsible for 166,000 deaths in 2000, due to additional mortality from malaria, malnutrition, diarrhea, and drowning.[80]

In the future, global warming is expected to continue to harm human health. More frequent heat waves are projected to lead to a rise in heat exhaustion and heat stroke, potentially resulting in death, especially among elderly and poor urban dwellers. Declining air and water quality, an increase in infectious diseases, and a shrinking food supply are expected to contribute to disease and malnutrition, increase the migration of affected populations, and increase armed conflict and global instability. Table ES.2 (page xiii) describes the predicted health effects of global warming.

A continued reliance on coal combustion for electricity production will contribute to the predicted health consequences of global warming.

Carbon capture and sequestration (CCS) has been promoted as an effective way to keep CO_2 emissions out of the atmosphere, but substantial research and development are required before it can be used on the scale needed to mitigate global warming. Even then, the danger remains that CCS storage areas, whether underground or under the ocean, could leak, negating the value of CO_2 capture and storage. CCS also incurs other threats to health, including the danger of asphyxiation in the case of a large-scale CO_2 leak and the acidification of ocean waters. Moreover, the application of CCS would require continued coal mining, transportation, combustion, and waste storage, thus prolonging the emission of coal's toxic pollutants that harm human health.

POLICY RECOMMENDATIONS

The U.S. is at a crossroads for determining its future energy policy. While the U.S. relies heavily on coal for its energy needs, the health consequences of that reliance are multiple and have widespread and damaging impact. Coal combustion contributes to diseases already affecting large portions of the U.S. population, including asthma, heart disease, and stroke, thus compounding the major public health challenges of our time. Coal

R04298

combustion also releases significant amounts of carbon dioxide into the atmosphere. Unless we address coal, the U.S. will be unable to achieve the reductions in carbon emissions necessary to stave off the worst health impacts of global warming. Based on that assessment, PSR finds it essential to translate our concern for human health into recommendations for public policy.

- Emissions of carbon dioxide should be cut as deeply and as swiftly as possible, with the objective of reducing CO_2 levels to 350 parts per million, through two simultaneous strategies:
  - Strong climate and energy legislation that establishes hard caps on global warming pollution coming from coal plants.
  - The Clean Air Act (CAA). Carbon dioxide and other greenhouse gas emissions from coal plants have been designated pollutants under the CAA. The EPA should be fully empowered to regulate carbon dioxide under the CAA so that coal's contribution to global warming can be brought to an end.
- There should be no new construction of coal-fired power plants, so as to avoid increasing health-endangering emissions of carbon dioxide, as well as criteria pollutants and hazardous air pollutants.
- The U.S. should dramatically reduce fossil fuel power plant emissions of sulfur dioxide and nitrogen oxides so that all localities are in attainment for national ambient air quality standards.
- The EPA should establish a standard, based on Maximum Achievable Control Technology, for mercury and other hazardous air pollutant emissions from electrical generation.
- The nation must develop its capacity to generate electricity from clean, safe, renewable sources so that existing coal-fired power plants may be phased out without eliminating jobs or compromising the nation's ability to meet its energy needs. In place of investment in coal (including subsidies for the extraction and combustion of coal and for capture of carbon and other pollutants), the U.S. should fund energy efficiency, conservation measures, and clean, safe, renewable energy sources such as wind energy, solar, and wave power.

Unless we address coal, the U.S. will be unable to achieve the reductions in carbon emissions necessary to stave off the worst health impacts of global warming.

These steps comprise a medically defensible energy policy: one that takes into account the public health impacts of coal while meeting our need for energy. When our nation establishes a health-driven energy policy, one that replaces our dependence on coal with clean, safe alternatives, we will prevent the deterioration of global public health caused by global warming while reaping the rewards in improvements to respiratory, cardiovascular, and neurological health.

Table ES.2: Predicted health effects of global warming

Predicted human health effects	Contributing factors	Global warming mechanism	Most-vulnerable populations
Heat cramps, heat syncope, heat exhaustion, heat stroke	Heat waves	• Greenhouse effect	Children, the elderly, urban dwellers, those with underlying conditions such as cardiovascular disease, obesity, and respiratory disease
Diarrhea spread by water-borne bacteria including E Coli, Shigella, and cholera	Flooding, infrastructure damage	• Increase in extreme weather events and storm surges • Sea level rise	Children most vulnerable to death from diarrheal disease
Drowning	Flooding	• Increase in extreme weather events and storm surges • Sea level rise	Children, the elderly
Exacerbations of asthma, chronic obstructive pulmonary disease, and other respiratory diseases	Worsening air quality, heat waves	• Greenhouse effect • Heat increases production of ground-level ozone • Heat increases electricity demand and resulting particulate emissions from fossil fuel combustion • Airborne allergens (such as pollen) predicted to increase with global warming	Children, the elderly, those with preexisting respiratory disease
Infectious diseases: Malaria, dengue fever, yellow fever, West Nile virus, Lyme disease, and other insect-borne infections, as well as rodent-borne infections	Increased ranges and populations of disease-carrying insects and rodents	• Warming climate expands geographic range of insect and rodent vectors • High temperatures boost reproductive rates, lengthen breeding season, and increase bite frequency of insect vectors • High temperatures boost parasite development	Children, those with impaired immune systems, the developing world
Heart disease, heart attacks, congestive heart failure and other cardiovascular diseases	Worsening air quality	• Heat increases production of ground-level ozone • Heat increases electricity demand and resulting particulate emissions from fossil fuel combustion	Adults and the elderly
Hunger, malnutrition, starvation, famine	Reduced crop yields; crop damage; crop failure; disruptions in forestry, livestock, fisheries	• Changes in the water cycle leading to drought • Heat decreases reproductive lifecycle of some major food crops • Expanded range of some insect pests • Increase in extreme weather events • Changes in ecology of plant pathogens • Loss of agricultural land due to sea level rise	Children, the poor
Mass migration; violence; war	Societal instability; infrastructure damage; reduced crop yields	• All of the above	Children, the elderly, those with other underlying medical conditions
Mental health problems	All of the above	• All of the above	Varied

1. *Introduction*

Almost half of the energy used to generate electricity in the United States comes from burning coal, as shown in Figure 1.1. Coal is a major component of the economy and forms the center around which political, economic, health, and environmental considerations coalesce. The U.S. holds extensive coal reserves, although how much of that coal is accessible at a commercially viable cost is subject to debate. The high-end estimate 491 billion tons, which would be enough to last as much as 250 years at the current rate of consumption, earned the U.S. the title of the "Saudi Arabia of Coal."[1] In 2006, the electric power industry burned 1.026 billion tons of coal (see Figure 1.2). The electric industry currently plans to build as many as 100 new coal plants, adding to the approximately 600 large coal-burning power plants already in existence.

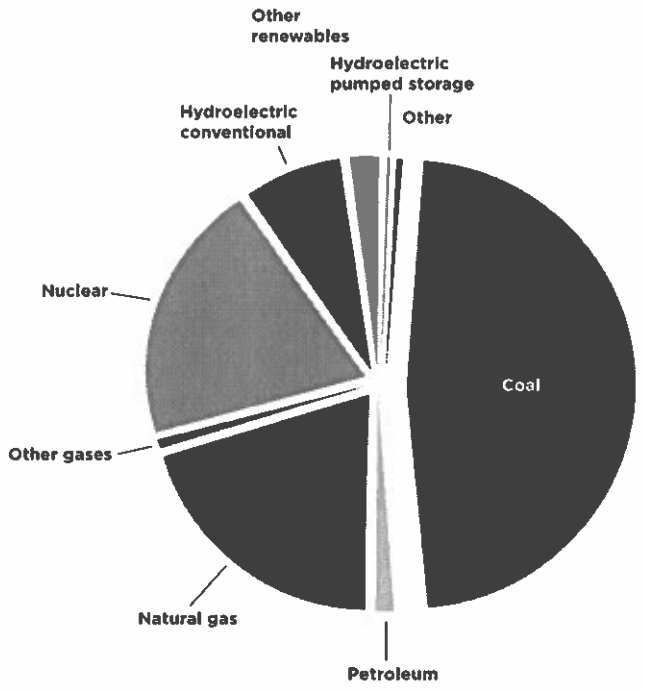
Using coal has a variety of major adverse impacts on health. Mining, transporting, burning, and disposing of the products of coal combustion all place human health at risk. With the passage of time, more and more adverse health effects have been attributed to the increasing reliance on coal. Studies of the health effects of hazardous air pollutants date clearly to 1872 with the publication of *Air and Rain: the Beginning of Chemical Climatology* by Robert Angus Smith. Since then, there have been a number of sentinel events that link episodes of severe air pollution to a variety of illnesses.[2] In October, 1948, almost half of the 14,000 residents of Donora, Pennsylvania were sickened when

ISTOCKPHOTO.COM

atmospheric conditions trapped toxic emissions from a nearby smelter: 20 died and 400 required hospitalization. In 1952, the infamous "killer fog" in London, lasting four days, sent death rates and hospital admissions soaring. Overall hospital admissions increased by 43%; those due to respiratory diseases rose by 163%. Almost 12,000 deaths

R04304

were attributed to this environmental disaster caused, in part, by burning coal.



The link between burning coal and adverse health was made strikingly clear in Dublin, Ireland in the 1990s.[3] Because of increases in the cost of fuel oil in the 1980s, Dubliners switched from oil to bituminous coal to heat their homes and provide hot water. Subsequent increases in air pollution were associated with an increase in in-hospital deaths due to respiratory diseases. This led the Irish government to ban the marketing, sale, and distribution of bituminous coal on September 1, 1990. In the year that followed, black smoke concentrations declined by 70% (35.6 μg/m³), respiratory deaths fell by 15.5%, and cardiovascular deaths fell by 10.3%. Approximately 450 lives were calculated to be saved that year by this measure, and hundreds of acute illnesses were prevented. Although burning coal was not the only cause of these illnesses, burning coal was clearly a major factor in the production of the complex mixture of airborne pollutants that had protean adverse effects on human health.

For each TerraWatt hour of electricity generated by coal, 24.5 deaths are expected in addition to 225 serious illnesses and 13,288 minor illnesses.

Many of coal's pollutants were identified by the U.S. Environmental Protection Agency in its 1998 report Report to Congress.[4] This report identified as many as 67 different hazardous air pollutants (HAPS) emitted from coal plants, but did not address particulates or oxides of nitrogen and sulfur (NO_x and SO_x), now referred to as criteria pollutants. Particulates, mercury, NO_x, SO_x, and the pollutants they give rise to, such as ozone, are now recognized as posing the greatest threats to health, and are the focus of much of this report.

Recent peer-reviewed reports provide estimates of the morbidity and mortality associated with burning coal. European data reported by Markandaya and Wilkinson show that for each TerraWatt hour of electricity generated (1 TWh = 10^{12} Watt hours), 24.5 deaths are expected (95% CI = 6.1–98) in addition to 225 serious illnesses (95% CI = 56.2–899) and 13,288 minor illnesses (95% CI = 3,322–53,150).[5] Burning lignite, a softer form of coal that yields more pollutants than bituminous coal, raises these numbers to 32.6 deaths (95% CI = 8.2–130), 298 serious illnesses (95% CI = 74.6–1,193), and 17,676 minor illnesses (95% CI = 4,419–70,704). To give these data perspective, consider the fact that nearly half of the 4,160 TWh of electricity generated in the United States in 2007 came from coal-fired power plants.[6] If these estimates are applied to the U.S., as many as 50,000 deaths per year may be attributable to burning coal. Although differences in population density between Europe and the U.S. are substantial and there are large boundaries on the 95% con-

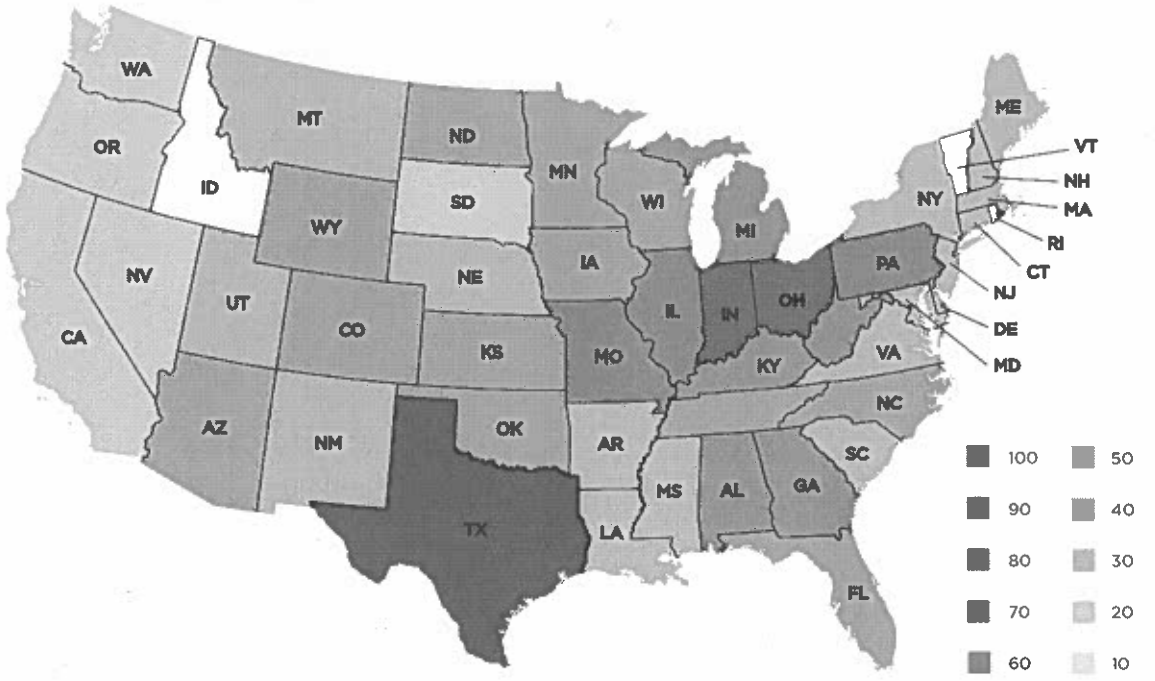


Figure 1.1: Sources of energy used for generation of electricity, 2006

fidence limits associated with these data, it is clear that burning coal has major adverse health effects.

In seeking to describe relationships between health and any single pollutant or any single source of the pollutant, notably burning coal, difficulties arise due to multiple sources of the pollutant in question and multiple health impacts. This is a particular issue with regard to SO_x, NO_x, and particulates, as there are many important sources of these pollutants in addition to burning coal. This is less of a problem in regard to mercury, where coal is the acknowledged largest single source of emissions. Thus, in this report we draw on literature that goes beyond that in which authors limit themselves to coal as the sole source of the pollutant in question.

In describing the health effects of coal combustion, this report utilizes an organ-system approach rather than a pollutant-based review. By considering coal's impact on the respiratory system, the cardiovascular system, and the central nervous system, we replace a piecemeal approach with a fuller and more integrated assessment of coal's overall effect on human health. To the best of our knowledge, this approach has not been taken in previous reviews of coal's health implications. To minimize bias, whenever possible we cite contemporary peer-reviewed medical literature and reports published by governmental agencies such as the U.S. Environmental Protection Agency and the Department of Energy. We hope that this report will provide physicians, other healthcare providers,

R04306

policy-makers, and concerned citizens with the information they need to make informed choices that affect the future of burning coal to produce electrical energy.

2. *Coal's Life Cycle*

Although people have burned coal for hundreds of years, the demand for coal exploded during the industrial revolution. Initially, coal powered the steam engine and therefore became the essential fuel for transportation during the nineteenth century, when steamships and railroads flourished. By fueling the steam shovel, coal became the vehicle for its own excavation. By the middle of the 1800s, coal replaced charcoal in the production of iron and steel, thus filling another key role in driving industrialization. Coal became a source of energy for the generation of electricity at the end of the 1800s.

Oil eventually replaced coal as the fuel of choice in the transportation industry. However, coal has once again become the dominant source of energy for the generation of electricity. Because more than 25% of the world's recoverable coal reserves are in the U.S. and because it is cheap, there has been a recent resurgence of coal as an energy source among utilities.[1] This modern coal boom is exemplified by the dozens of new coal plants currently in the planning or construction stage.

Today coal is the predominant source of energy used to produce electricity. Almost half of the energy used to generate electricity in the U.S. in 2007 came from coal, mined in such states as Wyoming, West Virginia, Kentucky, and Pennsylvania.[2] In addition to its major role in the generation of electricity, large amounts of coal are used by the steel industry. According to the World Coal Institute,

BELKNAP/ISTOCKPHOTO.COM

almost 70% of global steel production is dependent on coal.[3]

Coal is formed from fossilized prehistoric plants subjected to heat and pressure over millions of years. Coal is classified into four main types, or ranks, based on moisture and carbon content: lignite, sub-bituminous, bituminous, and anthracite (see Table 2.1). High-carbon coals produce the most energy when burned and low-carbon coals produce the least. Lignite is the lowest rank of coal, having the highest moisture content and the lowest energy content. Sub-bituminous coal is the next highest rank, with a lower moisture content and higher carbon content than lignite. Harder, black coals are higher in rank and include bituminous coal, the most abundant form of coal in the U.S., and anthracite, the hardest, richest in carbon and the rarest. Impurities such as sulfur and heavy

R04308

Table 2.1: The ranks of coal

Rank	Appearance	Percent carbon content	Uses	Percent of world reserves	Percent of U.S. production	Largest U.S. producers
Lignite	Brown, soft, flaky	25–35	Power generation	17	7	Texas, North Dakota
Sub-bituminous	Brownish-black, soft	35–45	Power generation, cement manufacture, industrial uses	30	44	Wyoming (Powder River Basin)
Bituminous	Black, hard	45–86	Power generation, cement manufacture, industrial uses	52	49	West Virginia, Kentucky, Pennsylvania
Anthracite	Black, hard, glossy	86–97	Domestic/industrial uses	1	Less than 0.5	Pennsylvania

metals are incorporated into coals as they are formed and are released when coals are burned or cleaned.

Electricity generation provides many benefits worldwide, and is synonymous with economic development, higher standards of living, and increased life expectancy.[4] However there are major health costs associated with the use of coal. Detrimental health effects are associated with every aspect of its life cycle, including mining, hauling, preparation at the power plant, combustion, and the disposition of post-combustion wastes. This section reviews in brief the human health effects of coal's life cycle.

MINING

Coal is extracted from underground and surface mines. The two main types of underground mines in the U.S. are longwall mines and room-and-pillar mines. In longwall mines, long sections of coal are removed without the use of supporting structures. This may lead to the subsidence of the land above. In room-and-pillar mines, sections of rock are not excavated (the "pillars") in order to provide structural support for the adjoining areas where all the coal is removed (the "rooms"). Both types of mines involve excavating shafts hundreds of feet deep, the installation of elevators, massive conveyance machinery, and air circulation technology.

Surface mining accounts for 69% of the coal mined in the U.S.[5] Used when the coal seam is close to the surface (less than 200 feet deep), it is cheaper than underground mining and often high-yield. In this method, vegetation, topsoil, and rock are blasted and removed down to the level of the coal seam, which is then mined. The top ten coal-producing mines in the U.S. are surface mines in the Powder River Basin of Wyoming.[6] "Mountaintop removal" is the name given to another type of surface mining, used to reach coal seams in mountainous terrain. It involves blasting down to the level of the coal seam—often hundreds of feet below the surface—and depositing the resulting rubble in adjoining valleys.

Coal mining leads U.S. industries in fatal injuries.[7] According to the National Institute for Occupational Safety and Health, the 2006 fatality rate in coal mining was 49.5 per 100,000 workers, more than 11 times greater than that in all private industry (4.2 per 100,000).[8] There were 47 occupational fatalities in coal mining in 2006, 34 in 2007, and 30 in 2008.[9] Underground coal mining is more dangerous than surface mining. Of 47 coal mining fatalities in 2006, 37 occurred in underground mining operations. The nonfatal injury rate in mining, of 3.9 per 100 full time workers in 2001, compares favorably to other private sector workers, where the average incidence rate of nonfatal injury was 5.4 in 2001.[10]

Coal mining is also associated with chronic health problems among miners. Black lung disease is caused by inhalation of respirable coal mine dust, which causes lung tissue scarring.

Although technology and prevention strategies have improved incidence and mortality rates in the past century, black lung disease still disables large numbers of ex-miners and claims many lives each year.[11] According to the National Institute of Occupational Safety and Health, black lung disease has been responsible for approximately 10,000 deaths in the past 10 years.

In addition to the miners themselves, communities proximate to coal mines may be adversely affected by mining operations. Injuries and even deaths may result from physical damage to surrounding communities due to blasting at surface mines and subsidence of underground mines. Surface mining also destroys forests and groundcover, leading to flood-related injury and mortality, as well as soil erosion and the contamination of water supplies. Rubble, or "overburden," is deposited on the surface, destroying plants and animals and introducing into the food web trace minerals and metals once deeply buried. One study of West Virginians found that people living in high coal-producing counties had higher rates of cardiopulmonary disease, chronic obstructive pulmonary disease, hypertension, lung disease, and kidney disease compared to people living in low coal-producing counties,[12] raising the possibility that coal mining operations may exacerbate a range of chronic health conditions among people living in nearby communities.

Coal mining operations may exacerbate a range of chronic health conditions among people living in nearby communities.

Flooding and contamination of water supplies are of particular concern in Appalachia, where mountaintop removal mining is widespread. The Environmental Protection Agency estimated in 2005 that mountaintop removal mining had adversely impacted 1,200 miles of streams in a study area that included parts of Kentucky, West Virginia, Virginia, and Tennessee. These 1,200 miles represented 2% of streams in the study area. The study further concluded that 724 miles of streams had been directly buried by valley fill related to mountaintop removal mining through 2001.[13] There are no official current estimates of the extent of the practice, but one advocacy organization estimated that by 2005, more than 450 mountain summits had been destroyed by mountaintop removal mining.[14] The human health effects of burying streams under piles of rubble have not been quantified, but include flood-related injury and mortality and contamination of drinking water and surface water resources with arsenic and other pollutants.[15]

After removal of coal from a mine, threats to public health persist. When mines are abandoned, rainwater reacts with exposed rock to cause the oxidation of metal sulfide minerals. These reactions generate acid and release contaminants such as heavy metals into the surrounding water system.[16] Red, orange, or yellow sediments in streams near abandoned mines are markers for this acidic mine drainage. The degraded water resulting from acid mine drainage renders the water undrinkable, and can corrode culverts and bridges.[17]

WASHING AND TRANSPORT

Coal is usually washed before it is transported to power plants to separate it from soil and rock impurities. Washing uses polymer chemicals and large quantities of water, and creates a liquid waste called slurry or sludge that must be stored. The slurry is the consistency of cement, and in addition to water, mud, and polymer chemicals, it contains heavy metals such as arsenic and mercury that are common in mined rock. Mine operators construct dams to impound the slurry in ponds, or inject it back into closed mines. Both slurry disposal strategies—the construction of surface impoundments and underground injection into closed mines—may leach chemicals into groundwater supplies. This is an aspect of mining that has not been examined closely.[18] In addition, both of these waste storage strategies can leak or break. Impoundment failures in the past have caused death and injury, including the 1972 Buffalo Creek, West Virginia, impoundment failure that killed 125 people and

R04310

injured 1,000. More recently, an impoundment breach in 2000 of about 250 million gallons of slurry near Inez, Kentucky, disrupted local water supplies but did not cause injuries or deaths.[19] Slurry injected underground into old mine shafts has the potential to release arsenic, barium, lead, and manganese into nearby wells, contaminating local water supplies.

Once coal is mined and washed, it must be transported to power plants. Coal is hauled to plants by train, truck, barge, and conveyor. Trains are the most economical way to move coal long distances and play the largest role in coal transport. In 2005, railroads accounted for 70% of coal shipments to power plants.[20] Together, railroad engines and trucks release over 600,000 tons of nitrogen oxide and 50,000 tons of particulate matter into the air every year in the process of hauling coal,[21] largely through diesel exhaust. Diesel engines currently produce approximately 1.8 million tons of NOx and 63,000 tons of small particles (less than 2.5 microns in diameter) each year.[22] These emissions adversely impact many organ systems, as this report will detail. Coal trains and trucks also release coal dust into the air as they move, degrading air quality and exposing nearby communities to dust inhalation.[23]

COMBUSTION

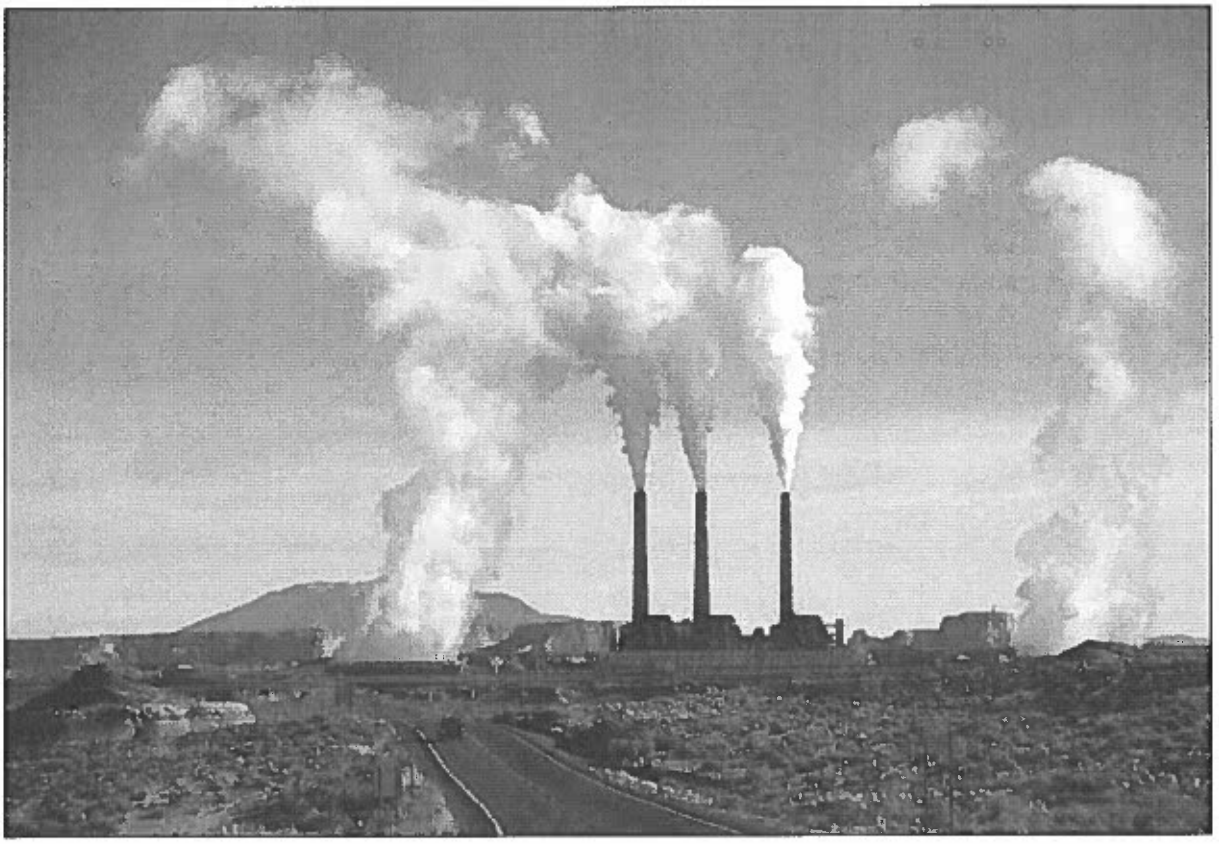
It is during the combustion phase of coal's lifecycle that our dependence on coal energy exacts the greatest toll on human health. Coal combustion releases over 70 harmful chemicals into the environment and contributes significantly to global warming (see Table 2.2). This section describes the pollutants emitted by coal combustion.

Coal combustion creates both solid and gaseous byproducts. Gas byproducts are emitted into the atmosphere through smokestacks. Some solids go into the atmosphere as well. Other solids are left behind at the plant as solid waste, also called coal ash. Some of the pollutants entering the air stay in the atmosphere for long periods; others fall to the earth and in turn pollute soil and water bodies. Some substances are not directly harmful but undergo chemical reactions in the atmosphere that create harmful secondary pollutants.

The pollutant composition of coal varies according to the geologic conditions of its formation. For example, plants that once lived and died in sea water formed coal with high sulfur content, while plants buried under fresh water formed low-sulfur coal. Thus, coals from different ranks and even from different mines differ not only in heat production and carbon content but also in pollutant composition. Such differences may affect local air quality concerns, as power plants may produce different pollution emissions depending on which coals are being burned.[24]

Notwithstanding local differences in pollutant composition, coal combustion causes pollution nationwide. Though coal supplies roughly 50% of the nation's electricity, it produces a disproportionate share of electric utility-related pollution. Coal plants emit approximately 87% of total utility-related nitrogen oxide pollution, 94% of utility-related sulfur dioxide pollution, and 98% of all utility-related mercury pollution.[25] Even across economic sectors, coal plants are responsible for a large share of human-caused air pollution: they are the single largest source of sulfur dioxide, mercury, and air toxic emissions and the second largest source of nitrogen oxide pollution.[26,27] Coal combustion is also responsible for more than 30% of total U.S. carbon dioxide pollution, contributing significantly to global warming.

Criteria air pollutants are a class of ubiquitous, harmful pollutants designated under the Clean Air Act. They are the only pollutants for which the EPA sets legal limits, called the National Ambient Air Quality Standards, on the amounts allowed in ambient air. These standards are based on health risk considerations. There are six criteria pollutants: nitrogen oxides, ozone, sulfur oxides, particulate matter, lead, and carbon monoxide. Coal combustion produces significant quantities of nitrogen oxides, sulfur oxides, and particulate matter, and contributes to the production of ground-level ozone.



Coal-fired power plants are second only to automobiles as the largest source of nitrogen oxide

Table 2.2: The health effects of power plant pollutants

Pollutant	What is it?	How is it produced?	Health effects	Most vulnerable populations
Ozone	Ozone is a highly corrosive, invisible gas	Ozone is formed when nitrogen oxides (NOx) react with other pollutants in the presence of sunlight.	Rapid shallow breathing, airway irritation, coughing, wheezing, shortness of breath. Makes asthma worse. May be related to premature birth, cardiac birth defects, low birth weight, and stunted lung growth.	Children, elderly, people with asthma or other respiratory disease. People who exercise outdoors.
Sulfur Dioxide (SO_2)	SO_2 is a highly corrosive, invisible gas. Sulfur occurs naturally in coal.	SO_2 is formed in the gases when coal is burned. SO_2 reacts in the air to form sulfuric acid, sulfates, and in combination with NO_x, acidic particles.	Coughing, wheezing, shortness of breath, nasal congestion and inflammation. Makes asthma worse. SO_2 gas can destabilize heart rhythms. Low birth weight, increased risk of infant death.	Children and adults with asthma or other respiratory disease.
Particulate Matter (PM)	A mixture of small solid particles (soot) and tiny sulfuric acid droplets. Small particles are complex and harmful mixtures of sulfur, nitrogen, carbon, acids, metals, and airborne toxics.	Directly emitted from coal burning. Formed from SO_2 and NO_x in the atmosphere.	PM crosses from the lung into the bloodstream resulting in inflammation of the cardiac system, a root cause of cardiac disease including heart attack and stroke leading to premature death. PM exposure is also linked to low birth weight, premature birth, chronic airway obstruction and remodeling, and sudden infant death.	Elderly, children, people with asthma.
Nitrogen Oxides (NO_x)	A family of chemical compounds including nitrogen oxide and nitrogen dioxide. Nitrogen occurs naturally in coal.	NO_x is formed when coal is burned. In the atmosphere can convert to nitrates and form fine acidic particles. Reacts in the presence of sunlight to form ozone smog.	NO_x decreases lung function and is associated with respiratory disease in children. Converts to ozone and acidic PM particles in the atmosphere.	Elderly, children, people with asthma.
Mercury	A metal that occurs naturally in coal.	Mercury is released when coal is burned.	Developmental effects in babies that are born to mothers who ate contaminated fish while pregnant. Poor performance on tests of the nervous system and learning. In adults, may affect blood pressure regulation and heart rate.	Fetuses and children are directly at risk. Pregnant women, children, and women of childbearing age need to avoid mercury exposure.
Carbon Dioxide	Coal has the highest carbon content of any fossil fuel.	Carbon dioxide is formed when coal is burned.	Indirect health effects associate with climate change including the spread of infectious disease, higher atmospheric ozone levels, and increased heat- and cold-related illnesses.	People of color, children, people with asthma.

DREAMSTIME.COM

pollution, producing 18% of total U.S. nitrogen oxide emissions.[28] Nitrogen oxides are respiratory irritants.[29] They also pose a serious health risk as ozone precursors. Ground level ozone, also known as smog, is formed when nitrogen oxides react with volatile organic compounds in the presence of heat and sunlight. According to the American Lung Association, 175.4 million Americans live in counties with unhealthy ozone levels, representing more than half of the total U.S. population.[30] Ground level ozone is one of the nation's most pervasive air pollutants, and is particularly harmful to children and the elderly.

Sulfur occurs naturally in coal. Upon combustion, sulfur dioxide, a respiratory irritant, is emitted from coal plants and once in ambient air forms acid rain and particulate pollution. Coal-fired power plants are responsible for two thirds of the nation's sulfur dioxide emissions.[31]

Particle pollution is a complex combination of solids and aerosols suspended in the ambient air. It is categorized by researchers by size: PM_{10}, less than 10 microns in diameter, and $PM_{2.5}$, less than 2.5 microns in diameter. (By comparison, a human hair is about 70 microns in diameter.) Particle pollution is linked to asthma attacks as well as cellular inflammation, a risk factor for a range of chronic diseases. It has been estimated that coal plants in the U.S. will release 217,000 tons of PM_{10} and 110,000 tons of $PM_{2.5}$ in 2010.[32] These emissions estimates do not include secondary particle pollution, formed by the condensation of atmospheric gases such as oxides of nitrogen and sulfur with other pollutants, many of which are also released by coal plants.

The criteria pollutants produced by coal combustion carry large costs to society. The National Research Council has estimated the external costs associated with emissions of nitrogen oxides, sulfur dioxide, and PM from coal-fired power plants in the U.S. at $62 billion in 2005.[33]

In addition to the emissions of criteria pollutants, coal combustion is also a major source

of Hazardous Air Pollutants (HAPs), a class of harmful pollutants for which emissions limits, as opposed to allowable ambient air levels, are set by the EPA. These emissions limits are dictated by the technologies available to control pollution instead of by health risk considerations. There are 189 HAPs designated under the Clean Air Act.

In EPA smokestack tests released in 1998, coal plants were found to emit 67 different HAPs, many of which are known or probable human carcinogens, neurotoxins that can harm brain development, and reproductive toxins. These 67 HAPs include arsenic, beryllium, cadmium, chromium, lead, manganese, mercury, nickel, hydrogen chloride, hydrogen fluoride, acrolein, dioxins, formaldehyde, and radionuclides.[34] Based on exposure and risk estimates, the EPA identified four coal-related HAPs as posing potential risks to human health: mercury, dioxins, arsenic, and nickel. Mercury is the HAP of greatest concern emitted through coal combustion, due to its impacts on the nervous system. In 2007, electric utilities were responsible for more than 70% of all mercury air emissions.[35] Almost all of this mercury came from coal combustion.

Table ES.1 (see pages x–xi) describes the major health effects linked to coal combustion emissions. These health effects damage the respiratory, cardiovascular, and nervous systems and contribute to four of the top five leading causes of death in the U.S.: heart disease, cancer, stroke, and chronic lower respiratory diseases. These health effects are discussed further in subsequent sections. Although it is difficult to ascertain the proportion of this disease burden that is attributable to coal pollutants, even very modest contributions to these major causes of death are likely to have large effects at the population level, given high incidence rates.

POST-COMBUSTION WASTES

Coal's health effects extend beyond combustion. The potential hazards posed by post-combustion wastes are not a new problem, but one that has received little attention. In 2007, in response to complaints by interest groups, the EPA surveyed a number of sites where coal ash slurry, the residue left after burning coal, is stored. It found that damage to human health or the environment was inflicted at nine of the sites and potential damage was present at another 25.[36] A subsequent risk assessment showed that toxic residues from coal ash storage sites had migrated into water supplies and threatened human health at approximately 24 sites.[37] Then in December, 2008, a spill of approximately one billion gallons of coal ash slurry in Tennessee inundated hundreds of acres and threatened to contaminate drinking water and waterways with toxic metals, including lead and arsenic. Thus, coal poses risks to health from the point it is extracted from the ground, through combustion, and even afterwards as a toxic waste.

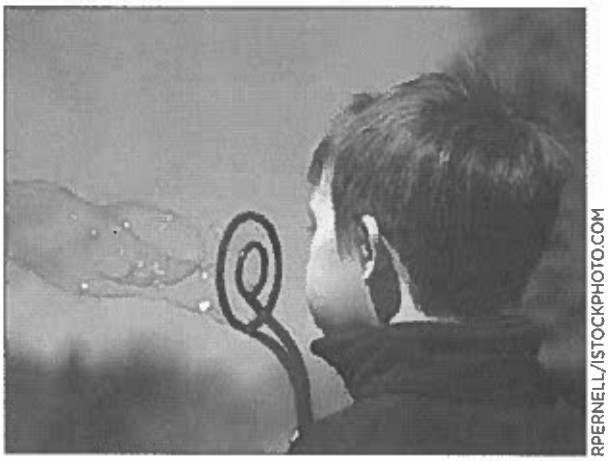
3. *Coal's Effects on the Respiratory System*



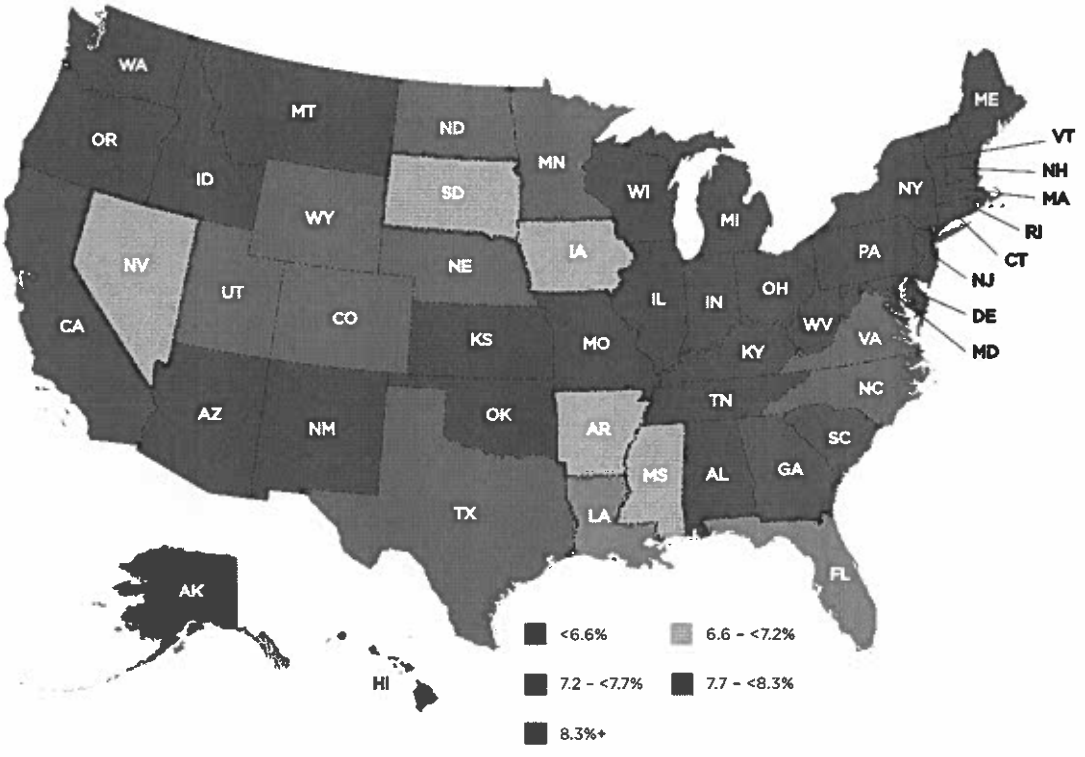
Virtually all airborne pollutants gain access to the body via the respiratory tract. Thus, it is no surprise that this important system is affected significantly by pollutants discharged into the atmosphere by electrical utilities that burn coal. These effects fall into several classes: *de novo* production of a condition, such as asthma, that did not exist prior to an exposure; an exacerbation of a previously-existing illness, again, such as asthma; and the development or progression of a chronic illness such as asthma, lung cancer, chronic obstructive pulmonary disease (COPD), and emphysema.

Data from the California Children's Health study have shown that air pollutants have clinically and statistically significant adverse effects on lung development.[1] In this prospective study, 1759 children were enrolled when they were in the fourth grade, when they were approximately 10 years old, and followed until age 18. Various measures of lung function were made periodically and correlated with their exposure to various pollutants. During normal development, the amount of air that can be forcibly exhaled in one second (FEV_1) increases with age. After controlling for various factors that could potentially confound the results, the investigators found that the FEV_1 failed to increase as predicted among children exposed to NO_2, acid vapor, and $PM_{2.5}$. Using a reduction of FEV_1 to 80% or less of the predicted value, children exposed to the highest levels of particulates were almost five times more likely to fall into the abnormal range than those with the lowest exposures. This impact on lung development is likely to be an additional risk factor for the subsequent development of other pulmonary diseases, such as asthma and chronic obstructive pulmonary disease.

ASTHMA

Asthma is a chronic disease of the lungs characterized by inflammation and narrowing of the airways. Patients with asthma experience recurrent episodes of dyspnea (shortness of breath), a sensation of tightness in the chest, wheezing, and coughing that typically occurs at night or early in the morning. Airway inflammation in asthmatics

RPERNELL/ISTOCKPHOTO.COM



R04316

causes swelling that narrows a bronchial tree that has been previously sensitized to inhaled irritants, including many air pollutants. Exposure to an inhaled irritant causes further narrowing of the airways and the production of mucus that makes airways even narrower. During severe attacks, the lungs fail to perform their task of exchanging carbon dioxide, produced by metabolic processes in the body, for oxygen. This can lead to hypoxia (low blood oxygen level), hypercarbia (high blood carbon dioxide level), and respiratory acidosis (acidification of the blood caused by carbon dioxide retention) that may, in turn, cause cardiac arrhythmias and death. There are about 22 million asthmatics in the U.S., including 6 million children.[2] The Centers for Disease Control and Prevention report that the number of persons with asthma increased by 84% from 1980 to 2004. As shown in Figure 3.1, more than half of the states report that 8.6% or more of its inhabitants have asthma. These high-asthma states are clustered in the northeast and Midwest.

During an asthma attack, the airway is constricted due to inflammation and contraction or spasm of the muscles that surround the airway. This is associated with swelling of the tissues of the airway caused by triggers, or stimuli, which in turn cause an immune response. Asthmatics are more sensitive to these triggers than non-asthmatics, a condition known as hypersensitivity. There are many triggers, including dust, smoke, pollen, and volatile organic compounds. Some of the

OXIDATIVE STRESS

The possibility that oxygen, or reactive forms of oxygen, might be toxic to certain cellular functions emerged in the 1950s. Subsequent research has focused on the importance of highly reactive forms of oxygen, known as oxygen free radicals, in biological systems. We now know that some of these free radicals exert critical controls over normal cellular metabolic process and cellular signaling. "Oxidative stress" is the term used to describe the physiological state characterized by an excessive concentration of these oxidizing free radical molecules.

Oxidative stress is one of several mechanisms implicated in the pathogenesis of diseases caused or made worse by pollutants formed by burning coal.

Free radicals are defined as atoms or molecules that contain at least one unpaired electron in an atomic or molecular orbit and are therefore unstable and highly reactive. Examples of reactive oxygen species (ROS) include the superoxide anion radical, formed by the addition of an electron to molecular oxygen (O_2); the hydroxyl radical, the neutral form of the hydroxl ion; and peroxyl radicals, the simplest of which is the hydroperoxyl radical, composed of one molecule of hydrogen and two molecules of oxygen. More complex peroxyl radicals have an organic group (abbreviated by an R) substituted for the hydrogen molecule.

ROS are a normal cellular constituent and play critical roles in the control of many cellular functions. However, the concentration of ROS can be increased through exposure to environmental substances such as air pollution, tobacco smoke, pesticides, and solvents. When the ROS concentration is excessive, these highly reactive molecules damage lipids, proteins, DNA, cell membranes, and other cellular components, producing oxidative stress, an important contributing factor in a variety of diseases.

In a contemporary review Valko, et al., summarize the current state of knowledge of oxygen free radicals and their importance in the production of a variety of diseases including cardiovascular and pulmonary disease, as well as other conditions including atherosclerosis, hypertension, rheumatoid arthritis, diabetes mellitus, neurodegenerative disorders such as Alzheimer's disease and Parkinson's disease, and normal aging.

Valko M, Leibfritz D, Moncol J, Cronin MTD, Mazur M, Telser J. Free radicals and antioxidants in normal physiological functions and human disease. Int J Biochem and Cell Biology 2007;39:44–84.

pollutants discharged by coal fired power plants may act as triggers and produce an asthma attack. These pollutants include sulfur dioxide, nitrogen oxides, and particulate matter. In addition, the carbon dioxide emissions from coal accelerate global warming, which is likely to increase the concentration in air of pollen from some plants, such as ragweed, and thereby contribute to the development of additional asthma attacks.

Genetic variability accounts for some of the differences in the sensitivity of individuals to asthma triggers.[3] Genetic studies have shown differences in the susceptibility to ozone that are due to polymorphisms (subtle differences in genes that control the expression of a trait) in the genes responsible for dealing with oxidative stress. Oxidative stress is created when oxygen ions, free radicals, or other reactive species are produced in excess of the body's ability to remove these molecules. Oxidative stress may be an important mechanism for the production of a variety of diseases (see text box). Genetic polymorphisms responsible for controlling the inflammatory response also increase an individual's susceptibility to the respiratory effects of ozone. Thus, the probability that an individual will develop asthma depends on exposure to a trigger, such as ozone, and the individual's susceptibility to that trigger, i.e., a complex combination and interaction between genetic and environmental factors. For a review of the genetic susceptibility

R04318

to the effects of air pollutants, such as ozone, particulates, nitrogen dioxide, and sulfur dioxide, on respiratory function see Yang, et al.[4]

Children appear to be more susceptible to the development of pollution-related asthma attacks than adults. There are several explanations for this increase in susceptibility. According to a review by Bateson and Schwartz, the susceptibility of children to the effects of air pollution is multifactorial and includes the following.[5] 1) Children have different rhythmic patterns of breathing than adults. 2) They are predominantly mouth-breathers, thereby bypassing the filtering effects of the nasal passages. This allows pollutants to travel deeper into the lungs. 3) They have a larger lung surface area per unit weight than adults. 4) They spend more time out of doors, particularly in the afternoons and during the summer months when ozone and other pollutant levels are the highest. 5) Children also have higher ventilation rates. i.e., volume of air per minute per unit body weight compared to adults. 6) When active, children may ignore early symptoms of an asthma exacerbation and fail to seek treatment, leading to attacks of increased severity. There are other factors that are important. The diameter of the airways in children is smaller than in adults and therefore airways may be more susceptible to the effects of the airway narrowing that is characteristic of asthmatic attacks. These factors, combined with the possible adverse impact of pollutants on lung development and the immaturity of enzyme and immune systems that detoxify pollutants, may all contribute to an increase in the sensitivity of children to pollutants produced by burning coal.[6]

CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD), CHRONIC BRONCHITIS AND EMPHYSEMA

Asthma is a reversible condition. When permanent damage to the airway occurs, a chronic obstructive airway condition is present.

COPD is a condition characterized by narrowing of the airway passages. Unlike asthma, these changes are permanent rather than reversible. Like asthma, exposures to pollutants that produce an immunological response are critical in the pathogenesis of the condition. The response in larger airways is referred to as chronic bronchitis. A cough that produces sputum is characteristic of chronic bronchitis. In the alveoli, the inflammatory response leads to a destruction of tissue, or emphysema. These two conditions usually co-exist. Exacerbations of COPD may be triggered by pollutants or infections. Although current and ex-smokers account for 80–85% of all patients with COPD, exposure to air pollutants, including those that are produced by burning coal, plays an important role in the pathogenesis of acute exacerbations and the development of COPD.

PULMONARY INFLAMMATION AND AIR POLLUTANTS

Inflammation of pulmonary tissues is a critical element in the pathophysiology of illness caused by air pollution. Reactive oxygen species, such as free radicals and oxygen ions, appear to be central to this process. To avoid some of the difficulties associated with in vitro studies, several investigators have studied the response to particulate pollution in experimental animals. Roberts, et al., instilled particles into the lungs of rats treated with a compound (dimethylthiourea) that is believed to blunt the response to reactive oxygen species.[7] After treatment, the lungs of the animals were lavaged (rinsed with saline) and biomarkers of pulmonary injury were measured. Treated animals exhibited less evidence of damage to their lungs such as toxicity to cells, cytokine gene expression (genes that control cellular communications), pulmonary inflammation and other markers of pulmonary injury. In a subsequent study, Rhoden, et al., instilled standardized urban air particles (active agent) or saline (placebo control) into the lungs of rats.[8] Half of the animals in each group were treated with a reactive oxygen species inhibitor. Pretreatment with the inhibitor blocked the deleterious effects of the particles, as shown by reductions in several markers of pulmonary inflammation. These studies show that common

air pollutants such as particulates interfere with a variety of basic cellular mechanisms and dispose to the development of inflammation, a process that leads to diseases such as asthma, COPD, and emphysema.

These two studies are representative of many that have been performed using a variety of agents and techniques. Although performed in animals and not humans, they are consistent with a larger body of scientific evidence that helps establish a cause-and-effect relationship between particulates and pulmonary disease. As noted above, inflammation is a critical element in the pathogenesis of attacks of asthma and exacerbations of COPD. It matters little whether the inflammation is caused by particulates or other pollutants.

Additional evidence to support the hypothesis that air pollutants produce oxidative stress is derived from many studies. Recently, Fitzpatrick, et al., studied 65 children with severe asthma, including 35 with a reduction in baseline airway function as shown by a forced expiratory volume of less than 80% of that predicted, i.e., their ability to move air rapidly out of the lung was impaired.[9] Bronchoalveolar lavage (rinsing the airway with saline) was performed and metabolites and enzymes related to oxidative stress were measured. In the asthmatics, the concentration of glutathione, an antioxidant that protects cells from free radicals, was reduced and the concentration of the oxidized form (glutathione disulfide) was increased. This made the children less able to withstand oxidative stress and more susceptible to the development of an asthmatic attack.

OZONE, AIR POLLUTION, AND ASTHMA

Ozone, a highly reactive gas that consists of three atoms of oxygen (O_3), is formed by the reaction of volatile organic compounds (VOCs) with oxides of nitrogen (NO_x) in the presence of sunlight. Coal combustion does not produce ozone directly, but both the NO_x and the VOCs released by coal plants are essential contributors to the formation of ground-level ozone, the primary ingredient in urban smog. Ozone is a powerful oxidizing agent

XAVIER GALLEGO MORELL/DREAMSTIME.COM

that irritates the lungs at concentrations typically encountered in urban settings, particularly in summer months. There are many studies linking increases in ozone to asthma and other pulmonary diseases (see Trasande and Thurston for review[10]).

One of the most compelling studies linking ozone with asthma exacerbations was performed by Gent, et al.,[11] who examined the effects of relatively low ozone levels on asthmatic children. Those authors conducted a prospective cohort study of 271 children younger than 12 who had physician-diagnosed asthma. The children were divided almost equally into groups who did or did not use daily maintenance medications. Rigorous statistical techniques were used to examine the relationship between ozone levels below EPA standards, respiratory symptoms, and the use of rescue medications as charted by the children's mothers on daily calendars. The authors found a significant association between ozone levels and symptoms, as well as the use of rescue medications in the children who used daily maintenance medications. No significant relationships were found between ozone levels and symptoms or medication use in the children who did not take daily maintenance medications. Thus, it appears that the threat to children posed by ozone is greatest among those with severe asthma, even when ambient ozone levels fall within the limits set by the EPA to protect public health.

R04320

Peel, et al., studied the relationship between a one standard deviation increase in ambient air pollutant levels and emergency room visits for various respiratory problems, including asthma.[12] They found the strongest association between increases in 24-hour PM_{10} levels, 24-hour increases in 10–100 nm particle concentrations, and 1-hour NO_2 concentrations and asthma attacks that occurred six to eight days after the peak. There were shorter delays between peaks of PM_{10}, ozone, NO_2, and carbon monoxide and emergency room visits for upper respiratory infections. During warm months, there was a 2.6% increase in asthma admissions after a 25 ppb increase in the ozone concentration. To give the 25 ppb increase perspective, the EPA eight-hour exposure standard in 2008 was set at 75 ppb. This study is one of many that establish a statistically rigorous link between a peak in the concentration of an air pollutant and the onset of a disease or disease symptom.

Increases in the risk of death from respiratory causes, including sudden infant death, were correlated with the concentration of PM_{10} and NO_2.

The evidence linking ozone levels to the development of asthma is less compelling than that linking ozone to asthma exacerbations. Gilmour, et al., reviewed five studies that address this issue.[15] A Dutch study of over 4,000 children enrolled at birth and followed for two years, focused on NO_2 and $PM_{2.5}$ attributed to traffic, found small but statistically significant associations between pollutant peaks and the development of symptoms of asthma.[14,15] Although this study focused on traffic as the source of the pollutants, burning coal can't be ignored as a source of NO_2 and $PM_{2.5}$. There were similar results from a second study of children in that age group from the Netherlands, Germany, and Sweden. The Children's Health Study of more than 6,000 children from southern California evaluated a wide range of ozone, particulates, oxides of nitrogen, and acids.[16] A significant association between ozone and asthma was confined to those children who participated in three or more sports. This result may be the consequence of the increases in the amount of air breathed per unit of time associated with exercise and the consequent increases in exposure to pollutants. Gilmour, et al., conclude that the results of all five of the studies they reviewed "support a modest increase in the risk for air pollution in relation...to asthma."[17]

The increase in susceptibility to pollutants among children appears to translate into pollution-related increases in infant mortality. Ritz, et al., reported increases in the risk of death from respiratory causes, including sudden infant death, with rises in the concentration of carbon monoxide, PM_{10}, and NO_2.[18] Bateson and Schwartz also cite a study reporting between 4 and 7 fewer infant deaths per 100,000 live births with a reduction in the concentration of total suspended particles of 1 $\mu g/m^3$.[19] To give this number perspective, Pope, et al., reported that there was a mean reduction in the $PM_{2.5}$ concentration of 6.52 $\pm$ 2.9 $\mu g/m^3$ in major U.S. metropolitan areas in the time interval between 1979–83 and 1999–2000.[20]

AIR POLLUTION AND COPD

Smoking tobacco is the most important risk factor for the development of COPD. Most authors report that approximately 85% of all cases of COPD can be attributed to this single, preventable cause. Data that have emerged during the past several years have shown that there is a smaller but important link between air pollution, including pollutants produced by burning coal, and the subsequent development of COPD exacerbations.

In a study of the residents of Helsinki, Finland, where coal-derived air pollutants account for a relatively small portion of total pollutant levels, pooled asthma and COPD emergency room visits increased on those days when there were increases in $PM_{2.5}$, coarse particles, and gaseous pollutants.[21] The Atlanta, Georgia, study of Peel, et al., found that when NO_2 or carbon monoxide increased by one standard deviation, emergency room visits for COPD increased by 2–3%.[22] Finally, in a study of hospitalization rates among Medicare enrollees, a 10 $\mu g/m^3$ increase in the concentration of $PM_{2.5}$

particles was associated with a same-day increase in COPD admissions of 2.5% (95% confidence interval (CI) = 2.1–3.2%).[23] These three studies of three different populations using different criteria all link increases in air pollutants to increases in exacerbations of COPD. Although they did not focus on pollutants derived exclusively from the combustion of coal, the pollutants they studied included those produced by coal burned by electrical utilities as well other sources.

LUNG CANCER

The National Cancer Institute estimates that in 2008 there were 215,020 new cases of lung cancer, the leading U.S. cancer killer in both men and women, with 161,840 deaths. While smoking tobacco, radon and other radioactive gases, secondhand smoke, asbestos, arsenic, nickel compounds, and other airborne organic compounds have been identified as risk factors for developing lung cancer, data from three large epidemiological studies show that air pollution may also be a risk factor.

First among these was a study of Seventh Day Adventists who lived in California.[24] This cohort of over 6,300 non-smoking white adults was followed from 1977 to 1992 and monitored for the development of lung cancer. These data were combined with monthly ambient air pollution data in various zip codes. For men, the interquartile range (the middle 50% of the range) increase for ozone of 100 ppb was associated with an increase in the relative risk (RR) for lung cancer of 3.56 (95% CI = 1.35–9.42). Lung cancer increases were also associated with significant increases in PM_{10} (RR = 5.21, 95% CI = 1.94–13.99) and for SO_2 (RR = 2.66, 95% CI = 1.62–4.39). Smaller increases among women were also found, however only the association with SO_2 was statistically significant. The difference between men and women was thought to be due to greater exposures among men.

In the Harvard Six Cities study, lung cancer death was positively associated with air pollution. The adjusted mortality rate ratio due to lung cancer for the most to least polluted cities was 1.26 (95% CI = 1.08–1.47).[25,26]

Complementary data were found in the American Cancer Society study.[27] This epidemiological study began with 1.3 million adults in 1982. From that set, approximately 500,000 adults were matched with air pollution data for their appropriate metropolitan area and vital statistics data through the end of 1998. Fine particulate increases of 10 $\mu g/m^3$ were associated with an 8% increase in lung cancer mortality. Increases in the concentration of oxides of sulfur were also associated with increases in lung cancer mortality.

These three large prospective epidemiological studies provide evidence that air pollution, particularly that due to particulates and ozone, may affect mortality due to lung cancer. Since some of the pollutants studied are formed directly or indirectly as the consequence of burning coal, it is possible that burning coal places those exposed to coal-related pollutants at greater risk for developing lung cancer.

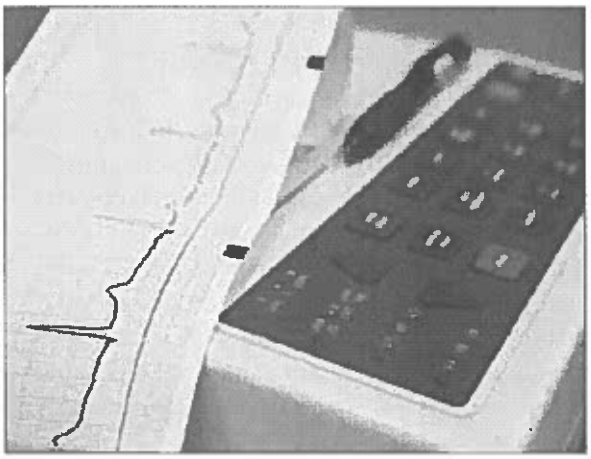
4. *Coal's Effects on the Cardiovascular System*



The American Heart Association (AHA), along with other organizations, has issued guidelines designed to aid health professionals as they seek to achieve primary and secondary prevention of the morbidity and mortality due to diseases of the cardiovascular system. Traditionally, these guidelines have focused on the control of hypertension, cholesterol levels, smoking, and other factors. More recently, these guidelines have been expanded to deal with lifestyle choices, such as diet, exercise, and avoidance of second-hand smoke. Controlling these risk factors has been the most important factor in the declines in death rates attributable to coronary heart disease over the past decades. However, because of accumulating evidence and a persistent concern that air pollutants are also linked to adverse cardiovascular health outcomes, the AHA convened an expert panel to evaluate this threat. The results of their deliberations, the single most authoritative review of this topic, were published in 2004.[1] In this section, we build on that prior publication, including studies published since it was written.

CARDIOVASCULAR DISEASE

Although death rates from coronary heart disease (CHD) have declined substantially during the past several decades, CHD remains a leading cause of death in the United States. Tables 4.1 and 4.2 summarize incidence rate and prevalence data from the National Heart Lung and Blood Institute 2009 Chartbook.[2] By any standard, the control of risk factors associated with CHD has important public health consequences even though the incidence and prevalence of CHD have fallen.

Figure 4.1 summarizes the pathophysiological mechanisms by which air pollutants, particularly particulate matter (PM), cause cardiovascular disease. Pulmonary inflammation and the presence of reactive oxygen species (ions, free radicals formed from oxygen) are both thought to be important mechanisms in the pathogenesis of cardiovascular disease. By convention, and for purposes of monitoring air to evaluate compliance with air quality standards, the PMs of greatest concern are those with a diameter of 2.5 μm or less ($PM_{2.5}$). These

small particles are the most likely to penetrate deeply into the lungs, reach the alveoli, and initiate the pathophysiological sequences leading to acute and chronic manifestations of CHD.

The mechanisms depicted in Figure 4.1 suggest numerous possible therapeutic interventions. Reducing the exposure to airborne pollutants is the most obvious of these and forms the rationale for PSR's Code Black campaign to prevent the licensing and construction of new coal-fired power plants. Substantial efforts, beyond the scope of this report, are being invested in controlling the immunological and inflammatory responses and oxidative stress associated with the inhalation of pollutants.

IMMEDIATE IMPACTS OF AIR POLLUTANTS ON THE CARDIOVASCULAR SYSTEM

In a study supporting the hypothetical pathogenic mechanisms outlined in Figure 4.1, Brook, et al., evaluated the effects of fine particles and ozone on the diameter of the brachial artery in 25 healthy adults.[3] The behavior of brachial arteries is thought to be representative of the behavior of coronary and cerebral arteries. This double-blind, randomized, crossover study evaluated the cardiovascular response to a two-hour inhalation of fine particles (approximately 150 $\mu g/m^3$) and ozone (120 ppb). These concentrations, which are encountered routinely in urban settings, resulted in a significant reduction in the diameter of the brachial artery, implying narrowing of other arteries. In spite of this evidence, important questions remain, e.g., are these participants representative of the population at greatest risk (screened healthy controls versus patients with significant coronary artery disease)?

Animal studies are well suited to studying pulmonary inflammation and oxidative stress, mechanisms that may be important in cardiac disease pathogenesis. Roberts, et al., instilled particles into the lungs of animals pretreated with a drug (dimethylthiourea) believed to blunt the response to reactive oxygen species.[4] The treated animals showed less evidence of pulmonary injury, as evidenced by a blunted inflammatory response and other markers of pulmonary damage. There was also a reduction in the activity of genes controlling cytokines. Cytokines, molecules involved in cellular signaling and communication, are critical in the development and control of immunological responses. In a similar study, Rhoden, et al., instilled standardized urban air particles into the lungs of rats and measured the formation of superoxide ions, a reactive oxygen species.[5] Again, pretreatment with an inhibitor blocked the adverse effects of the particles, as shown by measured reductions in the level of several markers of lung inflammation. In a study of hyperlipidemic rabbits, Suwa, et al., found that a four-week exposure to PM_{10} was associated with acceleration of atherosclerosis, an increase in the turnover of cells in atherosclerotic

Figure 4.1: Pathophysiological mechanisms by which air pollution causes cardiovascular disease

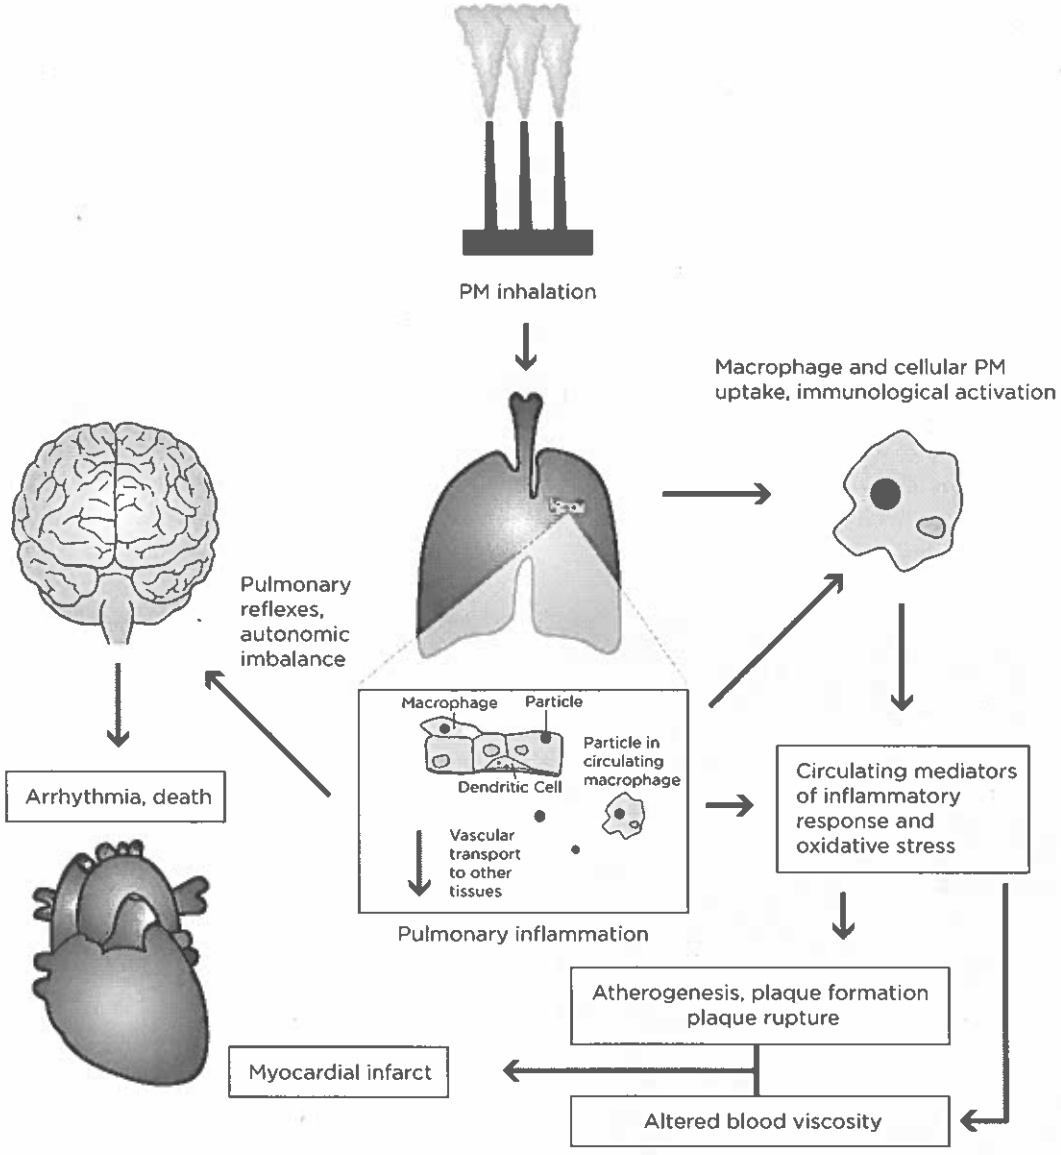

Figure legend:

Particles produced by burning coal are inhaled. Small particles, particularly those that are 2.5 µm or less in diameter, travel deep into the lungs, reaching the alveoli. Particles in the alveoli may have one of several fates: uptake by macrophages with subsequent stimulation of the inflammatory response and the immune system; uptake by dendritic cells, another pathway to immune system activation; or direct entry into the vascular compartment and subsequent transfer to other organs. Pulmonary reflexes, stimulated by inflammation, lead to imbalance of the autonomic nervous system and may potentiate cardiac arrhythmias such as ventricular fibrillation and atrial fibrillation. Inflammation and oxidative stress are important elements in the production and rupture of atherosclerotic plaques in coronary and cerebral arteries and may lead to myocardial or cerebral infarction. Increases in the viscosity of the blood also increase the risk of infarction of the heart or brain.

plaques, and an increase in the total lipid content of aortic lesions.[6] These selected studies show that pollutants produced by the combustion of coal have powerful effects on physiological processes that lead to disease endpoints, such as arterial occlusion and infarct formation.

Acute outcome studies typically focus on a single event, e.g., admission due to acute myocardial infarction or the discharge of an implanted cardioverter defibrillator (ICD). These events have a distinct time-of-occurrence that can found in hospital emergency room records or examination of defibrillator data extracted after a discharge. By examining these data in relationship to air quality data collected by monitoring stations, researchers have been able to examine the relationship between air pollution and hospital admissions for cardiovascular disease. Because of such studies, Peters, et al., hypothesized that there might be a link between transient increases in pollutant levels and therapeutic discharges of ICDs.[7] ICDs are permanently implanted in patients judged to be at risk for sudden death due to cardiac arrhythmias. These devices monitor heart rhythms continuously. When a rhythm disturbance such as ventricular fibrillation or ventricular tachycardia is detected, the ICD begins to pace or defibrillate the heart. Defibrillation is transient but quite painful, and patients are instructed to seek medical attention after an event. Modern ICDs typically include memory chips that store information for variable times. When the patient seeks medical attention after a discharge, technicians are able to retrieve relevant data, including the nature and time of the arrhythmia and the ICD discharge. Peters and her colleagues analyzed the ICD records from 100 events recorded in a single clinic in eastern Massachusetts and sought links between events and peaks in pollutant levels measured in that region. They considered daily average pollutant levels on the day of the event and one, two, and three days prior to the event. They found that an increase in the NO_2 concentration was followed by an increase in the probability of an ICD discharge two days later (odds ratio 1.8, 95% confidence interval (CI) = 1.1–2.9). Patients who experienced 10 or more ICD discharges (presumably an indication of more severe disease) exhibited associations with NO_2, CO, black carbon, and $PM_{2.5}$. Although they regarded this as a pilot study, they concluded that peaks in air pollution levels were associated with fatal or potentially fatal cardiac arrhythmias. They buttressed this claim by reviewing the results of animal studies linking pollutants to cardiac arrhythmias.

By examining how defibrillator discharges relate to air quality, researchers can explore how cardiovascular disease relates to air pollution.

BRADEN GUNEM/ISTOCKPHOTO.COM

Peters and her colleagues also investigated the relationship between acute myocardial infarctions (MI) and air pollutants.[8] In this study, a total of 772 records of patient interviews conducted within four days of an acute MI (a step that minimizes recall bias) were evaluated in the context of air

pollutant concentrations. By pairing the data from the day of the MI with three other control sets measured at exactly the same time of the day (on days when the subject did not have an MI), patients served as their own controls. Compared to control periods, there was an increase in the probability of an MI in association with elevations in $PM_{2.5}$ levels measured two hours before the MI (odds ratio for an increase in $PM_{2.5}$ of 25 $\mu g/m^3$ was 1.48, 95% CI = 1.09–2.02). In addition, there was a delayed response to a peak occurring a full day before an event (odds ratio for the same increase in $PM_{2.5}$ was 1.69, 95% CI = 1.13–2.34).

Two large studies using health outcomes such as mortality in relation to day-to-day changes in ambient air pollution levels have been critical in defining the health effects associated with pollutants. In a U.S. study, Dominici, et al., used ambient $PM_{2.5}$ concentrations and hospital admission rates in the Medicare National Claims History Files to look for associations between particulate levels and admissions for ischemic heart diseases, disturbances of heart rhythm, and congestive heart failure.[9] The data included 204 urban counties with a total of 11.5 million Medicare enrollees who lived an average of 5.9 miles from a $PM_{2.5}$ monitor. Using injuries as control, they found increases in all categories, with the largest found for congestive heart failure, where a 1.28% increase was found for an increase of 10 $\mu g/m^3$ in $PM_{2.5}$ concentration. Increases in admissions for ischemic heart disease, heart failure, and disturbances of heart rhythm tended to be higher in those 75 years or older than in those 65–74. Additional details are shown in Table 4.3. The greatest effects were observed in the northeastern U.S. where coal-fired power plants are most plentiful. Although the increases in the rates appear small, on the order of a single percent, the large number of Medicare enrollees translates the result into a very large effect when measured in terms of total hospital admissions, patient morbidity and mortality, and the cost of health care and lost opportunities.

Katsouyanni, et al., reported the short-term effects of PM_{10} on the health of the residents of

Table 4.3: Percent change in hospitalization rate per 10 $\mu g/m^3$ increase in $PM_{2.5}$ for all Medicare enrollees age > 65 years

Admission diagnosis	Lag days*	Percent rate increase (95% confidence interval)
Ischemic heart disease	2	0.44 (0.02–0.86)
Heart rhythm abnormality	0	0.57 (-0.01–1.15)
Heart failure	0	1.28 (0.78–1.78)

* Number of days between peak and greatest effect of $PM_{2.5}$

29 European cities with a total population of over 43 million, extending over a period of approximately 5 years.[10] Unlike the U.S. study, they included all age groups. However, the results were remarkably similar to those observed in the U.S. Medicare population. They report a 0.6% increase (95% CI = 0.4–0.8%) in the daily number of deaths for a 10 $\mu g/m^3$ increase in the PM_{10} concentration. They also found important modifiers of the PM_{10}-associated death rate, particularly with regard to NO_2 levels. Cities with high NO_2 concentrations had death rates that were approximately four times higher than found in cities with low NO_2 concentrations. Death rates in cities with warm climates were about 2.8 times higher than in cities with cold climates.

These examples extracted from the literature describing the effects of air pollution on acute morbidity and mortality are consistent: the small studies focused on individuals as well as large studies that rely on data extracted from large databases show adverse effects of pollutants on indicators of acute cardiovascular illness.

LONG-TERM IMPACT OF AIR POLLUTANTS ON THE CARDIOVASCULAR SYSTEM

Two studies linking the chronic effects of air pollutants on cardiovascular mortality are particularly relevant. The first of these is the Harvard Six Cities

R04328

study, reported by Dockery, et al.[11] This prospective cohort study followed over 8,100 adults for 14–16 years. The mortality rate in the most polluted city was 1.26% higher than the rate in the least polluted city (95% CI = 1.08–1.47%). This elevated rate persisted after controlling for important lifestyle confounders, including smoking cigarettes. Pope, et al., linked individual risk factor data from about 500,000 adults, metropolitan area air pollution data, and vital statistics and cause-of-death data. They found that an increase in the particulate concentration of 10 $\mu g/m^3$ was associated with a 6% increase in the risk of death due to cardiopulmonary causes. Because coal is a significant source of particulate pollution, these studies indicate that coal combustion has serious long-term impacts on the cardiovascular health of the U.S. population.

MITIGATING THE EFFECTS OF AIR POLLUTION

With the passage of the Clean Air Act in 1955 (with major revisions in 1970, 1977, and 1990), the U.S. embarked on a process to improve air quality in order to improve health. Pope, et al., evaluated the effects of the regulations and corresponding improvements in health in a recent paper.[12] In this study, the authors compared life expectancy in the late 1970s–early 1980s to life expectancy in the late 1990s–early 2000s in 211 counties in 51 metropolitan areas where fine particulate concentration data were available. They report a 0.61 + 0.20 year (+ standard error) increase in life expectancy after a decrease of 10 $\mu g/m^3$ in fine particle concentration. The two cities with the largest changes were Pittsburgh, PA, and Buffalo, NY, where major steel industries that consumed large amounts of coal were closed. A number of variables that could have confounded the results, such as smoking and socioeconomic class, did not have significant effects. This study showed that significant and measurable improvements in life expectancy followed the improvements in air quality mandated by the Clean Air Act.

5. *Coal's Effects on the Nervous System*

It is easy to understand that burning coal is likely to have an adverse impact on respiratory health: we inhale the products of combustion. It is less obvious that burning coal has important effects on the nervous system, particularly the brain. Cerebral vascular disease, i.e., stroke, and loss of intellectual capacity due to mercury are the two most important neurological consequences of burning coal.

THE BRAIN AND POLLUTION

The human brain is the organ that most clearly distinguishes us from other species. Our abilities to think abstractly, produce and enjoy music, art and literature, inquire about the nature of the universe, and a host of similar activities related to brain function are what makes us human. This uniquely human organ is also highly susceptible to disruption by what may appear to be relatively trivial acute or chronic abnormalities. Although the normal brain weighs 1,300–1,400 grams (about three pounds), the extremely high metabolic rate of the brain and the absence of significant energy stores within the brain mandate a high constant rate of blood flow in order to insure normal function and survival. When the body is at rest, between 15 and 20% of the cardiac output goes to the brain. Thus, even transient interruptions of the blood, oxygen, or glucose supplies to the brain may result in severe, permanent brain injury or brain death.

The complexity of the brain, coupled with its susceptibility to the effects of metabolic or physiological derangements or both, frequently leads to abnormalities of brain function that may be undetectable in an individual, but may have an enormous impact on the population as a whole. This, in turn, has public health consequences. This is illustrated in Figures 5.1 and 5.2, where the impact of a five-point decrement in IQ is depicted. The average IQ score is 100 and 95% of all individuals have IQ scores that fall between 70, the score below which one is considered to be retarded, and 130, the score above which one is considered to have superior intelligence. This is shown in Figure 5.1. Figure 5.2 demonstrates the effect of an across-the-board five-point decrement in IQ. For an individual, this

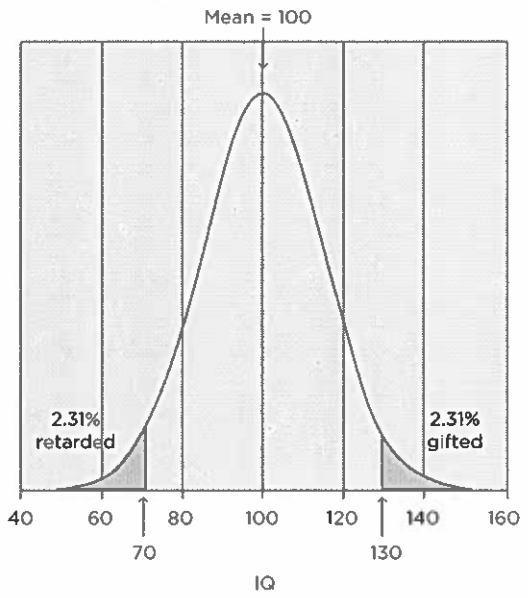

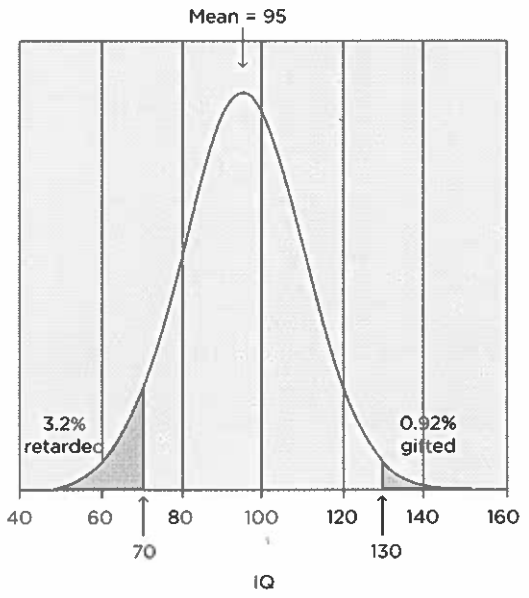

Figure 5.2: Change in IQ distribution with 5 point decrement

relatively small change would hardly be noticed. However, in a large population, substantial numbers of individuals are removed from the superior intelligence category and others are pushed down into the retarded category. The result is a smaller pool of individuals with outstanding intellects and a larger pool of individuals who require special resources to be able to function. It is this reality that makes it important to protect and preserve the brain's full potential.

CEREBRAL VASCULAR DISEASE

The same pathophysiological mechanisms that affect the coronary arteries and cause myocardial infarcts also apply to the arteries that nourish the brain, as shown in Figure 5.3. These common mechanisms include: stimulation of the inflammatory response in cerebral vessels leading to atherosclerotic plaque formation, rupture, and arterial occlusion; oxidative stress; and alterations in blood viscosity. In addition, arrhythmias may cause transient reductions of the cardiac output and cause hypoperfusion of the brain. The effects of reductions in the cardiac output are most prominent at the boundaries between major arteries (so-called watershed areas of the brain), and distal to sites of severe arterial stenosis.

The term stroke refers to a variety of acute cerebrovascular events including ischemic stroke, caused by occlusion of a cerebral artery by an atherosclerotic plaque or an embolus; cerebral hemorrhage, usually caused by rupture of a small artery in the brain; subarachnoid hemorrhage, often due to rupture of an aneurysm; or some other acute event due to a vascular cause. In the narrative that follows, unless otherwise stated, we will use the term stroke to mean an ischemic stroke caused by occlusion of a cerebral artery by an atherosclerotic plaque, the most common cause of stroke.

Although there have been major improvements in primary and secondary prevention of strokes in the past several decades, due to better care of

patients with hypertension and diabetes as well as improvements in smoking cessation efforts, stroke is still an important cause of death in the U.S. Current estimates indicate that the stroke death rate for men is 33.1 per 100,000 and 26.1 per 100,000 for women.[1]

Three large studies and several smaller studies have shown a correlation between air pollutants and acute strokes.

In their study of the relationship between fine particles ($PM_{2.5}$ or less) and hospital admission rates in the Medicare population, Domenici, et al., reported a 0.81% increase in the hospitalization rate for cerebrovascular disease (ICD 9 codes 430–438, 95% CI = 0.31–1.32%) for a 10 $\mu g/m^3$ increase.[2] This relationship was significant only on lag day zero (no lag between a peak and the admission) and not evident on lag days one and two. As with many of the other outcomes they considered in addition to cerebrovascular disease, this association was strongest in eastern parts of the U.S. when compared to western regions. This may be related to differences in the composition of PM due to the large number of coal-fired power plants in the east compared to the west.

In a second study of the Medicare population, Wellenius, et al., sought relationships between hospital admissions from 1986 to 1993 for ischemic and hemorrhagic strokes and increases in various air pollutants in nine major U.S. cities.[3] Admissions data were obtained from the Centers for Medicare and Medicaid Services and pollutant levels were obtained from the EPA. Pollutant levels are shown in Table 5.1. Note that PM_{10} levels were measured and not $PM_{2.5}$ levels as would be the case for more contemporary studies. They report that for an interquartile percentile increase in the PM_{10} concentration, there was a corresponding 1.03% increase in the admissions for ischemic stroke (95% CI = 0.04–2.04%) on the day of the increase. Similar results were observed for CO, NO_2, and SO_2 for ischemic strokes only. They did not find significant associations between pollutant levels and hemorrhagic strokes.

Figure 5.3: Pathophysiological mechanisms by which air pollution causes neurological disease

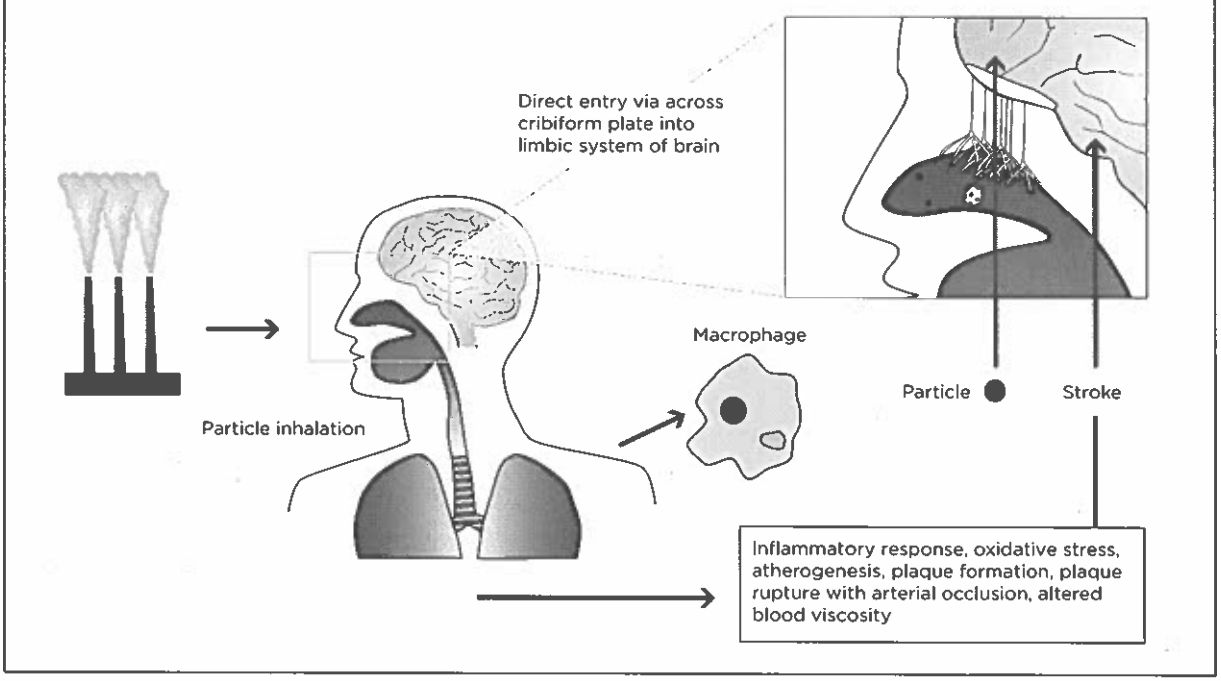

Table 5.1: Concentrations of various air pollutants in 9 U.S. cities

Pollutant	Percentile 25th	50th	75th
PM_{10} µg/m³	18.88	28.36	41.84
CO ppm	0.73	1.02	1.44
NO_2 ppb	18.05	23.54	29.98
SO_2 ppb	3.57	6.22	10.26

Source: Wellenius GA, Schwartz J, Mittleman MA. Air pollution and hospital admissions for ischemic and hemorrhagic stroke among medicare beneficiaries. Stroke 2005; 36(12):2549–2553.

Finally, data from post-menopausal women enrolled in the Women's Health Initiative and collected in 2000 show that for each increase of 10 µg/m³ in the $PM_{2.5}$ concentration, there was a 35% increase in the risk of a cerebrovascular event and an 83% increase in the risk of death from a cerebrovascular event.[4] The hazard ratio for the time to an acute cerebrovascular event, an indicator of relative risk, was reported as 1.35 (95% CI = 1.08–1.68). This observational study of post-menopausal women without a prior history of cardiovascular disease gains strength from the fact that the authors reviewed actual medical records, rather than relying on data from central databases. The restriction to this cohort of women loses some strength because the results may not be generalizable to men or younger women. They did not find any association between stroke and other air pollutants, including SO_2, NO_2, CO and O_3.

Two other studies conducted under more restricted circumstances have shown direct relationships between air pollutants and stroke. In a 2002 study of stroke mortality in Korea, Hong, et al., reported significant and increasing risk for death due to ischemic but not hemorrhagic stroke as same-day PM concentrations increased through four quartiles.[5] These authors also found significant temporal relationships between pollutants and stroke: same-day sulfur dioxide concentrations and ischemic stroke, a one-day lag between carbon monoxide and stroke, and a three-day lag between an ozone peak and stroke. In a more complex study of over 23,000 stroke admissions in Taiwan, Tsai, et al., reported significant positive associations between PM_{10}, NO_2, SO_2, CO, and O_3 when considered singly, and primary intracerebral hemorrhage and ischemic stroke admissions on days when the temperature was 20°C or greater.[6] On cooler days, the correlation between CO and ischemic stroke was the only factor that persisted. When they considered two pollutants together, there was a significant correlation between PM_{10} and NO_2 and both types of stroke.

In summary, even though a relatively small portion of all strokes appear to be related to concentration of PM, the fact that nearly 800,000 people in the U.S. have a stroke each year[7,8] makes the number of strokes attributable to PM a risk factor of importance. These studies emphasize the importance of measures designed to minimize PM concentrations in the air, including preventing the construction of new coal-fired power plants and developing and utilizing more effective technologies to reduce emissions from existing plants.

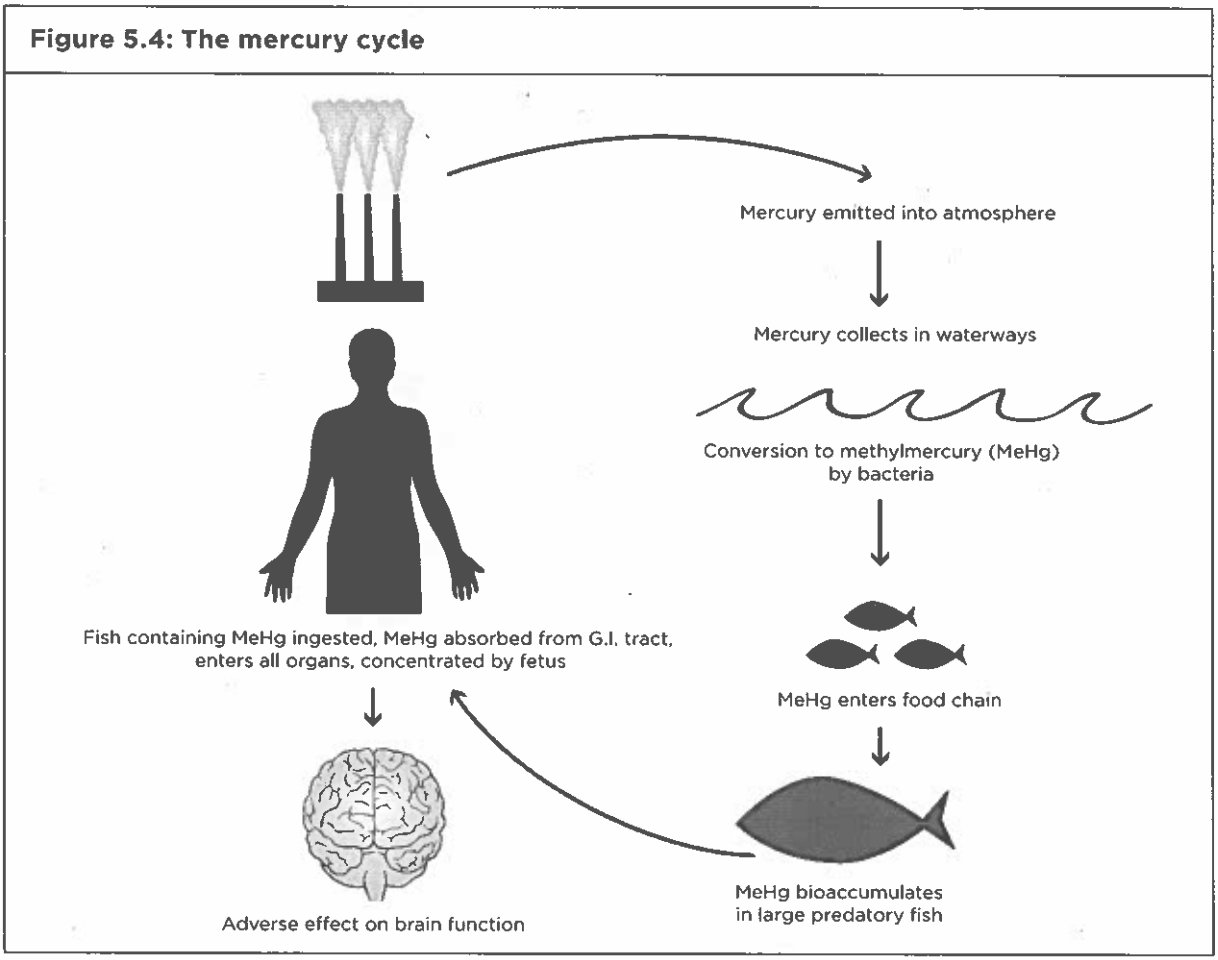
MERCURY

Coal contains trace amounts of mercury. When burned, this mercury evaporates and is emitted into the environment unless stringent control technologies are used to reduce those emissions. Coal-fired power plants are responsible for approximately one third of all emissions of mercury attributable to human activity, as shown in Table 5.2, making them the largest single source of mercury emissions. The 2007 Toxics Release Inventory listed point source releases of 7,935 pounds of mercury and 117,243 pounds of mercury compounds.[9] Point sources are stationary, single-site sources of a pollutant, such as a smoke stack at a power plant.

The mercury cycle is shown in Figure 5.4. Once mercury enters the atmosphere, it returns to the earth via rainfall, entering waterways. Mercury and other persistent toxicants in lakes and streams led various states, tribes, and territories to issue 3,221 advisories in 2004 urging caution when consuming fish from specific bodies of water, up from 3,089

Table 5.2: Anthropogenic sources of mercury

Source	Tons per year	Percent of total
Combustion	137.9	86.9
Electrical utilities	52.0	32.8
Municipal incinerators	29.6	18.7
Industrial boilers	28.4	17.9
Medical waste incinerators*	16.0	10.1
Other manufacturing	15.8	10.0



* Mercury emissions from medical waste incinerators are almost certainly lower at present due to regulations that have altered medical waste disposal methods.

the year before.[10] In the water, bacteria convert elemental mercury into methylmercury (MeHg), a form that is persistent and bioaccumulates. The concentration of MeHg increases as it passes up the food chain, reaching high levels in large predatory fish. The fish with the highest mercury concentrations are large tuna, swordfish, king mackerel, and tile fish. Marine mammals that eat fish also may have a large mercury burden. Humans are exposed to coal-related mercury primarily through fish consumption.

Since mercury is recycled in the environment and substantial amounts are released during volcanic eruptions, opponents of stricter mercury controls attempt to downplay the importance of coal-related emissions. Nevertheless, minimizing or eliminating coal-related mercury emissions is an important and concrete action that can be taken

Figure 5.4: The mercury cycle

R04334

to prevent additional amounts of mercury from entering the environment and affecting health.

In the 1950s, outbreaks of mercury poisoning in Minamata and Niigata, Japan, were caused by eating fish contaminated with mercury from industrial discharges. As a result, there were 3,000 confirmed cases and 600 deaths. A second outbreak occurred in Iraq, caused by eating seed-grain that had been treated with a fungicide containing MeHg.[11] This caused 649 deaths among 6,530 affected individuals. Until recently, a dose-response curve, derived from these exposures and interpolated to more typical blood mercury levels, served as the basis for determining the permissible daily intake of mercury.[12] Because of deficiencies in these data and their analysis, alternate populations were examined in great detail.

Based on three large-scale, prospective studies of cohorts children exposed *in utero* to MeHg in the Seychelles, the Faroe Islands, and New Zealand, the National Research Council recommended establishing a benchmark dose of 58 µg/L of mercury in the cord blood of newborns. The benchmark dose is the lower 95% confidence interval for an estimated dose that results in doubling the prevalence of children with neurodevelopmental test scores that are in the clinically impaired range.[13] This somewhat arbitrary choice is thought to provide an adequate margin of safety and to provide a rational basis for regulatory actions. Based on the National Research Council recommendations, the EPA applied a ten-fold safety factor, which is typical for EPA regulatory actions, and set the reference dose (RfD), the maximum tolerable daily dose, at 0.1 microgram of mercury per kilogram of body weight per day, the amount believed to lead to a mercury concentration of 5.8 µg/L mercury in cord blood.[14] To translate this standard into a practical form, it is necessary to know the maternal mercury blood level and the maternal-fetal mercury ratio. Fetal mercury levels are approximately 1.7 times those in the mother.[15]

Between 316,588 and 631,233 children are born in the U.S. each year with blood mercury levels high enough to cause lifelong loss of intelligence.

Based on the 1999-2000 National Health and Nutrition Examination Survey data,[16] approximately 15.7% of all American women of childbearing age were found to have blood mercury levels that would cause them to give birth to children with cord blood mercury levels of 5.8 µg/L mercury or more, i.e., above the target concentration. (Subsequent modeling by Stern suggested that the maternal:fetal ratio was overestimated in the earlier study.[17] However, direct measurements in a Swedish cohort suggest that the original ratio may be correct.[18]) Using these data and conservative estimates of blood mercury levels and their effect on intellectual performance, Trasande, et al., estimated that between 316,588 and 631,233 children are born in the U.S. each year with blood mercury levels high enough to impair performance on neurodevelopmental tests.[19] These authors further concluded that this lifelong diminution in intelligence costs society $8.7 billion per year (range $2.2–$43.8 billion in 2000 dollars). These cost estimates contrast sharply with others as low as $10 million dollars attributed to U.S. power plants by Griffiths, et al.[20]

HEALTH EFFECTS ON THE HORIZON

In prior sections, we have reviewed the peer-reviewed evidence published in leading medical journals that links pollutants produced by coal-burning power plants to diseases of the pulmonary, cardiovascular, and nervous systems. Emerging data that are based on smaller samples, and are therefore more speculative, suggest that there may be links between coal-derived pollutants and other diseases, such as Alzheimer's disease (AD) and diabetes mellitus, two of the most prevalent, costly, and debilitating chronic diseases of adults. If these early observations are upheld by more rigorous studies of large populations using contemporary epidemiological and statistical methods, such as those we refer to in earlier sections,

the public health implications will be enormous. Therefore, because of their possible importance, we will consider these potential links briefly.

ALZHEIMER'S DISEASE

The evidence linking air pollution and AD comes from studies comparing brains of dogs and humans living in highly polluted versus non-polluted cities in Mexico.[21,22] Animal data suggest that $PM_{2.5}$ crosses the nasal mucosa and enters the limbic system of the brain via the olfactory nerve.[23,24] Once in the brain, these PM cause inflammation and appear to lead to the deposition of amyloid, a neuropathological feature characteristic of AD. The authors suggest that "exposure to urban air pollution may cause brain inflammation and accelerate the accumulation of β-amyloid42, a putative mediator of neurodegeneration and AD pathogenesis." Similar findings were reported in animal experiments in which several strains of transgenic mice were exposed to PM.[25] The possible link between airborne pollutants and neurodegenerative diseases has not been firmly established. However it is potentially important because of the large and growing number of patients with AD and the disease's financial and societal impact.

DIABETES MELLITUS

The prevalence of diabetes mellitus (DM), particularly Type II DM, is increasing. In 2002, Lockwood observed a statistically significant relationship between the by-state prevalence of diabetes and the by-state air emissions of pollutants reported in the Toxics Release Inventory.[26]

In 2005, Brook postulated several mechanisms by which the inhalation of particulates might lead to the development of insulin resistance, a condition in which the body produces insulin but does not use it properly, thereby increasing the risk for the development of DM.[27] Again, the process begins with the inhalation of small particles that stimulate pulmonary inflammation and the generation of reactive oxygen species and oxidative stress. Subsequent pathways that involve the autonomic nervous system, the adrenal gland, and others are thought to lead to the development of insulin resistance and subsequently, to DM. This hypothesis gained credence with the publication of a paper linking NO_2 exposure with DM in women.[28] A positive relationship was found between NO_2 exposure and DM after controlling for several potential confounding factors such as age and body mass index. The authors conclude that their results "suggest that common air pollutants are associated with DM." That report used NO_2 levels as a surrogate marker for traffic-related air pollutants, including PM. Since substantial amounts of NO_2 and PM are emitted when coal is burned, there may be a link between NO_2 and PM derived from coal and DM.

DIABETES MELLITUS AND ALZHEIMER'S DISEASE

Converging evidence suggests that insulin resistance is a risk factor for a number of dementia-related conditions including Type II DM and impaired glucose tolerance, obesity, inflammation, ischemia, hypertension, cardiovascular disease, and abnormal lipid metabolism including hypercholesterolemia. To some extent, these associations blur the distinction between vascular causes of dementia and AD.[29] The putative mechanisms linking AD and DM include inflammation and oxidative stress. As discussed throughout this report, these two mechanisms are intimately related to exposure to various air pollutants, particularly fine particles, including those produced by burning coal.

SUMMARY

It is possible that the protean adverse health effects of burning coal may extend beyond those that are well established to include other common and costly chronic diseases. This possibility warrants vigilance and further investigation.

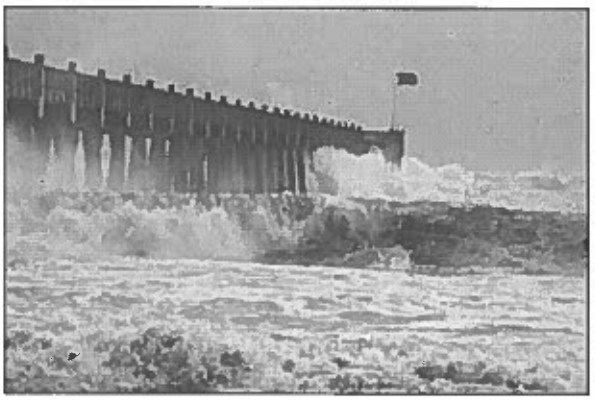
6. *Coal, Global Warming, and Health*



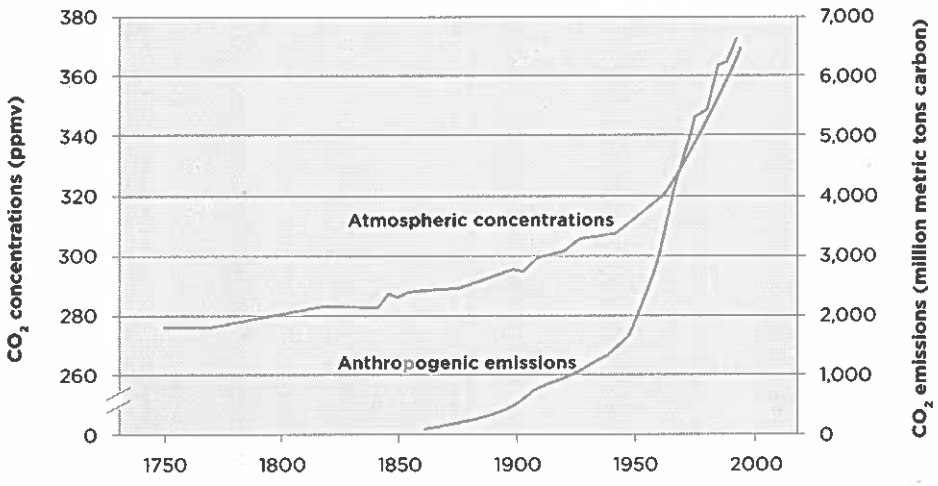
COAL'S CONTRIBUTION TO GLOBAL WARMING

In previous sections we have discussed the relationship between coal plant pollutants and human health. Here, we address coal's contribution to global warming, and the likely impacts of that warming on human health.

With very high carbon dioxide emissions due to combustion, and significant methane emissions from mining activities, coal is a major contributor to the buildup of greenhouse gases in the atmosphere. These gases allow solar energy to reach the planet's surface but delay that energy's escape into space, effectively trapping heat in the lower atmosphere.[1]

Atmospheric concentrations of greenhouse gases have increased markedly since 1750 as a result of human activities, especially the combustion of fossil fuels. Carbon dioxide (CO_2) is the most abundant greenhouse gas, and almost all U.S. CO_2 emissions (close to 98%) are due to fossil fuel combustion.[2] The level of atmospheric CO_2 now far exceeds pre-industrial values: Whereas the preindustrial level was 280 ppm, it is now approximately 385 ppm[3] (see Figure 6.1). China emits the most greenhouse gas of any country, but the U.S. emits the most greenhouse gas per capita.[4] Historically, the U.S. is responsible for over one-quarter of all anthropogenic greenhouse gases emitted globally.[5]

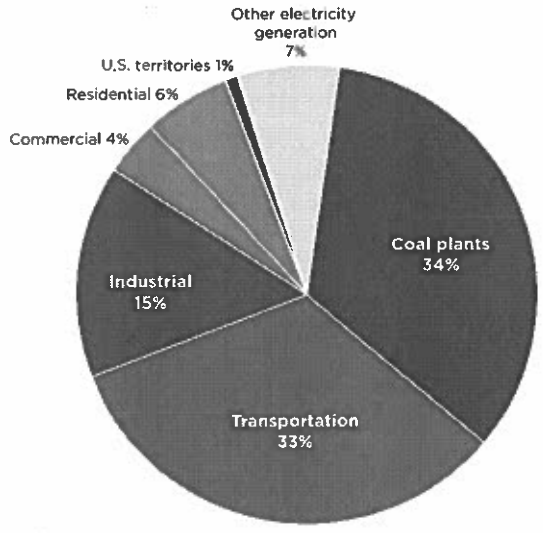
Coal-fired power plants are a major greenhouse gas source in the U.S., accounting for more than



BEERKOFF/DREAMSTIME.COM

one-third of our nation's CO_2 emissions (see Figure 6.2).[6] Within the electricity sector, coal generates roughly 50% of the electricity[7] yet emits over 80% of the sector's total emissions.[8] This disproportionate carbon footprint is due to the high carbon content of coal relative to other fossil fuels such as natural gas.

Methane emissions from coal mining are another important component of greenhouse gases.[9] Methane is produced when coal is formed and released when it is mined. Because methane is an occupational hazard in underground coal mines—it may explode or asphyxiate miners—it must be removed and ventilated into the atmosphere or burned. About 60% of methane emissions are now related to human activities,[10,11] with nearly 10% of that derived from coal mining and the remainder attributable largely to animal husbandry, waste management, and natural gas systems (see



R04338

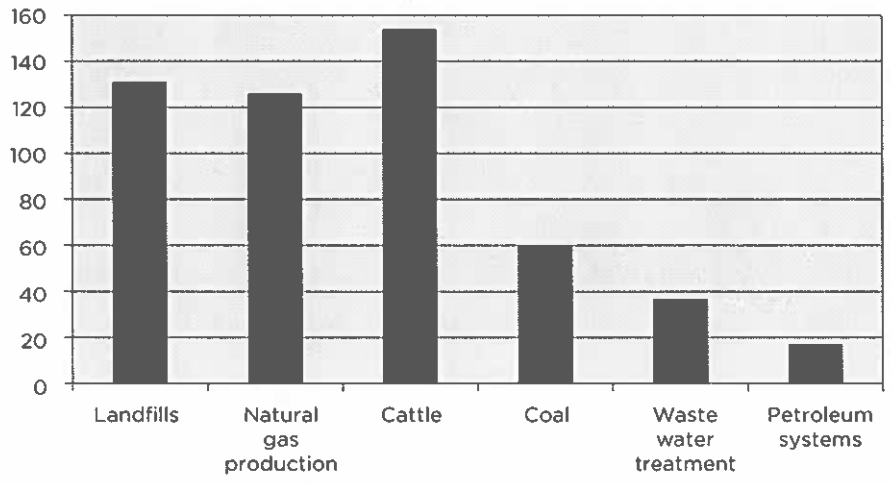
Figure 6.3).[12] Although methane has a short lifetime in the atmosphere—9 to 15 years, compared to CO_2's 100 years or more—it is approximately 23 times more effective than CO_2 in trapping heat in the atmosphere.[13,14]

GLOBAL WARMING'S IMPACT ON HUMAN HEALTH

The accumulation of greenhouse gases in the atmosphere is making itself felt on earth in the form of increases in global average land and ocean surface temperatures, increases in snow melt and receding glaciers, thawing of permafrost, increases in the mean sea level, and changes in precipitation.[15] These effects create conditions that threaten human health directly and indirectly.

The high temperatures associated with global warming have direct implications for human health. Historically, global average temperatures have been quite stable. However, since 1909 the average temperature has risen 0.74°C (1.33°F).[16] In the U.S., the number of heat waves in the eastern and western regions rose by about 20%

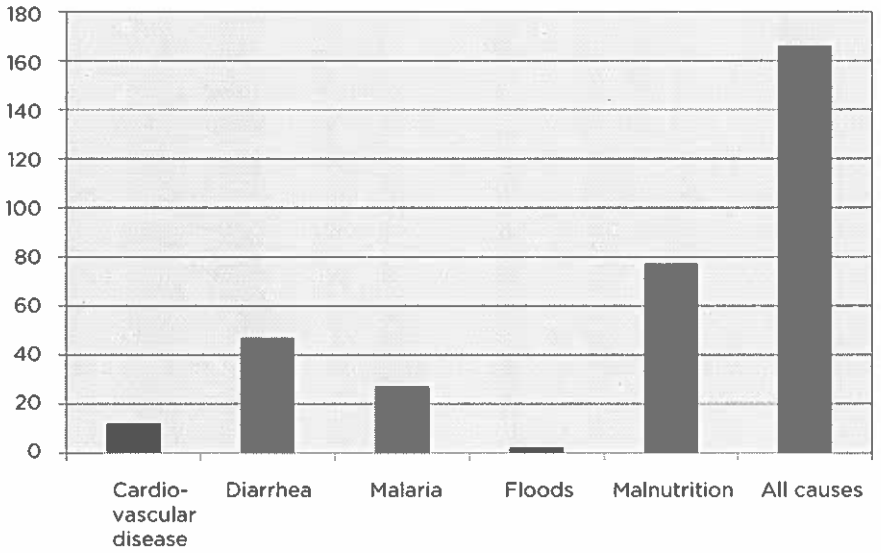


between 1949 and 1995.[17] Prolonged exposure to high temperatures can cause heat cramps, heat syncope, heat exhaustion, and heat stroke, which often leads to death. Advanced age is the most significant risk factor for heat-related deaths in the U.S., as the elderly are often less mobile, frequently home-bound and socially isolated, and may have thermoregulatory problems associated with multiple co-morbidities and medications that put them at higher risk for death during intense heat waves.[18] In addition, excessive heat exposure disproportionately affects people with certain pre-existing medical conditions, including cardiovascular disease, respiratory illnesses, and obesity.

It is difficult to quantify the number of deaths that result from heat waves, as heat-related deaths may be attributed to pre-existing conditions. However it is known that in 2003, between 22,000 and 35,000 people died as a direct result of the heat wave that swept Europe.[19,20] While it is impossible to attribute any specific heat wave to global warming, Stott, et al., concluded with a certainty of more than 90% that global warming more than doubled the probability of that heat wave occurring.[21]

In addition to the health effects directly associated with rising temperatures, global warming causes a profusion of interconnected public health problems.[22] Extreme-weather events and changing patterns of precipitation increase mortality from drowning. Flooding and infrastructure damage, along with temperature rise, increase the prevalence of insect- and water-borne diseases such as diarrhea, malaria, and dengue fever. High temperatures and continued fossil fuel consumption worsen air quality, impacting respiratory and cardiovascular health. Changing patterns of precipitation, rising temperatures, and extreme weather events cause crop damage and crop failure, affecting global food security. Competition for scarce resources such as food and water are predicted to cause mass migrations of environmental refugees, social destabilization, and war, while social destabilization and increasing global health problems are predicted to increase the risk of mental

Figure 6.3: Methane sources



Methane emissions (Tg CO_2 equivalents). Contributions from coal include both active and abandoned mines. Contributions from cattle include emissions due to enteric fermentation and manure management.

R04341

health problems, further adding to the burden on healthcare resources.

Many of these health effects are already evident. The World Health Organization (WHO) has quantified the annual impact of global warming on some health outcomes. WHO has estimated that global warming was responsible for 166,000 deaths in the year 2000 alone, due to additional mortality from malaria, malnutrition, diarrhea, and drowning. In addition, WHO estimated that in 2000, global warming caused increases in diarrhea, malaria, cardiovascular disease, and malnutrition that led to the loss of more than five million life years to disability from illness or premature death,[23] as shown in Figure 6.4.

The health burden of global warming, already large, is predicted to increase. Table ES-2 (see page xiii) shows the predicted health effects of global warming, the mechanisms that would drive these effects, and the populations most vulnerable to their implications.

RESPONDING TO GLOBAL WARMING

Events and activities that affect climate may not make themselves visible at once; rather, their impact may manifest years later. This is especially true of gradual phenomena such as the buildup of greenhouse gases in the atmosphere. The global warming effects that we currently experience were set in motion by greenhouse gases emitted over the past 250 years. By the same token, the greenhouse gases that we emit today might not affect us noticeably at the moment; they will manifest later—and, due to their persistence in the atmosphere and the substantial amount of heat absorbed by the oceans, will continue to be felt for decades to millennia to come. This delay in the felt consequences of current actions is known as "lag" in the climate system.[24]

Steps that would prevent further global warming include replacing coal-based generation of electricity with clean, non-fossil fuel energy sources.

The rise in average global temperatures has set in motion cycles of mutually reinforcing warming events. One example is the melting of polar ice. Polar ice melt reduces the amount of light-colored surface area that reflects the sun's rays, while expanding larger areas of dark land and ocean that absorb heat. This adds to overall warming, resulting in more ice melting. Rising temperatures in northern regions also cause the permafrost to melt. Permafrost is permanently frozen soil, sediment, or rock that remains at or below 0°C for at least two years. Because it is so cold, it can tolerate the introduction of considerable heat without thawing. However, when it does thaw, it releases potentially vast amounts of methane frozen in the mud and ice. Because methane is a potent greenhouse gas, this also accelerates global warming. Thus, one warming phenomenon feeds another, creating positive feedback cycles.[25]

These and other feedback cycles push us closer to a "tipping point": a point at which the accumulation of small changes in a steady state will force a change in that state that is sudden, significant, and usually irreversible.[26] In regard to climate, the tipping point will be reached when the gradual changes set in motion by burning fossil fuels—the accumulation of greenhouse gases, rising temperatures, and positive feedback loops—overwhelm our ability to offset them. At that point, the momentum of global warming will become irreversible on a human time scale. Therefore, action must be taken now to prevent such a scenario.

There are two categories of action that must be taken in response to global warming: mitigation and adaptation. Mitigation means preventing further global warming; it encompasses steps that would slow and stop the emission of greenhouse gases.[27] Significant forms of mitigation include replacing coal-based generation of electricity with clean, non-fossil fuel energy sources such as wind and solar; substituting non-fossil fuels for the gas and diesel we burn in vehicles; and reducing the need for energy by achieving increases in energy efficiency and conservation.

Adaptation refers to steps that would reduce vulnerability to the actual or expected negative

R04342

effects of climate change, such as building cities and healthcare infrastructure that can withstand extreme weather events, preparing emergency response plans, and developing drought-resistant crops.[28] With the effects of climate change already being felt, adaptation is necessary to protect vulnerable people and nations. At the same time, as a societal response adaptation is insufficient. If we continue to emit large amounts of greenhouse gases, global warming will continue and its effects will intensify. Eventually the damage wrought by floods, storms and sea level rise, drought and desertification, disease and hunger, habitat destruction and human displacement will overcome our capacity to protect ourselves. While adaptation measures are necessary, focusing our energies there to protect public health is insufficient. Adaptation does not prevent the triggering of climate tipping points such as those described above. The true protection of health and of life ultimately lies in prevention.

Lag in the climate system, especially when considered in conjunction with positive feedback

CARBON CAPTURE AND SEQUESTRATION

Carbon capture and sequestration (CCS) technology involves capturing the CO_2 from coal emissions, compressing it until it forms a liquid, and transporting the liquid CO_2 through pipelines to a geologically appropriate underground storage area where it would be stored ("sequestered") permanently.

Viewed through a public health lens, CCS poses several obstacles which would have to be resolved before it could be considered a viable option:

Concentrated CO_2 can be lethal. Concentrated CO_2 can asphyxiate people, as demonstrated in 1986 by the spontaneous release of CO_2 at Lake Nyos, Cameroon, that killed 1,700 people. Care must be taken to avoid pooling or leakage of CO_2 during both transport and storage.[29]

Permanent storage may not be possible. Storage would have to be leak-proof for geological periods of time.[30] If at any point in time stored CO_2 escaped into the atmosphere, it would contribute to global warming. If it were to leak into underground aquifers, it could dissolve and release contaminants such as arsenic, lead, mercury, and organic compounds, or could alter water acidity, affecting water quality.[31]

CCS would perpetuate coal pollution. During the time that CCS technology is being developed and safety and liability issues are being addressed, carbon emissions from coal plants would continue unabated. Even if CCS technology were successful, it would sustain the dependence on coal for the generation of electricity, perpetuating the release of other pollutants into the atmosphere, including particulates, sulfur dioxides, nitrogen oxides, and mercury, and contributing to the health-related problems associated with coal mining and the long-term storage of both pre- and post-combustion coal wastes.

CCS would divert funds from clean energy. The cost of research, development, construction, and implementation of CCS would be high.[32] The pipelines alone, reaching from every coal-powered plant in the country to appropriate storage areas, would require the construction of an extensive infrastructure system.[33] Funds spent on CCS development, construction, and deployment would be unavailable for investment in clean, safe energy from non-carbon-based sources.

Given the costs and difficulty of implementing CCS on a timeline and a scale that would effectively mitigate the health effects of global warming, the unreliability of permanent storage for geological periods of time, and the costs to health from coal's traditional pollutants, PSR has concluded that CCS is not a preferred option for developing the nation's energy future.

R04343

ISTOCKPHOTO.COM

loops and tipping points, has implications for our response to global warming. Even if CO_2 emissions cease today, average global temperatures will continue to rise. Therefore, current readings of CO_2 levels do not provide a full appraisal of the damage we have already inflicted on the climate system. This in turn means that we must be conservative in regard to future greenhouse gas emissions: Since the full impact of the emissions we have already released have not yet been felt, we should be cautious in assuming that we can predict the impacts of additional emissions.

The dynamics of climate change mean that we cannot take an unhurried approach to stopping global warming. We may be nearing climate tipping points; when we reach them, no human action or agency will be able to stop the climate change we will have set in motion. We must take action now, while there is still time to protect health and well-being on the planet.

7. *Policy Recommendations*

The U.S. is at a crossroads for determining its future energy policy. While the U.S. relies heavily on coal for its energy needs, the health consequences of that reliance are multiple and have widespread and damaging impact. Coal combustion contributes to diseases already affecting large portions of the U.S. population, including asthma, heart disease, and stroke, compounding major public health challenges of our time. It interferes with lung development, increases the risk of heart attacks, and compromises intellectual capacity. Coal pollutants affect all major body organ systems and contribute to four of the five leading causes of mortality in the U.S.: heart disease, cancer, stroke, and chronic lower respiratory diseases. Although it is difficult to ascertain the proportion of this disease burden that is attributable to coal combustion, even very modest contributions to these major causes of death are likely to have large effects at the population level, given high incidence rates.

The health effects of coal are not limited to diseases caused by combustion byproducts. Utilizing coal for energy also harms human health through the processes of mining, washing, transport, and post-combustion waste storage. Moreover, coal combustion is the largest point-source emitter of CO_2 in the U.S., contributing to the buildup of greenhouse gases that causes global warming. Although global warming is often framed as an environmental problem, it is likely to have significant public health consequences on a global scale, including increases in heat stroke, diarrhea, malaria, drowning, food shortages, mental health problems, and war. Many of these effects are already apparent. Reducing our nation's dependence on coal is essential if we are to achieve the reductions in carbon emissions necessary to stave off the worst health effects of global warming.

DHUSS/ISTOCKPHOTO.COM

Based on that assessment, PSR finds it essential to translate our concern for human health into

R04346

recommendations for public policy. The first of those recommendations is that emissions of CO_2 be cut as deeply and as swiftly as possible, with the objective of reducing CO_2 levels in the atmosphere to 350 parts per million. The reduction of CO_2 emissions, an urgent necessity for achieving satisfactory health outcomes, should be pursued through two simultaneous strategies: 1) strong climate and energy legislation that establishes hard caps on global warming pollution coming from coal plants; and 2) the Clean Air Act. Since its enactment, the Clean Air Act (CAA) as implemented by the EPA has been effective in reducing a wide variety of air pollutants, from nitrous oxides to volatile organic compounds. CO_2 and other greenhouse gases emitted by coal plants have been designated pollutants under the CAA. The EPA should be fully empowered to regulate these gases under the CAA so that coal's contribution to global warming can be brought to an end.

A medically defensible energy policy must take into account the public health impacts of coal while meeting our need for energy.

Secondly, PSR recommends that there be no new construction of coal-fired power plants, so as to avoid increasing health-endangering emissions of CO_2 as well as criteria pollutants and hazardous air pollutants. CO_2 emissions from coal could increase 60% by 2030 if current plans to invest hundreds of billions of dollars in new and old coal-fired power plants are realized. Those emissions would push greenhouse gas levels ever higher, potentially reaching a tipping point at which we would face the most extreme health consequences of global warming. For these reasons, PSR chapters across the nation have contributed to the effort to halt the permitting of new coal plants, adding the medical voice to licensing deliberations and helping to influence a number of decisions not to construct new plants.

The U.S. should dramatically reduce fossil fuel power plant emissions of sulfur dioxide and nitrogen oxides so that all localities are in attainment for national ambient air quality standards. In addition, we should establish a standard, enforceable by the EPA and based on Maximum Achievable Control Technology, for mercury and other hazardous air pollutant emissions from electrical generation.

Finally, the nation must develop its capacity to generate electricity from clean, safe, renewable sources so that existing coal-fired power plants may be phased out without eliminating jobs or compromising the nation's ability to meet its energy needs. In place of investment in coal (including subsidies for the extraction and combustion of coal and for capture of carbon and other pollutants), the U.S. should fund the improvement of energy efficiency, the expansion of conservation measures, and the research, development, and implementation of clean, safe, renewable energy sources such as wind energy, solar, and wave power.

These steps comprise a medically defensible energy policy: one that takes into account the public health impacts of coal while meeting our need for energy. When our nation establishes a health-driven energy policy, one that replaces our dependence on coal with clean, safe alternatives, we will prevent deterioration of global public health caused by global warming while reaping the rewards in improvements to respiratory, cardiovascular, and neurological health.

Date:	Friday, January 17, 2020 3:56:25 PM
Attachments:	IL0077666 Post Hearing Comments_PRN SC SAFE.pdf

Dear Ms. Lieberoff and other Illinois EPA officials;

On behalf of Prairie Rivers Network, Sierra Club and Southern Illinoisans Against Fracturing Our Environment, attached are post-hearing comments regarding the proposed NPDES Permit IL0077666 for the Pond Creek mine. As these comments will explain, the proposed permit plainly cannot be legally granted by the Illinois Environmental Protection Agency (IEPA) based on the current record. Please do not hesitate to reach out to us for further clarification.

In 4 emails following this one, I will be including the exhibits to this comment letter. Please include those in the record with this submission.

Thank you,
Andrew

facebook | twitter

downstream water bodies and would use these waters more frequently were they not affected by pollution from this facility and other sources. Our members are threatened by the proposed degradation of the Big Muddy, Pond Creek and other downstream and adjacent waters. Our members and others rely on clean waters in the Big Muddy watershed for activities including hunting, recreational fishing, commercial fishing, trapping, paddling, boating, birdwatching and other wildlife viewing.

Southern Illinoisans Against Fracturing Our Environment (SAFE) is an organization based in Southernmost Illinois and has members who live adjacent to the Big Muddy River, and who enjoy kayaking, canoeing, and birdwatching along the river. Members living next to the river experience issues with flooding of the Big Muddy with regularly occurring precipitation events as we did last weekend, January 11 when 4-5" pushed flood waters into the back yard of members' homes. Numerous SAFE members were present at the IEPA hearing on December 18, 2019, including Jan Thomas, Cameron Smith, Tabitha Tripp, and Tenney Naumer.

Legal Overview

The hearing and documents obtained through the Illinois Freedom of Information Act (FOIA) disclosed that the permit cannot be legally granted under 35 Ill. Adm. Code 302.102, 302.105, 304.105, 309.141(a) and (d), 309.143(a) and 309.146 because the draft permit as written does not ensure compliance with Illinois water standards or permitting rules and would violate at least the following applicable regulations:

- **35 Ill. Adm. Code 302.105(a)** (Tier 1 antidegradation) by allowing increased discharges of chloride, sulfate, total suspended solids and other pollutants that will adversely affect existing uses of the Big Muddy River and Pond Creek and other creeks in the area. Among the ways in which existing uses will be impacted will be through chemical and biological processes resulting from allowed discharges that will cause increased methyl mercury, increased phosphorus, increased cyanobacteria and decreased dissolved oxygen (DO) in the water column. Damage to existing uses may also occur through damage to creeks not receiving discharges from the mine but that may be affected in quality from reduced stream flow caused by groundwater moving downward to fill areas vacated by groundwater filling the mine.
- **35 Ill. Adm. Code 304.105, and 309.141(d) and 309.143** by increasing the levels of methyl mercury and phosphorus, decreasing DO levels, and causing violations of narrative standards in the Big Muddy. The Big Muddy is already listed as impaired by methyl mercury, low DO and TSS in the receiving segment and numerous downstream segments and as potentially impaired by phosphorus.
- **35 Ill. Adm. Code 302.105(c)** (Tier 2 antidegradation) by allowing new discharges to the Big Muddy River and Pond Creek that are not necessary to accommodate important social or economic development but, on the contrary, will harm social and economic development by further wedding the local economy to an industry without a long term future and a company likely to leave the community with a large environmental hazard

Re: NPDES Permit No. IL0077666, Notice 7516c- Williamson Energy, LLC

Dear Ms. Lieberoff and other Illinois EPA officials;

The proposed permit plainly cannot be legally granted by the Illinois Environmental Protection Agency (IEPA) based on the current record. Further, any attempt to remedy the grossly defective draft permit and permit record with new documents or a revised permit cannot be allowed to result in a new permit being issued without re-noticing the revised permit and allowing a further public hearing based on a properly supported public notice and antidegradation analysis.

As shown at the public hearing held December 18, 2019, and confirmed by the comments and science submitted with this written comment including the attached comments of Dr. Matthew Baker (Ex. A) and Dr. JoAnn Burkholder (Ex. B), the permit would allow substantial harm to the environment and its issuance would violate numerous provisions of law.

Commenting Organizations

This letter includes the post-hearing comments of Prairie Rivers Network, Sierra Club and Southern Illinoisans Against Fracturing Our Environment (SAFE).

Prairie Rivers Network (PRN) works to protect water, heal land, and inspire change and their energy program works to reduce the impact of coal on rivers and groundwater across the state. PRN has 1200 members, including members who live near and use the Big Muddy River watershed and downstream areas for fishing, paddling, birdwatching, and other recreational activities. Amanda Pankau, staff member of Prairie Rivers Network, attended the hearing and gave testimony and asked clarifying questions.

Sierra Club has 100,000 members and supporters across Illinois who seek to restore and protect a clean and healthy environment for all residents of Illinois. Sierra Club members attended the hearing and gave testimony, including Lucia Amorelli, Jean Sellar, Jane Cogie, Connie Schmidt, Barbara McKasson, and Albert Ettinger. Our members are affected by pollutant discharges into Pond Creek, the Pond Creek tributary, the Big Muddy River and

that will have to be cleaned up with public funds. Neighbors of the mine will continue to be harmed by the mining operations. Further, the mining of coal, to the extent it occurs and the coal is burned in China or elsewhere, will harm the local economy (and the world economy) by increasing the emission of greenhouse gases.

- **35 Ill. Adm. Code 302.105(a), 35 Ill. Adm. Code 304.105, and 309.141(d), 309.143, and 309.146** by allowing a mixing zone that (the misrepresentations made in the record by the applicant notwithstanding) will in fact result in violations of applicable water quality standards outside the mixing zone by allowing increased discharges subject to implementation of a complex dilution and monitoring formula by an applicant that has proven itself utterly incapable of complying with the limits and reporting requirements of its current relatively simple permit and by allowing a mixing zone in Pond Creek where no dilution is available.
- **35 Ill. Adm. Code 302.102(a), 302.105(a), 35 Ill. Adm. Code 304.105, and 309.141(d) and 309.143** by failing to protect mussels.
- **35 Ill. Adm. Code 146** by failing to require monitoring adequate to determine compliance with the complex dilution scheme contemplated by the permit.
- **35 Ill. Adm. Code 302.102, 302.105(a), 35 Ill. Adm. Code 304.105, and 309.141(d) and 309.143** because the reasonable potential test on which the public document relies was not properly performed at least with regard to mercury, copper, iron, nickel, and selenium. It appears that cadmium and manganese have also not been tested properly.
- **35 Ill. Adm. Code 302.102, 302.105(a), 35 Ill. Adm. Code 304.105, and 309.141(d) and 309.143** because the testing done for mercury was not done with sufficient sensitivity to determine whether there is a reasonable potential for the discharge to cause or contribute to violations of the applicable 12 ng/L water quality standard (35 Ill.Adm.Code 302.208(f)).[1]

I. Tier 1 Antidegradation - Existing uses are not being Protected in Violation of 35 Ill.Adm.Code 302.105(a).

The discharger purports to be establishing a complex scheme to prevent violations of Illinois water quality standards outside the mixing zone for numerous pollutants, but the scheme for meeting the standard is unlikely to be implemented and the criteria are not protective of existing uses as to numerous pollutants. The segment of the Big Muddy where the proposed discharge will be located is designated as impaired for Aquatic Life, Fish Consumption and Primary Contact Recreation. However, fishing occurs in the Big Muddy and over ten thousand pounds of fish are caught from the river each year, according to IDNR data (Ex. I)

In particular, the permit is not protective of existing uses because the impact of the increased chloride, conductivity, sulfate, total suspended solids (TSS), copper, iron, manganese, and nickel has not been properly considered and the cumulative effect of the increased

[1] 415 ILCS 5/11 and the Illinois Pollution Control Board regulations require that IEPA "ensure" that every NPDES permit prevent discharges of pollutants that have a reasonable potential of violating any Illinois water quality standard. Prairie Rivers Network v. Illinois PCB 2016 IL App (1st) 150971 par. 26.

concentrations of all of these pollutants together has been totally ignored.[2] Further, the background levels of chloride have not been properly stated and the amount of acidity and other pollutants that will enter the waters is not being properly monitored.

The reality is that the permittee intends to continuously discharge at the maximum allowable flow rate in order to get rid of all the saline groundwater pouring into the mine. Their own report admits this.[3] This is also shown through estimating how much discharge could have been received by the Big Muddy based on the historical flow record. The mine estimates that, currently, 2.7 million gallons per day of mine water will need to be pumped out, and this could increase up to 3.5 mgd.[4] Assuming that the chloride concentrations reach levels similar to those seen at Sugar Camp mine, as is anticipated,[5] the load that the Big Muddy could carry without violating the 500 mg/L chloride standard at the edge of the mixing zone would range from 1.8 to 4.7 mgd, based on historical flow records.[6] On the low end of that range (drier years), when the Big Muddy could only take an average daily discharge of 1.8 mgd from the mine, the river would not have been able to assimilate the entire 2.7 mgd of mine waste without violating water quality standards (which, again, could increase to 3.5 mgd in the future). This means that the mine would be discharging at its limit the whole year. Even at the high flow end of this estimate, where the Big Muddy could supposedly assimilate 4.7 mgd, the mine would still be often be pumping near the limit. The flow limitations from the mixing equation, then, are not some theoretical maximum that the mine might hit. The mine will be operating at this limit nearly all the time when the infiltrating groundwater reaches anticipated levels.[7]

Continual discharge at maximum levels would raise the background chloride concentrations of the Big Muddy downstream to higher levels. A crude approximation, assuming the applicant can meet the limit of 500 mg/L Chloride in ¼ of the river for mixing, shows that the chloride levels in the river would increase as follows:

> Background Concentration: 108 mg/L starting level
> Mix with Sugar Camp: 0.25 * 500 mg/L + 0.75 * 108 mg/L = 206 mg/L
> Mix with Pond Creek: 0.25 * 500 mg/L + 0.75 * 206 mg/L = 280 mg/L

---

[2] The limits of the testing and the sensitivity of the testing methods is such that increased loading of a number of other pollutants is probable.

[3] Conceptual Diffuser Design: "The controlled low-flow periods have in the past extended for more than a year. The Mine cannot hold water for that long of a period. At the same time, the Mine cannot discharge the full amount of water that it needs to at the low flow condition. The solution is to discharge some water all of the time, increasing the discharge as conditions allow." page 6-1

[4] Anti-degradation Assessment Pond Creek No. 1 Mine ((November 18, 2016) ("Anti-degradation Assessment") pg 16

[5] Conceptual Diffuser Design page vii

[6] Conceptual Diffuser Design page viii

[7] Indeed, the diffuser design document states "The controlled low-flow periods have in the past extended for more than a year. The Mine cannot hold water for that long of a period. At the same time, the Mine cannot discharge the full amount of water that it needs to at the low flow condition. The solution is to discharge some water all of the time, increasing the discharge as conditions allow."

In other words, the entire Big Muddy downstream would be forced to sustain concentrations above the United States Environmental Protection Agency (U.S. EPA) recommended chronic chloride standard of 230 mg/L, which recent science shows is not adequate to protect aquatic life (see infra), and any additional downstream discharge of chloride would push the Big Muddy further beyond the current outdated and insufficiently stringent U.S. EPA recommended criteria.[8]

A. Increased loadings of chloride will harm existing uses.

The applicant purports that it will establish a complex scheme for prevention of violation of the Illinois 500 mg/L acute chloride standard. However, it appears that the permit applicant does not intend to monitor directly for chloride in either the discharge or the Big Muddy River but, rather, will be estimating chloride levels from conductivity data. Problems with the correlation are discussed in Section V below.

Considering just the direct effects of chloride alone, there are at least four fatal problems that preclude granting the permit under 302.105(a) and numerous other provisions of law.

First, the monitoring proposed is not properly spelled out or enforceable and the applicant intends to monitor conductivity rather than chloride directly. The levels of chloride present given a particular level of conductivity varies from place to place and time to time as was admitted by the Agency during the hearing. See also, Comment of Dr. Burkholder (Ex. B, p.6). Thus, the permit applicant has not presented any sound methodology for making a reasonable estimate of chloride levels with the equipment that it plans to use. Moreover, as will be discussed further in Section V below, it is apparent that this discharger, which has committed numerous permit violations as well as violations of reporting requirements, is utterly incapable of implementing the complex monitoring and discharging scheme it pretends that it will utilize.

Second, the available data indicates that for the Antidegradation Assessment the applicant and IEPA are using an estimate of the background level of chloride that is lower than that shown by the available data. The current antidegradation assessment prepared by the mine notes that the 90th percentile background level of Chloride is 30 mg/L,[9] and the report states this number comes from Illinois EPA. An evaluation of available chloride data just upstream of the proposed discharge shows that a proper Antidegradation assessment would include an updated 90th percentile background for chloride. The last five years of water quality data from the Big Muddy at Plumfield (segment N-11) just north of the proposed discharge point show that the 90th percentile chloride concentration is greater than 103 mg/L. See also, Comment of Dr. Baker (Ex. A, p.3).

Further, the entire scheme assumes without evidence that all of the chloride discharged into the Big Muddy will flow downstream without any adverse impact and that no chloride will be stored

[8] The U.S. EPA chronic water quality standard for chloride is contained in Ambient Water Quality Criteria for Chloride - 1988 EPA 440/5-88-001 (February 1988) available on the U.S. EPA website.
[9] Antidegradation Analysis page 12 (pdf 13)

in groundwater, side channels, sediment or biota to re-emerge into the river at a later time when the applicant under its scheme may be discharging chloride at a higher rate than would be allowed. If a portion of the high chloride discharged during high-flow periods is still present in the system when flows decrease, violations of the 500 mg/L acute standard can be expected. See also Comment of Dr. Burkholder on the chemical interactions between the overlying water and stream sediments (Ex. B, p.5).

Still further, it is clear that the Illinois 500 mg/L chloride standard is not protective of existing uses against chronic toxicity especially during warm weather. As was discussed by Professor David Soucek of the University of Illinois in IPCB 18-32, the entire record of which is incorporated by reference in opposition to this permit. A properly protective chronic standard adjusted to account for the water temperature and hardness factors that may be present during the proposed discharges would require prohibiting discharges that would cause chronic levels in the Big Muddy to exceed the levels indicated as safe by Dr. Soucek's studies and the studies on which he relied (Ex. C).

B. Impact of increased and high conductivity has not been assessed.

There is abundant scientific evidence to suggest that total conductivity itself is a parameter that may affect existing uses. See Comment of Dr. Baker (Ex. A, p.3). This was further documented in the Draft Field Based Methods for Developing Aquatic Life Criteria (U.S. EPA 2016) (Ex. D). Neither the applicant nor IEPA have apparently given any thought as to how increased conductivity might affect existing uses in Pond Creek or the Big Muddy River. The available evidence indicates that harm to existing uses will occur.

C. Increased chloride and sulfate will increase toxic mercury levels.

It is well established that the Big Muddy is already impaired by methyl-mercury pollution and that increased chloride in a water body will increase the level of mercury released from the sediments in a water body that will take toxic forms (methyl-mercury and others). See Illinois 303(d) list[10]; Comments of Dr. Burkholder (Ex. B, pp. 1-2); and Hearing Transcript (Barb McKasson at p.110-111). Accordingly, the permit would allow increased impairment of existing uses, harm public health and commercial fishing, as well as violate other provisions of Illinois Law to be discussed below.

Moreover, as discussed in Section III below, potential mercury levels in the discharge have not been tested using sufficiently sensitive methods or using a proper reasonable potential analysis.

[10] Currently available at:
https://www2.illinois.gov/epa/topics/water-quality/watershed-management/tmdls/Pages/303d-list.aspx

D. The effects of increased sulfate, TSS, copper, iron, cadmium, selenium, hydrogen sulfide, acidity, and nickel on existing uses have not been properly determined

No effort has been made to properly estimate the high levels of these pollutants that may occur in the discharge under the USEPA Technical Support Document EPA/505/2-90-001, PB91-127415 (March 1991)[11]. The fact that the applicant has chosen to take very few samples is no excuse for not using the proper multipliers needed to determine the potential levels of those pollutants. See *Illinois EPA v. Illinois PCB*, 386 Ill. App. 3d 375, 387 (Ill. App. 2008).[12]

Further, the potential for the discharge to cause the creation of toxic hydrogen sulfide must be considered given the increase in sulfate that would be allowed in this permit. See Comment of Dr. Burkholder (Ex. B, p. 5). Still further, the increased toxicity in the mixing zone will have the effect of increasing biological oxygen demand and, thus, increasing the existing violation of the DO standard in violation of 302.105(a) and the other cited regulations that prohibit allowing a discharge that will cause or contribute to violations of state water quality standards. See also, 40 CFR 122.44(d) and Comment of Dr. Burkholder (Ex. B, p.4)

Still further, it appears that levels of extreme acidity may be found in the discharge as shown by the discharge monitoring report for Outfall 7 in September 2016, June 2017, December 2017, March 2018 for low pH, and at Outfall 8 in September 2016, June 2017, and December 2017 for low pH (Ex. F). The Big Muddy is already impaired by low pH. Given these problems with low pH discharges, we question why the Agency is permitting outfalls 006, 007 and 008 as acid mine drainage. IEPA cannot grant a permit unless the proposed discharge will not increase the existing pH impairment.

E. The cumulative effects of all the increased pollutants and the effects of existing low dissolved oxygen conditions and other stressors must be considered.

Any proper analysis of the potential effect of the proposed discharge would consider the cumulative effects of all of the pollutants and stresses that it is proposed to increase together and in the context of the fact that the Big Muddy River is already plagued by dissolved oxygen levels that regularly fall below applicable Illinois water quality standards. The proposed discharge is very likely to exacerbate the existing aquatic life impairment. See comment of Dr. Baker (Ex. A, p.3) and comment of Dr. Burkholder (Ex. B, p.6-7).

F. IEPA must consider the effects of the proposed discharges on Pond Creek and on other creeks in the vicinity of the mine.

---

[11] Currently available at: https://www3.epa.gov/npdes/pubs/owm0264.pdf

[12] IEPA in 2016 did a reasonable potential analysis of some of the outfalls based in each case on one sample (Ex. E). Reasonable potential was found at one or more outfalls for cadmium, copper, nickel, mercury, and silver. Cadmium was found at levels above the acute standard in numerous outfalls.

IEPA must also determine the potential effect of allowing this discharge on creeks in the area of the mine, the existing uses of which may be affected by drawdowns of groundwater and surface waters that may be connected to the saline aquifer the mine is now draining.

G. The permit makes no assessment of the effect of the discharge on mussels.

The permit and the antidegradation assessment make no attempt to address impacts to mussels or even assess if mussels are present in the area, despite clear direction that Illinois' antidegradation policy calls for the maintenance and protection of existing uses, including the prevention of a shift from pollution-sensitive to more pollution-tolerant community and the loss of species diversity (Section 302.105(a)(1)). Sensitive mussels have been shown to be killed in chloride/sulfate mixtures when sulfate is much lower than what would be allowed in the permit.[13]

---

[13] Freshwater mussels are one of the most imperiled groups of organisms. Nearly 70 percent of these species are designated either as threatened, endangered or in decline (Williams, JD, ML Warren, KS Cummings, JL Harris, RJ Neves. 1993. Conservation status of freshwater mussels of the United States and Canada. Fisheries 18, 6-22.) Recent studies have shown that for some contaminants, freshwater mussel glochidia and juveniles are more sensitive than standard test organisms, leading to concerns that U.S.EPA chronic criteria, which are 230 mg/L, do not adequately protect freshwater mussels Wang, N., CD Ivey, RA Dorman, CG Ingersoll, J Steevens, EJ Hammer, CR Bauer, and DR Mount. 2018b. Acute toxicity of sodium chloride and potassium chloride to a unionid mussel (Lampsilis siliquoidea) in water exposures. Environmental Toxicology and Chemistry. First published: 19 June 2018, https://doi.org/10.1002/etc.4206. Wang, N., JL Kunz, RA Dorman, CG Ingersoll, JA Steevens, EJ Hammer, and CR Bauer. 2018a. Evaluation of chronic toxicity of sodium chloride or potassium chloride to a unionid mussel (Lampsilis siliquoidea) in water exposures using standard and refined toxicity testing methods. Environmental Toxicology and Chemistry. 21 Aug. 2018, https://doi.org/10.1002/etc.4258,

In Gillis, PL. 2011. Assessing the toxicity of sodium chloride to the glochidia of freshwater mussels: implications for salinization of surface waters. Environmental Pollution 159: 1702-108, it is pointed out that for glochidia, the end point for studies of acute chloride toxicity is not death, but loss of ability to attach to a host species, which is necessary for their survival, and renders them "effectively dead." In their study of acute chloride toxicity of Fatmucket, *Lampsilis siliquoidea*, juveniles and glochidia, Wang et al. (2018b) state that including their more recent mussel data in the toxicity database would "likely lower the [USEPA Water Quality Criteria 230 mg/L] and [Water Quality Standards] for [Chlorides]." Wang et al (2018a) made a similar statement in their study of the chronic chloride toxicity of the Fat Mucket, in which they state "inclusion of the data from the present study and recent publications to update the national chronic water quality criterion or Iowa chronic water quality standard would likely lower the criterion or standard."

A study by the Great Lakes Environmental Center (GLEC) and the Illinois Natural History Survey (INHS) tested the acute toxicity of chloride to four freshwater invertebrate species including a species of fingernail clam, *Sphaerium simile*. GLEC and INHS found that "[f]ingernail clams are approximately 5.6 times more acutely sensitive to chloride at 50 and 200 mg/L total hardness than tubificid worms, and approximately 2.7 to 4.2 times more sensitive than the snail" USEPA. 2008. Final Draft Report. Acute toxicity of chloride to select freshwater invertebrates. Prepared for the USEPA by Great Lakes Environmental Center and Illinois Natural History Survey. 28 Oct. 2008.
(footnote continues on following page)
(footnote 13 continued) In terms of chronic long-term effects on invertebrate assemblages, in Wallace, AM and RG Biastoch. 2016. Detecting changes in the benthic invertebrate community in response to

Also see Comment of Dr. Burkholder (Ex. B, p.7). A 2012 study of mussels in the Big Muddy by the Illinois Natural History Survey (Ex. G) found their presence in nearly all of the nearby tributaries in the Big Muddy, which likely indicates that they are present in the main stem of the river (however, the main stem was too deep for the Survey staff to assess at the time of their study). If mussels are found, harming those mussels would be improper as a forbidden impact on existing uses (35 Ill.Adm.Code 302,105(a)(1)). Worse, this particular permit proposes a flow that will discharge and mix at the bottom of the river first, subjecting any mussel bed there to the highest of chloride concentrations.

The permit cannot be issued if the presence of mussels has not been assessed.

II. Tier 2 Antidegradation - The permit violates 35 Ill. Adm. Code 302.105(c) because the new discharges have not been shown to be necessary to accommodate important social and economic development and the record establishes that the new discharges would be socially and economically destructive.

The Anti-degradation Assessment filed by the applicant relies on a number of patently false statements regarding the need for and future of the coal industry and completely fails to consider anything but the alleged benefits of keeping the mine open. In fact, the benefits are extremely unlikely to be realized while the damage to be done to the environment and the local economy is deadly certain.

A. Workforce analysis ignores the applicant's financial perils.

The applicant's claims regarding future jobs and need for the coal are wildly inaccurate. There is no reason to believe the applicant will continue to operate for long, even if it receives this destructive permit. As explained at the hearing, stock prices of the applicant and related companies such as Foresight Energy have crashed. In 2019, eight major coal mining companies, including Murray Energy, filed for bankruptcy. The January 14, 2020, U.S. Energy Information Administration Short-Term Energy Outlook forecasts that coal production will reach a four-decade low in 2020, stating that coal-fired power plant retirements, electricity from lower coast natural gas and new renewables, and declining exports are expected.[14] Indeed, the whole Southern Illinois coal industry is in a downward spiral. Recent analysis from the Institute for Energy Economics and Financial Analysis reports that "Illinois Basin's coal industry is entering a period of structural decline," and "within the next 20 years, virtually all of the U.S. coal-fired

---

increasing chloride in streams in Toronto, Canada. Freshwater Science 35(1): 353-63, it is found that in streams in Toronto, Canada, the macroinvertebrate community demonstrated the most taxa changes (declining frequency and abundance of taxa sensitive to chloride and increasing frequency and abundance of taxa tolerant of chloride) at a threshold of approximately 50 to 90 mg Cl-/L. The authors point out that this is below the Canadian Water Quality Guideline of 120 mg Cl-/L for chronic exposure and suggest that chloride may be having nonlethal effects on the benthic macroinvertebrate communities in the Toronto, Ontario region.

[14] "SHORT-TERM ENERGY OUTLOOK," US Energy Information Administration, accessed on 1/14/20: https://www.eia.gov/outlooks/steo/report/coal.php

plants that currently buy the basin's coal will be either retired or little used, the result of an economic and technologically driven energy transition in the electric power industry that favors lower-cost and cleaner alternatives." (Ex. H)

The insinuation in the Do Not Mine alternative that Illinois power plants are reliant on Illinois coal is false, as few power plants in Illinois actually burn Illinois coal, and most Illinois coal is shipped out of state. The absurd idea that 4.7 million American homes would go dark without this mine is untrue, and ignores the reality that coal is more expensive than other generation sources and that Illinois is a huge exporter of energy - so we have some to spare. What is proposed here, then, is to sacrifice the Illinois environment and economy, produce more toxic coal ash, and pump more CO2 and other co-pollutants into the atmosphere so that foreign countries can buy cheaper coal with which to pollute the atmosphere.

While the claimed benefits are illusory and, to the extent they exist, may continue for only a certain window of time, the probable social and economic results of granting this permit can leave massive public costs and have clearly damaging impacts to the long-term social and economic well-being of the area. These costs have not been taken into account.

Workers will continue to face uncertainty over employment and benefits. The United Mine Workers of America website is following the Murray Energy bankruptcy proceedings and has posted that existing employment agreements can be changed by who owns the mine after bankruptcy proceedings. While Mr. Murray exited his company as CEO, having paid himself $14 million in 2019 before declaring bankruptcy, mine workers face an unknown future regarding their employment, health and retirement benefits. There is every reason to believe miners will be cheated, as were miners at the Blackjewel Mine, where the miners, in an act of protest, had to resort to blockading a train carrying coal,[15] and similar protests have begun in Kentucky against Quest Energy.[16] The miners at Blackjewel eventually got their pay, but only after taking organized action against the company. Regarding health benefits, in November, 2019, Murray Energy owed $155 million to the Black Lung Trust fund, but was offering to pay only $1.1 million.[17]

Williamson Energy LLC, a subsidiary of Foresight Energy GP LLC, has 80% holdings by Murray and 20% from the Cline Group. Foresight stocks are 6 cents a share as of January 15, 2020. Murray Energy announced Chapter 11 Bankruptcy on October 29, 2019, claiming $2.7 billion in

[15] "Blackjewel Coal Miners to Get Millions in Back Pay After Train Blockade" New York Times, 1/17/20, https://www.nytimes.com/2019/10/24/us/blackjewel-coal-miners.html

[16] Kentucky miners block coal train in protest for pay," NBC News, 1/15/20 https://www.nbcnews.com/news/us-news/kentucky-miners-block-coal-train-protest-pay-n1116096

[17] "Black Lung Trust Fund Likely Burdened by Murray Bankruptcy," WFPL, 11/20/19, https://wfpl.org/black-lung-trust-fund-likely-burdened-by-murray-bankruptcy/

debt and more than $8 billion in actual or potential liabilities including worker pensions and health care.[18]

In December, 2019, Congress passed the American Miners Act as part of federal spending legislation approved before year end to avoid a government shut-down. The Act will put pension and healthcare costs for approximately 120,000 union mine workers under federal payment via funds taken out of the Abandoned Mine Lands (AML) reclamation fund. The fund was intended to pay for environmental degradation and hazards left in the 200 years of coal mining across the United States before U.S. laws were established but now will be used in large part to pay for miner pensions and healthcare with the result that the Illinois taxpayer can be expected to pay the clean up cost of the mines.[19]

The trajectory of the coal industry is clear. As of November 2019, 48% of the Fortune 500 and 63% of the Fortune 100 are vowing to cut their greenhouse gases by increasing their use of green energy and improving their energy efficiencies.[20] BlackRock, the world's largest money manager with $7 trillion in assets, announced it will make sustainability and climate risks key tenets of its investing strategy and exit investments in thermal coal, along with other actions"[21]

B. Flooding

The negative economic effects of discharge on flooding in Big Muddy must also be weighed on the scale. While a demonstration has been attempted to show that the increased discharges to be caused by the proposal would not be large, even small increases cannot be discarded as insignificant when there are already flooding problems that will be increased. Obviously, nearly every individual source of floodwater can claim that, considered in isolation, it is insignificant. It is in the very nature of flooding that it is the result of large numbers of small factors that collectively lead to disaster. See Galloway Report on 1993 Flood (Ex. J, p.94). Due to climate change, it is already a given that "extreme weather events will become more frequent and intense,"[22] including the frequency of flooding.[23]

[23] "Changing climate is likely to increase the frequency of floods in Illinois. Over the last half century, average annual precipitation in most of the Midwest has increased by 5 to 10 percent. But rainfall during

Further, increased salinity and other pollutants in Big Muddy floodwaters will increase damage done by flooding to farm fields, golf courses, and other facilities that are flooded.

C. Climate Change

Mining and burning coal pursuant to the proposed permit would itself be destructive of the environment and economy because coal extracted from this mine will cause increased emissions of climate-warming greenhouse gases. "Transformations in the energy sector—including the displacement of coal by natural gas and increased deployment of renewable energy—along with policy actions at the national, regional, state, and local levels are reducing greenhouse gas emissions in the United States."[24]

We are in a climate change emergency. The earth has warmed by 1°C from 1901, the warmest in modern civilization, and warming is projected to reach 1.5°C between 2030-2050 under all best case scenarios.[25] "[H]uman activities, especially emissions of greenhouse gases, are the dominant cause" of record-breaking, climate-related weather extremes in recent years.[26] Catastrophic climate change will occur if global warming exceeds 1.5°C, yet to stay under 1.5°C warming, greenhouse gas emissions must be reduced 45% from 2010 levels by 2030, and reach net zero by 2050. With current global emissions, earth currently is on track to reach 3°C global warming by 2100.

With most of Illinois at 1°F warming as of 2016,[27] permitting the Pond Creek mine not only would be unconscionable, it would go against Illinois law and policy. The Illinois Constitution provides as a state public policy the duty of each person "to provide and maintain a healthful environment for the benefit of this and future generations."[28] Illinois further provides individual rights to a "healthful environment" and individual enforcement "against any party, governmental or private."[29]

---

the four wettest days of the year has increased about 35 percent, and the amount of water flowing in most streams during the worst flood of the year has increased by more than 20 percent. During the next century, spring rainfall and average precipitation are likely to increase, and severe rainstorms are likely to intensify. Each of these factors will tend to further increase the risk of flooding." United States Environmental Protection Agency, "What climate change means for Illinois" (Aug. 2016).

[28] Illinois Constitution Article XI.

[29] Illinois Constitution Article XI.

Supporting a stable and sustainable economy requires good stewardship of the environment. Absent unprecedented efforts, climate change will increase losses in infrastructure and property, and slow economic growth.[30] Any temporary economic growth would be outweighed irrevocably by short- and long-term climate change consequences.

D. Economic impacts on neighbors and land of long wall mining at site

The Pond Creek mine is a longwall mine. This is a highly automated and high extraction form of coal mining, taking out nearly the entire coal seam, with room and pillar mining done only for access corridors to the longwall panels. Once the longwall equipment is removed, the ground subsides unevenly, often by the depth of the coal seam that was removed. This has permanent, earthquake-like impacts on the ground surface in the land permitted for mining, referred to as the shadow area. The original Williamson Energy application to IDNR for this mine stated on page 280 that, "High extraction mining in the proposed shadow area can be expected to cause considerable surface subsidence." What were once flat farm fields may become uneven and drainage systems farmers have worked decades to improve often have to be replaced. Local property owners face dewatering of their ponds, private wells, or flooding in areas that previously were not a problem due to the geologic changes from the longwall void underground and surface land subsidence. Surface stream flow can be disrupted. While the mines are to restore what is economically and technologically feasible, it is highly questionable that the full impacts on neighbors and area lands and water resources will ever be returned to pre-mining condition. Homes undermined by the mine have been torn down and while some will be rebuilt, family life is disrupted and property owners face years ahead where the ground can still settle and shift. The emotional and health toll imposed on residents is never factored in. One example of subsidence damage is the destruction of the company's own groundwater wells, as noted in their groundwater monitoring reports.

Local residents have repeatedly tried to appeal to state agencies for enforcement of regulations regarding air quality, water concerns, and noise problems at the Pond Creek Mine. Illinois Pollution Control Board case PCB 2007-145 went on from 2007 to 2014 and the death of one of the petitioners (Ex. K). Concerns in this case are very similar to PCB case 2007-135 in which a local resident details the daily coal dust, noise, loss of right to enjoy one's own property and safety concerns in living next to Pond Creek Mine (Ex. L). Loss of property value and long-term harm from longwall mining are not calculated. Long-wall subsided lands can have prompt surface subsidence but residual movement can continue for years.The original mine permit had longwall indicated for 4,630 acres and Revision 2 to the original IDNR Permit 375 added 7,000 more acres that can be subsided by longwall extraction.

The 229.78 acres under consideration for approval in this draft NPDES will enable the Pond Creek Mine to continue to use the centuries old management method of a surface coal slurry

[30] *See* United States Global Change Research Program, "Summary Findings, Fourth National Climate Assessment Volume II" at Section 2 (2018).

impoundment Refuse Disposal Area (RDA) for waste water from mining including washing coal. Land that was once productive farmland and wetlands has been covered by a monstrous high hazard dam impoundment that will be approximately 190 feet high and over 400 acres in size. The area covered by this slurry refuse disposal cannot be used by future generations for farming or building, and will contain heavy metals and pollutants that can leach into the area watershed for generations to come. Outfalls 009 and 009ES will allow the mine to add more discharges to Pond Creek. The proximity of this expansion to the unnamed Pond Creek tributary at Outfall 009ES shows the eastern wall for the RDA running approximately parallel to the course of this drainage. This mine has a history with IDNR of RDA wall collapse.

The mine has not supplied any explanation for what the extraction of millions of gallons a day of groundwater withdrawn in their mining operations may do to the surrounding area. It is not known if sinkholes or other hazards could occur. Not only is the mine causing this huge disruption in groundwater, it can take advantage of public water resources that at times have been rationed by area communities. Both the Pond Creek Mine and the Sugar Camp Mine have an agreement through a third party for use of Rend Lake water in the "Rend Lake Water Supply Withdrawal Agreement between the State of Illinois, Adena Resources, LLC and Akin Water District, September 21, 2007 and Amendment Number One, August 14, 2009," (Ex. S) with up to 6.5 million gallons total per day allowed. Pond Creek Mine could use up to 2.2 mgd of Rend Lake public water.

E. Inadequate Alternatives Analysis

Finally, there has been a completely inadequate consideration of treatment alternatives - costs are not fully quantified. We are asked to just take the company's word that doing the better thing is too expensive.[31] We are provided with rough estimates of what the applicant thinks more advanced treatment would cost but no idea of the profits that might be made from the mine against which to weigh such costs.

The applicant's summary rejection of better treatment certainly cannot be accepted by IEPA given that other coal mines are actually using wastewater treatment methods that the applicant claims cannot be used, in operating mines in West Virginia and Poland. See "Case history on the reduction of chlorides from mine water" (Ex. T); See also Leatherwood Creek Report (Ex. U) and "Treatment and disposal of saline wastewater from coal mines in Poland" (Ex. V).

III. Mixing Zone Rules - The proposed discharge violates numerous provisions of the rule concerning mixing zone rules 35 Ill. Adm. Code 132.102

[31] A new document regarding consideration of alternatives was apparently given to the Agency only days before the hearing. The public certainly has not had time to analyze this study and its dubious conclusion that nothing can be done to treat the mine's wastewater other than letting most of the solids settle and then piping it to Pond Creek or the Big Muddy.

A mixing zone may not, of course, be allowed when the water quality standard for the constituent in question is already violated in the receiving water (35 Ill.Adm.Code 132.102(b)(9)). Here, it appears that the discharge may cause a violation of that rule in numerous ways:

A. Mercury in the Big Muddy

The testing of mercury in the discharge is not adequate to determine whether the discharge will directly increase the bioavailable toxic form of mercury level due to the insensitive testing method and the failure to allow for variability as required by the U.S. EPA TSD which has been recognized by the Illinois PCB. However, it is clear, as explained above, that the discharge of chloride and sulfate will increase the level of bioavailable methyl mercury and other toxic form of mercury and, thus, violate 35 Ill.Adm.Code 132.102(b)(9) as well as other rules that preclude causing increased violations of water quality standards.

B. Acidity in the Big Muddy

It appears that the permit will allow decreased pH in a water body already listed as impaired by low pH, given inadequate monitoring and violations at Outfall 7 in September 2016, June 2017, December 2017, March 2018 for low pH, and violations at Outfall 8 in September 2016, June 2017, and December 2017 for low pH. See US EPA DMR Report (Ex. F) and Echo Report (Ex. R).

C. Total suspended solids and biochemical oxygen demand in the Big Muddy

As explained above, the permit will allow an increased loading of Total Suspended Solids (TSS), and the discharge would lead to an increase in biological oxygen demand (BOD) with the effect that the existing violations of the TSS and Dissolved Oxygen standards will be exacerbated in further violation of 35 Ill.Adm.Code 132.102(b)(9). See also Comment of Dr. Burkholder.

D. Mussel presence in the Big Muddy

As noted earlier in Section I, if mussel beds are found at the discharge location, the proposed mixing zone would not be allowed (**35 Ill. Adm. Code 302.102(b)(4)**). However, the applicant has made no effort to assess for mussels at the discharge location, while the mixing zone itself would impact the bottom of the river most severely. There is reason to believe mussels may be present at this location in the Big Muddy due to the presence of mussel in the major tributaries (Ex. G).[32]

[32] As explained above, because mussels are not protected by the 500 mg/L standard, they will also be harmed well outside the supposed mixing zone.

E. Iron in the Big Muddy

The proposed permit limit for total Iron (3 mg/L daily average, 6 mg/L daily max) has not been shown to meet the applicable water quality standard of 1 mg/L dissolved iron. The Antidegradation Analysis offers no rationale for why the dissolved portion of the total iron would not be above the water quality standard of 1 mg/L. The Big Muddy is impaired for iron, as noted in the public notice. The permittee should not be granted a mixing zone to meet iron limits when the Big Muddy is already impaired for iron.

F. IEPA may not allow increased chloride or TSS loading to Pond Creek

Pond Creek has no dilution capacity for at least chloride, TSS and low DO. As noted in the public notice, Pond Creek is impaired for chlorides. Further, the mine's own reports indicate that the chloride standard has been frequently violated by their discharge from Outfall 007 into Pond Creek (Ex. F). Direct samples of the creek itself found chloride levels well above 500 mg/L, both in May of 2019 (Ex. M, p.6) and August of 2019 (Ex. P, p.3). Therefore, a mixing zone cannot be permitted as is proposed in Special Condition 14 for Outfall 009 (35 Ill. Adm. Code 302.102(b)(9)). Still further, given that IEPA lists Pond Creek as also impaired by "cause unknown" in its 303(d) report, it should not be allowing any increased discharge of a pollutant into Pond Creek that may be part of the unknown cause of the impairment.

IV. The proposed permit does not ensure compliance with other Illinois water quality standards in violation of 35 Ill. Adm. Code 302.210, 304.105, and 309.141(d) and 309.143

As discussed above, the permit does not ensure that the discharge will not cause or contribute to the violation of Illinois water quality standards because, in addition to violating the regulations regarding antidegradation and mixing zones, the permit fails to ensure that the discharge will not cause or contribute to violations of the standards regarding:

- **Mercury** - because (i) the sensitivity of the testing to determine reasonable assurance of meeting the 12 ng/L human health standard is inadequate and (ii) the effect of chloride and sulfate pollution on levels of methyl mercury and other toxic forms of mercury has not been considered.
- **Chloride** - because (i) the complex scheme to prevent violation of the 500 mg/L acute standard is not described in detail, ignores the danger of chloride and cannot be implemented by this applicant and (ii) Pond Creek has no dilution capacity.
- **Conductivity and TSS** - because the permit allows discharges that may cause or contribute to violations of the other toxic substances criteria (35 Ill.Adm.Code 302.210).
- **Copper, iron and nickel** - because the reasonable potential has not been properly calculated using the U.S. EPA Technical Support Document.
- **Dissolved Oxygen** - because the impact of the discharge in raising Biochemical Oxygen Demand levels in the mixing zone and outside the mixing zone has not been considered.

- **pH** - because of the failure to review the applicants discharging monitoring reports showing the potential for a very acidic discharge. See report from Outfall 7 on discharge of pH of 3.3 on Mar. 31, 2018 (Ex. N) and US EPA DMR report (Ex. F) on discharge from Outfall 7 in September 2016, June 2017, December 2017, March 2018 for low pH, and at Outfall 8 in September 2016, June 2017, and December 2017 for low pH.
- **Cadmium** - It is clear that there are high levels of cadmium coming from the mine (Ex. E). The company reports that it found only low levels of cadmium in its very limited monitoring of what it now dubiously claims will be water representative of the discharge. (Anti-degradation Assessment Table 2-1 Water Holding Cell Data) This conclusion, which is hard to credit given the data earlier considered by the Agency, must be treated with great caution by IEPA and only be accepted after independent verification to assure the discharge will not cause or contribute to a violation of the cadmium standard. Cadmium is limited at Outfalls 001 through 007 but should be limited at all outfalls given the very limited testing, the history of this applicant's non-compliance, and the uncertainties caused by lack of knowledge regarding future operations.

V. The Proposed Permit, in violation of 35 Ill. Adm. Code 309.146, does not require adequate or feasible monitoring to determine compliance.

A. Complex Monitoring Scheme - The permit proposes a complex monitoring scheme for compliance at Outfall 009 and Outfall 011, then requires insufficient monitoring to achieve it.

Monitoring and reporting must be adequate to track compliance with all conditions under 35 Ill.Adm.Code 309.146 but the monitoring proposed in the permit completely fails to do so.

Regarding the chloride monitoring scheme proposed for both Outfall 009 into Pond Creek and Outfall 011 into the Big Muddy, the proposed permit limits the applicant's discharge based on a mixing equation, but fails to identify how all the inputs to that mixing equation will be monitored, how often that monitoring will occur, how they will be reported, and how often reporting will occur. To evaluate the mixing equation, the discharger needs to continuously monitor the flow and concentrations upstream in the Big Muddy as well as the flow and concentration of their effluent. Yet the permit contains no requirements whatsoever for monitoring the flow or concentration of the effluent, and gives no clarity on how the concentration of chloride in the effluent will be measured (correlation or otherwise).

Even if the monitoring scheme was clear, the reporting is insufficient for IEPA or the public to evaluate whether the mixing equation is being met. There is no daily reporting of upstream conductivity, upstream flow, effluent conductivity, or effluent flow. There is a continuous downstream monitor of chloride, but relying on a single sensor downstream does not guarantee

that discharge has not been in violation of limits. The inputs to the mixing equation should all be monitored, and the reporting should be at least daily, if not hourly[33].

The permit specifies the location of the downstream monitor such that it minimizes protections. It requires that the downstream monitor be placed in "a sufficient distance downstream of the associated outfall to ensure that complete mixing has occurred." This seems like an unwarranted gift to the permit applicant, essentially granting them as much mixing as they want. Instead, the permit should require that the downstream monitor be placed as close to the edge of the mixing zone as possible, so we know that Illinois waters are being protected and that the mixing zone is as small as possible (35 Ill.Adm.Code 302.102(b)(12)).

Lastly, the permit allows the permittee to reduce or eliminate monitoring requirements, clear error given that the antidegradation assessment explicitly identifies that the groundwater seeping into the mine is likely to significantly increase in chloride concentration (and associated pollutants). The permit should anticipate an increase in the amount and toxicity of the discharge, never allow an elimination of monitoring, and explicitly require an increase in monitoring.

To make this monitoring scheme more feasible, the permit should, at a minimum:

- Require Williamson Energy to create a Quality Assurance Project Plan for the chloride monitoring scheme and give the public an opportunity to comment on the plan.
- Require Williamson Energy to report enough information to evaluate whether the mixing equation is being met. This means monitoring the effluent flow rate and concentration as well as the upstream flow rate and concentration in real time, and reporting that data back to the public. At a minimum, whenever these values are measured and flow in the pipe should be adjusted, it should be reported, at least daily.
- Make it clear how the chloride in the effluent is being monitored. If that monitoring is to be a correlation to conductivity, the effluent and the receiving waters will need correlations developed based on years of data and allowing for variability because it is clear that wide swings in conductivity occur in the Big Muddy (Ex. O).
- Identify whether the result of the mixing equation or the downstream measurement of chloride, or both, are the regulated constraint for chloride concentrations.
- Require a plan for validating the correlation of conductivity to chloride, and stipulate that the correlation has to be sufficiently developed for use, and reviewed by the public, before the permit is granted or the permittee can begin discharging. Conductivity should always be reported with chloride when using the correlation.
- Specify the location of the downstream monitoring to be as close to the estimated boundary of the mixing zone as possible.
- Require accurate monitoring of all of the constituents of the discharge using methods sufficiently sensitive to detect any violations of numeric or narrative water quality standards.

[33] The reporting would not need to be in real time (ie. the public does not need real time access), but the reported data should be hourly.

- ❑ Clearly identify a maximum discharge limit for the pipe.

B. History of Violations and Failure to Monitor Properly - Because the permit applicant has already shown itself incapable of compliance with its existing relatively simple permit through numerous permit violations and failures to report, detailed independent monitoring is necessary.

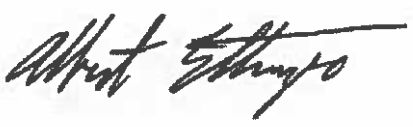
"In granting permits, the Agency may impose reasonable conditions specifically related to the applicant's past compliance history with this Act as necessary to correct, detect, or prevent noncompliance." 415 ILCS 5/39(a) Here, there is no reason to believe the permit applicant can comply with the proposed permit and any permit granted by the Agency would have to subject to strict terms necessary to detect or prevent noncompliance.

The Williamson Energy's inability to properly report discharge is demonstrated by an August 2019 Inspection Report memo by Illinois EPA inspector Brian Rodely (Ex. P). The report notes that "DMR's appear to have been submitted with no discharge reported during non-precipitation events despite the daily influent of approximately 2.7 million gallons of underground mine water. The water mass balance of influent water and discharged water does not appear consistent." Further, the inspection notes "Analysis not conducted of discharges, inadequate frequency of sampling, and invalid/ unrepresentative sample as required by permit." Additionally, the Illinois Attorney General took action against the mine in Illinois Pollution Control Board Case PCB 2019-085 (Ex. Q). The case was regarding a 2016 IEPA Emergency Response Unit inspection citing black, tar-like material in an unnamed tributary of Pond Creek. It was settled in June of 2019. Continued concerns are clear from the Inspection Report memo that states a near-by property owner commented the IEPA should take samples on a weekend when dark gob water is released when the mine knows it will not be caught.

While self-monitoring is norm in NPDES permit, it would be irresponsible to rely on self-monitoring in this case, given the mine's history of reporting issues and especially with the complex monitoring scheme proposed in this permit. Were this permit to be granted, a third-party should be used to monitor the chloride in the Big Muddy, such as the United State Geological Survey and independent monitoring should be required at the discharge points to the Big Muddy and Pond Creek.

The permit applicant is a frequent violator of their current NPDES permit. In June 2019, ECHO reports (Ex. R) show that the mine violated its effluent limits for chloride and sulfate at Outfall 002. This also occurred in 2017. In 2018 it violated its chloride and sulfate limits at Outfall 006. It violated its pH limit at Outfalls 007 and 008 in three quarters in 2017 and 2018. The mine received a letter of violation from IEPA in August 2016.

C. Correlation curves must be established and included in the permit rather than waiting to develop them after the permit is issued and the dataset used as the basis, and the supporting statistics, should be provided to the public.



The permit proposes monitoring chloride concentrations by establishing a correlation to conductivity, but offers no guidance on how this correlation is established or whether the Agency needs to approve the correlation. If the permittee begins discharging before the correlation is established, it is impossible for the Agency to evaluate compliance. The correlation needs to be part of the permit. That way both the Agency and the public have the opportunity to review the correlation. This is especially important because chloride is not the only chemical constituent which can change conductivity, and the Big Muddy already has a wide variability in conductivity (Ex. O) so the correlation will never be very accurate and will be tricky to establish.

Conclusion

The permit as proposed is plainly illegal and must be denied.

Moreover, even a vastly improved permit cannot properly be issued without re-noticing the permit and giving the public a fair chance to review the improvements and determine whether they cure the many fatal flaws in the draft. No permit can legally be issued without such fundamental alterations that the changes would necessarily be beyond a logical outgrowth of the totally deficient record on which the draft was based. See, 35 Ill.Adm.Code 309.120. Given that the antidegradation analysis, the reasonable potential analysis, the data collection, and the monitoring have not been set forth in sufficient detail to allow the public a reasonable chance to gauge the effects of the permit; and given the fact that all of the data from this discharger are suspect, a new draft permit should only be issued after the appropriate studies are done by IEPA itself; any data supplied by the permit applicant are shown to have been collected with solid QA/QC; and a revised record is created for public comment.

We look forward to continuing to work with the Agency to protect water quality.

Review of Proposed Discharges to the Big Muddy River and Pond Creek by Williamson Energy: Permit No. IL0077666

January 15, 2020

To Whom it May Concern:

I am a Professor of Environmental Science with more than 20 years of experience in the fields of aquatic ecology and watershed science. I received a PhD in Aquatic Ecology from the University of Michigan, Ann Arbor in 2002 and worked as a Research Associate at the Smithsonian Institution from 2002-2005. I have expertise in analyzing biological community data, characterizing and modeling physical and chemical drivers, and diagnosing causes of biological change in aquatic ecosystems using field observations and quantitative analytical techniques. I have applied these approaches to understand variation in community response to hydrologic, thermal, and chemical gradients in Michigan rivers, to identify land use thresholds in Maryland watersheds, to evaluate biological community response to hydrologic and chemical stressors in Maryland, Ohio, West Virginia, and Massachusetts streams. I have experience in analyzing stream hydrology and geomorphology in basins throughout the Midwest, Chesapeake Bay watershed, and New England, and applied similar techniques to rivers and streams in Argentina and Brazil. I have served as a manuscript reviewer for over 50 peer-reviewed journals and federal agencies including USEPA, USGS, USFS, and NSF. I currently serve as an Associate Editor for the international journal *Freshwater Science*. Over the past 10 years, I have conducted workshops for federal and state agencies and at regional aquatic biology meetings in which I trained attendees about statistical methods for analyzing biological data. I have also held an appointment as a Research Professor with the USGS where I provided advice to agency scientists regarding analysis and interpretation of observational data. More information on my background and qualifications in provided in the attached *Curriculum Vitae.*

At the request of the Sierra Club, I have reviewed certain materials relating to proposed new discharges to the Big Muddy River and Pond Creek from the Pond Creek No. 1 Mine. It is my understanding that Williamson Energy has applied for a revision of its 2005 NPDES permit, in which it proposes to substantially alter its current discharges into Pond Creek and add an additional discharge into the Big Muddy River, some 12 miles away. In deciding whether to approve this permit revision, my understanding is that the Illinois Environmental Protection Agency (IEPA) must act to *protect* and *maintain* water quality standards in Illinois. The list of materials reviewed is provided at the end of this document. From these materials, I have developed the following opinions:

1) The discharges described in the NPDES renewal and the anti-degradation documents exceed levels known to be harmful to aquatic life. Whether it involves the high levels of TDS or Specific Conductivity (SC), high

concentrations of sulfate, chlorides, or various metals, the discharges described here will impact sensitive taxa in any receiving freshwater body (e.g., Pond et al. 2008, Pond 2010, Timpano et al. 2011, Pond 2012, US EPA 2013, Suter and Cormier 2013, Pond et al. 2014, Griffith 2017). Although the region has higher background levels of conductance than regions with more resistant rock types and dilute waters, regional background concentrations are nonetheless similar to what is found discharging from calcareous rocks (Griffith 2014), and in any case the proposed mining discharges dwarf natural concentrations by orders of magnitude. Recent investigations of anthropogenic stressors suggest that such novel environmental gradients are associated with ecological thresholds (Hobbs et al. 2006, King et al. 2011, Bernhardt et al. 2012, Voss et al. 2015).

2) Proposed amendments to NPDES # IL0077666 involving discharges into Pond Creek represent excess chloride for a stream *already listed for chlorides* in the states 303(d) impairment summary. Approving any permit to allow additional discharges of an impairment-listed pollutant represents a clear violation of the intent of the Clean Water Act and Illinois administrative codes [35 Ill. Adm. Code 302.102(b)(9)]. Moreover, previous description of the conditions in Pond Creek characterizes its flow above the outfall as *intermittent*. If this is the case, there will be times during the year when the mining company effluent constitutes the majority, if not all, of the flow in the stream. Under such conditions, there will be very limited potential for mixing. Effluent limitations must be at least as stringent as the water quality standards they seek to meet.

3) There seems to be discrepancy in the water quality standards for various analytes, and under such circumstances EPA limits should be considered. The anti-degradation document lists reporting levels for chloride at 500 mg/l and sulfate at 1182 mg/l, well above the current EPA levels of 230 mg/l for chronic and 860 mg/l for acute chloride impacts to aquatic life (EPA 1988, Wang et al. 2018). Moreover, levels for sulfate toxicity are listed as low as 600-800 mg/l in the literature (Soucek and Kennedy 2005, Elphick et al. 2011, Wang et al. 2016) but much higher here. In the groundwater well documentation I reviewed, there appeared to be an altogether different set of standards (200 mg/l chloride and 400 mg/l sulfate) being applied (and the state reviews appear to be allowing reports from Williamson Energy that are rife with obvious errors, suggesting lax oversight). A single numeric requirement does not account for the difference between for acute and chronic effects or for differences across taxa, and even then the typical WET tests that help drive EPA chronic toxicity levels are of a relatively limited duration. Most testing for such limits are performed on crustaceans, mollusks, fish, or highly tolerant macroinvertebrates due to the challenges in raising sensitive taxa in a controlled environment (Kennedy et al. 2004, Kunz et al. 2013). More recent work has suggested both that sensitive organisms

respond differently than tolerant taxa and that a typical test does not consider the impacts of discharges throughout the life history of the organisms (Clements and Kotalik 2016, Voss and Bernhard 2017).

4) Proposed amendments to NPDES # IL0077666 involving discharges into the Big Muddy River represent toxic additions to the water body. In this case, the mining company has made an effort to mitigate the effects of the discharges through the proposed use of five single-port diffuser system. However, background chloride levels (listed by IEPA as 30.1 mg/l to purportedly represent the 90th percentile of stream observations) are too low. According to IEPA ambient water quality data set. The 30.1 mg/l level provided is not the 90th percentile (which is actually >103 mg/l) but the *50th percentile or the median* of IEPA observations. Secondly, the existing observations represent irregular monthly grab samples that are incapable of accurately representing dynamic levels of concentration extremes apparent in USGS conductivity data form the same reach. Both point to much higher extant levels of chloride and other solutes than assumed in the modeling simulation offered by Williamson Energy and used to guide their proposal. Further, the Big Muddy River is itself already listed as impaired for a number of stressors including mercury, iron, PCBs, and sulfate in 2014, and the proposed discharges would simply be adding to the sulfate load. In that situation, where pollutants already exceed the allowable in-stream concentrations, a mixing zone should not be permitted.

The materials included in the permit application are insufficient to make a reasoned conclusion that impacts of the proposed discharge will not impact aquatic life.

Recent work has suggested that conductivity related to both chlorides and sulfates can produce both acute and chronic toxicity as well as reduced metabolism and lowered abundance of sensitive taxa (Clements and Kotalik 2016, Voss and Bernhard 2017). The fact that the stream is already impaired does not relieve the mining company or IEPA from establishing effluent limits protective of water quality standards, including those meant to protect aquatic life. There is little to no consideration of the addition of more chlorides, sulfates, or other pollutants to these streams or effects on other taxa (e.g., Wang et al. 2007, Timpano et al. 2010, Bier et al. 2012). What consideration that exists is implicitly focused entirely on concentrations and not also on the impact of loads.

Second, cumulative or synergistic effects are likely to occur in a stream where additional stressors and harmful pollutants are present (Omerod et al. 2010). I have observed this myself in mining impacted streams, where conditional analysis showed that impacts of habitat degradation or thermal stress were enhanced by the presence of mining effluent (Baker 2014). Other studies have taken such impacts and interaction into account when investigating the effects of mining discharges (e.g., Gerritson et al. 2010,

Merriam et al. 2011, Cook et al. 2015). Cumulative effects have lately been the focus of study where multiple NPDES permits contribute to downstream impairment (Lindberg et al. 2011, Merriam et al. 2015, Nippgen et al. 2017, McManus et al 2020). IEPA has not taken these cumulative or synergistic effects into account at all in the proposed permit.

In order to developed an informed opinion about the effects of the proposed discharges, the agency should require more information about Pond Creek and the Big Muddy (up and downstream of the confluence) prior to issuance of any permit to better understand the impacts of the mine discharge. In addition, I have the following specific concerns:

1) There does not appear to be a margin of safety in the proposed plans. Given that the design parameters suggest the mining company will be operating near its discharge capacity nearly all of the time to dispose of excess water, there is potential for violation of its limits due to poor calibration of the diffusers with river flow, effluent concentrations, or temporary system failure. Since the limits themselves appear to be at or above concentrations where tests detect aquatic degradation (again, the tests themselves are structured to return a level where one is sure that harm has occurred) their plans are based on a faulty premise, any disruption in their best-case scenario should result in a violation of the standard and a virtual guarantee of aquatic harm. From the documentation provided, it does not appear to include recommended allowances (USEPA Technical Support Document) for permit limits set with limited and variable data.

2) No consideration of cumulative effects. The Anti-degradation document mentions that Sugar Camp mine, owned by the same company as Pond Creek mine, will be discharging into the Big Muddy River upstream of Outfall 11. Assuming they operate effectively with no mishaps and appropriate monitoring (again, this is best-case planning with no safety margin), the mine apparently plans to discharge sufficient chloride to raise a quarter of river flow to 500 mg/l chloride. By the time that water reaches the downstream Pond Creek mine discharge, the entire river will have a chloride concentration of in excess of 140 mg/l from mine inputs alone. If Pond Creek mine is also discharging at or near its maximum, the entire river downstream of Pond Creek mine outfall will be around 240 mg/l chloride from mine discharge alone (i.e., above the EPA chronic standard). This does not account for any other sources of chloride or any other pollutants, from the mine or other sources, nor does it consider how this proposed discharge will mix with Pond Creek itself, below their downstream confluence.

3) No collection of pre-mining data. As I understand this history of these permits, there has been no effort to understand how past discharges from the Pond Creek mine have impacted stressed aquatic communities and to distinguish those effects. Other mining states are discovering to

their regret that large fractions of their freshwater resources, including regional fish populations (Griffith et al. 2012, Hitt and Chambers 2014, Griffith et al. 2018) are now impaired due to mining. Why hasn't there been greater consideration of these impacts?

4) No mention of potential interactions among stressors. For example, one obvious issue is that the Big Muddy River has been listed as impaired for both mercury and sulfate, and there is a robust literature linking the methylation of mercury to the presence of high concentrations of sulfate and sulfate reducing bacteria (e.g., Jeremiason et al. 2006, Olof Regnell et al. 2019, Lazareva et al. 2019). It seems as though the IEPA is willing to consider adjusting chloride standards given the presence of sulfate, but will not consider adjusting sulfate standards (indeed allows a more lax standard than elsewhere) in the presence of high levels of mercury. Given the potentially toxicity of methylmercury and its ability to bioaccumulate in the food web, I am quite surprised to see no mention of this factor in the permit documents.

My impression of the overall picture here is that the mining company is asking the state for permission to further impair public waters. Indeed, the request to discharge into the Big Muddy is an effort to take advantage of its greater assimilatory capacity so that the mine can increase its discharges without so obviously violating its original permit. This is strikingly similar to remedy proposals from Appalachian mining companies that have been found liable for violating their NPDES permits in federal court (S.D. W.Va. 2:13-5006). The fallacy here is that neither the Big Muddy River nor Pond Creek is an unimpaired stream, so regardless of efforts to limit discharges, they mining company will still be adding to impairment and inhibiting further recovery efforts.

The Anti-Degradation document presents several alternatives to the increased level of effluent discharge. It discards each of them as too difficult, too uncertain, or too expensive. The implication is then, that environmental degradation is less expensive because the company does not bear the full cost of disposal. The State is thus asked to approve the sole alternative that would keep the mine in operation. It is not my place to decide for the State of Illinois whether this bargain for economic benefit is worth the environmental cost. Both the cost and the benefit of the mine will depend on its expected lifespan. In the documentation, I found two distinct estimates of the expected life of the mine: >10 years or >20 years. These estimates were made in 2005. Since the mine is already 15 years old, it would appear that 5-10 years from now is an optimistic interpretation of those initial projections.

I am concerned that the proposed permit revision may only solve part of the company's water management problem. The revised proposal variously describes excess water on the order of 2.3-3.5 mgd and indicates expected discharges of between 1.83 and 4.73 mgd at Outfall 11, depending on river

flow conditions. These projections are far too optimistic given the errors in the mixing simulations mentioned above, so the company would be unable to discharge the expected amount. Further it remains unclear how *in situ* concentrations will vary with higher flows. Whereas high flows with dilute concentrations should pose little difficulty for assimilating their pollutant load, what is the plan for handling excess effluent during a drought or when high flows also flush road salts? This remains absent from the planning documents.

The materials that I have reviewed lead to the conclusion that the proposed discharges will cause harm to aquatic life, that there is an surprising amount of unknown risk being taken on by the IEPA. IEPA did not require the necessary documentation or background information to ensure compliance with state water quality standards, and it is clear more work needs to be done.

Submitted Respectfully,

CURRICULUM VITAE

MATTHEW E. BAKER
Department of Geography & Environmental Systems
University of Maryland, Baltimore County
211 Sondheim Hall, 1000 Hilltop Circle
Baltimore, Maryland 21250
Phone: (410) 455-3759
mbaker@umbc.edu

EDUCATION

Ph.D. 2002 University of Michigan, Ann Arbor, MI (Aquatic Ecology)

M.S. 1996 University of Michigan, Ann Arbor, MI (Terrestrial Ecology)

B.A. 1992 Emory University, Atlanta, GA (English and Ecology)

EXPERIENCE IN HIGHER EDUCATION

2016-present	*Professor*, University of Maryland, Baltimore County, Department of Geography and Environmental Systems
2015-2016	*Interim Chair*, University of Maryland, Baltimore County, Department of Geography and Environmental Systems
2015-present	*Graduate Program Director*, University of Maryland, Baltimore County (Shady Grove Campus), Professional Studies Program in Geographic Information Systems, Department of Geography and Environmental Systems
2011-2016	*Associate Professor*, University of Maryland, Baltimore County, Department of Geography and Environmental Systems
2009-present	*Faculty Fellow*, University of Maryland, Baltimore County, Center for Urban Environmental Research and Education
2008-2011	*Assistant Professor*, University of Maryland, Baltimore County, Department of Geography and Environmental Systems
2008-2013	*Adjunct Assistant Professor*, Utah State University, Department of Watershed Sciences, The Ecology Center
2005-2008	*Assistant Professor*, Utah State University, Department of Watershed Sciences, The Ecology Center, Western Center for Monitoring and Assessment of Freshwater Ecosystems

PROFESSIONAL EXPERIENCE

2018-present	*Expert Witness*, Whiteford, Taylor & Preston L.L.P., Baltimore, Maryland
2014-present	*Expert Witness*, Appalachian Mountain Advocates, Charleston, West Virginia
2014-2015	*Maryland Fellow*, National Center for Socio-Ecological Synthesis (SESYNC)
2014-2015	*Expert Witness*, Internal Revenue Service, Office of Chief Counsel, Baltimore, Maryland
2011-2017	*Research Professor*, U.S. Geological Survey, New England Water Science Center
2002-2005	*Research Associate*, Smithsonian Environmental Research Center, Ecological Modeling and Spatial Analysis Laboratory

HONORS RECEIVED

2015	IRC Summer Faculty Fellowship, College of Humanities, Arts, and Social Sciences, UMBC
2014	Finalist, Boggess Best Paper Award, American Water Resources Association (Weller & Baker 2014)
2014-2015	Faculty Research Fellowship, College of Humanities, Arts, and Social Sciences, UMBC
2011-12	UMBC Faculty Teaching Scholar
2010	Faculty1000 selection for recommended reading (Baker & King 2010)
2009	Summer Faculty Fellowship, UMBC
2007	William B. Gardner Foreign Travel Award
2006	Finalist, New Faculty Advisor of the Year
2005	Faculty1000 selection for recommended reading (King et al. 2005)
2002	US-IALE, Best Student Presentation Award Winner
2002	US-IALE NASA-MSU Award Winner
2000-1	Jeffery Lund Award for outstanding scholarship in Forest Ecology
2000-1	Samuel A. Graham Award for excellence in Forest Biology
1996-8	Merit based scholarships
1995-6	Samuel A. Graham Award for excellence in Forest Biology
1993 Xi	Sigma Pi Forestry Honor Society
1992-5	Merit based scholarships

RESEARCH SUPPORT

2019-2020	Baker M (Principal) "Mapping woodland patches across major urban areas of the Eastern US", USDA Forest Service $15,000

2018-2024	Baker M (Principal) "High-resolution stream mapping across the Chesapeake Bay Watershed" Sponsored by the U.S. Environmental Protection Agency Chesapeake Bay Program, $1,200,000
2018-2020	Baker M (Principal) "Patapsco River Restoration Phase II: Post-Removal Survey" Sponsored by American Rivers/NOAA, $107,380
2018-2019	Baker M (Principal) "Patapsco River Restoration Phase II: Pre-Removal Survey" Sponsored by the American Rivers/NOAA, $93,680
2017-2019	Baker (Principal) "Continuous mapping of channel features for monitoring aquatic habitat and sediment flux in coastal systems" Sponsored by Maryland SeaGrant, $44,974
2017-2019	Baker (Principal) "New measures of aquatic habitat for assessing restoration resilience" Sponsored by Maryland SeaGrant, $43,706
2017-2020	Baker M (Co-PI), Yu M (Principal) "Acquisition of Hybrid CPU/GPU Nodes for the Interdisciplinary UMBC High Performance Computing Facility" Sponsored by the National Science Foundation (NSF-MRI), $550,000
2016-2018	Baker M (Principal) "Scalable applications for mapping stream channels from high resolution terrain data" Sponsored by the Chesapeake Bay Trust, $74,997
2015-2016	Baker M (Co-Principal), Miller A (Co-Principal) "Long term monitoring—physical response to lower Patapsco River dam removals: Patapsco River restoration project" Sponsored by the National Oceanographic and Atmospheric Administration, $170,189
2014-2017	Baker M (Co-Principal), Armstrong D (Principal) "Urbanization and Massachusetts streams: Unpacking the biological effects of impervious cover" Sponsored by Massachusetts Department of Fish & Game, $405,000
2013-2015	Baker (Principal) "Riparian Indicators of Eco-Hydraulic Function for Improved Watershed Management and Monitoring" Sponsored by Maryland SeaGrant, $82,500
2012-2015	Baker M (Sen. Pers.), Gobbert M (Principal) "Acquisition of Hybrid CPU/GPU Nodes for the Interdisciplinary UMBC High Performance Computing Facility" Sponsored by the National Science Foundation (NSF-MRI), $300,000

2011-12 Baker M (Co-Principal), Armstrong D (Principal) "Application of Threshold Indicator Taxa Analysis (TITAN) to assess the effects of land-use, impervious cover, dams, and water withdrawals on fish taxa in Massachusetts" Sponsored by the US Geological Survey and Massachusetts Department of Fish & Game, $34,000

2010-11 Baker M (Principal) "Thresholds in aquatic communities in response to exurbanization and environmental change" Sponsored by Maryland SeaGrant, $58,010

2010-15 Baker M (Co-Principal), Swan C (Principal) "The role of network topology and environmental filtering in shaping the ecology of spatially structured communities" Sponsored by the National Science Foundation, $410,000

2010-11 Baker M (Co-Principal), Armstrong D (Principal) "Coordinated Assessment and Protection of New England's Coldwater Fishery Resources: Development of a multivariate TITAN" Sponsored by US Environmental Protection Agency and Massachusetts Department of Fish & Game, $50,000

2010-2015 Baker M (Collaborator), Vigliano P (Principal) "Habitat template and stream fish assemblages of sub basins of Nahuel Huapi lake, Patagonia Argentina" Sponsored by the Argentinian National Scientific and Technical Research Council (CONICET), $70,000 (approximate)

2010-14 Baker M (Sen. Pers.), Welty C (Principal) "Acquisition of Liquid Water Isotope Analyzer Capability for Advancing Hydrologic Research in Baltimore Ecosystem Study LTER" Sponsored by the National Science Foundation (NSF-MRI), $244,694

2009-14 Baker M (Co-Principal), Vidon P (Principal) "Greenhouse gas emissions form riparian zones across a regional hydrogeomorphic gradient" Sponsored by the US Department of Agriculture, $399,000

2007-09 Baker M (Co-Principal), Ramsey D (Principal), "Assessment of ecosystem condition in Grand Teton National Park" Sponsored by the US Department of Interior National Park Service, $100,000

2007-09 Baker M (Principal) "A pilot study of trout invasions in low productivity environments of Andean Patagonia" Utah State University Community Research Initiative, $19,000

2007 Baker M (Principal) "Remote analysis of watershed attributes using

Shuttle Radar Topography Mission data: Andean Patagonia" Utah State University Water Initiative, $6,000

2007-09 Baker M (Co-Principal), Kasahara T (Principal) "Evaluating the effect of climate and topography on water residence time and hydrologic scaling in semi-arid, alpine catchments" Sponsored by the Inland Northwest Research Alliance Water Research Consortium, $62,500

2007 Baker M (Collaborator), Beard K (Principal), "Spatial distribution of frog invasions on tropical islands" Sponsored by the National Science Foundation-ADVANCE, $7200

2007 Baker M (Principal) Utah State University New Faculty Competitive Research Grant, $15,000

2006-10 Baker M (Principal) "A strategic planning tool for targeted buffer restoration and enhanced coastal stewardship " Sponsored by the National Oceanographic and Atmospheric Administration, $308,968

2005-08 Baker M (Sen. Pers.) Prince S (Principal), "A watershed Classification System for improved Monitoring and Restoration: Indicators of Watershed Impairment" Sponsored by the US Environmental Protection Agency, $800,000

1998-02 Baker M (Graduate Student author) Wiley M (Principal), "Ecosystem Structure and Function at the Land-Water Interface" Sponsored by the Michigan Department of Natural Resources, $250,000

1997 Baker M (Graduate Student Supervisor) Wiley M (Principal), "Aquatic Community Assemblage Structure in Relation to Macro-Habitat Units in Lower Michigan" Sponsored by The Nature Conservancy, $60,000

Ph.D. STUDENTS

Tanushree Biswas, 2009, committee member, USU
John Lowry, 2010, committee member, USU
Daniel Miles, 2011, committee member, UMBC
John Olsen, 2012, committee member, USU
Nicholas Magliocca, 2012, committee member, UMBC
Garth Linder, 2014, committee member, UMBC
Jonathan Dandois, 2014, committee member, UMBC
Anna Johnson, 2015, committee member, UMBC
Molly Van Appledorn, 2016, Chair, UMBC
Maira Bezerra, 2017, committee member, UMCP

Mariya Shcheglovitova, 2020, committee member, UMBC
Peter Chirico, PhD candidate, committee member, UMBC
Dorothy Bowory, PhD candidate, committee member, UMBC
April Sparkman, PhD candidate, committee member, UMBC
Peter Claggett, 3rd year, Chair, UMBC
Alex Rittle, PhD candidate, Chair, UMBC
Adam Dixon, PhD candidate, committee member, UMBC
Gina Lee, PhD candidate, committee member, UMBC
Ohad Paris, 3rd year, committee member, UMBC
Ben Daniels, 2nd year, committee member, UMBC

MASTER'S STUDENTS

Kristi Green, 2008, committee member, USU
S. Kirk Dahle, 2009, committee member, USU
Molly Van Appledorn, 2009, Chair, USU
Andrew Hill, 2010, Co-Chair, USU
Amanda Schulz, 2010, Co-Chair, USU
Jennifer Li, 2011, committee member, UMBC
Mattie Whitmore, 2011, Co-Chair, UMBC
Matthew Panunto, 2012, Chair, UMBC
Christina Simini, 2012, Chair, UMBC
Daniel Jones, 2013, Co-Chair, UMBC
Haley Martin, 2013, Co-Chair, UMBC
Mitchell Donovan, 2014, committee member, UMBC
Christopher Zink, 2014, Chair, UMBC
Janet Fairbank, 2014, Chair, UMBC
Michael Glassman (withdrew 2015), Chair, UMBC
Alex Martin, 2016, committee member, UMBC
Charles Wahl, 2015, committee member, UMBC
Katherine Ralston, 2017, Chair, UMBC
Marina Metes, 2018, committee member, UMBC
Zach Clifton, 2018, Chair, UMBC
Rikke Jepsen, 2018, committee member, UMBC
Daniel Cunningham, 2019, committee member, UMBC
Hayley Oakland, 2020, Chair, UMBC
Beatriz Shobe, 2nd year, committee member, UMBC
Kaitlyn Holtsclaw, 2nd year, Chair, UMBC
Michelle, Katoski, 1st year, Chair, UMBC
Nicati Robidoux, 1st year, Chair, UMBC

UNDERGRADUATE STUDENTS

Santiago Muevar, Research Assistant, 2018, UMBC
Ryan Woolbridge, Research Assistant, 2018, UMBC
Kristian Nelson, Research Assistant, 2018, UMBC

Raleigh, NC 27606
January 15, 2020

Mr. Albert Ettinger
53 W. Jackson #1664
Chicago, Illinois

Dear Mr. Ettinger,

In response to your request made on behalf of the Sierra Club, I am sending these comments about draft NPDES Permit No. IL0077666 for Williamson Energy, LLC's Pond Creek Mine. As background, there were 47 permitted coal mines in the Big Muddy River watershed as of about 15 years ago (IEPA 2004). About 88% of the Upper Big Muddy River watershed has an annual minimum water table depth of 79 centimeters (~31 inches) or less, and in about 20% of the watershed the annual minimum water table depth is only 15 centimeters (~6 inches), with hydric soils (LimnoTech 2018). Thus, coal mining operations in this watershed threaten both surface water and groundwater with contamination from mining wastes.

The permit includes three new alkaline discharges from sediment pond operation and maintenance, the focus of these comments, by the Pond Creek Mine: outfalls 011, 009, and 009ES. Outfall 011 would discharge to stream segment N-11 of the Big Muddy River. That entire stream segment is on the Illinois draft 2016 303(d) list of impaired waters for aquatic life use (low dissolved oxygen [DO], iron, pH, total suspended solids [TSS], sedimentation/siltation); mercury and PCBs (fish consumption); and fecal coliforms (primary contact recreation).

The other two proposed outfalls would drain from a new refuse disposal area with sediment basin. Outfall 009 would discharge to Pond Creek (tributary of Big Muddy River segment N-11). Outfall 009ES would discharge to an unnamed tributary of Pond Creek that already receives discharges from the mine's outfalls 001, 002, 003, 004, 005, 006, 007, and 008. The entire length of Pond Creek is on the state's 2016 draft 303(d) list, including the stream segment (NG-02) that would receive the discharges from outfalls 009 and 009ES. Coal mining and agriculture are the major land uses in the watershed (Carpenter et al. 2018). Both streams are impaired for aquatic life use (alteration in stream-side or littoral vegetative cover, changes in stream depth and velocity patterns, loss of instream cover, chlorides, low DO, and sedimentation/siltation) (IEPA 2019). While mercury contamination is not listed as a cause of impairment to Pond Creek or the unnamed tributary, IEPA (2004) has described mercury contamination via atmospheric deposition as an interstate/international issue affecting many Illinois waters. The Illinois Department of Public Health (2019) has posted fish consumption advisories due to mercury contamination for the "Big Muddy River and Tributaries" in Franklin and Williamson Counties (which include Pond Creek and the unnamed tributary) as well as six other counties in the Big Muddy River watershed. Thus, mercury contamination is affecting Pond Creek and its unnamed tributary, as well as the Big Muddy River. The following comments emphasize Big Muddy River segment N-11, but the issues and the underlying science are also applicable to the Pond Creek and unnamed tributary segments that would be affected by the permitted discharges.

A. *The high chloride and sulfate concentrations added to the water column of the substantial mixing zones would significantly increase mercury release from the sediments and, in turn, increase the potential for mercury contamination and toxicity to fish and other beneficial aquatic life.* These effects would occur because there are strong chemical interactions between the overlying water and the sediments (Wetzel 2001). Mercury contamination is already contributing to the

degradation of this stream segment (IEPA 2016).

Elevated chloride – An abrupt, pronounced increase in mercury release from the sediments of aquatic systems has been reported, as a conservative estimate, when chloride (Cl^-) concentrations reach or exceed 2×10^{-2} M (709 mg/L) (Wang 1991). The dramatic mercury release with increasing chloride has been attributed to the dissolution of adsorbed mercury through its complexation with chloride. The IEPA is considering a permit level of 500 mg chloride/L outside the mixing zones, within the same order of magnitude as the threshold value of 709 mg/L for major mercury release from the sediments. The mining company would be allowed to discharge up to 12,000 mg chloride/L at the point of discharge to the Big Muddy River (maximum volume allowed – 5,000 gallons per minute). More than 90% of the total mercury present in the water and sediments generally is sorbed onto and held in the sediments (Wang 1991 and references therein). As mercury is already contributing to degradation of this segment, appreciable mercury can be expected to have accumulated over time in the sediments. The substantial mixing zone for the Big Muddy River that would be allowed by this permit, encompassing up to $1/4^{th}$ the river volume in the area, and the high chloride concentration discharged, would result in major mercury release from the sediments throughout the mixing zone. Some of that mercury would be moved by currents beyond the mixing zone. Pond Creek segment N-2 and the unnamed tributary, receiving effluents from outfalls 009 and 009ES respectively, would also be permitted at 500 mg chloride/L along with a mixing zone for outfall 009 (IEPA 2019), and would be similarly impacted.

The threshold value for major mercury release from the sediments may be substantially lower: In other work (Farrell et al. 1990), the fraction of total mercury-II (Hg^{+2}) bound in the form of chloro-complexes increased as the chloride concentration of the water increased; and the total toxic activity of the mercury chloro-complexes increased as a near-linear function of the total chloride concentration – but there was no significant increase in the mole fraction until the total chloride concentration was 10^{-3} M (35 mg chloride/L). The data again suggested a threshold for mercury release, at 35 mg chloride/L; this concentration corresponded to the chloride level at which significant decreases, related to mercury toxicity, were observed in growth of the test organisms. The permit level of chloride under consideration by IEPA, 500 mg chloride/L (outside mixing zones) would be more than 10-fold higher than that estimated threshold.

Elevated sulfate – High inputs of sulfate to the overlying water can also stimulate methyl-mercury production and release from anoxic sediments (Gilmour et al. 1992, Benoit et al. 1999, Jeremiason et al. 2006). Bacterial sulfate reduction and mercury methylation in freshwater sediments are strongly related (Gilmour et al. 1992); mercury methylation is dependent on sulfate availability (as an electron acceptor) because sulfate-reducing bacteria mediate the biotic methylation of mercury (Mitchell et al. 2008). There is feedback inhibition, wherein the high pore-water sulfide concentrations that can result from rapid sulfate reduction (see section E below) can inhibit mercury methylation (Gilmour et al. 1992 and references therein). The bacteria involved in mercury methylation under high sulfate conditions also require sufficient organic carbon (Gilmour et al. 1992, Harmon et al. 2004, Mitchell et al. 2008), which would be supplied by the organic carbon in the anoxic sediments and the decomposition of dead and dying aquatic organisms in the mixing zones (outfalls 011, 009).

B. *The mine discharges at outfalls 011, 009, and 009ES will exacerbate the TSS conditions in the receiving streams.* Excessive total suspended solids are already contributing to the degradation of these stream segments.

For all streams and rivers in the Upper Big Muddy River watershed, IEPA has developed a loading reduction strategy target of 32.2 mg/L (IEPA 2016), or 39.3% TSS reduction (LimnoTech

2018). These targets were based on an average of what were described as "validated, real-world data (1999-2013) for the nearby Upper Kaskaskia watershed, which [still] contains several streams that are in full support of aquatic life." Pond Creek segment NG-02 has an even higher loading reduction strategy target of 62.7% TSS reduction (Limnotech 2018). Yet, the effluent standards for TSS in mine drainage are established pursuant to 35 Ill. Adm. Code 406.106 (Illinois Pollution Control Board 2019), which allow 35 mg TSS/L. In the permit IEPA applies the statute as a "30-day average" without indicting the number of samples that will be taken per month (at least three are required; 35 Ill Adm. Code 304.104). This allows for much larger concentrations over a monthly period as long as the average is *35 mg TSS/L*. The daily maximum – outside the mixing zones (also for outfall 009ES) – is double the value in the mine drainage statute, *70 mg TSS/L*, as allowed by statute (35 Ill Adm. Code 304.104). It is noteworthy that the same approach is applied by IEPA to iron and manganese, effectively doubling the concentrations stated as acceptable in statute 35 Ill. Adm. Code 406.106.

Many adverse impacts on stream ecosystems have been documented from excessive suspended sediment loading, including marked effects on fish and macroinvertebrate diversity and abundance (e.g., Newcombe and MacDonald 1991, Wood and Armitage 1997, and references therein). The extent of the impacts on aquatic life strongly depends on the TSS concentration x the duration of exposure (Newcombe and MacDonald 1991). Macroinvertebrates, zooplankton sensitive fish species, and other beneficial organisms can be stressed or killed at ~25-30 mg TSS/L depending on the environmental conditions, and if subjected to such concentrations for hours to days. In allowing a daily concentration of up to 70 mg TSS/L, there is no evidence that IEPA considered the need to protect aquatic biota during critical conditions such as reproductive and recruitment periods (e.g., see Sweeten and McCreedy 2002).

C. *Harmful toxigenic cyanobacteria will have a competitive advantage over other algae in the environmental conditions created by the Pond Creek Mine's alkaline effluent, including high specific conductance, high chloride, and enhanced phosphorus (P) release from the sediments.* Cyanobacteria also generally have high tolerance for limited light and toxic heavy metals relative to other algae.

The Pond Creek Mine alkaline waste effluent discharged at the three proposed new outfalls and existing outfalls would have elevated concentrations of salts with strong bases and carbonates. The resulting elevated chloride/salinity and alkalinity are characteristic of rivers and streams affected by what has come to be called the *freshwater salinization syndrome* (Kaushal et al. 2018). A major cause of this syndrome is alkaline coal mine wastes, and a major symptom is contaminant mobilization (e.g., mercury as noted above).

Pertinent to benthic cyanobacteria, high concentrations of sulfate and chloride have been shown to enhance phosphorus release from the sediments (Caraco et al. 1993, Zak et al. 2006, Jin et al. 2013). Most toxigenic cyanobacteria are "phosphorus loving" (Burkholder 2009 and references therein) – that is, they have high P optima and would be expected to be stimulated by the enhanced sediment P release. The hypoxic conditions that are contributing to the degradation of this stream segment (IEPA 2016) would further enhance sediment P release (Carlton and Wetzel 1988, Stumm and Morgan 1995).

Various toxic cyanobacteria have also been shown to be capable of withstanding major increases in salinity as influx of chloride salts. For example, growth rate and toxin production of freshwater *Microcystis aeruginosa* were unaffected by salinity levels up to nearly 1/3rd strength seawater (salinity 10), and *M. aeruginosa* could withstand short-term salinity shock up to half-strength seawater (salinity 17.5) (Tonk et al. 2007). In other research, *M. aeruginosa* tolerated salinities as high as 14 (Verspagen et al. 2006). Additional studies demonstrated that several tested freshwater

and brackish cyanobacteria taxa were more salinity-tolerant (up to salinities of 15-20) than other co-occurring algae (Moisander et al. 2002). In laboratory experiments with freshwater and brackish cyanobacteria, inorganic nitrogen supplies (nitrate or ammonium) or organic nitrogen as glutamate significantly enhanced salt tolerance (Reddy et al. 1989). These nitrogen substances inhibited sodium influx, thought to be a major mechanism involved in cyanobacteria tolerance of substantial salinities (Reddy et al. 1989).

Cyanobacteria additionally tend to have high tolerance for limited light in comparison to many other algae (Graham et al. 2016 and references therein), as well as high tolerance of toxic heavy metals (Baptista and Vasconcelos 2006, Cassier-Chauvat and Chauvat 2015, Shilpi et al. 2015). They also have effective mechanisms that enable them to avoid washout in river environments, and they can thrive along the river bottom during high-flow conditions (Quiblier et al. 2013, McAllister et al. 2016). These traits collectively give cyanobacteria major advantages over other algae in freshwaters affected by coal mining alkaline effluents (e.g., Valkanas and Trun 2018). The Pond Creek Mine's alkaline effluent will promote their growth over other, beneficial algae.

D. *Fauna that die in the substantial mixing zone of the Big Muddy River*, the smaller mixing zone of Pond Creek, and the outfall area of the unnamed tributary, *will increase biochemical oxygen demand and exacer-bate the low dissolved oxygen conditions* both in this stream segment and in downstream waters. Low-oxygen conditions are already contributing to the degradation of these stream segments.

A wealth of peer-reviewed science publications have documented "devastating effects" on aquatic communities from coal mine waste pollution, whether the effluent is added continuously or episodically (e.g, Maccausland and McTammany 2007, Bier et al. 2015, Giam et al. 2018, and references therein). Many biota (invertebrates, fish, salamanders, etc.) are killed outright in areas affected by the discharged effluent, and their taxonomic richness and abundance are significantly depressed as a long-term outcome (Giam et al. 2018). The resulting biochemical oxygen demand for decomposition of these organisms will exacerbate the low dissolved oxygen conditions that are already contributing to the degradation of these three stream segments, in and downstream from the mixing zones (outfalls 011, 009) and discharge area (outfall 009ES).

E. *The permit mistakenly asserts that the highly toxic coal mine effluent will not cause <u>any</u> long-term impacts. The writing does not account for* (i) *the effects of chloride and sulfate on mercury (see part A, above); and* (ii) *the substantial resuspension/downstream movement of pollutants, which <u>will</u> promote chronic physiological stress, disease, and death of sensitive biota* both within the mixing zones/discharge area and well beyond them.

Intermittent riverine resuspension of pollutants is recognized as such a "common, ubiquitous" reality (Kleeberg et al. 2013) that books have been written about it (e.g., Van Rijn 1993, Westrich and Förstner 2007), and studies have tracked toxic contaminant movement downstream in rivers via resuspension of settled materials (e.g., Theis et al. 1988, Jamieson et al. 2005, Schneider et al. 2007). Despite this wealth of peer-reviewed, published science, the permit section entitled "Fate and Effect of Parameters Proposed for Increased Loading" does not make a science-based assessment of either the fate or the effects of the mining pollutants considered, nor can this information be found elsewhere in the permit. The writing states (pp.15, 17):

> Chloride and sulfates would remain dissolved in the water and would move through the downstream continuum. Manganese, iron, nickel, copper, and total suspended solids will most likely settle and become part of the bed sediment.... Because of the near-real-time continuous monitoring of upstream and down-

> stream conditions in the receiving stream, and the ability of the permittee's diffuser to adjust to flow and background concentration conditions, discharges will always [emphasis added] be into a waterbody that is below water quality standards and in concentrations and flow combinations that will not cause or contribute to an exceedance downstream of the mixing zone. No adverse impacts [emphasis added] to streams would occur as all water quality standards are expected to be met in the receiving water....The proposed activity will result in only short-term, temporary increases in pollutant loading [emphasis added] and will not result in long-term or permanent impacts to existing uses including aquatic life habitat.

Corrective information is provided as follows:

- The permit writing asserts that [all of the] chloride and sulfates will remain dissolved in the water and "move through the downstream continuum" without mention of any ill effects. The well-established reality instead is that there are strong chemical interactions between the overlying water and the stream sediment pore waters. That is, in part, why high chloride and high sulfate promote toxic mercury release from the sediments (section A, above).

  ** Based on a review of chloride fate and transport in watersheds, streams, and lakes, once added to streams, (i) much of the chloride moves from the overlying water into sediment pore water (Kennedy et al. 1984; also see Lerman and Weiler 1970, Effler et al. 1990, Besser et al. 2009); there it undergoes a large suite of competitive equilibrium reactions with ionic mercury species (making toxic mercury more bioavailable; see section A of this letter and supporting references therein) and other metals; and (ii) some of the chloride, still in the overlying water, is moved downstream by currents (Ward et al. 2013). Analogously as for chloride movement through soils in watersheds, initial pore-water concentrations (from the water column) in streams and lakes can be elevated near the sediment surface (Lerman and Weiler 1970, Effler et al. 1990, Lax and Peterson 2008). Within chloride-unsaturated sediments, chloride moves mostly vertically downward through the sediments, driven by diffusion. As high loading to the overlying water continues, the pore water becomes a long-term chloride source to sub-surface groundwater (decades; Lax and Peterson 2008, Kelly et al. 2012 and references therein).

  It should be noted that much of the high sulfate added to the overlying water ***also*** moves into the pore water (e.g., see Ng et al. 2017 and references therein), where it promotes toxic methylmercury production (see Section A of this letter) and toxic hydrogen sulfide production (below), can be directly toxic to biota (Elphick et al. 2011), etc.

  ** *High concentrations of sulfate in the water*, such as those that would be allowed by the permit in all three affected stream segments, *lead to* ***production of hydrogen sulfide*** *in the sediments* (Stumm and Morgan 1995, Bernhardt and Palmer 2011). This occurs because the elevated water-column sulfate concentrations will stimulate microbial sulfate reduction in the sediments: the microbes use sulfate (SO_4^{-2}) instead of oxygen (which is not available in anoxic sediments, or sparse in hypoxic sediments) in their consumption of organic matter. The sulfur (S) in the sulfates is converted to sulfide (HS^-), then to hydrogen sulfide (H_2S). Hydrogen sulfide is toxic to many organisms, from plants and other beneficial aquatic life to humans (Lamers et al. 1998, Bagarinao 1992, Reiffenstein et al. 1992). It has been implicated in mass mortalities of fish and other aquatic life (Bagarinao 1992 and references therein).

  ** In addition to being directly toxic under some conditions (Elphick et al. 2011), *the high*

sulfate will also promote eutrophication through ***phosphorus release*** *from the sediments* of the three streams (Bernhardt and Palmer 2011, and references therein): Sulfide binds strongly with iron in sediments and converts it to pyrite minerals, which is beneficial in reducing bioavailable iron; but much of the phosphorus in freshwaters is bound to iron minerals. In the high-sulfide surficial sediment environment resulting from the high water-column sulfate, the sulfide interferes with the iron-P bonds so that phosphorus is released to the water column (Caraco et al. 1989, 1993). By this mechanism, high sulfate additions to the overlying water is known to promote eutrophication of freshwaters (van der Welle et al. 2008, Myrbo et al. 2017).

- The permit *guestimates* (p.15) that "manganese, iron, nickel, copper, and TSS will most likely settle and become part of the bed sediment in the river." Peer-reviewed science has shown that at least a portion of the toxic heavy metals (e.g., cadmium, manganese, zinc, nickel) and TSS in alkaline mine waste effluent settle out and become embedded within the microbial biofilm matrix at the sediment/water interface (Bier et al. 2015). The permit writing indicates no consideration for resuspension/downstream movement of that "bed sediment" in the three affected streams.

- The permit writing, assuring readers of "near-real-time continuous monitoring upstream and downstream", is *highly misleading because only flow (upstream) and one chemically related parameter (conductivity) will be monitored continuously* upstream and downstream from the three outfalls (IEPA 2019). ***Most parameters will not be monitored adequately for assessment of compliance*** (see, e.g., Robertson and Roerish 1999, Stansfield 2001):

  ** The only information given about continuous (if that is the meaning of the permit writing, "full flow measurement", which is not clear) flow is that, "the upstream flow should be based on the full flow measurement upstream of the proposed outfall 011 that shall be approved by the Agency".

  ** Metals in the discharges at the three outfalls, other than iron, will be monitored ***twice per year and only total concentrations*** will be measured. Regarding the latter point, *dissolved concentrations* are generally much more important for assessment of toxicity to aquatic biota, not total. Thus, it is not possible from the extremely sparse data (2 samples over an entire year) to gain insight about the threat of these metals to beneficial aquatic organisms.

  ** Sulfate and dissolved iron will be monitored from the effluent ***monthly*** when discharging.

  ** *There is no requirement to monitor chloride at any of the three outfalls. Instead, chloride will be* calculated from conductivity data taken by two conductivity meters, one installed upstream, the other downstream from each outfall. The calculated value would be the only requirement in discharge monitoring reports. The conductivity meters are described as continuously monitoring, but no information is given as to the data collection frequency. Furthermore, the permit provides no information about the equation selected to derive calculated chloride values from conductivity data (for example, no information to address the question of how statistically strongly conductivity is correlated with chloride along the concentration gradient). The permit also provides no information science literature in support of the selected equation, or whether a robust background dataset was used to customize it for the Big Muddy River prior to applying the equation.

  ** Upstream from the discharge areas, the three streams will be monitored ***once per year,***

and only for discharge rate, sulfate, chloride, and hardness (exceptions: flow and conductivity as described above).

** Downstream from the discharge area, the river will be monitored ***four times per year***, and only for discharge rate, sulfate, chloride, and hardness (exception – conductivity data as described above). Moreover, the permit provides steps that the mining company could take to request reduction or elimination of any downstream monitoring requirements.

** Other mention of continuous monitoring in the permit writing (p.13) was that during operations of the pipeline, continuous flow monitors would be installed to provide protection against leakage.

** No information was included in the permit about the frequency of monitoring TSS upstream or downstream of discharge locations, or in the effluents. "Monthly averages" must be based on at least three samples over a monthly period (35 Ill Adm. Code 304.104).

- The permit writing provides unrealistic assurances that (i) there will never be any violations of the water quality standards. Moreover, the writing makes mistaken assurances, without basis in science, that there will be no adverse impacts whatsoever, and no long-term impacts to existing uses including aquatic life habitat.

** The Pond Creek Mine has had numerous previous violations of water quality standards (e.g., excessive iron, chloride, and manganese; see https://echo.epa.gov/detailed-facility-report?fid=IL0077666). Why, from now on, should IEPA or readers of the permit believe that the mine operation will be "perfect"?

** As stated, a large body of peer-reviewed science repeatedly has shown that coal mine effluents cause major, long-term impacts to receiving waters in degraded water quality; otherwise-degraded habitats; physiological stress, disease, and death of beneficial aquatic life; and replacement of those organisms with highly tolerant, noxious, usually undesirable taxa (e.g., see Maccausland and McTammany 2007, Giam et al. 2018). Considering the scientific information presented above, there is no question but that the mine's discharged effluent will cause or contribute to further degradation of the Big Muddy River.

F. *Interactive effects of some pollutants, and enhanced bioavailability in low-oxygen conditions characteristic of the three affected stream segments, have not been considered* in the permit.

Coal mine alkaline effluent contains many toxic contaminants other than those considered for regulation in the three streams by this permit, such as antimony, arsenic, barium, cadmium, chromium, cobalt, lead, manganese, nickel, phenols, selenium, silver, and zinc (Watzlaf et al. 2004). Many metals in the above list are essential micronutrients, but become toxic at concentrations higher than needed for normal growth (Nies 1999). Others (e.g., cadmium and lead) have no known beneficial role in biota and are toxic even at extremely low concentrations (Rand and Petrocelli 1995). Toxic metals – including the substantial mercury that will be released from the sediments in and around the mixing zones (above) – and other substances are known to act additively or synergistically (Marking et al. 1977), yet none of these serious impacts were addressed in the permit. The following examples illustrate the high potential for synergistic and additive, adverse effects to beneficial aquatic life in the three stream segments affected by mining waste contamination from outfalls 009, 009ES, and 011:

- *Additive, adverse effect of [chloride + sulfate]* – The acute toxicity of chloride and sulfate ($NaCl + Na_2SO_4$) mixtures to juvenile unionid mussels in hardwaters (within the range

characteristic of the river segment affected by the Pond Creek Mine discharge) significantly increased with sulfate additions at or above 350 mg/L (Wang et al. 2018). The permit allows single values for sulfate as high as 2,120 mg/L (IEPA 2019, p.14). The fatmucket mussel species tests is reported to occur in the Big Muddy River drainage (Shasteen et al. 2012). The lower range of EC50s (median effective concentration, that is, the concentration expected to produce death or other effect in 50% of the test population) for fatmucket glochidia (sensitive larval stage) was reported at 441 mg chloride/L. The permit allows for chloride concentrations outside the mixing zones as high as 500 mg/L (IEPA 2019). These data indicate that permit levels derived individually for chloride or sulfate will not be protective at moderate to high, co-occurring concentrations of the two ions. Additive toxicity of NaCl + Na_2SO_4 mixtures has also been reported from acute toxicity testing with the zooplankter *Ceriodaphnia dubia* (Erickson et al. 2017).

- *Synergistic, adverse effect of [nickel + mercury]* on the fatty acid composition of fish muscle tissues (Senthamilselvan et al. 2016). This impact is germane given that the body burden of mercury in fish already warrants warnings against human consumption and is a cause of degradation for listing the Big Muddy River – segment N-11 on Illinois' 303(d) list. According to IEPA (see https://www2.illinois.gov/epa/topics/water-quality/watershed-management/tmdls/Pages/303d-list.aspx), this river segment has been so listed for the past decade, indicating that substantial mercury contamination has occurred, ongoing.

- *Synergistic, adverse effect of [chromium + mercury]* on the histology and physiology of fish (Dwivedi et al. 2012). This impact is germane as explained above.

Such information helps to explain the recent finding that one coal mine constitutes a regional source of stress to stream fish assemblages: Daniel et al. (2015) tested threshold responses of fish metrics to coal and mineral mine densities. As expected, increased mine densities were associated with declines in multiple fish metrics, and mines had a worse impact on fish communities than other human-related land uses – *and just one mine in a watershed adversely affected fish throughout that watershed.* Synergistic and additive effects of the wide array of toxic pollutants in the effluent discharged to the Big Muddy River, Pond Creek, and the unnamed tributary by the Pond Creek Mine would contribute to this regional effect. That mine is not the only coal mine in the Big Muddy River watershed (e.g., see U.S. Energy Information Administration 2011, 2016). These points underscore the need to have a margin of safety in the permit to account for synergistic and additive impacts of the many pollutants in the mine waste effluents proposed for discharge at outfalls 009, 009ES, and 011 and the existing mine outfalls.

Overall, in view of the issues raised above, it is my opinion that the proposed discharge to Big Muddy River segment N-11, Pond Creek segment NG-02, and the unnamed tributary to Pond Creek by the Pond Creek Mine would increase levels of toxic mercury to the detriment of fish consumption and public health; increase levels of harmful algae to the detriment of swimming and other recreational uses; and cause major harm to aquatic life, long-term.

Sincerely,

JoAnn M. Burkholder

Curriculum Vitae

JoAnn Burkholder

Professor and Director, NCSU Center for Applied Aquatic Ecology,
Department of Applied Ecology /
Jointly Appointed in the Department of Plant and Microbial Biology

Contact Information

Center for Applied Aquatic Ecology (CAAE), North Carolina State University (NCSU)
620 Hutton Street - Suite 104, Raleigh, NC 27606
Telephone (919) 515-2726 or -3421; FAX (919) 513-3194
Email jburk@ncsu.edu Center website https://caae.cals.ncsu.edu/; projects.ncsu.edu/wq

Education

Undergraduate:	Iowa State University	Zoology	B.Sc., 1975
Graduate:	University of Rhode Island	Aquatic Botany	M.Sc., 1981
	Michigan State University	Botanical Limnology	Ph.D., 1986

Research Interests

Algal nutritional physiology and ecology, spanning the salinity gradient from freshwater to estuarine and marine species; and chronic effects of eutrophication (nutrient over-enrichment and associated pollutants) on aquatic ecosystems

Professional Experience

2013 - present	Director, CAAE, Department of Applied Ecology, NCSU
2013 - present	Professor, Department of Applied Ecology; jointly appointed to the Department of Plant & Microbial Biology (formerly the Department of Plant Biology), NCSU
1999 - 2012	Director, CAAE, Department of Plant Biology, NCSU
1998 - 2012	Professor, Department of Plant Biology (formerly the Department of Botany), NCSU
1993 - 1997	Associate Professor, Department of Botany, NCSU
1993 - 2012	Affiliate Professor, Department of Marine, Earth and Atmospheric Sciences (MEAS), NCSU
1986 - 1992	Assistant Professor, Department of Botany, NCSU
1982 - 1986	Graduate Research Assistant, Michigan State University (W.K. Kellogg Biological Station), Hickory Corners, MI
1981 (fall)	Instructor, *Introductory Chemistry* (for science majors), Quinebaug Valley Community College, Danielson, CT
1979 - 1980	Instructor of *Marine Botany,* summers, St. Georges College Prep. School, Newport, RI
1978 - 1981	Graduate Research Assistant and Graduate Teaching Assistant, Department of Botany, University of Rhode Island, Kingston, RI
1976 - 1977	Environmental Scientist, EcolSciences, Inc., Rockaway, NJ
1974 - 1975	Undergraduate Research Assistant, Limnology Laboratory, Department of Zoology, Iowa State University, Ames, IA

Awards and Distinctions

2016	Women of Achievement Award, General Federation of Women's Clubs of North Carolina
2015	Fred A. Harris Fisheries Conservation Award, American Fisheries Society - North Carolina Chapter (recognizes non-Chapter members who have distinguished themselves by service or

commitment to the fisheries resources of North Carolina)

2009 Borlaug Joint Award for Service to the Environment and Society, College of Agriculture and Life Sciences/ College of Natural Resources, NCSU

2008 William Neal Reynolds Distinguished Professor, College of Agriculture and Life Sciences, NCSU, for excellence in research

2008 J. Compton River Achievement Award, River Network, lifetime achievement for leadership in research to advance water quality protection

2007 Darbaker Prize, Botanical Society of America, for excellence in research

2004 Fellow, American Association for the Advancement of Science (AAAS)

2003 Honorary Doctorate, Knox College, Galesburg, IL

2003 Provasoli Award, best paper of 2002, *Journal of Phycology*

2001 Honorary Doctorate, Southampton College - Long Island University

2000 Fellow, Aldo Leopold Leadership Program, Ecological Society of America

1999 Hutner Award, Society of Protozoologists, for excellence in microalgal research

1998 Scientific Freedom and Responsibility Award, AAAS

1998 Distinguished Service in Environmental Education Award, Environmental Educators of North Carolina

1998 Distinguished Scholarly Achievement Award, NCSU Honors Convocation

1998 Conservationist of the Year Award, National Wildlife Federation

1998 Conservationist of the Year Award, Governor of North Carolina and the North Carolina Wildlife Federation

1998 Jack Bayless Award – outstanding presentation of the year, South Carolina Fishery Workers Association, and the North and South Carolina chapters of the American Fisheries Society

1997 Admiral of the Chesapeake Award, Federal and State Leadership Summit, Washington, DC

1997 Outstanding Achievement Award, Society of Business and Professional Women of North Carolina

1997-2000 Pew Fellow in Marine Conservation, the Pew Foundation

1994 Outstanding Research Award, NCSU Alumni Association

Honors to the NCSU CAAE

2013 The CAAE was recognized as the reason why NCSU placed 31st among the top 50 "Colleges Saving the World" (http://www.onlinecollegesdatabase.org/50-colleges-saving-the-planet).

2012 The CAAE received the highest evaluation possible (Excellent) by an outside Peer Review Panel that reviewed in detail the Center's performance over its entire span of operation. The panel was organized by the NCSU College of Agriculture and Life Sciences as required by the UNC Board of Governors.

Other Honors

2013 Invited presentation on Harmful Algae - Capital Hill Briefing, representing the Coastal and Estuarine Research Federation

2007 Theodore L. Jahn and Eugene C. Bovee Award, International Society of Protozoologists, for best graduate student research paper, to doctoral candidate Hayley Skelton (coauthors of the paper, Burkholder and Parrow)

2001 Elected member, Alumni Hall of Fame, Rock Valley College, Rockford, Illinois

2001 Convocation speaker, Appalachian State University

2001 Convocation speaker, Southampton College - Long Island University

1998 Special recognition for excellence in research, Phi Kappa Phi

1998 Invited testimony, Congressional Hearing on the Value of Estuaries, US Senate, Senate

	Environment and Public Works Committee
1998	Invited testimony, Congressional Hearing on Harmful Algal Blooms, US Senate, Committee on Commerce, Science and Transportation
1997	Invited testimony, Congressional Hearing on Fisheries Conservation, Wildlife and Oceans, US House of Representatives – Committee on Resources
1997	Invited testimony, Congressional Hearing on Harmful Algae and Human Health, US House of Representatives – Committee on Government Reform and Oversight
1997-1999	Science Advisor, Governor's Commission on *Pfiesteria*, Maryland
1993-1994	Member, North Carolina Coastal Futures Committee (governor-appointed)
1993-1995	Member, Board of Directors, Partnership for the Sounds (directive, environmental education for eastern North Carolina)
1992-1997	Member-at-large, North Carolina Marine Fisheries Commission (governor-appointed)
1985	Elected member, Phi Kappa Phi, Michigan State University
1984-1986	Graduate fellow, Department of Botany and Plant Pathology, Michigan State University

Selected Research Accomplishments

(with thanks to my graduate students, postdoctoral research associates and other research associates, and collaborators)

Freshwater Ecosystems

- First to maintain automated platform stations with depth profiling capability for advanced research and monitoring of North Carolina reservoirs; the real-time data from these stations is also helping to safeguard drinking water supplies depended upon by ~750,000 people.
- Experimentally quantified interactions between nutrient and sediment loadings in controlling noxious algal blooms in turbid reservoirs.
- First to document widespread occurrence, at low levels, of cyanotoxins in major potable water supplies in North Carolina.
- Documented novel nutritional and physical adaptations of a cryptic group of dinoflagellates in reservoirs affected by episodic suspended sediment loading.

Estuarine and Marine Ecosystems

- Discovered that water-column nitrate enrichment from sewage and other sources inhibits *Zostera marina*, the dominant seagrass of north temperate U.S. waters, as a direct physiological effect.
- Co-discovered the toxic dinoflagellates, *Pfiesteria piscicida* and *Pfiesteria shumwayae*, as causative agents of major estuarine fish kills; this research also led to colleagues' discovery of a group of *Pfiesteria* toxins new to science.
- First to design and maintain a series of automated platform stations for advanced research and monitoring of a North Carolina estuary; coauthor of a patent for an automated depth profiler.
- First to show that shallow lagoonal estuarine ecosystems are resilient to the adverse effects of hurricanes, recovering within 4-5 years.
- Helped to develop a model for water mass transport to the Neuse Estuary; used the model and a detailed dataset for improved quantification of nutrient loads, including decadal trend analysis.

Grants (past ~decade)

My research routinely involves analyzing the species composition and abundance of phytoplankton in samples from lakes, reservoirs, rivers, estuaries, and marine coastal environments. For example, my research associate, Ms. Elle Allen, and I recently analyzed 1,000 phytoplankton samples from lakes across the nation as part of a major contract to Dr. Beaver from the U.S. Environmental Protection Agency.

Support for my research and education outreach has been obtained from the National Science Foundation,

National Park Service, U.S. Environmental Protection Agency, National Oceanic and Atmospheric Administration, U.S. Department of Defense, the Burroughs Wellcome Fund, the Park Foundation, the Z. Smith Reynolds Foundation, the NCSU Research and Innovation Seed Funding Program, and the North Carolina Clean Water Management Trust Fund.

Professional Consulting

1989	Phytoplankton Analyst - Duke Power and Light Company, Charlotte, NC (samples from local reservoirs: species identifications, quantification of cell numbers and biovolumes)
1990-1992	Phytoplankton Analyst - consulting firm of Dr. J. Beaver (samples from central Florida lakes with major cyanobacteria blooms: species identifications, quantification of cell numbers and biovolumes)
2004	Expert Witness - requested by several concerned citizens groups to review impacts of Georgia Pacific, Inc. on marine coastal ecosystems on the west Florida shelf
2005	External Reviewer (1 of 2) – contracted by the higher administration at Miami University of Ohio to review the academic and research programs of the Department of Botany. Our review resulted in new positions, a strengthened Bioinformatics Facility, and other significant support for the department.
2005	External Reviewer – contracted by the Harris Chain of Lakes Restoration Council in Florida to review the sampling protocols and two annual environmental reports from a commercial laboratory/consulting firm on water quality and cyanobacteria blooms in the Harris Lake Chain. Included a presentation at a public Council meeting.
2006-2010	Panelist on a review team of the *South Florida Environmental Report* (*SFER*) for the South Florida Water Management District. Formally critique the annual draft report (selected chapters, ~1,200 pages), emphasizing water quality sampling/ compliance and water quality programs/ restoration in the Kissimmee River basin, Lake Okeechobee, the Everglades, and eight estuarine ecosystems; and environmental education outreach programs
2006	Coauthor of the report, *Indicators for Restoration*, for the South Florida Ecosystem Restoration Task Force
2009	Panel Representative who presented key findings of review of the draft 2010 *SFER* to the the Board of Governors of the South Florida Water Management District, Key Largo, FL
2009 - 2018	Consultant on eutrophication issues in lakes and streams for PEER (Public Employees for Environmental Responsibility - Mississippi River Collaborative), the Minnesota Center for Environmental Advocacy, Earthjustice, and the Natural Resources Defense Council
2010 - 2011	Consultant on U.S. Environmental Protection Agency's Science Advisory Board - Ecological Process and Effects Committee Augmented for the Ballast Water Advisory
2019	Consultant on nitrate toxicity in drinking water and surface freshwaters, and on a coal Mining permit, for the Sierra Club

Burkholder JM, Glasgow HB, Fensin E (1996) *Neuse Estuary Biomonitoring Study – May 1993 – December 1995.* Report of the first three years of a five-year study, to the U.S. Marine Air Station – Cherry Point, Cherry Point, NC. Aquatic Botany Laboratory, NCSU, Raleigh, 86 pp.

Burkholder JM (1998) *The Toxic* Pfiesteria *Complex: A Scientific Discussion of its History, Ethology, and Impacts on Human Health.* Office, Assistant Secretary of the Army - Installations, Logistics and Environment. Pentagon, Washington, DC.

Burkholder JM, Glasgow HB, Deamer-Melia N (1998) *Neuse Estuary Biomonitoring Study – Physical, Chemical, and Biological Characteristics of Water Samples Collected from the Neuse Estuary in the Vicinity of Cherry Point, North Carolina, May 1993 - April 1998.* Final Report of a five-year study, to the U.S. Marine Air Station, Cherry Point, NC. Aquatic Botany Laboratory, NCSU, Raleigh, 110 pp.

Burkholder JM (1999) *The Role of Toxic* Dinoflagellates *in Fish Lesions.* Issue paper prepared for the U.S. Army. Office, Assistant Secretary of the Army - Installations, Logistics and Environment. Pentagon, Washington, DC.

Burkholder JM, Glasgow HB (1999) *Neuse Estuary Biomonitoring Study, with Additional Information on Overall Nutrient Loading to the Mesohaline Estuary.* Final Report to the U.S. Marine Air Station – Cherry Point. Department of Botany, NCSU, Raleigh, 134 pp.

Burkholder JM, Glasgow HB, Rublee PA, Shumway SE (2001) *The Toxic Dinoflagellate,* Pfiesteria, *as a Potential Biosensor of Estuarine Stress.* Final Report to the U.S. EPA, Washington, DC, 108 pp.

Touchette BW, Burkholder JM, Glasgow HB (2001) *Distribution of American Water Willow (*Justicia americana *L.) in the Narrows Reservoir.* Final Report to Alcoa Power Generating Inc., Badin, NC, 51 pp.

van der Schalie WH, Shedd T, Widder M, Kane AS, Reimschussel R, Sarabun J, Burkholder J, Glasgow H (2001) *Real-Time Monitoring for Toxicity Caused by Harmful Algal Blooms and Other Water Quality Perturbations.* Report EPA/600/R-01/103, U.S. EPA, Washington, DC.

Burkholder J, Glasgow H, Deamer N, Melia G, Litzenberger T (2003) *Response of* Pfiesteria piscicida, *Microbial Predators and Prey, and Fish to Common Dithiocarbamate Fungicides and Heavy Metals.* Final Report to the U.S. EPA, Research Triangle Park, NC, 26 pp. + appendix.

Burkholder JM (2010) *Assessment of Water Resources and Watershed Conditions in the Kennesaw Mountain National Battlefield Park, Georgia.* Draft Report to the Southeast Coast Inventory and Monitoring Network of the National Park Service, Southeast Regional Office, Atlanta, GA, 71 pp.

Burkholder JM, Allen EH, Kinder CA (2010) *Assessment of Water Resources and Watershed Conditions in Ocmulgee National Monument, Georgia.* Natural Resource Report NPS/SECN/NRR—2010/276. National Park Service, Fort Collins, CO, 81 pp.

Burkholder JM, Allen EH, Kinder CA, Morris E (2010) *Assessment of Water Resources and Watershed Conditions in the Chattahoochee River National Recreation Area, Georgia.* Draft Natural Resource Report NPS/SECN.NRR-2010/274. National Park Service, Fort Collins, CO, 202 pp.

Burkholder JM, Rothenberger MB (2010) *Assessment of Water Resources and Watershed Conditions in Horseshoe Bend National Military Park, Alabama.* Natural Resource Report NPS/SECN.NRR-2010/268. National Park Service, Fort Collins, CO, 51 pp.

United States Department of Environmental Protection (U.S. EPA) (2011) *Efficacy of Ballast Water Treatment Systems: A Report by the EPA Science Advisory Board (SAB)*. U.S. EPA SAB Ecological Processes and Effects Committee Augmented for the Ballast Water Advisory. Report #EPA-SAB-11-009. U.S. EPA, Washington, DC, ~150 pp. Burkholder was an Augmented Panel Member and a coauthor of this report.

Burkholder JM, Allen EH, Flood S, Kinder CA (2015) *Natural Resource Condition Assessment - Horseshoe Bend National Military Park*. Natural Resource Report NPS/SECN/NRTR—2015/981. National Park Service, Fort Collins, CO, 270 pp.

Burkholder JM, Allen EH, Flood S, Kinder CA (2017) *Natural Resource Condition Assessment - Ocmulgee National Monument, Georgia*. Natural Resource Report NPS/SECN/NRTR—2017/1521. National Park Service, Fort Collins, CO, 179 pp.

Burkholder JM, Allen EH, Flood S, Kinder CA (2017) *National Resource Condition Assessment - Cape Lookout National Seashore, North Carolina*. Natural Resource Report NPS/SECN/NRTR—2017/xxx. National Park Service, Fort Collins, CO, 248 pp.

Burkholder JM, Allen EH, Flood S, Kinder CA (2018) *National Resource Condition Assessment - Moores Creek National Battlefield, North Carolina*. Natural Resource Report NPS/SECN/NRTR—2018/xxx. National Park Service, Fort Collins, CO, 202 pp.

Burkholder JM, Allen EH, Flood S, Kinder CA (2018) *National Resource Condition Assessment - Congaree National Park, South Carolina*. Natural Resource Report NPS/SECN/NRTR—2018/xxx. National Park Service, Fort Collins, CO, 324 pp.

Non-Referred and Popular Press Articles and Reports

Burkholder, J.M. (2019) *Nitrate in Drinking Water and Surface Freshwaters: Occurrence, Impacts, and Recommendations for Protection of Human Health and Aquatic Life*. Report prepared for the Sierra Club. Department of Applied Aquatic Ecology, North Carolina State University, Raleigh, NC.

Burkholder, J.M. (2018) *A Synopsis on Developing Numeric Nutrient Criteria for Freshwaters*. Report prepared for the Mississippi River Consortium.

Burkholder JM (2006) A major potable water supply reservoir poised for increased cyanobacteria blooms. *LakeLine* (summer), pp. 49-51.

Burkholder JM (2003) Science and the press. On-line modules (editor, N. Kriesberg), NCSU, Raleigh.

Burkholder JM (1993) Golf course runoff: View from below the water surface, pp. 18-23. In: *Is Golfing Green? The Impact of Golf Courses on the Coastal Environment*. Symposium Proceedings (sponsored by the NC Coastal Federation and the NCSU Cooperative Extension Service through the NC Sea Grant College Program), Wilmington.

Patent

U.S. Patent #7,040,157. "Variable depth automated dynamic water profiler", Reed, Glasgow, Burkholder, Toms, May 2006 (NCSU; patent sold to YSI, Inc.).

Professional Activities (examples)

Co-Editor of Book: (2017) *Harmful Algal Blooms and Their Management: A Compendium Desk Reference*, by Shumway SE, Burkholder JM, Morton SL (eds.). Elsevier, New York.

Editorial

Guest Co-Editor, special issue, *Harmful Algae* (Intraspecific Variation, 2009)
Guest Co-Editor, special issue, *Harmful Algae* (Harmful Algae and Eutrophication), 2007
Guest Co-Editor, special issue, *Harmful Algae* (Ecology of *Pfiesteria*), 2006
Editorial Board, *Journal of Experimental Marine Biology and Ecology*, 2005 - 2016
Editorial Board, *Harmful Algae,* 2002 - 2019
Editorial Board, *Journal of Eukaryotic Microbiology*, 1996-1999
Editorial Board, *Journal of Phycology*, 1995-1997

Other Society Service

Member, Organizing Committee, International Symposium on Harmful Algae, 2009-2010
Member, Organizing Committee, National Symposium on Harmful Algae, 2000, 2002, 2003
Member, Ethics Committee, American Society of Limnology and Oceanography, 1996-1997
Member, Harmful Algae Technical Advisory Committee, Maryland Department of Natural Resources, 1998-2001
Session Chair, Ecology of Aquatic Protozoa session, XIth Meeting, International Congress of Protozoology, 2001
Session Chair, New Harmful Algae, 10th International Conference on Harmful Algal Blooms, 2000
Session Chair, *Pfiesteria* in the Southeast, 1st National Symposium on Harmful Algae, 2000
Session Chair, Harmful Algae, 15th Biennial International Conference of the Estuarine Research Federation,

1999
Session Co-Chair, Harmful Algal Blooms, Annual Summer Meeting, American Society of Limnology and Oceanography, 1998
Session Co-Chair, Harmful Algal Blooms, Joint Meeting - American Society of Limnology and Oceanography and American Geophysical Union, 1997
Chair, Hutchinson Award Committee, American Society of Limnology and Oceanography, 1996
Board of Directors, American Society of Limnology and Oceanography, 1994-1997
Session Chair, Ecology of Freshwater Algae, Joint Meeting - International Phycological Congress and Phycological Society of America, 1991
Session Chair, Phytoplankton, Annual Meeting, American Society of Limnology and Oceanography, 1988

External Panels and Reviews

Member, panel review of the annual South Florida Environmental Report for the South Florida Water Management District, 2006-2011
Examiner ("Opponent") of doctoral candidate Johannes Hagström, Kalmar University, 2006
Member, review team for the Department of Botany, Miami University of Ohio, 2005
Member, review team for the Marine Sciences Programs, Institut für Meereskunde, Salzau, Germany, 1998
National Science Foundation, Biological Oceanography Panel, 1995
UNC Water Resources Research Institute Panel, 1991-1993
Member, review team, Lake Okeechobee Ecosystem Project, South Florida Water Management District, 1991

Workshops (Invited Participant)

Aquatic Plant Biology, Ecology and Identification – participant and invited speaker at a NCSU – Extension conference, Raleigh, NC, 2018
The Importance of Algal Mixotrophy in Trophic Models of the Oceans – participant and invited speaker at an international workshop sponsored by the Leverhume Foundation, University of Maryland - Horn Point, Cambridge, MD, 2013
Taxonomy and Ecology of Algae in the Southeast – co-organizer of a workshop for members of the North Carolina Lake Management Society (NALMS – Southeast Chapter), sponsored by NALMS, 2009, 2010, 2011, 2012
Falls Lake Symposium: Christian Creation Stewardship – keynote speaker of a workshop attended by scientists and theologians, to encourage church memberships to become involved in environmental stewardship of the Falls Lake potable water supply, sponsored by the concerned citizens group, Wake Up Wake County, and organized by Drs. Bob George (editor, Theoecology Journal, online) and Bruce Little (Center for Faith and Culture, Southeastern Theological Seminary), 2012
Algae Affecting Potable Water Supplies – AWWA, Savannah, GA, 2010
Identifying Harmful Cyanobacteria in North Carolina Potable Water Supplies – Organizer; two workshops for potable water treatment plant operators, sponsored by the NC Department of Health and Human Services, 2006
Occurrence of Toxigenic Cyanobacteria in the USA, International Symposium on Harmful Cyanobacterial Blooms, US Environmental Protection Agency (EPA), 2005
National Plan for Harmful Algal Research, Ecological Society of America and the National Oceanic and Atmospheric Administration (NOAA), 2004
Social and Environmental Impacts of Concentrated Animal Feed Operations, The University of Iowa and the National Institute of Environmental Health Sciences (NIEHS), 2004
Conflicted Science / Integrity in Science Conference and Workshop, Center for Science in the Public Interest, Washington, DC, 2003
Estuarine Fish Disease, Delaware Department of Natural Resources & Environmental Control, 2000

Harmful Algae Technical Advisory Committee Workshop, Maryland Department of Natural Resources (MD DNR) and Maryland Department of Environment (MD DE), 2000, 2001, 2002
Re-evaluation of Microbial Water Quality: Powerful New Tools for Detection and Risk Assessment, American Academy of Microbiology, 2000
Conservation Medicine Workshop, Center for Conservation Medicine of Tufts University, 1999
Harmful Algal Blooms: Research and Monitoring Programs, US EPA - Region IV, 1998
Pfiesteria Workshops - Sampling and Identification (organizer), NCSU, 1998
Pfiesteria Sampling and Identification Protocols, Centers for Disease Control & Prevention, 1998
European Harmful Algal Blooms (EUROHAB) Science Initiative, Marine Science and Technology Programme of the European Commission, 1998
Pfiesteria and Water Quality Monitoring Standards Workshop, NOAA, 1998
Pfiesteria and Human Health Workshop, Maryland Department of Health and Mental Hygiene and the Maryland Medical Team, University of Maryland and Johns Hopkins, 1998
State/Federal *Pfiesteria* Working Group - Monitoring Protocols, U.S EPA and NOAA, 1998
Maryland Technical Advisory Committee Workshop on *Pfiesteria*, Fish Kills and Water Quality Monitoring, MD DNR, Baltimore, MD, 1998
Pfiesteria Workshop, 14th Biennial International Conference of the Estuarine Research Federation, Providence, RI, 1997
The Cambridge *Pfiesteria*/Nutrients Workshop, convened by Governor Glendening of Maryland, 1997. The final report, *The Cambridge Consensus*, was used by the governor and the Maryland legislature to change policy about non-point water pollution control in tributaries to Chesapeake Bay and led to passage of the Maryland Water Quality Act of 1998.
Impacts of Toxic *Pfiesteria*/*Pfiesteria*-like Dinoflagellates on Fisheries and Human Health, US EPA (Philadelphia, PA; Washington, DC; Pensacola, FL), 1997; Delaware Department of Environment and Water Resources, 1997
Harmful Algal Blooms and Human Health, NIEHS, 1997
Pocomoke River Fish Disease, MD DNR, 1997
Climate Variability and Human Health, American Society of Microbiology, 1997
Developing an Environmental Education Video on Water Resource Issues in North Carolina, Z. Smith Reynolds Foundation, 1997
Control of Blue-Green Algae in Rainbow Springs, Florida, Department of Fisheries and Aquaculture, University of Florida, 1996
Sustainable Marine Fisheries, National Academy of Sciences Ocean Studies Board, 1996
Disease Events and Meteorology along the US Atlantic Coast, Harvard Medical School, 1995
National Nutrient Assessment Workshop – Estuaries, US EPA, Washington, DC, 1995
Harmful Algal Blooms - Research Initiative Development, NSF / NOAA, 1994
Seagrasses and Eutrophication Impacts, US EPA / Sarasota Bay National Estuary Program, 1993
Techniques in Sampling and Identification of *Pfiesteria* – NOAA, 1992; Florida Department of Environmental Protection - Florida Marine Research Institute, 1992; MD DNR, 1993; MD DE, 1993; Delaware Division of Water Quality, 1993
Target Issues: Development of RFP guidelines for a New NOAA Coastal Ocean Program Initiative on Harmful Algal Blooms, NOAA, 1992
Phytoplankton of the Southeastern United States, North Carolina Department of Environment, Health and Natural Resources (NC DEHNR) and Duke Power Company, 1992
Target Issues for Funding Support of Research on Toxic Phytoplankton, NOAA, 1992
Improved Data Base and Optimal Approaches for Modeling Water Quality in the Albemarle-Pamlico Estuarine System, US EPA and NC DEHNR, 1992
Water Quality Regulations for Protection of Seagrass Habitat on the Gulf Coast, US EPA, 1992
Improved Standards for Protecting Water Quality in the Albemarle-Pamlico Estuarine System, US EPA, 1991
Teaching Aquatic Botany to High School Students (organizer), NCSU, 1987, 1988

Light Microscope-Autoradiography of Microalgae (organizer), Bowling Green State University, Bowling Green, OH, 1987

Research Presentations

Water Quality (Eutrophication, Seagrasses, etc.)

2019

Lindor NL, Burkholder JM. Nutrient profiles, phytoplankton biomass, and algal assemblages in Falls Lake, North Carolina. UNC Water Resources Research Institute, Raleigh (with published abstract).

Buczek SB, Cope WG, Shehdan M, Bishop WM, Richardson RJ, Burkholder JM, Kwak TJ, Jessup J, Black TR. In situ Evaluation of Freshwater Mussel Sensitivity to Prescribed Algaecide Applications in a North Carolina Piedmont Reservoir. North Carolina Chapter of the American Fisheries Society, Morganton, NC (with published abstract).

2018

Burkholder JM, Kinder CA, Reed RE, James J, Mackenzie L, Allen EH. Changing Water Quality in Falls Lake, the Triangle's Major Potable Source Water. UNC Water Resources Research Institute, Raleigh, NC (with published abstract).

Lindor N, Burkholder JM. Eutrophication, nutrient stoichiometry, and phytoplankton blooms in a southeastern U.S. reservoir. Fall meeting of the North Carolina chapter of NALMS, Raleigh (with published abstract).

2016

NC Water Resources Research Institute, Raleigh, NC (Inventory and Assessment of the Present Status of Water Resources at Cape Hatteras and Cape Lookout National Seashores – Burkholder, Allen, Flood, and Kinder). Annual conference of the NC Water Resources Research Institute, Raleigh, NC.

2015

Decadal Analysis of Water Quality in Falls Lake, the Triangle's Major Potable Water Source (Burkholder et al., presentation and published abstract). Annual conference, NC Water Resources Research Institute, Raleigh, NC.

2014

Long-Term Data Show Continued Water Quality Degradation in the Neuse Estuary, and Inadequate Protection by the Total Nitrogen TMDL (Burkholder et al., presentation and published abstract). Annual conference, NC Water Resources Research Institute, Raleigh, NC.

Why Bother? - Who Needs Models for Mixotrophs in Coastal Ecosystems? (invited presentation, Burkholder) Leverhulme Trust Phytoplankton Mixotrophy Workshop, Swansea, United Kingdom.

Unprecedented Toxin-Producing Cyanobacterial Blooms in the Cape Fear River (Mallin et al., presentation and published abstract), Summer Meeting, Sciences of Limnology and Oceanography, San Diego, CA.

2013

Outside Peer Review of the Marine Programs of the UNC System for the UNC Board of Governors, Morehead City, NC - The NCSU CAAE was later given an excellent evaluation by the Panel in its final report.

Coastal and Estuarine Research Federation, San Diego, CA - Onset of unprecedented toxin-producing cyanobacteria blooms in the Cape Fear River system, North Carolina - Mallin MA., Burkholder JM, McIver MR, Metheny JD, Strangman WK, Zimba PV, Wright JL (presentation, with published abstract).

Coastal and Estuarine Research Federation, San Diego, CA - Comparative ecotoxicology of an agricultural herbicide on benign and toxigenic estuarine phytoplankton - Flood S, Burkholder J, Cope G (poster with published abstract).

2012

NC Water Resources Research Institute, Raleigh, NC – The NCSU Center for Applied Aquatic Ecology Falls Lake Monitoring and Research Program - Burkholder J, Reed R, Kinder C, Allen E, James J, Mackenzie L (poster with published abstract)

Falls Lake Creation Care Symposium, Wake Forest, NC - Status of Water Quality in Falls Lake - J. Burkholder. The goal of this national symposium was for scientists to inform theologians about citizens' potential roles, including church congregations, in assisting with natural resource stewardship issues (keynote presentation, with published abstract)

2011

NC Water Resources Research Institute, Raleigh, NC (excessive ammonium concentrations throughout the Falls Lake water column, and implications for the Falls Lake Rules; with published abstract)

American Water Works Association National Webinar, online technology used to monitor algae and associated environmental conditions (invited, with published abstract)

LOICZ Open Science Conference 2011 – Coastal Systems, Global Change and Sustainability, Yantai, China (Shumway SE, Burkholder JM: mitigating coastal eutrophication – are filter-feeding shellfish the answer?) (plenary, with published abstract)

2010

NC Water Resources Research Institute, Raleigh, NC (status of water quality in the most important potable water supply in North Carolina; with published abstract)

2009

National Shellfisheries Association, Savannah, GA (bivalve shellfish aquaculture and eutrophication; with published abstract)

North Carolina Academy of Science, Warren Wilson College, Swannanoa, NC (documenting microbial changes in reservoirs using metagenomics – coauthor; with published abstract)

Department of Civil and Environmental Engineering, Northwestern University, Chicago, IL (decadal analysis of land use, water quality, and phytoplankton assemblages in a coastal watershed)

20th Biennial Conference of the Coastal and Estuarine Research Federation (increasing ammonium in eutrophic estuaries, and its potential importance in governing phytoplankton assemblages; with published abstract)

2008

Department of Occupational and Environmental Health, U IA (water quality and algal blooms in watersheds influenced by industrialized agriculture)

NOAA National Symposium on Shellfish and the Environment, Warwick, RI (chronic effects of eutrophication on shellfish)

American Society of Limnology and Oceanography, St. Johns, Newfoundland, Canada (microdynamics of physical/chemical structure in a lagoonal estuary - lead, R. Reed; with published abstract)

North Carolina Water Quality Monitoring Forum, Charlotte (recent advances in technology for tracking algal blooms and related environmental conditions; with published abstract)

2007

Horn Point Environmental Laboratory, U MD (chronic eutrophication of the Neuse Estuary)

NC Water Resources Research Institute, Raleigh (CAAE's Falls Lake Monitoring and Research Program; with published abstract)

NC Water Resources Research Institute, Raleigh (groundwater and benthic nitrogen flux in the Neuse Estuary - lead, K. Null; poster with published abstract)

NC Water Resources Research Institute, Raleigh (long-term impacts of changing land use practices on water quality and phytoplankton assemblages in the Neuse River ecosystem - lead, M. Rothenberger; poster

with published abstract)
Annual Conference of the North Carolina Academy of Science, Greenville (inorganic nitrogen flux across the sediment-water interface in the Neuse Estuary - lead, K. Null; poster with published abstract).
Conference, Water Initiatives: What's on the Horizon for Lake Users and Managers, Greensboro.
19th Biennial Conference of the Estuarine Research Federation, Norfolk, VA (temporal and spatial variability in high-resolution, cross-estuarine physical/chemical structure in the Neuse Estuary – lead, R. Reed; poster with published abstract).
19th Biennial Conference of the Estuarine Research Federation, Norfolk, VA (multivariate analysis of phytoplankton and environmental factors in a eutrophic estuary - lead, M. Rothenberger; poster with published abstract).

2006
Department of Biology, Cornell University (water quality trends in the Neuse Estuary)
Department of Marine Sciences, U CONN (water quality trends in the Neuse Estuary)

2005
Department of Biology, UNC Greensboro (water quality trends in the Neuse Estuary)
Wilkes Community College, Wilkesboro, NC (honors seminar series - water quality issues)

2003
Center for Science in the Public Interest: Conflicted Science Conference, Washington, DC (water quality and confined animal feed operations [CAFOs]; with published abstract)
Yale University - Conference, The Chicken (environmental impacts of CAFOs; with published abstract)

2002
Medical School, Harvard University (marine diseases, anthropogenic influences)
Wilkes Community College, Wilkesboro (honors seminar series - water quality issues)

2001
Washington College (Chesterton, MD; environmental impacts of CAFOs)
Veterinary, Wildlife and Ecological Toxicology Department, Veterinary Biosciences College of Veterinary Medicine, U IL (national water quality issues)
School of Design, NCSU (environmental effects of CAFOs)
Wilkes Community College (honors seminar series - water quality issues)
American Society of Agronomy and the Soil Science Society of America (Northeast Branch) – annual meeting, URI (environmental effects of CAFOs; with published abstract)

2000
American Fisheries Society - annual meeting, St. Louis, MO (environmental effects of CAFOs; with published abstract).
American Society of Agronomy, Crop Science Society of America, and Soil Science Society of America - joint meeting, Minneapolis, MN (nutrient management on CAFOs, and effects on surface water resources; with published abstract)
Association of Southeastern Biologists, Chattanooga, TN: Plenary Speaker (national water quality issues; with published abstract)
Rock Valley College - Natural Resources and Community Action Series, Rockford, IL: Plenary Speaker (national water quality issues)
U MASS, Amherst - Environmental Policy Seminar Series (invited; national water quality issues)
Yale University, School of Forestry (national and state water quality issues)
Department of Zoology, U WA - Seattle (national water quality issues)
American Fisheries Society (NC chapter), New Hill, NC (impacts of Hurricane Floyd on water quality in the Neuse River and Estuary, and Pamlico Sound; with published abstract)

1999
US Department of Agriculture - National Resources Conservation Service, Washington, DC (state water quality issues)
Simon Fraser University - Oceans Limited Conference, Vancouver, British Columbia, Canada (chronic effects of eutrophication; with published abstract)
Department of Biology, University of Louisville, Louisville, KY (chronic effects of eutrophication)

1998
Society of Environmental Toxicology and Chemistry - annual meeting, Charlotte, NC: Keynote Speaker (effects of chronic eutrophication; with published abstract)

1997
Conference, Nutrients in the Neuse River: Working Toward Solutions (sponsor, UNC Water Resources Research Institute [WRRI]), NCSU (effects of chronic eutrophication; with published abstract)

1996
National Association of Biology Teachers - annual meeting, Charlotte, NC (effects of chronic eutrophication; with published abstract)
Texas A&M University, Corpus Christi (effects of pulsed nutrient enrichment on seagrass physiology)
Department of Zoology, Oregon State University (OSU), Corvallis (seagrasses and eutrophication)

1995
Statewide Nutrient Summit (sponsors, NC Sea Grant, NC DEHNR), NCSU (effects of chronic eutrophication; with published abstract)
Water Quality Research and Extension Overview, College of Agriculture and Life Sciences (CALS), NCSU (surface water quality research in CALS; with published abstract)

1994
NC Academy of Sciences - annual meeting, Manteo - Keynote Speaker (state water quality issues; with published abstract)

1993
NC WRRI Seminar Series, Keynote Accomplishments in Research on Water Resources in NC, Raleigh (seagrasses and water-column nitrate enrichment; with published abstract)
Horn Point Environmental Laboratory, U MD (seagrasses and water-column nitrate enrichment)

1992
NC WRRI Seminar Series, Keynote Accomplishments in Research on Water Resources in NC (sediment and phosphorus loading: predicting reservoir water quality; with published abstract)
American Society of Limnology and Oceanography - annual meeting, Edmonton, Alberta, Canada (seagrasses and eutrophication; with published abstract)

1990
Department of Zoology, U WI - Madison (algal phototrophy *vs.* heterotrophy in turbid reservoirs)

1987
Department of Biology, Bowling Green State University, Bowling Green, OH (biological interactions that structure stream plant communities)

1986 (nutrient interactions - macrophytes, epiphytes)
Department of Botany, NCSU
Department of Biology, Fordham University, Bronx, NY
Savannah River Ecology Laboratory, Aiken, SC

University of Michigan Biological Station, University of Michigan, Pellston, MI

1985

Department of Biology, West Virginia University, Morgantown, WV - importance of benthic microalgae in stream ecosystems

Massachusetts Audubon Society, Lincoln, MA - effects of acid deposition on aquatic ecosystems

Harmful Algal Research

2019

Glibert PM, Wilkerson FP, Dugdale RC, Raven JA, Dupont CL, Leavitt PR, Parker AE, Burkholder JM, Kana TM. Pluses and minuses of ammonium and nitrate uptake and assimilation by phytoplankton and implications for productivity and community composition, with emphasis on nitrogen-enriched conditions. ASLO – Puerto Rico (with published abstract).

2018

Buczek SB, Cope WG, Shehdan M, Bishop WM, Richardson RJ, Rice JA, Burkholder JM, Kwak TJ. Evaluation of Freshwater Mussel Sensitivity to Algaecides Used in Attempts to Control Giant *Lyngbya*. North Carolina Chapter of the American Fisheries Society, Morganton, NC (with published abstract).

Burkholder JM, Allen EH. Potable Source-Water Reservoirs in the Southeast: Forecast for Cyanobacteria Blooms. Southeast Chapter of the North American Lake Management Society, Asheville, NC (with published abstract).

2017

Droughts, Internal and External Nutrient Supplies, and Toxic Cyanobacteria Outbreaks in Potable Source Waters of the Southeast (Burkholder and Allen, presentation and published abstract). Society for Freshwater Science, Raleigh, NC.

Ecotoxicology of Herbicide Exposure on Harmful Estuarine Phytoplankton under Varying Nutrient Conditions (Flood, Burkholder and Cope, poster presentation and published abstract. Microbial Toxicology conference, New York.

2013

Leverhume Foundation International Workshop, U MD - Horn Point, Cambridge, MD (algal mixotrophy and water-column nutrients)

2010

North American Lake Management Society (NALMS), Winston-Salem, NC (climate change and harmful algal blooms in the Southeast; with published abstract)

Webinar Lecture Series, Northwestern University, given at the University of British Columbia, Vancouver, BC, Canada (overview on harmful algae)

2008

Burdick Lecture, Department of Biology, Alfred University, Alfred, NY (*Pfiesteria*, other harmful dinoflagellates - toxicity, impacts)

Annual Toxicology and Risk Assessment Conference, Cincinnati, OH (the toxins of inland algae; with published abstract)

2007

Joint meeting of the Phycological Society of America and the International Society of Protozoologists (cyanobacteria in eutrophic turbid impoundments of the North Carolina Piedmont - lead, J. Burkholder; poster with published abstract)

Joint meeting of the Phycological Society of America and the International Society of Protozoologists

(axenic cultivation of a heterotrophic dinoflagellate - lead, H. Skelton; with published abstract)
4th National Symposium on Harmful Algae, Woods Hole, MA (axenic cultivation of *Pfiesteria shumwayae* on a semi-defined medium; poster with published abstract)

2006
Kalmar University, Kalmar, Sweden (*Pfiesteria*, other harmful dinoflagellates - toxicity, impacts)
American Society of Limnology and Oceanography - annual summer meeting: Plenary Speaker, Victoria, British Columbia, Canada (stimulation of harmful algae by eutrophication; with published abstract)

2005
North American Lake Management Society (NALMS) - National Meeting, U WI - Madison – Keynote Speaker (cyanobacteria in potable water supplies - with published abstract)
GEOHAB (Global Ecology and Oceanography of Harmful Algal Blooms) Symposium, Nutritional Ecology of Harmful Algae, Baltimore, MD (importance of intraspecific variation – with published abstract)
Medical School, Harvard University (harmful algae and seafood safety)
NALMS Southeast Chapter Meeting, Asheville, NC (cyanobacteria in potable water supplies - with published abstract)
American Water Works Association - Source Water Protection Symposium, West Palm Beach, FL (cyanobacteria in potable water supplies - with published abstract)

2004
XIth International Conference on Harmful Algae, Cape Town, South Africa: Plenary Speaker (intraspecific variation in toxicity, behavior and nutrition; with published abstract)
St. Johns Water Management District, Orlando, FL (effects of harmful algae on fish and mammalian health)
International EnviroVet Program, Harbor Branch Oceanographic Institute, Fort Pierce, FL (marine diseases)
Department of Oceanography, U WA - Seattle (science, policy)
Shannon Point Marine Laboratory, Western Washington University (science, policy)
NSF Undergraduate Education Honors Program, NCSU (science, policy)

2003
Elon University - Voices of Discovery Seminar Series: Keynote Speaker (*Pfiesteria*)
International EnviroVet Program, Harbor Branch Oceanographic Institute (toxic dinoflagellates)
Florida Institute of Technology (toxic dinoflagellates)
Conference on Emerging Waterborne Pathogens, NC Department of Health and Human Services (DHHS), Wilmington, NC: Two presentations - toxic dinoflagellates; toxic cyanobacteria)

2002
Hopkins Marine Laboratory, Stanford University, Monterey, CA (*Pfiesteria*, other toxic dinoflagellates - science, policy, science ethics)
National Ocean Service, NOAA, Charleston, SC (progress in *Pfiesteria* research)
Symposium, Climate Change and Fisheries in the Gulf of Maine (sponsor, NOAA), College of the Atlantic, Bar Harbor, ME (harmful algae and climate change)
Department of Biology, UNH, Durham (toxic dinoflagellates).
Department of Biology, Williams College, Williamston, MA (toxic dinoflagellates)
Department of Biology, Miami University of Ohio, Athens (toxic dinoflagellates)

2001
XIth International Congress of Protozoology, Salzburg, Austria (dinoflagellates - complex life histories and feeding behaviors; with published abstract)
George Clark Lecture Series, Wetlands Institute, Cape May, NJ (*Pfiesteria*, other dinoflagellates)
Society for Risk Analysis, Research Triangle Park (biomarkers for species and toxins)
Environmental Lecture Series, Ashland University, Ashland, OH (harmful algae and eutrophication)

Marine Conservation Biology Series, Wheaton College, Springfield, MA (chronic effects of harmful algae on fish and mammalian health)

2000

IXth International Conference on Harmful Algal Blooms, Hobart, Tasmania, Australia: Plenary Speaker (toxic *Pfiesteria*; with published abstract)

Elliott-Nowell-White Symposium, Delta State University, Delta State, MS: Keynote Speaker (chronic and sublethal impacts of harmful algae on mammalian health)

Society of Toxicology of Canada - annual meeting, Montreal, Quebec, Canada (toxic dinoflagellates; with published abstract)

Department of Biology, State University of NY - Syracuse (toxic dinoflagellates)

Brookhaven National Laboratory, Brookhaven, NY (toxic dinoflagellates)

State University of New York - Stony Brook (toxic dinoflagellates)

XIIIth World Congress of the International Society of Toxinology, Paris, France (toxic *Pfiesteria*)

Centers for Disease Control & Prevention, Atlanta - conference, *Pfiesteria*: From Biology to Public Health (ecology and conservative analysis of role in fish kills; with published abstract)

National Association of Biology Teachers - Biotechnology Conference. VPI, Blacksburg (harmful algal research)

University of Mississippi, Oxford - Conference, Sustainability of Wetlands and Water Resources (toxic dinoflagellates)

Department of Biology, University of Memphis (toxic dinoflagellates)

Society of Microbiology - Northeast Chapter, Sturbridge, MA (toxic dinoflagellates)

Society of Toxicology - annual meeting (sponsor, US EPA), Philadelphia (toxic dinoflagellates; with published abstract)

Southeastern Estuarine Research Society - annual meeting in conjunction with the 29th Benthic Ecology Meeting and the annual meeting of the Atlantic Estuarine Research Society, Wilmington, NC (toxic dinoflagellates; with published abstract)

1999

National Academy of Sciences - Workshop on Critical Research Needs, Washington, DC (research needs to advance understanding about harmful algae)

Lake Biwa Research Institute, Forum on Water Quality, Kyoto, Japan: Keynote Speaker (*Pfiesteria*, other toxic dinoflagellates)

Woods Hole Oceanographic Institute, Falmouth, MA (toxic dinoflagellates)

Veterinary School, Tufts University, Grifton, MA (toxic dinoflagellates)

Department of Biology, Yale University (improved mitigation of harmful algal blooms)

Georgetown Conference on Policy and *Pfiesteria*, Georgetown University, Washington, DC: Keynote Speaker (science, policy of *Pfiesteria*; with published abstract)

American Association for the Advancement of Science (AAAS) - annual meeting, Anaheim, CA, session, "Human Health Risks in the Ocean" (chronic and sublethal impacts; with published abstract)

AAAS - annual meeting, Anaheim, CA, session "Harmful Algal Blooms" (toxic *Pfiesteria*; with published abstract)

Department of Geology, University of Oslo (Oslo, Norway) (toxic *Pfiesteria*)

Society of Protozoologists - annual meeting, Raleigh: Keynote Speaker (toxic *Pfiesteria*; with published abstract)

Department of Ecology Evolution and Behavior, U MN - Minneapolis (toxic dinoflagellates; with published abstract)

Phi Beta Kappa Seminar Series, Elon University (toxic *Pfiesteria*)

Honors Seminar Series, Southampton College, Southampton, NY (toxic dinoflagellates)

Department of Biology, Barton College, Wilson (toxic dinoflagellates)

Department of Biology, Davidson College, Davidson (toxic dinoflagellates)

Wilkes Community College, Wilkesboro (toxic dinoflagellates)
Department of Biology, NC A&T University, Greensboro (toxic dinoflagellates)
Department of Pathology, UNC Chapel Hill (toxic dinoflagellates)
Department of Biology, UNC Greensboro (toxic dinoflagellates)
Department of Biology, University of Louisville (toxic dinoflagellates)
Sigma Xi - NC Chapter meeting, Appalachian State University, Boone, NC (toxic *Pfiesteria*)

1998

AAAS - annual meeting, Philadelphia, session, "Management of Harmful Marine Microbes: When Science and Politics Don't Mix" (harmful algae; with published abstract)
Medical School, Harvard University (harmful algae)
Shallow Water Conference (sponsor, US EPA), Atlantic City, NJ: Keynote Speaker (effects of toxic *Pfiesteria* on fish and mammals; with published abstract)
Gordon Conference - annual meeting, Ventura, CA (acute/chronic effects of toxic dinoflagellates; with published abstract)
Department of Biology, Rutgers University (chronic effects of toxic dinoflagellates)
Department of Biology, URI (toxic dinoflagellates)
Department of Pharmacology, U GA - Athens (toxic dinoflagellates)
American Biological Safety Association - 41st Annual Biological Safety Conference, Lake Buena Vista, FL: Eagleston Lecture (*Pfiesteria*, other toxic dinoflagellates; with published abstract)
Wildlife Disease Association - 47th Annual Conference, U WI - Madison (toxic *Pfiesteria*; with published abstract)
Department of Biology, Purdue University (toxic dinoflagellates)
American Institute of Biological Sciences - 49th annual meeting (toxic dinoflagellates; with published abstract)
Microbiology Society of NC - annual meeting, Research Triangle Park: Keynote Speaker (*Pfiesteria*, other toxic dinoflagellates)
NC Water Resources Association - Conference on Water Pollution Issues in NC, Asheville: Keynote Speaker (*Pfiesteria*, other toxic dinoflagellates; with published abstract)
Northeast Algal Symposium - annual meeting, Plymouth, MA – Keynote Speaker (toxic *Pfiesteria*; with published abstract)
American Society of Limnology and Oceanography - joint summer meeting with the Ecological Society of America, Symposium Session Honoring Minority Students: Keynote Speaker (*Pfiesteria*, other harmful algae; with published abstract)
Stanford University, Institute of Ecosystem Ecology (toxic *Pfiesteria*)
NASA, Goddard Space Center, Baltimore, MD (*Pfiesteria*, other toxic dinoflagellates)
Keynote Seminar Series in Marine Sciences, Wilmington, DE (sponsors, U DE, DE Sea Grant): Presentation (*Pfiesteria*)
Friends of the Library, NCSU (*Pfiesteria*, other toxic dinoflagellates)
Department of Biology, Auburn University (toxic dinoflagellates)
Department of Environmental Sciences, Drexel University, Philadelphia (toxic *Pfiesteria*)
Department of Biology, Hampden Sydney College, Hampden-Sydney, VA (toxic dinoflagellates)
Department of Biology, UNC Charlotte (*Pfiesteria*, other toxic dinoflagellates)
Headquarters, US EPA, Washington, DC (toxic *Pfiesteria*)
Distinguished Lecturer Series, Old Dominion University, Norfolk, VA (*Pfiesteria*)

1997

Society for Conservation Biology - annual meeting, Victoria, British Columbia, Canada (harmful algae and eutrophication; with published abstract)
Department of Biology, University at Buffalo, Buffalo, NY (*Pfiesteria*, other toxic dinoflagellates)
Departments of Zoology and Oceanography, OSU (toxic algae)

3rd Annual Conference on Population-Level Effects of Marine and Estuarine Contamination, Charleston, SC (science, policy; with published abstract)
Wagner College, Staten Island, NY (special college-wide seminar, toxic *Pfiesteria*)
Department of Biological Science, Florida State University, Tallahassee (toxic dinoflagellates)
Department of Botany, Duke University (*Pfiesteria*, other toxic dinoflagellates)
Conference on Fisheries, Habitat and Pollution (sponsors, SC Sea Grant, TerrAqua Environmental Science and Policy Institute), Charleston, SC (chronic and sublethal effects of harmful algae; with published abstract)
Institute of Ecosystem Studies, Millbrook, NY (chronic and sublethal effects)
American Fisheries Society, NC Chapter - annual meeting, Lake Wylie, SC (*Pfiesteria*; with published abstract)

1996
AAAS - annual meeting, session Global Change and Emerging Infectious Diseases (effects of harmful algae on fish and mammalian health; with published abstract)
NATO Workshop, Physiological Ecology of Harmful Marine Phytoplankton, Bermuda Biological Station for Research (raptorial dinoflagellates; with published abstract)
Sigma Xi - UNC Greensboro and NCCU Chapters: Keynote Speaker (toxic *Pfiesteria*)
Department of Biology, Southampton College, Long Island University, Southampton, NY (toxic dinoflagellates)
Department of Biology, University of Cincinnati, Cincinnati (toxic dinoflagellates)
NIEHS, Research Triangle Park (toxic *Pfiesteria*)
Whitney Laboratory, U FL - St. Augustine (toxic dinoflagellates)
Department of Biology, Wake Forest University, Winston-Salem (toxic dinoflagellates)
Association of Women in Science, UNC Chapel Hill (*Pfiesteria*, other toxic dinoflagellates)
Texas A & M University, Corpus Christi, TX (*Pfiesteria*, other toxic dinoflagellates)

1995
Society of Protozoologists - annual meeting, U AL, Tuscaloosa, AL: Keynote Speaker (toxic *Pfiesteria* and its microbial, macroinvertebrate and vertebrate prey; with published abstract)
5th Pan American Symposium on Animal, Plant and Microbial Toxins, Baltimore, MD (*Pfiesteria*; with published abstract)
Department of Toxicology, NCSU (toxic dinoflagellates)
Department of Biology, U MD, Baltimore, MD (toxic *Pfiesteria*)

1994
First International Conference on Ecosystem Health and Medicine, Ottawa, Ontario, Canada (effects on human health; with published abstract)
E-MAP Monitoring Program, US EPA, Research Triangle Park (emerging toxic algae - effects on fisheries and public health)
Department of Biology, University of Richmond (emerging toxic algae)
Department of Environmental Health, Boston University (toxic dinoflagellates)
Department of Biology, SUNY - Stony Brook (toxic dinoflagellates)
International Society for Evolutionary Protistology - Biennial Meeting, Halifax, Nova Scotia, Canada: Keynote Speaker (*Pfiesteria* and its prey; with published abstract)
Institute of Ecology, U GA - Athens (harmful heterotrophic dinoflagellates)
Department of Fisheries and Aquaculture, U FL - Gainesville (toxic dinoflagellates)

1993
Fifth International Conference on Modern and Fossil Dinoflagellates (Zeist, the Netherlands): Keynote Speaker (toxic *Pfiesteria*; with published abstract)
Beta Beta Beta Biological Honors Society, Elon University: Keynote Speaker (effects of toxic *Pfiesteria* on estuarine food webs)
Chesapeake Biological Laboratory, Solomons, MD (toxic dinoflagellates)

Southeastern Fisheries Society, Reidsville, NC (toxic dinoflagellates and fish health)
Dauphin Island Marine Laboratory, Dauphin Island, AL (toxic dinoflagellates)
Department of MEAS, NCSU (*Pfiesteria*)

1992

Vth International Symposium on Toxic Algae, Newport, RI (toxic *Pfiesteria*; with published abstract)
Southeast Regional Directors of the Sea Grant College Program - annual meeting: Keynote Speaker (*Pfiesteria*)
Department of Zoology, NCSU (toxic *Pfiesteria*)
US Geological Survey, Raleigh (toxic *Pfiesteria*)
NC Statewide Phytoplankton Meeting, Duke Power Company (Huntersville, NC: Keynote Speaker)
Department of Biology, UNC Wilmington (*Pfiesteria*, other toxic dinoflagellates)
Department of Biology, Appalachian State University, Boone, NC (toxic dinoflagellates)
Department of Biology, UNC Greensboro (toxic dinoflagellates)
US EPA, Narragansett, RI (*Pfiesteria*, other toxic dinoflagellates)
Department of Biology - Marine Sciences Group, UNC Chapel Hill (toxic dinoflagellates)
Bodega Marine Laboratory, U CA - Davis, Bodega Bay (toxic dinoflagellates)

Other Algae

2012

Phycological Society of America, Charleston, SC (Mixson, S. and J. Burkholder - enhancing lipid production in the marine microalga *Dunaliella* through environmental stressors; with published abstract)

2010

Webinar, Northwestern University special summer course for graduate students, given at the University of British Columbia, Vancouver, BC (the ecology of periphyton)

2007

Society of International Limnologists (SIL) - 30th Congress of the International Association of Theoretical and Applied Limnology, Montreal, Quebec, Canada (importance of benthic microalgae across freshwater, estuarine and marine ecosystems; with published abstract)

1999

Society for General Microbiology - Symposium, Microbial Signaling and Communication, University of Edinburgh, Edinburgh, Scotland (signaling in dinoflagellates; with published abstract)

1991

Department of Biology, VPI, Blacksburg, VA (phytoplankton survival of pulsed suspended sediment loading)

1990

Center for Reservoir Research, Hancock Biological Station, Murray State University, Paducah, KY (phytoplankton and periphyton dynamics in turbid, eutrophic reservoirs)
Department of Zoology, NCSU - Aquatic Ecology Seminar Series (mutualistic symbioses involving algae)
Department of MEAS, NCSU (role of benthic microalgae in eutrophication of freshwater and coastal marine habitats)

1989

Experimental Lakes Area (ELA), University of Manitoba, Winnepeg, Manitoba, Canada (relative importance of the water column and macrophytes as nutrient sources for epiphytes)
Hampton University, Hampton, VA (biotechnology in aquatic ecology)
Department of Biology, University of Louisville, Louisville, KY (use of autoradiography to examine nutrient dynamics of microalgal biofilms)
Duke Marine Laboratory, Beaufort (nutrients and epiphytes – unifying trends in freshwater and marine ecosystems)

1988
Department of Biology, UNC Chapel Hill - Marine Macroalgae Seminar Series (epiphytes)
Department of Biology, East Carolina University (phosphorus sources for epiphytic microalgae)
Department of Botany, Duke University (nutrient sources for epiphytic microalgae)
Environmental Section, Carolina Power and Light Company, New Hill, NC (epiphytic microalgae - role in nutrient cycling of lakes)

Science Ethics and Environmental Issues

2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015
Park Scholars Program, NCSU (role of science ethics in environmental issues)

2005
Department of Epidemiology, UNC Chapel Hill, Forum "Funding, Academic Freedom, and Public Responsibility" (industry and water quality)
2004
Department of Biology, Cornell University (toxic algae)
Department of Civil Engineering, NCSU (water quality)
Department of Biology, UNC Asheville (water quality)

2003
New York Metropolitan Association of College and University Biologists – 36th Annual Conference, Wagner College, Staten Island: Keynote address (role of science ethics in natural resource issues)
NSF Environmental Education Program, NCSU (toxic algae, water quality)

1999
Department of Geology, University of Oslo, Oslo, Norway (toxic algae, water quality)
Park Foundation Lecture Series, College of Journalism, UNC Chapel Hill (critical role of journalists in environmental science education and ethics)

1998
Metcalf Institute for Marine and Environmental Journalism - annual board meeting, URI: Keynote Speaker (how environmental journalists can help to strengthen science ethics)

Academic Contributions

Courses Taught

- PB 595A, *Aquatic Plant Ecology* (4 credits; 1987 - present, fall alternate years; updated each time)
- PB 595W / AEC 495/592, *Environmental Issues in Aquatic Ecology* (3 credits, 1990 - present, usually fall alternate years) - special topics/current events graduate course, updated each time
- PB/MB 774, *Phycology* (3 credits including laboratories; 1987 - present, spring alternate years, updated each time)
- BO 595E, *Ecology, Evolution and Diversity* – (2003; course coordinator, Jon Stuckey); mini-course: designed and taught one of eight modules on aquatic vascular plants as bioinvaders
- PB 824C, *Plant Biology Colloquium* (1 credit) – co-taught with Nina Allen (spring 2002, 2004, 2006) or Bill Thompson (spring 2009, 2011, 2013); graduate students receive training to give presentations, write grant proposals, and critique grant proposals)
- HON 398, *Honors Seminar on Aquatic Ecology* (1 credit, spring 2008) – seminar/discussion course for undergraduate honors students on aquatic natural resource issues in North Carolina

- EMS 496/622/822 or TDE 490/610 – STEM Education Seminar Course, *Environmental Issues in Estuarine Ecology and Pedagogical Applications* (1 credit, spring 2010), co-taught with P. Simmons and A. Clark.
- AEC 495/592, *The Biology, Ecology and Diversity of Algae* (3 credits including laboratories; spring 2019.)

Major or Co-major Advisor of Graduate Students

Nicole Lindor, Ph.D. (Plant and Microbial Biology, in progress, 2014-)
Received a WRRI grant ($10,000, 2018)

Stacie Flood, Ph.D. (Plant and Microbial Biology, 2017)
Thesis: Ecotoxicology of estuarine phytoplankton growth and toxicity in response to atrazine exposures.
Post-Graduate Position: Postdoctoral research associate, U.S. EPA, Research Triangle Park, NC (2017).

Stephanie Mixson, Ph.D. (Plant and Microbial Biology [department name change from Plant Biology] - 2013)
Thesis: *Dunaliella* spp. under environmental stress: Enhancing lipid production and optimizing harvest
Honor: Secured a grant to help support her dissertation research, from the Charles A. and Anne Morrow Lindbergh Foundation (2010)
Post-Graduate Position: Analytical Development Specialist, Medicago USA, Research Triangle Park (2013)

Eva Ngulo, M.A. (Plant Biology, 2011)
Final paper: Influence of clay treatment on noxious planktonic cyanobacteria

Kimberly Null, Ph.D. (MEAS; co-advisor with Dr. Dave DeMaster), 2010
Thesis: Ammonium dynamics in a shallow lagoonal estuary
Honors: Secured two grants to help support her dissertation research, from the NC Academy of Science (2006) and the Geological Society of America (2006)
Post-Graduate Positions: Post-Doctoral Research Associate, University of California - Santa Cruz, then Post-Doctoral Research Associate, East Carolina University - Greenville, NC (research in Antarctica)

Hayley Skelton, Ph.D. (MEAS; co-advisor, Dr. Dan Kamykowski), 2008
Thesis: Nutritional features and feeding behavior of the heterotrophic dinoflagellate, *Pfiesteria shumwayae*
Honor: Won the Theodore L. Jahn and Eugene C. Bovee Award for best graduate student research paper, annual meeting of the International Society of Protozoologists, Providence, RI (2007)
Post-Graduate Positions: Post-Doctoral Fellow, National Research Council, NOAA / University of Connecticut (2008), then Supervisor of Algal Culturing, Algenol Biofuels, Fort Myers, FL (2009)

Meghan Rothenberger, Ph.D. (Plant Biology), 2007
Thesis: Long-term impacts of changing land use practices on water quality and phytoplankton assemblages in the Neuse Estuary ecosystem, North Carolina
Honors: Won best graduate research presentation, Graduate Student Forum, Department of Plant Biology (2007)
Won best Ph.D. dissertation of the year (2007) at NCSU, from the NCSU Graduate School (2008)
Post-Graduate Positions: Post-Doctoral Associate, CAAE (Visiting Professor, UNC Greensboro; then assistant professor at Lafayette College, Easton, PA)

Susan Pate, M.Sc. (Botany), 2006
Thesis: Impacts of the toxic dinoflagellate *Alexandrium monilatum* on three ecologically important shellfish species
Post-Graduate Position: Laboratory Administrator (Biotechnology), Duke University

Matthew Parrow, Ph.D. (Botany), 2003
Thesis: Feeding, reproduction, and sexuality in *Pfiesteria* spp. and cryptoperidiniopsoid estuarine heterotrophic dinoflagellates
Honor: Won the Kellar Award for outstanding dissertation research (NCSU), 2004
Post-Graduate Positions: Post-Doctoral Associate, CAAE (now Assistant Professor, UNC Charlotte)

Paul Cancellieri, M.Sc. (Botany), 2001
Thesis: Chemosensory attraction of *Pfiesteria* spp. to fish secreta
Post-Graduate Position: Teacher, Durant Middle School, Raleigh

Howard Glasgow, Ph.D. (MEAS; co-advisor; main advisor, Dr. Dan Kamykowski), 2000
Thesis: Biology and impacts of toxic *Pfiesteria* complex species
Post-Graduate Position: Researcher, CAAE (permanently disabled by a neurological illness)

Jeffrey Springer, M.Sc. (MEAS; co-advisor, Dr. Dave Eggleston), 2000
Thesis: Interactions between two commercially important species of bivalve molluscs and the toxic estuarine dinoflagellate, *Pfiesteria piscicida*
Honor: Won the Best Student Presentation Award at the Annual Meeting of the National Shellfish Association, Seattle, WA, 2002
Post-Graduate Position: Research Associate, CAAE

Naomi Tsurumi, M.A. (Botany), 2000 Thesis: Influence of Industrialized Swine Agriculture on Air Quality
Post-Graduate Position: Environmental Policy M.A. program, Duke University

Brant Touchette, Ph.D. (Botany), 1999
Thesis: Physiological and developmental responses of eelgrass (*Zostera marina* L.) to increases in water-column nitrate and temperature
Post-Graduate Position: Assistant Professor, Elon University (now associate professor)

Elizabeth Fensin, M.Sc. (Botany), 1997
Thesis: Population dynamics of *Pfiesteria*-like dinoflagellates, and environmental controls in the mesohaline Neuse Estuary, North Carolina, USA
Post-Graduate Position: Research Assistant, North Carolina Department of Environment and Natural Resources (then called the NC Department of Environment, Health, and Natural Resources)

L. Michael Larsen, Ph.D. (Zoology; co-advisor with Dr. Sam Mosley), 1995
Thesis: Responses of *Diaphanosoma brachyurum* (Cladocera: Suicide) and other zooplankton to clay loading and algal food quality in a turbid southeastern reservoir.
Post-Graduate Position: Assistant Professor, Campbell University, Fayetteville, NC (now Professor and Department Chair, Biology)

Leslie (Taylor) Taggett, M.Sc. (Botany), 1995
Thesis: Nitrate reductase activity of two intertidal macroalgae across gradients of temperature, salinity and desiccation
Post-Graduate Position: Research Assistant – Analytical Chemistry Laboratory, NC DEHNR

Virginia Coleman, M.Sc. (Botany), 1993
Thesis: Community structure and productivity of epiphytic microalgae on eelgrass (*Zostera marina* L.) under water-column nitrate enrichment
Post-Graduate Position: Research Associate – Algal Laboratory, NC Department of Environment and Natural Resources

Phumelele Gama, M.S. (Botany), 1992
Thesis: Phytoplankton response to a sediment loading gradient in a mesotrophic reservoir
Post-Graduate Position: Lecturer of Botany, University of Zululand, South Africa

Deborah Everitt (Tan), M.S. (Botany), 1992
Thesis: Seasonal dynamics of macrophyte communities from a stream flowing over granite flatrock in North Carolina, USA
Post-Graduate Position: Stream Scientist, MD Department of Natural Resources

Other Graduate Student Committee Memberships

Postdoctoral Associate Advisor

Meghan Rothenberger, 2007: Present position, Assistant Professor, Lafayette College

Matthew Parrow, 2004-2006: Present position, Assistant Professor, UNC Charlotte
Brant Touchette, 2000-2002: Present position, Associate Professor, Elon University
Cheng Zhang, 1999-2003: Present position, Research Scientist, North Carolina Department of Environment and Natural Resources

Visiting Fulbright Scholar

Allasanne Ouattara, Ivory Coast, 2008-2009: Professor from the University of Abobo-Adjamé

Activities in Other Academic Programs

Kenan Fellows Program (for gifted K-12 teachers)

Mentor to Amanda Warren (2009-2010)
Mentor to Susan Randolph (2009-2010)
Mentor to Diane Whittaker (2007-2008)
Secondary mentor to Gayle Powell (2007-2008)
Panelist on selection committee for Kenan Fellows (2007-2009)

Other NC State Service

Chair, Tenure Promotion Evaluation Committee (for Dr. A. Krings; departmental – Plant and Microbial Biology, 2016-2017)
Member, Focus Group guiding the Office of the Executive Vice Chancellor and Provost in creating a Strategic Communications Plan for the Provost's office (University, 2016)
Member, CALS Innovation and Efficiency Committee (college, 2015)
Member, Big Ideas Committee (college, 2014-2015)
Member, Post-Tenure Review Committee (departmental – Applied Ecology, 2014-)
Member, William Neal Reynolds Distinguished Professor Selection Committee (college, 2014)
Member, College of Agriculture and Life Sciences Research Committee (college, 2011-2016)
Member, Executive Committee, Applied Ecology (departmental, 2013-)
Member, Advisory Committee for the NCSU publication, *Results: Research and Innovation at North Carolina State University* (university, 2013-)
Member, Advisory Committee, Plant Biology (departmental, 2011-2013)
Chair, Plant Biology Post-Tenure Evaluation Committee (departmental – Plant and Microbial Biology, 2012)
Member, Selection Committee for Evolutionary Ecologist Position (departmental – Plant and Microbial Biology, 2007)
Member, Larry A. Whitford Botany Scholarship/Fellowship Award Committee (departmental, Plant and Microbial Biology, 2004-2007)
Member, Plant Biology Mentoring Committee for Alexander Krings (departmental, 2007-2009)
Member, Plant Biology Mentoring Committee for Bill Hoffmann (departmental, 2004-2006)
Member, Plant Biology Undergraduate Curriculum Committee (departmental, 2007-2010)
Member, Search Committee, Plant Biology - Evolutionary Ecologist (departmental, 2006)
Member, Water Quality Committee (university, 2004-)
Member, Water Resources Curriculum Committee (university, 2003-)
Member, Ad Hoc Committee on Marine Science (university, 2003-)

Education Outreach (examples, past five years)

K-12 Students and Teachers

The CAAE's *Falls Lake Water Quality Forensics Program* (2019-): Is providing hands-on education about freshwater science, water quality assessment, influential characteristics of watersheds, the direct connection between water quality and human health, and the importance of citizen stewardship in protecting potable source-waters. Thus far, about 2,400 students have participated (8th/rising 9th graders; also 1st-2nd graders).

The CAAE's *Floating Classroom Program* aboard the research/education ship, *RV Humphries*: Provided hands-on education in aquatic science (1/2-day cruise on the Neuse Estuary for 282 8th graders and their teachers (2016), 278 8th graders and their teachers (2015), 345 9th graders and their teachers (2014), 360 9th graders and their teachers (2013), and 480 9th graders and their teachers (2012) from Wayne County schools in economically depressed areas.

General Citizenry

Neuse River Documentary (led by Mr. Bill Leslie, WRAL Television Station; panel participant in public forums in Raleigh and New Bern, NC about the documentary, 2019)

Randleman High School, Randleman, NC – senior science classes, invited presentation on harmful algae (2018)

League of Women Voters, Chapel Hill, NC – invited presentation on water quality issues in NC (2018)

Environmental Seminar Series - Water, High Point University (invited presentation on North Carolina's environmental report card, 2017)

Women's Club of Raleigh, Raleigh, NC, (invited presentation on the safety of the area's drinking water, 2016)

Other Service - Member, City of Raleigh Stormwater Commission, 2015-2016

Society Memberships – American Association for the Advancement of Science (AAAS), Association for the Sciences of Limnology and Oceanography (ASLO), Coastal and Estuarine Research Federation (CERF), North American Lake Management Society (NALMS), Phi Kappa Phi, Phycological Society of America, Sigma Xi

Electronic Filing: Received, Clerk's Office 3/14/2019

BEFORE THE ILLINOIS POLLUTION CONTROL BOARD

IN THE MATTER OF:		
PROPOSED AMENDMENTS TO:	)	
35 Ill. Adm. Code 302.102 and 302.208(g)	)	R18-32
WATER QUALITY STANDARDS	)	
FOR CHLORIDES	)	

INTRODUCTION

Based on the hearing in this matter held January 23, 2019, this Amended Petition is intended to present a revised water quality standard for chlorides based upon stream temperature at the time of sampling. Recent literature regarding chloride toxicity has been incorporated herein. The proposed language has been modified with respect to winter temperatures, and the toxicity data used to derive the standards have been updated with additional recent literature. The toxicity data have been normalized based on hardness and sulfate. In addition, a temperature relationship was derived based upon a recent article by Jackson and Funk (2019)[1] coupled with the temperature data generated as part of this project. The result is a single year-round water quality standard based upon the stream temperature, hardness, and sulfate at the time of sampling for chlorides.

STATEMENT OF REASONS

The Illinois Pollution Control Board (Board), in R08-9 (Subdocket D) adopted water quality standards on the Chicago Area Waterways (CAWS) and the Lower DesPlaines River (LDPR), including for chlorides. With the exception of the Chicago Sanitary & Ship Canal (CSSC), the Board adopted a chloride water quality standard of 500 mg/L from May 1st through November 30th, and the same standard for the remainder of the year, effective three years after the effective date of those rules. The intent of the three-year delay was "to allow time for the work group to develop a proposal to address chloride and a water body wide variance." (Final Notice Opinion and Order of the Board, R80-9, p 32.)

The focus of the various work groups has been on developing and implementing Best Management Practices (BMPs) to reduce the application of highway de-icing salts, the principal cause of elevated chlorides during the winter (and spring) months in the receiving streams. Elevated chlorides are not unique to the CAWS and LDPR during the winter months; elevated chloride concentrations occur on all urban streams in Illinois. The General Use Water Quality Standard for chlorides, as found in 302.208(g), is 500 mg/L, identical to what the Board has adopted for the CAWS and LDPR, excluding the CSSC.

[1] Jackson, J.K. and Funk, D.H. Temperature affects acute mayfly responses to elevated salinity implication for toxicity of road de-icing salts. *Phil. Trans. R. Soc. B 374: 20180081.*

Electronic Filing: Received, Clerk's Office 3/14/2019

More efficient application of sodium chloride for highway de-icing is being implemented. However, as the 500 mg/L standard is a *not-to-exceed* standard, the question is: can BMPs achieve the necessary reduction under the worst storm events? For example, on the North Branch of the Chicago River, data from 2004 to 2014 reveal a maximum chloride concentration of 1,134 mg/L, necessitating a reduction of 55 percent in salt application during the worst events. (Huff, October 2015.[2]) It is appropriate to question whether simply implementing BMPs can consistently achieve this type of reduction. For smaller streams, the required reductions can be even greater. For example, Hickory Creek at Vine Street reached 1,476 mg/L in 2014, necessitating a reduction of 66 percent in salt application during the worst storm events to achieve 500 mg/L. (Huff, Feb 2015.[3]) Despite these elevated winter concentrations some of the impacted waterways still host aquatic communities who score at the upper end of the moderately impaired category of the state aquatic life scale. This observation supports the position that elevated winter concentrations are less destructive to aquatic communities than elevated warm weather concentrations.

While focusing on efficient utilization of de-icing salts is appropriate, there are concerns that implemented alone, BMPs will not achieve the target of 500 mg/L for these worst storm events. These concerns were the basis behind assembling a group of municipalities and sanitary districts, industries, The Salt Institute, a watershed group, and the Illinois Tollway to fund additional research on cold-temperature toxicity of chlorides. The results from these additional toxicity tests form the basis behind this Rulemaking request, as the findings show chlorides are less toxic at colder temperatures, thereby justifying a relaxed chloride standard during the colder months. Illinois already utilizes a similar approach for ammonia for which there are less stringent winter standards, so there is precedent for such an approach. In addition, the Board adopted higher winter chloride standards for the CSSC in R08-9 (Subdocket D).

Given the current water quality violations, chlorides are or should be identified as a cause of impairment for nearly all urban streams in Illinois. The ones not identified as impaired due to chlorides are likely due to the lack of sufficient monitoring. The impact of chlorides being identified as a cause of impairment is a serious impediment to future growth of any kind in the urban areas of Illinois. If increased pavement, housing, or parking lots are planned, then the required de-icing salts will need to be more than offset within the watershed. Finding these offsets is becoming more difficult. BMPs are being implemented as part of the watershed variances currently before the Board, and these same BMPs cannot be used as offsets for new growth. Alternatives to chloride de-icing are not technically feasible on a region-wide basis, when considering safety and mobility. This has been demonstrated by the Connecticut Department of

Electronic Filing: Received, Clerk's Office 3/14/2019

Transportation, that for a seven-year period used a mixture of sand-salt (7:2) and compared the accidents to a seven-year period with just salt and found a 19 percent increase in nonfatal injuries and a 33 percent increase in accidents with the sand-salt mixture compared to just salt.[4] So while a reduction in salt usage is an achievable goal, it is technically infeasible to reduce its use for de-icing practices sufficiently to consistently meet the 500 mg/L water quality standard.

Another consideration would simply shut down the highway system during snow events where there would be a potential to exceed the water quality standard. From the information generated in the Technical Support Document, this would vary from an average one storm per year to over five storm events, and the duration of each shut down would last for multiple days. Nationwide, a one-day shutdown of the snowbelt states would yield a loss of $2.6 billion per day, and a loss of retail of $870 million per day.[5] Not only would this be economically unreasonable, the social impacts would not be acceptable to the citizens of Illinois.

I. History and background to the present proceeding

The 500 mg/L Illinois general use water quality standard for chloride was adopted by the Board in 1972 in R71-14, based on the testimony of a "recognized expert in fish biology," that 500 mg/L would be a safe limit. (Opinion of the Board, March 7, 1972.) This Illinois General Use Water Quality Standard has remained in effect for the past 45 years.

U.S. EPA in 1988 published the *Ambient Water Quality Criteria for Chloride-1988* (EPA 440/5-88-001, February 1988) that recommended a four-day limit of 230 mg/L and a one-hour average limit of 860 mg/L that should not be exceeded more than once every three years on the average.

In January 2009, C. Stephan of the USEPA issued a draft update deriving chloride toxicity, factoring in hardness and sulfate concentrations, and utilizing a normalized hardness of 300 mg/L and normalized sulfate concentration of 65 mg/L. Temperature was not a factor in the Stephan document, with data generated at the USEPA guideline temperatures, 25°C for most species. Much of the more recent literature on chloride toxicity relates to the impact of sulfate and hardness concentration on the toxicity.

As nearly all of the toxicity data derived for chlorides have been generated at summer-type temperatures, the results do not accurately reflect the toxicity of chlorides at winter temperatures. This proposal sets forth the findings of both a literature search and toxicity testing with the four sensitive aquatic species (Fingernail clams, mayflies, Amphipod, and *C. dubia*) at 10°C and 25°C. Due to limited funding, hardness and sulfate were not varied as part of the testing, just temperature.

Electronic Filing: Received, Clerk's Office 3/14/2019

The original Petition called for a winter chloride standard during the months of December through April. It was clear from the first hearing that a standard based upon actual stream temperature at the time of sampling was a preferred approach, and this Amended Petition has made this change. Factoring in sulfate and hardness in the derivation of chloride water quality standards was suggested during the hearing as well. The proposed language incorporates this request, assuming the same relationship for hardness and sulfate that was derived at temperature at 25°C applies at 10°C. This also seems like a reasonable approach until such time as further research is completed, so in a sense, the proposed standard herein can be viewed as interim water quality standard. Given that the hardness and sulfate relationship for aquatic species was based on one species, utilizing the temperature data from Jackson and Funk, combined with our data to establish a temperature relationship, is appropriate.

A. Purpose and Effect of Regulatory Proposal

The Board's existing 500 mg/L General Use Standard for chlorides is exceeded in all urban streams during snow melt periods in Illinois. For the CAWS and LDPR, the winter 500 mg/L water quality limit goes into effect on December 1, 2019. Most of the urban watersheds in Illinois are working on seeking watershed variances from the 500 mg/L standard. As noted in the introduction, the compliance plans are centered around BMPs for de-icing practices. This is a sound and necessary approach that will reduce chloride concentrations in our waterways. However, it is not likely to consistently achieve the not-to-exceed 500 mg/L standard in many of the urban streams.

This work was undertaken to improve the understanding of chloride toxicity under winter temperatures. The results show that chlorides are less toxic at colder temperatures, and therefore higher water quality standards can be derived for the winter months. The recent publication referenced earlier by Jackson and Funk (2019) demonstrated that the temperature effect on chloride toxicity is a linear relationship, which allowed us to use our data derived at two different temperatures to develop a mathematical relationship, combined with the Jackson and Funk data. If the proposed chloride water quality standards are adopted, it is expected that many smaller streams will be able to achieve the water quality standards through the implementation of BMPs. On larger streams, due to the duration of the chloride spikes, achieving the proposed chronic standard during snow melt periods will prove difficult.

Specifically, the proposed standard consists of the following amendments.

1. **Remove Chloride from Section 302.208(g), Numeric Standards for Chemical Constituents, Single-Value Standards:** Based on the difference in chloride toxicity at colder temperatures, it is appropriate to draft a new section to include chloride standards.

Electronic Filing: Received, Clerk's Office 3/14/2019

g) Single-value standards apply at the following concentrations for these substances:

Constituent	Unit	Standard
~~Chloride (total)~~	~~mg/L~~	~~500~~

2. Add Section 302.214 Chlorides

a. Acute chloride standard (Cl_{AC}):

$Cl_{AC} = (1+(0.045)(25-T))* NFAV*(Hardness/300)^{0.205797} *(Sulfate/65)^{-0.07452}$

Where NFAV is the Normalized Acute Value of 518 mg/L.
Hardness (as $CaCO_3$ in mg/L), Sulfate (as SO_4 in mg/L), and Temperature (°C) are the stream results at the time the sample was collected.

b. Chronic chloride standard (Cl_{CV}):

$Cl_{CV} = (1+(0.045)(25-T))* CCC*(Hardness/300)^{0.205797} *(Sulfate/65)^{-0.07452}$

Where CCC is the Normalized Criteria Continuous Concentration of 300 mg/L.
Hardness (as $CaCO_3$ in mg/L), Sulfate (as SO_4 in mg/L), and Temperature (°C) are the stream results at the time the sample was collected.

To calculate the attainment status of chronic standards, the concentration of the chloride result is divided by the calculated water quality standard for the sample to determine a quotient. The water quality standard is attained if the mean of the sample quotient is less than or equal to one for the duration of the averaging period.

The Cl_{CV} shall not be exceeded more than once every three years by the arithmetic average of at least four consecutive samples collected over any period of four days.

3. Amend Section 302.407 Chemical Constituents as follows:

g. Numeric Water Quality Standards for Other Constituents

2) ~~From July 1, 2015 until July 1, 2018, the following concentrations for Chloride and Total dissolved solids shall not be exceeded except in waters for which mixing is allowed pursuant to Section 302.102 of this Part.~~

Electronic Filing: Received, Clerk's Office 3/14/2019

~~Constituent~~	~~Unit~~	~~Standard~~
~~Chloride during the period of May 1 through November 30~~	~~mg/L~~	~~500~~
~~Total Dissolved Solids during the period of December 1 through April 30~~	~~mg/L~~	~~1,500~~

~~3) Beginning July 1, 2018, the Chloride and Total Dissolved Solids standards in subsection (g)(2) of the Section are repealed and the following concentration for Chloride shall not be exceeded except in waters for which mixing is allowed pursuant to Section 302.102 of this Part:~~

~~Constituent~~	~~Unit~~	~~Standard~~
~~Chloride~~	~~mg/L~~	~~500~~

~~Where:~~

~~mg/L = milligram per liter~~

Add Section 407(g)(2) Chlorides

a. Acute chloride standard (Cl_{AC}):

$$Cl_{AC} = (1+(0.045)(25-T))^{*} NFAV^{*}(Hardness/300)^{0.205797} {}^{*}(Sulfate/65)^{-0.07452}$$

Where NFAV is the Normalized Acute Value of 518 mg/L.
Hardness (as $CaCO_3$ in mg/L), Sulfate (as SO_4 in mg/L), and Temperature (°C) are the stream results at the time the sample was collected.

b. a chronic chloride standard:

$$Cl_{CV} = (1+(0.045)(25-T))^{*} CCC^{*}(Hardness/300)^{0.205797} {}^{*}(Sulfate/65)^{-0.07452}$$

Where CCC is the Normalized Criteria Continuous Concentration of 300 mg/L.
Hardness (as $CaCO_3$ in mg/L), Sulfate (as SO_4 in mg/L), and Temperature (°C) are the stream results at the time the sample was collected.

To calculate the attainment status of chronic standards, the concentration of the chloride result is divided by the calculated water

Electronic Filing: Received, Clerk's Office 3/14/2019

quality standard for the sample to determine a quotient. The water quality standard is attained if the mean of the sample quotient is less than or equal to one for the duration of the averaging period.

The Cl_{CV} shall not be exceeded more than once every three years by the arithmetic average of at least four consecutive samples collected over any period of four days.

II. Technical Feasibility and Economic Justification

A. The Board and the Agency have always supported science-based standards, and this proposed regulatory rule change is consistent with this approach. New research, financially supported by the consortium that was assembled to examine the chloride standards, forms the basis for the proposed changes. This work was undertaken because the current chloride water quality standard is neither technically feasible to achieve nor ecologically or economically justified. The Agency has promoted a pathway forward of watershed variances, relying on Best Management Practices to achieve a 500 mg/L, while at the same time USEPA is promoting even more restrictive water quality standards. However, there was no testimony in the CAWS proceedings that achieving the 500 mg/L winter chloride standard was technically feasible, economically reasonable, or ecologically justified. Proceeding with the Agency's watershed approach will require the regulated community to continue striving to achieve an unachievable standard until someone comes up with an alternative approach, which is exactly what this proposal is intended to do.

B. The temperatures in the waters in Illinois are colder in the winter months. Yet, nearly all of the aquatic toxicity testing conducted prior to the testing contained in this Petition is at temperatures experienced during the summer months, with the majority of studies being conducted at what would be considered near maximum temperatures experienced in Illinois streams (25°C).

C. In summary, the expectation is that if the proposed winter water quality standards are adopted, the watershed approach based on implementing BMPs will become technically feasible and economically reasonable for many urban streams in Illinois, as supported by the stream data presented in the Technical Support Document (Attachment 2).

III. Facts in Support

The original Petition included several Attachments in support of the proposed changes and are not resubmitted herein. A supplement to the Technical Support Document has been prepared with additional supporting information regarding the proposed water quality standards proposed herein.

Electronic Filing: Received, Clerk's Office 3/14/2019

IV. Conclusion

The current general use chloride water quality standard is unattainable in many urban streams in Illinois during the winter months. Cold temperature toxicity testing of chlorides developed in support of this Petition has demonstrated that at colder temperatures chlorides are less toxic to aquatic organisms. The recent work by Jackson and Funk has established that a linear relationship exists between temperature and chloride toxicity, that has been used with the research we conducted to develop mathematically derived water quality standards based on temperature. Based on these findings, a new chloride standard is proposed for General Use waters, derived using the USEPA protocol for developing water quality standards.

This Amended Petition, along with the original Petition, satisfies the requirements of Section 102.202 of the Board's rules because the Petition:

- Details the language of the proposed rule change;
- Presents the facts that support the proposal including the environmental, technical, and economic justification;
- Includes a statement of the purpose and effect of the proposal;
- Includes a synopsis of the expected testimony;
- Describes the results of the current knowledge on cold temperature toxicity of chlorides and the findings of the research associated with the request;
- Demonstrated the proposed rule change is consistent with federal law.

WHEREFORE, Petitioner, Huff & Huff, Inc. respectfully requests that the Illinois Pollution Control Board adopt revised chloride water quality standards for the winter months, as proposed herein.

TECHNICAL SUPPORT DOCUMENT SUPPLEMENT FOR A WINTER WATER QUALITY STANDARD

March 2019

By

James E. Huff, P.E.

Electronic Filing: Received, Clerk's Office 3/14/2019

1. INTRODUCTION

The Illinois Pollution Control Board's General Use Water Quality Standard for chlorides has been 500 mg/L since the early 1970s. Since the adoption of this water quality standard, sales of de-icing salts in the United States have doubled, with a similar increase in chloride concentrations in the receiving streams (Kelly et al., 2012). In Docket R8-09 (Subdocket D), the Board expanded the 500 mg/L chloride water quality standard to include the Chicago Area Waterways (CAWS) and Lower DesPlaines River, excluding the Chicago Sanitary & Ship Canal (CSSC), where site-specific standards were adopted. However, the Board provided three years before the chloride water quality standard would apply during the winter months to the CAWS and Lower DesPlaines River, in recognition of the current water quality exceedances of this 500 mg/L level. Chloride concentrations above the 500 mg/L level are not unique to these two waterways but occur during snow melt periods in nearly all urban streams within Illinois.

The current focus in Illinois to address these chloride exceedances is in pursuing variances from the Board, with a commitment to developing and implementing Best Management Practices (BMPs) to reduce the application of highway de-icing salt. While implementing BMPs is a worthwhile activity, the potential to achieve a *not-to-exceed* limit of 500 mg/L in urban streams under the worst storm conditions is not realistic. As USEPA has also proposed a more restrictive chloride water quality criterion, the 500 mg/L standard has a potential to be significantly reduced at some future date.

Toxicity testing for chlorides has consistently demonstrated the need for restrictive water quality standards. However, this laboratory testing has been conducted at water temperatures between 23 and 25°C, basically near peak summer temperatures. Winter temperature toxicity studies on chlorides are limited. We know that growth and reproduction for most aquatic organisms are limited at colder water temperatures, which raises the question of the appropriateness of the many chronic concerns during the winter months.

In addition, some species are absent from the water column during the winter months. As part of the justification for the site-specific water quality standards in R8-09, Citgo presented data on its collection of Cladocera (water fleas, including *Ceriodaphnia*) from the CSSC. Cladocera population peaked in the summer and steadily declined as the water temperatures cooled. By October 29th, no Cladocera were collected within the CSSC. This finding is not surprising when one considers the life cycle of zooplankton.

Based on the work funded by Citgo as part of R8-09, questions were raised about the impact temperature has on the toxicity of chlorides. Huff & Huff, Inc. solicited funding from a cross section of salt users to fund additional research on cold temperature toxicity of chlorides. The actual toxicity testing for three species (the amphipod *Hyalella azteca,* the fingernail clam *Sphaerium simile,* and mayfly *Neocloeon triangulifer)* was conducted by Dr. David Soucek and Amy Dickinson at the Illinois Natural History Survey (INHS), and the daphnia test (*Ceriodaphnia dubia*) was conducted by the New England Bioassay (NEB) Laboratory in Manchester, Connecticut. The INHS is recognized as the leading research laboratory on aquatic toxicity of chlorides and sulfates.

Electronic Filing: Received, Clerk's Office 3/14/2019

Presented herein are the findings from this research, which include more recent literature and cold temperature toxicity testing on four of the most sensitive species to chlorides. Also included herein is an analysis of the duration of exposure to elevated chlorides and derivation of suggested winter water quality standards for chlorides. The proposed water quality standards are then derived, incorporating temperature into the equation.

Electronic Filing: Received, Clerk's Office 3/14/2019

2. SUMMARY OF MORE RECENT LITERATURE

The literature survey on the toxicity of chlorides was completed in late 2017, with a focus on temperature effects on this toxicity. There has been minimal research on the effect of temperature on the toxicity of chlorides. Chloride toxicity in general has focused on some of the most sensitive aquatic species, including *C. dubia, N. triangulifer, H. azteca and S. simile,* the same organisms that were studied under the current work. Since completion, there have been additional studies published that are relevant to these proceedings.

Jackson and Funk (2019) of the Stroud Water Research Center presented salinity toxicity data on four species of mayflies representing three different families tested at winter and summer temperatures, using sodium chloride during 96-hour static tests at temperatures ranging from 5 to 25°C. The four mayflies were *Neocloeon triangulifer, Leptophlebia cupida, Maccafertium modesum*, and *Procloeon fragile*. The mayflies were tolerant of high chloride values at low temperature and were less tolerant as temperature increased. For the four species of mayflies, the LC_{50} for chlorides increased with decreasing temperatures, at rates ranging from 201 to 305 mg/L chlorides for every degree C drop in temperature. Taking the least temperature sensitive mayfly species, when the stream temperature declines from 20°C to 10°C, the LC_{50} increases by over 2,000 mg/L as chlorides. The correlation the authors found extended from 5 to 25°C.

Hardness and sulfates have both been recognized as having an impact on the toxicity of chlorides, with the following equation generally recognized today as reflecting this relationship:

$$Acute\ Water\ Quality\ Std = Normalized\ Acute\ Value*(Hardness/300)^{0.205797}\ (Sulfates/65)^{-07452}$$

This relationship was based on the two studies of one species (*C. dubia*), as explained by Stephan (2009). Stephan further explained that any covariance analysis would yield similar exponents. This equation was utilized by Stephan (2009) in his derivation of chloride water quality standards, as well as Pennsylvania and Iowa.

Jackson and Funk (2018) found a linear inverse relationship between temperature and chloride acute toxicity. They utilized actual stream water from White Clay Creek, with a mean hardness of 97 mg/L and sulfate of 17.3 mg/L. Without any adjustments to a *normalized* hardness and sulfate, they evaluated four species of Mayflies the LC_{50} for chlorides increased with decreasing temperatures, at rates ranging from 201 to 305 mg/L chlorides for every degree C drop in temperature. The relationship held for temperatures ranging from 5 to 25°C. An additional key finding from Jackson and Funk is the linear relationship between temperature and toxicity.

Electronic Filing: Received, Clerk's Office 3/14/2019

3. DERIVATION OF A TEMPERATURE RELATIONSHIP

Based on the Jackson and Funk study, a linear relationship exists between temperature and chloride toxicity. This is a key finding, as our study evaluated two different temperatures (10°C and 25°C) from which a linear relationship can be derived. Our research found the following changes:

Species	Change in Acute Toxicity
C. dubia	-68.8 mg/L/degree C
S. simile	-83.1 mg/L/degree C
N. triangulifer	-31.2 mg/L/degree C
H. azteca	-30.1 mg/L/degree C

Combining our data with the Jackson and Funk (2018) data yields the following:

Species (Common Name)	Change in Acute Toxicity, mg/L Cl/°C
C. dubia (Cladoceran)	-68.6
S. Simile (Fingernail clam)	-83.1
N. triangulifer (Mayfly)	-31.2
H. azteca (Amphipod)	-30.1
N. triangulifer (Mayfly)	-305.2
P. fragile (Mayfly)	-237.4
L. cupida (Mayfly)	-243.7
M. Modestum (Mayfly)	-201.1

Normalizing the change in toxicity based on the LC_{50} results yields a change of 4.5 percent per degree C decrease in temperature. Note that Jackson and Funk found a five-fold greater impact from temperature, which may be attributable at least to the use of actual stream water, as compared to the use of laboratory synthetic dilution water. Also, Jackson and Funk cultured its mayflies at 20°C, versus Soucek's culturing temperature of 25°C, and this may have impacted the sensitivity to temperatures.

This leads to the following equation for the acute water quality standard:

Acute Water Quality Std =

$$[NFAV+1.045NFAV(25-T)]*(Hardness/300)^{0.205797}\ (Sulfates/65)^{-07452}$$

Chronic Water Quality Std=

$$[1+(0.045)(25-T)]*[CCC*(Hardness/300)^{0.205797}\ (Sulfates/65)^{-07452}]$$

Where NFAV is the Normalized Final Acute Value and CCC is the Criterion Continuous Concentration at 300 mg/L hardness, 65 mg/L sulfate and 25°C.

These equations would be valid for all seasons, based upon the temperature, hardness, and sulfate in the stream at the time of sampling for chlorides.

Electronic Filing: Received, Clerk's Office 3/14/2019

4. DURATION OF ELEVATED CHLORIDES IN RECEIVING STREAMS

Elevated chlorides in Illinois streams are episodic events. The levels reached and the duration are functions of the amount of salt applied in response to a storm event, the subsequent temperatures, the base flow in the receiving streams, and antecedent period from the previous snow event (which determines the background chloride concentration before the storm runoff). The smaller the drainage area, the flashier the chloride response will be, typically with spikes of chlorides above 500 mg/L lasting one-to-two days. As the stream size increases, the duration where the chlorides will remain above 500 mg/L can last a week or more. However, these longer durations typically have a return interval longer than three years on most urban streams.

Three data sources for spikes in chlorides or surrogate measurements (conductivity or Total Dissolved Solids or TDS) were used to look at the duration of snow melt events. First, the Citgo Lemont Refinery has measured the chlorides concentration on the CSSC for over a decade. Second, the Metropolitan Water Reclamation District of Greater Chicago (MWRD) has monitored conductivity on many Chicago Area Waterways, each with an individually-derived chloride concentration. The third data source is from the DuPage River/Salt Creek Workgroup (DRSCW), which also has monitored conductivity, with correlation to chlorides. Each of these three datasets provides information on the duration to chlorides spikes on a variety of stream sizes. Each of the three is discussed below.

4.1 Lemont Refinery Chloride Monitoring on the Chicago Sanitary & Ship Canal

Presented in the original Technical Support Document, Appendix C, is the Lemont Refinery's chloride data table for the winter months. The average concentration each winter ranged from a low of 128 mg/L (based on limited data in 2012) to 393 mg/L in 2014. More relevant to our analysis is the duration of elevated chlorides when such events occur. The CSSC represents the largest stream segment, especially associated with urban runoff, so the durations of elevated chlorides would be expected to be longer on this waterbody than all others in Illinois. The chronic water quality standard on the CSSC is 620 mg/L, so using this value, the following table was constructed:

CSSC at Romeoville

Event	# of days 4-day running average above 620 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
2017	0	568
2016	0	660
2015	0	904
2014	5	720
2013	2	711
2012	0	145
2011	4	1,099
2010	1	870
2009	1	881

Electronic Filing: Received, Clerk's Office 3/14/2019

CSSC at Romeoville

Event	# of days 4-day running average above 620 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
2008	7	896
2007	4	998
2006	0	454
2005	1	835

*Note the duration in days is an extrapolation; typically, samples were collected two days per week.

There were 25 events over the 12-year period, with exceedances of the four-day 620 mg/L chronic standard, or an average of two events per year. The average duration of these exceedances was approximately 5 days. Three events had durations greater than 7 days, or a frequency of occurring once per 3.6 winter seasons. The acute standard on the CSSC is 990 mg/L, and documented exceedances occurred twice over the 11-year period, a recurrence frequency of once every 5.5 years.

4.2 MWRD Conductivity Monitoring on the Chicago Area Waterways

The MWRD has a series of conductivity probes throughout the CAWS, and data from 2007 through April 2017 were available for analysis. Using the MWRD conversion from conductivity to chlorides allows for more accurate estimates of duration. The results for the CSSC at Cicero, just above the discharge from the Stickney treatment plant, are summarized below:

CSSC at Cicero

Event	# of days 4-day running average above 620 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
Thru April 30, 2017	0	500
2016	0	465
2/15/2015	8	812
1/14/2014	9	916
3/6/2013	7	918
2/12/2013	3	822
2/19/2011	2	719
2010	0	612
12/26/2009	0	634
3/3/2008	0	690
2/12/2008	9	1,241
12/17/2007	11	860
3/1/2007	6	1,008

Over the eleven years on the CSSC at Cicero Avenue, the number of four-day periods when the existing chronic standard of 620 mg/L was exceeded was 55 days, or an average of five days per year. The acute standard (990 mg/L) was exceeded twice over this period, or a recurrence interval of approximately every five years. Durations above the chronic standard longer than seven days

Electronic Filing: Received, Clerk's Office 3/14/2019

occurred four times over the period of record, or a recurrence interval of once every 2.7 years. These results are similar to the Lemont Refinery's data presented above.

On the North Branch of the Chicago River, Kinzie Street is just above the confluence with the Main Stem Chicago River. This station has been monitored by the MWRD from 2007 to 2013. Using 640 mg/L for the chronic winter threshold from the original proposal, and 1,010 mg/L for the acute threshold, also from the original proposal, yields the following on the North Branch of the Chicago River.

North Branch at Kinzie Street

Event	# of days 4-day running average above 640 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
3/8/2013	1	876
3/1/2013	4	1,075
2012	0	644
2011	0	718
2010	0	699
2009	0	690
2/9/2008	11	1,160
12/13/2007	3	914
2/27/2007	8	1,092

Over the seven years, the number of days when the chronic winter level of 640 mg/L was exceeded was 27 days, or an average of four days per year. An acute value of 1,010 mg/L was exceeded in three events over this seven-year period, or a recurrence interval of approximately every 2.3 years. Durations above the chronic standard longer than seven days occurred twice over the period of record, or a recurrence interval of once every 3.5 years.

For the Cal-Sag Channel, the MWRD has robust records at Cicero Avenue, from 2007 to 2017 for conductivity. Like the North Branch, this station is downstream of one of the major water reclamation facilities.

Cal-Sag at Cicero

Event	# of days 4-day running average above 640 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
2017	0	341
2016	0	454
2015	0	646
2014	0	387
2011	0	551
2/25/2010	2	723
2009	0	568
2008	0	668
2007	0	622

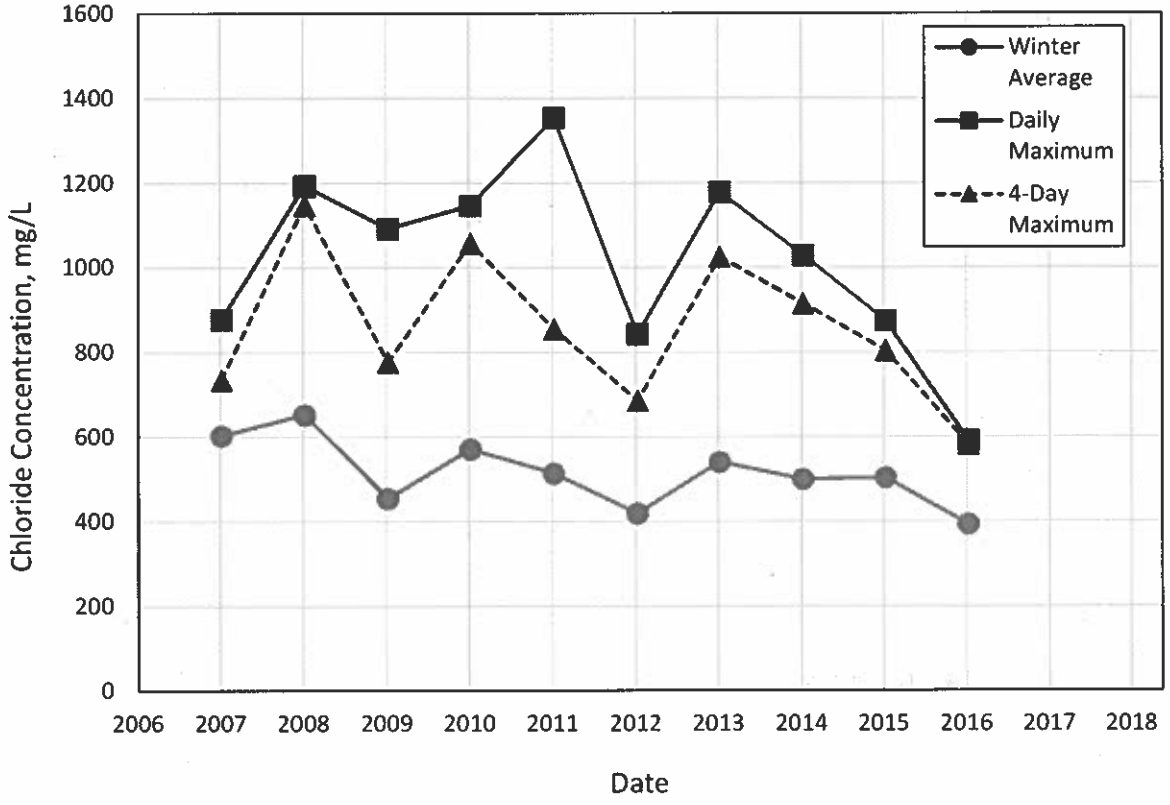
Electronic Filing: Received, Clerk's Office 3/14/2019

Over the nine years, the number of days when the chronic winter level of 640 mg/L was exceeded was 2 days, or an average of once every 4.5 years. An acute value of 1,010 mg/L has not been exceeded on the Cal-Sag at Cicero over the nine-year period of record, with a maximum estimated chloride of 723 mg/L that occurred on February 25, 2010.

A summary of the MWRD data on the Chicago Area Waterways indicates that most elevated chloride periods last less than seven days, with the peak duration above some chronic level of 11 days.

4.3 DuPage River and Salt Creek Conductivity Data

The DuPage River/Salt Creek Workgroup (DRSCW) has monitored conductivity and chlorides on its waterways since 2007, and their data provide an excellent picture of intermediate-sized streams in urban areas. Salt Creek at Wolf River reflects closer to the downstream end, and below the Fullersburg Woods Dam, so the chloride spikes are dampened to a minor degree at this location. This stream also receives considerable wastewater effluents from the municipalities along the waterway. The following table summarizes the winter days above 640 mg/L and the maximum estimated chlorides.



Salt Creek at Wolf Road

Event	Estimated Duration above 640 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
2016	0	591
3/25/2015	5	771
3/12/2015	13	861
2/9/2015	9	874
3/13/2014	10	1,028
1/11/2014	5+	931
12/21/2013	2	742
3/7/2013	14	1,178
2/13/2013	1	645
2/8/2013	5	811
2/27/2011	6	815
2/16/2011	4+	990
1/19/2011	1+	**1,353**
2/23/2010	21	1,146
2/11/2010	7	894
2/10/2009	2	670
3/1/2008	11	984
2/9/2008	26	1,193
2/12/2007	4	877

Electronic Filing: Received, Clerk's Office 3/14/2019

The durations at this station are longer than at the other stations tabulated, and this may be due to the dam immediately upstream, retarding the flushing of the chlorides. However, the dam would also dampen the peak chloride concentrations. Overall, there appears to be a declining trend in both peak chlorides and in the durations. However, some of this recent improvement may be attributed to the milder winters over the last two years. Figure 1 clearly depicts this trend, including in the winter average chloride concentrations.

Figure 1: ANNUAL CHLORIDE CONCENTRATION - WINTER MONTHS (2007-2016)
SALT CREEK AT WOLF ROAD

DRSCW also monitored the East Branch of the DuPage River at Hobson Road (HR) in Woodridge and Unincorporated DuPage County, Illinois from 2008 to 2015. The results are presented in the following table.

East Branch DuPage River at Hobson Road

Event	Estimated 4-Day Duration above 640 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
2/9/2015	4	819
3/22/2014	8	859
2/20/2014	2	987

Electronic Filing: Received, Clerk's Office 3/14/2019

2/20/2013	6	1,097
2012	0	788
1/19/2011	3	980
2/23/2010	8	1,172
2/11/2010	3	782
2009	0	513
2/5/2008	17	1,017

The peak recorded chloride was 1,172 mg/L at Hobson Road, and the longest duration above 640 mg/L was 17 consecutive days, back in 2008. Since 2008, eight consecutive days is the longest duration above 640 mg/L.

On the West Branch of the DuPage River, the DRSCW has monitored at Arlington Drive (AD) in Hanover Park, DuPage County, Illinois from 2007 to 2015, with the following chloride winter spikes.

West Branch DuPage River at Arlington Drive		
Event	Estimated 4-Day Duration above 640 mg/L Chlorides, days	Maximum Chloride Concentration Recorded, mg/L
2015	0	589
3/8/2014	1	696
2/19/2014	2	812
3/8/2013	3	758
2012	0	612
1/29/2011	3	731
2010	0	719
2009	0	750
2/9/2008	6	826
2007	0	599

The West Branch is the furthest west, and the least urbanized compared to the East Branch and Salt Creek. The peak chloride over the nine years was 826 mg/L, so no exceedances of the proposed acute standard of 1,010 mg/L. Five events exceeded 640 mg/L for a 4-day period, or less than one event annually.

Electronic Filing: Received, Clerk's Office 3/14/2019

5. DERIVATION OF WATER QUALITY STANDARDS

Under federal regulation, 40CFR131.5(c), one of the minimum requirements for water quality standards is that the criteria be sufficient to protect the designated uses. In 1985, the United States Environmental Protection Agency (USEPA) published *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses* (Stephan, et al., 1985). This document outlines the methodology for deriving water quality criteria, and notes for the chronic criteria, that a four-day averaging period is appropriate, and that a 20 to 30-day period is unacceptable. The four-day period was intended to "prevent increased adverse effects on sensitive life stages by limiting the durations and magnitudes of exceedances of the CCC." (CCC is the Criterion Continuous Concentration, or chronic criteria.) (pg. 5.)

Stephan, et al., goes on to note that, "most bodies of water could tolerate exceedances once every three years on the average. In situations in which exceedances are grouped, several exceedances might occur in one or two years, but then there will be, for example, 10 to 20 years during which no exceedances will occur." (pg 6). This is consistent with the data presented in the previous section, where there are years with no exceedances and other years when exceedances are more frequent. This USEPA document notes that, "Whenever adequately justified, a national criterion may be replaced by a site-specific criterion," (pg 6).

Stephan (2009) updated the chloride database and derived a Criterion Maximum Concentration (CMC) of 602.4 mg/L. Since that time, there have been additional toxicity tests. Adding to Stephan's (2009) database, Table 1 was prepared. The data in Table 1 are limited to studies where hardness and sulfate data are presented. In the case of Jackson and Funk (2019), the LC_{50} results for all temperature tests were *normalized* to 25°C using the slopes presented for each species in the paper, and a geometric mean was utilized for the normalized LC_{50}.

Table 1 presents the data utilized with the normalized acute values (NAV), the species mean acute values (SMAV), and genus mean acute values (GMAV), again starting with Stephan's (2009) list and adding to it the more recent results, including our results (INHS 2018 and NEB 2018).

Table 2 presents the USEPA protocol for deriving acute standards, by ranking the GMAVs, and utilizing the four most sensitive species to compute the normalized CMC. The CMC is computed to be **518.3 mg/L** at 25°C, 300 mg/L hardness, and 65 mg/L sulfate.

Table 3 presents the acute water quality standard at various temperatures, hardness, and sulfate levels, based upon the normalized CMC, the linear relationship with temperature normalized to 4.5 percent per degree decline from 25°C, and the accepted hardness and sulfate correlations. This is provided just as an example of the typical water quality standards.

Table 4 presents the derivation of the Acute:Chronic Ratio (ACR) for both invertebrates and vertebrates, and includes the results from Dr. Soucek's work, as well as the New England Bioassay work. A separate ACR is then applied to the vertebrates and invertebrates based on the data where both test results are reported. A Final ACR (FACR) of 3.45 is calculated as the geometric mean of the available Species Mean ACRs (SMACR) for invertebrates and an FACR of 7.33 is calculated for vertebrates as the geometric mean of the two available SMACRs. The chronic values are then

Electronic Filing: Received, Clerk's Office 3/14/2019

derived following the USEPA *Guidelines* and Stephan's 2009 "Derivation of Alternative Chronic Value" method from "*Calculation of Aquatic Life Criteria for Chloride*" and placed in the second part of Table 4 in ascending order of sensitivity. The four most sensitive species are presented, and the Criterion Continuous Concentration (CCC) of **300.5 mg/L** is computed based on the normalized values of 25°C, 300 mg/L hardness, and 65 mg/L sulfate. Three mayflies and the fingernail clam are the most sensitive species based on Table 4, with the mayfly data dominated by the Stroud 2015 study.

Table 5 presents examples of the chronic water quality standard based on varying temperature, hardness, and sulfate levels, again simply for illustrative purposes.

Electronic Filing: Received, Clerk's Office 3/14/2019

6. COMPARISON OF PROPOSED WINTER STANDARDS TO RESEARCH RESULTS

Four species were selected for chloride toxicity evaluation at winter temperature, and the results were presented in Section 5 of the original Technical Support Document.

As described in Section 5, extended exposure tests were conducted. The *C. dubia* test, where the organisms were exposed to elevated chlorides for 35 days, yielded a No Observable Effects Concentration (NOEC) of 782 mg/L chlorides at 10°C, above the range of computed chronic water quality standards presented in Table 5. The laboratory testing of *C. dubia* demonstrates that this sensitive species would readily be protected if the proposed criterion was adopted.

For the Fingernail clam toxicity testing, run for 28 days of exposure to various chloride concentrations, no chronic effects were detected with concentrations of 1,000 mg/L chlorides at 10°C. This result also demonstrates that a chronic water quality standard illustrated in Table 5 would be protective of this sensitive species.

The third sensitive species, the Mayfly *Neocloeon triangulifer,* showed no chronic effects found in chloride concentrations up to 750 mg/L. At the highest dose of exposure, 1,500 mg/L chlorides, no chronic effects were observed, but survival declined to 55 percent (compared to 0 percent survival at 25°C). Again, the chronic standards illustrated in Table 5 would be protective of this sensitive species.

The final species evaluated, the amphipod *Hyalella azteca* (Burlington strain) did not survive well at 10°C, with only about a 50% survival rate at 7 to 10 days, independent of the chloride concentration. However, based on the acute testing at the two temperatures, at 25°C the 96-hour LC_{50} was 1,733 mg/L versus 2,185 mg/L at 10°C, or a ratio of 1.26. Applying this same ratio to the 28-day chronic test at 25°C result of 516 mg/L yields an estimated chronic value at 10°C of 650 mg/L from 28 days of exposure to chlorides. Again, this sensitive species will be protected with a 4-day chronic water quality standard illustrated in Table 5.

In summary, using the acute-to-chronic ratio, as described in the previous section, results in a conservative chronic water quality criterion, which will be protective of the most sensitive species.

Electronic Filing: Received, Clerk's Office 3/14/2019

[4] SMAV was recalculated for the temperature adjustment to 25 °C, using the following equation: [AV + (25 - T)*48]*[(300/Hardness)$^{0.305797}$]*[(65/Sulfate)$^{0.074521}$].

*New SMAVs were calculated as the geometric mean of the Normalized Acute Values (NAV) for the *italicized* genus/species using NAVs taken from "*Summary of Data Concerning the Acute Toxicity of Sodium Chloride To Aquatic Animals* " (Stephan, 2009).
Bold cells signify data added from additional studies to accompany Stephan 2009 data.

Electronic Filing: Received, Clerk's Office 3/14/2019

Table 2
Ranked GMAV in mg Cl/L
Calculation of Final Acute Value (FAV) and Criterion Maximum Concentration (CMC)
SMAVs and GMAVs are normalized to hardness of 300 mg/L, sulfate of 65 mg/L, and temperature of 25 °C

Rank	GMAV	Type, *Genus species* (Common Name)	Cumulative Probability, P	$Ln(GMAV)^2$	Ln(GMAV)	$p^{1/2}$
4	1,386	*Sphaerium simile* (Fingernail clam)	0.118	52.34	7.234	0.343
3	1,294	*Neocloeon triangulifer* (Mayfly)	0.088	51.34	7.165	0.297
2	1,148	*Maccaffertium modesum* (Mayfly)	0.059	49.64	7.045	0.243
1	872	*Procloeon fragile* (Mayfly)	0.029	45.85	6.771	0.171
			Σ P	**Σ ($ln(GMAV)^2$)**	**Σ ln(GMAV)**	**Σ $p^{1/2}$**
			0.294	**199.16**	**28.216**	**1.054**
					$(\Sigma ln(GMAV))^2/4$	**$(\Sigma p^{1/2})^2/4$**
					199.037	**0.278**

$S^2 = [\Sigma (ln(GMAV)^2) - (\Sigma ln(GMAV))^2/4] / [\Sigma P - (\Sigma p^{1/2})^2/4]$
$S^2 =$ [199.162 - 199.037] / [0.294 - 0.278]
$S^2 =$ 7.652
S = 2.766

$L = [\Sigma ln(GMAV) - S*(\Sigma p^{1/2})] / 4$
L = [28.216 - 2.766*1.054] / 4
L = 6.325

$A = S*(0.05)^{1/2} + L$
A = 2.766*0.05^(1/2) + 6.325
A = 6.944

$FAV = e^A = exp(A)$
FAV = exp(6.944)
FAV = 1,037

Criterion Max Concentration (CMC) = FAV/2= 518.3 mg/L

Electronic Filing: Received, Clerk's Office 3/14/2019

Table 3
Calculation of Acute Water Quality Standard for Chloride at Varying Water Temperature, Hardness, and Sulfate

Equation: Acute Water Quality Standard (WQS) for Chloride:

Acute WQS = $[CMC + 1.045*CMC*(25 - T)]*(Hardness/300)^{0.205797} * (Sulfate/65)^{-0.07452}$

From Table 2, the Criterion Max Concentration (CMC) = 518.3 mg/L

which simplifies to:

Acute WQS = $[1+(0.045)(25-T)]*[518.3*(Hardness/300)^{0.205797} * (Sulfate/65)^{-0.07452}]$

where Acute WQS is in mg Cl/L, T is in °C, Hardness is in mg/L as $CaCO_3$, and Sulfate is in mg SO_4^{2-}/L

	FACR
Vertebrate	**7.33**
Invertebrate	**3.45**

NOTES:

1 The SMACR for N. triangulifer is the geometric mean from (Soucek, Dickinson / INHS; 2015) and (Stroud 2015), which represents four ACRs between the lower and upper chronic limits for the chloride testing from INHS and one ACR from Stroud (8.4).

2 The SMACR for Oncorhynchus mykiss is the geometric mean from (Stephan 2007 and 2009) and (Elphick 2011), which represents three ACRs for the species (7.308, 9.1, and 5.14).

3 The SMACR for Pimephales promelas is the geometric mean from (Birge et al 1985) and (Elphick 2011), which represents two ACRs for the species (10.2 and 5.80).

4 The SMACR for Daphnia amigua is the geometric mean from (Stephan2009) and (Harmon et al 2003), which represents two ACRs for the species (4.148 and 5.4).

5 The SMACR for Daphnia magna is the geometric mean from (Stephan2009) and (Elphick 2011), which represents two ACRs for the species (1.97 and 8.62).

6 The SMACR for Hyalella azteca is the geometric mean from (Soucek 2018) and (Elphick 2011), which represents two ACRs for the species (3.65 and 1.17).

7 The FACR for Invertebrates is the geometric mean of the SMACRs for invertebrates. Per the *"Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses"*, the SMACRs for invertebrates do not vary more than a factor of ten and therefore the FACR calculated as the geometric mean of the SMACRs is appropriate.

8 The calculated FACRs for vertebrates and invertebrates are used to calculate the pGMCVs in the below table, as: pGMCV = GMAV/FACR.

Electronic Filing: Received, Clerk's Office 3/14/2019

Soucek Progress Report 2017

Electronic Filing: Received, Clerk's Office 3/14/2019

Progress update 12/04/17

Fingernail clams:

-Collected ~300 adult clams in April 2017 from Spring Creek, near Loda, IL, Iroquois County.

-Juvenile clams released in laboratory were acclimated to reconstituted water and appropriate test temperature (25 and 10 °C).

-For each temperature, the test system provided for two water volume additions per day for the duration of the test to ensure sufficient dissolved oxygen and minimized ammonia.

-Because of limited juveniles for testing, acute and chronic tests were conducted concurrently with mortality data from day 4 used to estimate median lethal concentrations (LC50s).

-Overall average % measured Cl/nominal Cl for both tests combined was 96.5 (min = 90.6; max = 101.4)

-25 °C test:

Amphipods:

-We culture two genetically distinct "strains" of *Hyalella azteca*. Most ecotox labs culture and test "US Lab" strain. This is a southern species, and it did not do well at 10 °C in initial experiments. A couple of labs in Canada culture and test with the "Burlington" strain. This is a northern species.

-We conducted control tests with Burlington strain at 10 °C and they survived well (but see below). Acute and chronic testing were/will be conducted with the Burlington strain for this project.

-We used 23 °C as the upper temperature for *Hyalella* because that is the typical acute test temperature for this species.

-Both acute tests have been completed (data below).

- For acute tests, overall average % measured Cl/nominal Cl for both tests combined was 102.3 (min = 96.9; max = 113.1)

-Acute data:

Amphipod (*Hyalella azteca* (Burlington strain)) sodium chloride acute data (23 C)				
nominal Cl	measured Cl acute	# dead (of 20)	96-h LC50 (mg Cl/L)	95% C.L.
27.6	29.0	1	1733	1592 - 1887

Stroud Report #: 2012007

Electronic Filing: Received, Clerk's Office 3/14/2019

1. Introduction

The Environmental Quality Board of Pennsylvania on July 7, 2012 proposed amending 25 Pennsylvania Code Chapter 93.7 relating to the water quality standard for chloride. The Board proposed adopting the Iowa equation-based aquatic life criteria for chloride based on the best available sound science (PA Bulletin 12-1292). This review is in response to the proposed standard for chloride in surface waters and builds on a previous report (Stroud Water Research Center 2010) that evaluated the water quality standard for chloride proposed by the EQB in 2010.

Chloride criteria for aquatic organisms are needed in Pennsylvania to protect aquatic life in our surface waters. Chloride can enter surface water via road salt runoff (e.g., following brine application for dust suppression, or following deicer application or storage), or through wastewater or other industrial discharge. In 2010, the EQB of Pennsylvania proposed adopting the recommended criteria from the US EPA (EPA 1988) for Aquatic Life Uses for Cold Water Fishes (CWF), Warm Water Fishes (WWF), Migratory Fishes (MF), and Trout Stocking (TSF). Those criteria were an acute criterion of 860 mg chloride/L and a chronic criterion of 230 mg chloride/L.

We found a number of faults with the criteria proposed in 2010 and the conclusions of the previous report are attached as **Appendix 1** at the end of this document. The changes proposed in 2010 were not adopted by the EQB, in part because they did not incorporate the latest available science. Some of the concerns identified by us in 2010 have been addressed by the proposed Iowa equation based criteria. However, the Iowa equation based criteria do not adequately address some critical scientific gaps which we feel will leave some species at risk of harm. In this comment, we suggest some options that the EQB may consider. Due to the large amount of uncertainty that remains, one option that may be rapidly incorporated would be to re-derive the chronic criterion and apply a safety factor to provide an enhanced level of protection.

The acute and chronic criteria equations proposed by the EQB of Pennsylvania are based on reports by Stephan (2009 a,b,c,d,e,f,g,h). We will use these reports as the basis of our review and critique.

2. Strengths of the proposed standard

2.1. EPA has not officially adopted new national criteria since 1988 (EPA 1988). The derivation of the 2009 Iowa criteria incorporated data from recent chloride toxicity studies.

2.2. The most significant development with the 2009 Iowa Criteria is an acknowledgement that the toxicity of chloride to aquatic organisms varies depending upon the other ions present. Specifically, the criteria use equations to account for changes in toxicity due to water hardness (i.e., cation content [primarily calcium and magnesium, but could also include iron and manganese] of water) and sulfate concentrations.

2.3. The 2009 Iowa criteria also clarified rules of data inclusion or exclusion. The 2009 criteria included static tests that were excluded in 1988 (Stephan 2009a). The approach was to include a test unless there was an obvious reason to exclude it (Stephan 2009a).

Electronic Filing: Received, Clerk's Office 3/14/2019

3. Weaknesses and concerns resulting from implementing the proposed standard

3.1. These proposed criteria are based on toxicity studies of dissolved chloride that has dissociated from sodium chloride (NaCl), although chlorides dissociated from calcium chloride ($CaCl_2$), magnesium chloride ($MgCl_2$), or potassium chloride (KCl) may be present in surface water and can be more toxic to aquatic organisms (e.g., Mount et al. 1997).

3.1.1. In 1988, the EPA noted that "the chlorides of potassium, calcium, and magnesium are generally more toxic to freshwater species than sodium chloride" (EPA 1988 p. 7), but there was insufficient data on the toxicity of the chlorides of calcium, magnesium, or potassium to derive criteria.

3.1.2. The relationship between the toxicity of the chloride of sodium and the toxicity of the chlorides of potassium, calcium and magnesium has held over time. Below are the ***ratios*** of the LC_{50} concentrations for the chloride of calcium (Ca), magnesium (Mg), or potassium (K) to the LC_{50} concentration for the chloride of sodium (Na) for the same species and test water (Stephan 2009a p. 10):

- Ca/Na (n=5): 0.57-0.98
- Mg/Na (n=3): 0.34-0.55
- K/Na (n=5): 0.11-0.25

Note: a ratio <1 indicates that the chlorides dissociated from calcium, magnesium, or potassium caused mortality at a lower concentration.

3.1.3. The chlorides of calcium, magnesium, or potassium may be present in the environment in such a way that they threaten surface waters.

- Potassium, magnesium, or calcium chlorides are used as deicers (Salt Institute 2004, Chang 2009).
- Potassium chloride can be present in the effluent from hydraulic fracturing for natural gas extraction (URS Corporation 2011), and is also commonly used as a water softener.
- Use of liquid brine salts as dust suppressants on roadways and at construction sites (Piechota et al. 2002)

3.2. The proposed chronic criteria may be above the level that causes adverse impacts to aquatic organisms in Pennsylvania.

3.2.1. The proposed criteria are based solely on studies of animals and do not consider toxicity to aquatic plants. Stephan (2009a, 2009b, 2009c, 2009d, 2009g) did not indicate why plants were not considered in the derivation of the Iowa Criteria. In 1988, the EPA noted that the alga *Spirogyra setiformis* was extremely sensitive to the effects of chloride (71 mg/L; growth, chlorophyll, C^{14} fixation; 10d; Shitole and Joshi 1984) as was the desmid *Netrium*

Electronic Filing: Received, Clerk's Office 3/14/2019

digitus (200 mg/L; growth inhibition; 21d; Hosiaisluoma 1976). However, the 1988 criteria did not include plant species in the derivation because "a Final Plant Value, as defined in the Guidelines, cannot be obtained because no test in which the concentrations of chloride were measured and the endpoint was biologically important has been conducted with an important aquatic plant species" (EPA 1988). These concentrations for plants are below the SMCV observed for vertebrate and invertebrate animals (Table 1) suggesting that plants may be more sensitive to chloride than are animals.

3.2.2. Recent research with freshwater mussels suggests that the glochidia of some species may be more sensitive to chloride than the current suite of aquatic organisms for which data is available (Gillis 2011, Pandolfo et al. 2012). Stephan included data from juvenile freshwater mussels or freshwater mussels that do not have a glochidia stage (i.e., *Villosa delumbis* and *Lampsilis fsciola*, Bringolf et al. 2007; *Villosa iris* and *Lampsilis siliquoid*, Wang 2007; *Sphaerium simile*, GLEC and INHS 2008), but Stephan excluded all studies with glochidia because of their unique life-history which requires that they attach to a fish host in order to survive (Stephan 2009a p. 7[d]). The unique life history of most freshwater mussel species makes it difficult to design toxicology studies with them. However, freshwater mussels are among the most imperiled organisms in Pennsylvania (PNHP 2012), therefore it is important that water quality criteria be protective of them. One "very important question is 'What species-specific toxicity-test duration is ecologically relevant for glochidia?'" (Stephan 2009a p. 7[d]).

3.3. The proposed chronic criterion is not robust.

3.3.1. The genus mean chronic values (GMCV) should not have been calculated directly from the species mean chronic values (SMCV) without first correcting for hardness and sulfate.

3.3.1.1. The SMCV from different experiments were not normalized for hardness and sulfate (Stephan 2009c). As a result, the SMCV are not directly comparable because the toxicity of chloride varies depending upon the chemical composition of the water in which the test was done (e.g., Mount et al. 1997, Soucek 2007, Elphick et al. 2011). Therefore, calculating the GMCV as the geometric mean of the SMCV for a given species is not appropriate. It should be noted that the species mean acute values (SMAV) were corrected for hardness and sulfate before calculating the GMAV (Stephan 2009g).

3.3.2. There is inconsistency in the meaning of the species mean chronic value (SMCV). The SMCV determined by Stephen (2009c) refer to different levels of impairment for different species.

3.3.2.1. Stephen (2009c) used the geometric mean of the no observed effect concentration (NOEC) and lowest observed effect concentration (LOEC) to determine the SMCV. The NOEC and LOEC refer to test concentrations used in the experiments, but the amount of impairment at the NOEC and LOEC varied among experiments (Table 1). Therefore the SMCV determined by Stephen (2009c) refer to different levels of impairment for different species.

Electronic Filing: Received, Clerk's Office 3/14/2019

3.3.3. Different researchers analyzing the same data have arrived at different results and different conclusions.

3.3.3.1. The guidelines that different researchers have used to determine which studies should be included and the interpretation of the EPA 1985 guidelines differ between researchers (e.g., EPA 1988, Stephan 2009a). As a result the rules to determine the appropriate studies and data to use to derive chloride criteria are not interpreted in a consistent manner and researchers have differed in the tests they included or excluded. For example, Stephan (2009c, 2009e) excluded an acute and chronic study of *Rana sylvatica* by Sanzo and Hecnar (2006) because they used technical grade sodium chloride, but Elphick et al. (2011) included this study when deriving a chronic criterion.

3.4. The proposed chronic criterion does not account for uncertainty in data and methods.

3.4.1. The proposed chronic criterion equation may allow for chloride concentrations in surface waters of Pennsylvania above the concentration shown to cause harm to aquatic organisms during laboratory experiments. For example, the SMCV for some species in Table 1 are near or exceed the normalized chronic criterion of 389 mg chloride/L which Iowa adopted for surface waters where sulfate and hardness are not known. The SMCV in Table 1 would need to be corrected for hardness and sulfate to confirm that the chronic criterion would exceed the SMCV. In 1988, the EPA affirmed that the proposed chronic criterion was below the three SMCV available at that time (EPA 1988). Stephan in 2009 did not affirm that the proposed chronic equation was below the level shown in laboratory experiments to impair aquatic organisms.

3.4.2. The proposed chronic criterion equation includes a correction for hardness and sulfate although the exponents for hardness and sulfate are based on studies in two labs (GLEC and INHS 2008, p29 & 36) of only one species (*C. dubia*) under acute conditions (Stephan 2009f). Stephan (2009f) presents evidence that "supports the concept" that "the sulfate exponent might be more negative than indicated by the GLEC and INHS (2008) data" (Stephan 2009f p. 4). A negative exponent for sulfate means that a higher sulfate concentration lowers the LC_{50} for chloride. Thus, reliance on the 2009 Iowa equations may not offer the intended level of protection to aquatic organisms in Pennsylvania.

3.4.3. The endpoints of chronic tests conducted under laboratory conditions (e.g., survival, reproduction) may not reflect the most sensitive response in nature. In nature, a stress response may occur at lower concentrations than what are observed under controlled laboratory settings. A similar pattern is seen with behavioral responses such as avoidance, coughing or rapid breathing by fish, or increased activity (Atchison et al. 1987, Scott and Sloman 2004, Hellou 2011). Behavioral responses have been poorly documented or not measured in most laboratory experiments of chloride toxicity, therefore it is unknown how the behavior of aquatic organisms in nature would be affected by elevated chloride.

3.4.4. There has been no attempt to account for the fact that the available data represents only a small percentage of the species found in Pennsylvania. Including studies conducted since the 2009 Iowa criteria were derived results in a different acute-to-chronic ratio (ACR) and

Electronic Filing: Received, Clerk's Office 3/14/2019

acute and chronic criteria (e.g., Elphick et al. 2011). It is to be expected that additional data may change the criteria, such as occurred between the derivation of the 1988 criteria and the 2009 criteria (e.g., ACR= 7.594, EPA 1988; ACR = 3.187, Stephan 2009h; ACR = 3.50, Elphick et al. 2011). Focusing on species found in Pennsylvania may also alter the criteria.

3.4.5. Different methods to derive the chronic criterion may result in different criterion. Stephan (2009c, 2009h) used the ACR whereas Elphick et al. (2011) derived a chronic criterion directly from chronic studies. (chronic criterion = 307 mg/L, Elphick et al. 2011; chronic criterion = 428 mg/L, Stephan 2009h). It should also be noted that other factors, such as if how hardness and sulfate were accounted for, could also account for differences in the criterion.

3.4.6. The lack of robustness in the derivation of the chronic criterion is further evidence of uncertainty.

Table 1: Data used to derive the species mean chronic values (SMCV) by Stephan (2009c). The SMCV is the geometric mean of the NOEC and the LOEC. A subset of this data was used to calculate the genus mean chronic values and the acute-to-chronic ratio, which was used to derive the proposed chronic criterion.

Category	Species	Endpoint	NOEC (mg/L)	LOEC (mg/L)	SMCV(mg/L)	Reference
Fish – non-salmonid	Fathead minnow	33d; survival	352 (9% reduction)	533 (15% reduction)	433.1	(Birge et al. 1985)

		7d; Reproduction	<455-819	455-1092	<629	
Cladoceran	*Ceriodaphnia dubia*	7d; Reproduction	N/A	370.6 (EC20)	370.6	(Harmon et al. 2003)
Cladoceran	*Daphnia ambigua*	10d; Reproduction	N/A	292.4 (EC20)	292.4	(Harmon et al. 2003)
Cladoceran	*Daphnia magna*	10d; Reproduction	2184	2597 (EC50)	2382	(Cowgill and Milazzo 1990)
Cladoceran	*Daphnia pulex*	21d; Reproduction	314 (0% reduction)	441 (27% reduction)	372	(Birge et al. 1985)
Frog	*Rana sylvatica*	90d; Survival	N/A	625 (62% reduction)	<625	(Sanzo and Hecnar 2006)

[1] Unpublished memorandum sent directly to C. Stephan from R. L. Spehar on June 24, 1987. Data is not available on-line (scholar.google.com, search "chloride author:Spehar", Aug. 3, 2012).

[2] Data not presented in Stephan (2009c) and document not available for download (Aug. 3, 2012)

[3] Stephan (2009c) did not use the NOEC to calculate the SMCV.

[4] WISLOH 2007 refers to an unpublished study that could not be found on the Wisconsin State Laboratory of Hygiene webpage (http://www.slh.wisc.edu/, search "chloride", Aug. 3, 2012). IDNR (2007) presents results from the WISLOH lab covering the period 2000-2007, however the results in that report (Table 4: *C. Dubia* chronic toxicity 703 mg Cl/L; Table 7: *C. dubia* chronic toxicity: 427 mg Cl/L) do not match those presented by Stephan (2009c). Corsi et al. (2010) present results from the WISLOH lab over the same time period, but the studies do not appear to be the same as the ones reviewed by Stephan (2009c) because the Corsi study focused on surface waters receiving road run-off.

[5] Data was presented in a poster at the SETAC meeting and is not available on-line (Aug. 3, 2012)

[6] The geometric mean for *C. dubia* survival in the study by Cooney et al. (1992) was not calculated by Stephan (2009c) because reproduction was more sensitive.

Electronic Filing: Received, Clerk's Office 3/14/2019

4. Point of Clarification

4.1. As written in PA Bulletin 12-1292 it appears that Pennsylvania will adopt the Iowa criteria *in toto*, including Iowa's criteria for waterbodies where sulfate and hardness are not known. Iowa defined normalized acute and chronic criteria to be applied to waterbodies where sulfate and hardness are not known that were based on the statewide background values for hardness (200 mg/L) and sulfate (63 mg/L). Average hardness and sulfate concentrations may be different in PA and therefore the normalized acute and chronic criteria for Iowa may not be appropriate for PA.

5. Summary and Recommendations

5.1. The chloride criteria proposed by the EQB on July 7, 2012 are an improvement over the criteria that were proposed in 2010. Specifically, the proposed criteria incorporate characteristics of the receiving waters that affect chloride toxicity. However, as was highlighted in our previous review, the newly proposed criteria based on the Iowa standard may not be protective of aquatic life in Commonwealth streams, rivers, and lakes. Examples of uncertainty are:

5.1.1. The proposed chronic criterion may allow for ambient chloride concentrations in surface waters in Pennsylvania above the concentrations shown to cause harm to aquatic organisms in laboratory experiments.
5.1.2. The criteria are based only on the chloride of sodium although the chlorides of calcium, magnesium or potassium may enter surface waters of Pennsylvania and are more toxic to aquatic organisms.
5.1.3. The proposed criteria are derived from only a few species found in Pennsylvania.
5.1.4. There are only seven species (6 after excluding the frog, *Rana sylvatica* which Stephan [2009g] excluded because the sodium chloride used in the experiment was technical grade) for which there are acceptable chronic data (Table 1).
5.1.5. Glochidia and plants were not included in the derivation of the acute or chronic criteria.
5.1.6. The proposed criteria may not be protective of our more sensitive stream dwelling invertebrate species, particularly early life history stages (e.g., glochidia of mussels or early life stages of other invertebrates).
5.1.7. Exponents for hardness and sulfate in the acute and chronic criteria equations may be under-protective.
5.1.8. The species mean chronic values (SMCV's) were not corrected for hardness and sulfate concentrations.
5.1.9. The SMCV refer to different levels of impairment for the different experiments and species.
5.1.10. The SMCV are not corrected for hardness or sulfate.
5.1.11. The endpoints of laboratory toxicity studies do not include behavioral responses. Behavior may be affected at lower chloride concentrations than are survival, reproduction or growth.

5.2. Following are some recommendations on how the EQB may address uncertainty.

Electronic Filing: Received, Clerk's Office 3/14/2019

5.2.1. Include a safety factor in the derivation of the chronic criterion. At a minimum, that safety factor should be sufficient to ensure that the chronic criterion is below the SMCV or GMCV. Following are some reasons that a safety factor should be used:

5.2.1.1. "Safety factors are used to provide an extra margin of safety beyond the known or estimated sensitivities of aquatic organisms" (EPA 1985 p 36).

5.2.1.2. The acute criterion incorporates a safety factor (i.e., 2) but the chronic criterion does not. The 1985 EPA guidelines indicate that a safety factor of 2 is always to be used when calculating the acute criterion (called the criterion maximum concentration in EPA 1985, p 54, item XI.B.) but does not give a rationale for this using this safety factor. Although the EPA did not include a safety factor when deriving the chronic criterion in 1988, the chronic value was below the level shown to cause harm to the three species for which data were available at that time (EPA 1988). It is unclear if the proposed chronic criterion is below the level shown to cause harm because the SMCV in Table 1 have not been corrected for hardness or sulfate.

5.2.1.3. The acute and chronic criteria are based solely on studies using the chloride of sodium, but the chlorides of potassium, magnesium or calcium may be present in surface waters of Pennsylvania and are more toxic to aquatic organisms than is the chloride of sodium.

5.2.1.4. Environmental impacts (including avoidance) may occur at lower concentrations then those that affect growth or survival.

5.2.1.5. British Columbia (Nagpal et al. 2003) used a safety factor of 5 in the derivation of the chronic guideline. Their justification for this safety factor was as follows:

- Chronic data available from the literature were scant;
- In a recent study, Diamond et al. (1992) found a LOEC/NOEC ratio for reproduction of 3.75 in *C. dubia* exposed to NaCl for 7 days. Also, LC_{50}/LC_0 of 3 and LC_{100}/LC_0 of 4 were obtained by Hughes (1973), whereas the DeGreave et al. (1991) data yielded LC_{50}/NOEC ratios that ranged from about 1.0 to 6.9;
- Additional protection may be required for those species that are more sensitive but have not yet been tested in the literature.

5.2.2. A new review of chloride toxicity studies should be conducted to generate a more complete and up-to-date list of species and genus mean acute and chronic values. The references sited at the end of this comment include a few studies that have been published since 2009. A new review should:

5.2.2.1. Resolve the controversy regarding aquatic plants and glochidia.

5.2.2.2. Clearly define rules to include or exclude a study and document the rationale for studies that are excluded;

5.2.2.3. The species mean acute values and species mean chronic values should be calculated using a consistent and biologically meaningful endpoint. For example,

Electronic Filing: Received, Clerk's Office 3/14/2019

Elphick et al. (2011) used probit regression to determine an endpoint that was consistent among species (e.g., the IC10).

5.2.2.4. Derive species mean chronic values normalized for hardness and sulfate;

5.2.2.5. Explore the possibility of deriving chronic criterion directly from the data rather than using the ACR (e.g., Elphick et al. 2011);

5.2.2.6. Include in the review toxicity studies with the chlorides of potassium, magnesium or calcium. Although conducting additional experiments with species found in Pennsylvania is the preferred approach, it may be appropriate to use the ratios cited above (3.1.2) to derive the SMAV or SMCV. For example, the chloride of potassium appears to be 4-10x more toxic to aquatic organisms than is the chloride of sodium.

Conclusions

After reviewing four different approaches for deriving water quality chloride criteria to protect aquatic life (Stephan et al. 1985, Evans and Frick 2001, Nagpal et al. 2003, Iowa DNR 2009) and the data underpinning PA's proposed criteria (EPA 1988) and the Iowa criteria (Stephan 2009a,b,c), it is clear that:

1) All approaches set chloride criteria that are at least several times greater than natural baseline chloride concentrations, and therefore represent a measurable and significant change in the chemical composition of freshwater ecosystems in the NE United States. The question that the current evidence is unable to answer is: will these criteria result in significant biological change? There is limited evidence of the biological impact of previous elevated chloride levels in aquatic ecosystems in the U.S. or Canada. Past monitoring efforts (see introduction) suggest that some streams regularly reach the acute criterion, but there has not been a noted change in biota following these pulses, largely because of a dearth of biological data following these episodic events. One study has demonstrated that macroinvertebrate drift increases in response to pulsed chloride input (Blasius and Merritt 2002). Another study has demonstrated losses of species in stream fish communities with small changes in chloride levels across a regional-scale analysis (Meador and Carlisle 2007), and the composition of algal species has been observed to change when chloride concentrations increase (Evans and Frick 2001). Nonetheless, there are limited data on biological changes accompanying changing chloride concentrations in the natural environment. We could not find any studies evaluating the influence of chloride on vital stream functions such as primary production, stream metabolism, or nutrient uptake or processing, all of which are important indicators of water quality for aquatic ecosystems.

2) All of these criteria are based on data for invertebrate and fish species that are not a random subset of stream invertebrate and fish species. Rather, most of the species with chloride data are known to be not especially sensitive to changes in environmental condition, which is one reason they survived well in the laboratory and became standards in laboratory bioassay protocols. The most recent iteration of the taxa that qualify based on EPA standards (in Stephan 2009a,b,c) doesn't include any classically sensitive stream invertebrate species such as stoneflies, mayflies, and caddisflies, all of which are important indicators of stream condition and are integral in the regulatory definition of stream impairment. Our concern is that criteria intended to protect most (e.g., 90% or 95%) of the species with chloride data might actually protect a much smaller proportion of all species that occur in a natural community because the natural community includes many species known to be sensitive to environmental change while the laboratory studies are biased toward species known to be at least moderately tolerant of environmental change. This is one reason to approach the acute and chronic criteria with a strong safety factor.

Electronic Filing: Received, Clerk's Office 3/14/2019

3) Data available are primarily from acute toxicity studies, but the chronic criterion may be more important for long-term structuring stream communities and maintaining designated use for aquatic life. For example, fish tend to be moderately tolerant of acute chloride stress relative to macroinvertebrates, but they are one of the more sensitive taxa to chronic chloride stress. For example, fat head minnows (Birge et al. 1985) experienced the greatest mortality between days 9 and 21 and therefore had one of the highest acute-to-chronic ratios examined. The dearth of chronic studies on both invertebrates and fish is troubling. It is likely that, like some amphibians (e.g., spotted salamander), embryonic and early life stages of some fish will be more sensitive than is currently recognized.

4) The majority of chloride criteria developed to date are limited to or dominated by data on NaCl chloride toxicity, the least toxic salt. This point is routinely justified by the fact that NaCl is the most anthropogenically abundant of these four salts. However, no special guidance is given for permitting salt applications or industrial effluents known to include significant amounts of chloride derived from the more toxic non-sodium salts, including Marcellus Shale wastewater.

5) Using the data provided in Stephan 2009a (Table 2 herein), we have calculated both the acute (CMC) and chronic (CCC) criteria using the methods of the EPA (Stephan et al. 1985, EPA 1988), Evans and Frick (Evans and Frick 2001), British Columbia (Nagpal et al. 2003), and Iowa (Iowa DNR 2009) and have compared the range of values with the proposed PA values (Table 3). The range of acute values is 564 – 830 mg/l Cl- and the range of the chronic values is 91 – 428 mg/l Cl-. This comparison eliminates the variability in the choices each of the authors have made with regard to studies included or excluded. We note that the PA proposed acute value is the least protective criterion, primarily because it is not based on more recent acute toxicity studies. We recommend that PA adopt an acute criterion that is reflective of these new data. The method adopted by British Columbia is the most protective of aquatic life among these approaches. BC invoked a precautionary principle that acknowledged both the uncertainty of the available data and analyses and the importance of protecting their aquatic life. Since BC adopted their criteria, only new acute datasets have become available and the values in Table 3 utilize those data but use the BC approach to arrive at a final value (i.e., lowest SMAV/2[safety factor]). The BC use of a safety factor of 2 for the acute criteria was also consistent with what the EPA had done. However, BC was the only entity to apply a safety factor for the chronic criterion (5). We feel that the use of a safety factor for chronic criteria derived from the use of an ACR is clearly justified given the very limited number of chronic toxicity studies, and the desire to protect species that may be more sensitive than those used in the standard laboratory bioassays. We recommend that PADEP adopt the same methodology that BC has used for calculating both acute and chronic data. We feel that this is particularly important for the chronic criteria, as there is the potential for permitted discharges (particularly from the Marcellus Shale gas drilling industry) to raise chloride concentrations in streams to near the chronic criteria level. Given the paucity of data determining thresholds for chronic effects, this approach is warranted. At the very least, a safety factor should be applied to any of the other methods producing a chronic criterion.

We have a number of concerns that are specific to the actions and options available for PADEP:

6) Protecting CWFs and TSFs based on ACRs that included more chloride-tolerant *Daphnia* is not justified when it may expose rainbow trout to chloride concentrations approaching their chronic

Electronic Filing: Received, Clerk's Office 3/14/2019

levels (1,324 mg/l Cl^- killed 46% of individuals in an early life stage test and at 643 mg/l Cl^- killed <4%). Trout are an integral component in the definition of these two aquatic life uses. The proposed chronic value of 230 mg/l is potentially a concern for biotic assemblages in Pennsylvania. For example, Meador (2007) suggests that optimum Cl^- values are low (3-35 mg/l) and we infer that if those Cl^- concentrations are exceeded it may result in changes in fish community structure. Similarly, not having a temperature component also seems to invite season-specific impairments of macroinvertebrates in TSFs and WWFs based on the recent findings of Silver et al. (2009), based on the seasonal movement of organisms into and out of various life history stages, and based on variation in their metabolic rates in response to seasonal changes in water temperature. Adding a temperature component to the chloride criteria would require further research on temperature effects.

7) The Evans and Frick (2001) method has the benefit of being reproducible and open to interpretation. Their use of nearly all of the valid acute LC_{50} data in Fig. 7-2 (Evans and Frick 2001), and the calculation of a sigmoid curve function (including 95% confidence intervals) that describes the percent of genera affected versus chloride concentration, is readily digestible by the public. However, the sigmoid curve function can be generated using various numbers of terms (parameters) in the equation and/or various equations (e.g., sigmoid, logistic, Weibull). The result of choosing a slightly different function can result in differences in acute and chronic values. To use this approach requires a valid justification for the choices made in fitting the curve to these data. Furthermore, these data still represented a small subset of aquatic species, and were biased towards lab friendly species that are easiest to culture (e.g., *Daphnia*). Since the selection of taxa was not a random subset of the aquatic species at large, most criteria based on the animals selected are primarily protective of those species tested (e.g., being protective of 95% of those taxa might only be protective of 50% of all species). This point is not limited to Evans and Frick but is valid for all of the approaches we have reviewed. This is the primary reason that the application of a safety factor is needed. The Evans and Frick (2001) study did not apply a safety factor to either their acute LC_{50} relationship or the derived chronic relationship.

8) More data is generally better, but there is a need for more consideration of how data gets incorporated. The Stephan (2009a,b,c) approach of calculating a predicted genus mean chronic value from the species mean acute values does not seem justified in this case. The GMCVs are not much better than guesses, and there is no attempt to correct for this inherent uncertainty. Adding GMCV values above the lowest four gives the false sense of increased precision of the true distribution of the GMCV, which has the result of increasing the final chronic value (FCV). We feel it would be appropriate to apply a safety factor to the chronic criteria to acknowledge the uncertainty in the FCV.

9) The use of hardness and sulfate equations (Iowa DNR 2009) in PA will improve protections and application of the chloride criteria only to a limited extent since the range of criteria in PA would be narrow (based on EMAP site values for hardness and sulfate in PA). Secondly, the hardness and sulfate exponents in the Iowa criteria were based on data from an acute toxicity study of only one species (*C. dubia*), although four species were studied and three were sensitive to hardness. No data were available on the relationship between hardness or sulfate and chronic toxicity. In the end, Iowa uses a default value for hardness and sulfate if no other data are available. This is akin to setting a fixed criterion value but allowing site-specific deviations if one

Electronic Filing: Received, Clerk's Office 3/14/2019

gathers the appropriate data. Clearly, more species-specific data are needed to better understand the relationship between chloride toxicity and hardness or sulfate.

10) As noted above, previous reviews of chloride considered only NaCl and considered road salt to be the most likely source of chloride. We feel that the current proposed standard should explicitly acknowledged that these criteria are specific to NaCl derived chloride, and guidance should be given to address cases when significant chloride is derived from salts (i.e., KCl, $MgCl_2$ and $CaCl_2$) that have proven to be more toxic sources of chloride.

Our review of four approaches (Stephan et al. 1985, Evans and Frick 2001, Nagpal et al. 2003, Iowa DNR 2009) for deriving chloride criteria to protect aquatic life identified a number of weaknesses in the available data and the analyses used to derive criteria. We were especially concerned with (1) the near absence of important stream-inhabiting and stream-classifying species such as mayflies, stoneflies, and caddisflies, (2) the dependence on relatively few chronic studies, and (3) the choice of excluding some studies that were very important (e.g., fat head minnow Birge et al. 1985). We believe these weaknesses justify using a very conservative approach to assigning criteria. All four approaches to set acute and chronic criteria would result in chloride concentrations at least several times greater than base flow concentrations commonly observed in Pennsylvania streams in their most natural condition (i.e., Exceptional Value and High Quality Waters). The lowest criteria for chloride were derived by the Canadian Province of British Columbia (Nagpal et al. 2003) – they acknowledged the weaknesses in available data, and applied safety factors of 2 for the acute criterion and 5 for the chronic criterion. Given the limits in the available data, and the potential that treated wastewaters from Marcellus Shale drilling may result in near-criterion chloride concentrations 356 days per year (versus the 30 days of a standard chronic bioassay), we believe the British Columbia criteria (either the originally adopted criteria or our re-calculated criteria in Table 2) would be the most protective of aquatic life for Pennsylvania streams, especially for the trout and many pollution-sensitive macroinvertebrate species that characterize Cold Water Fishes streams.

Hazard/Risk Assessment

CHRONIC TOXICITY OF CHLORIDE TO FRESHWATER SPECIES: EFFECTS OF HARDNESS AND IMPLICATIONS FOR WATER QUALITY GUIDELINES

JAMES R.F. ELPHICK,† KELLI D. BERGH,*‡ and HOWARD C. BAILEY†
†Nautilus Environmental, Burnaby, British Columbia, Canada
‡Rescan Environmental Services, Vancouver, British Columbia, Canada V6E 2J3

(*Submitted* 7 *January* 2010; *Returned for Revision* 21 *March* 2010; *Accepted* 22 *July* 2010)

Abstract—Toxicity tests using nine freshwater species (*Ceriodaphnia dubia*, *Daphnia magna*, *Oncorhynchus mykiss*, *Pimephales promelas*, *Lumbriculus variegatus*, *Tubifex tubifex*, *Chironomus dilutus*, *Hyallela azteca*, and *Brachionus calyciflorus*) were conducted to evaluate their sensitivity to chloride. Acute-to-chronic ratios (ACRs) from these tests indicate the ACR of 7.59 employed by the United States Environmental Protection Agency (U.S. EPA) in deriving its water quality guideline for chloride may be conservative; a revised ACR of 3.50 is presented here. The endpoints used to calculate the ACR included 24-h to 96-h median lethal concentrations (LC50s) for acute tests, and 48-h to 54-d inhibition concentration (ICx) values for growth or reproduction for chronic exposures. Data from the present chronic toxicity tests, and other investigators, were used to propose a water quality guideline for long-term exposure to chloride using a species sensitivity distribution (SSD) approach. The 5th percentile from the SSD was calculated as 307 mg/L and proposed as the water quality guideline. Cladocerans were the most sensitive species in the dataset. *Ceriodaphnia dubia* was used to evaluate the relationship between water hardness and sensitivity to chloride. A strong relationship was observed and was used to establish a hardness-related equation to modify the proposed water quality guideline on the basis of water hardness, resulting in values ranging from 64 mg/L chloride at 10 mg/L hardness to 388 mg/L chloride at 160 mg/L hardness (as $CaCO_3$). These data suggest that current water quality guidelines for chloride may be overly conservative in water with moderate-to-high hardness, and may not be sufficiently protective under soft-water conditions. Keywords—Chloride Aquatic toxicology Species sensitivity distribution Effluent Water quality guideline

INTRODUCTION

Chloride is ubiquitous in natural waters and is essential in a wide range of biological functions, including facilitating a variety of ion-exchange mechanisms through trans-membrane chloride channels. It forms salts with each of the major cations (Na, K, Ca, and Mg), but is highly soluble and exists primarily in the environment as a dissociated monovalent anion.

Freshwater organisms are generally hyperosmotic in their internal fluids relative to the external environment and maintain an active gradient of chloride across membranes through use of active pumps and/or bicarbonate exchange mechanisms at exterior surfaces such as the gill [1,2]. Increasing concentrations of chloride in the external environment may decrease this gradient and associated energy requirements; however, chloride can exhibit toxicity at elevated concentrations once homeostatic mechanisms are overwhelmed. Toxicity may result from osmotic stress related to overall ionic strength or disruption of individual cellular processes in which chloride plays a role [2].

The toxicity of chloride is of interest in aquatic environments as a result of its tendency to occur at elevated concentrations in effluents from industrial operations that involve subsurface mining (including coal, potash, metal, and diamond mines) [3–5], and oil and gas extraction [6]. In addition, chloride salts are widely used in road salts and, consequently, stormwater and snow-melt runoff often contain high concentrations of chloride in areas of application [7].

The EKATI Diamond Mine, operated by BHP Billiton Diamonds, is located in the southern Arctic ecoregion, 300 km northeast of Yellowknife in the Northwest Territories, Canada. The receiving environment at this mine is comprised of a series of low ionic-strength lakes. Chloride concentrations have increased in the receiving environment as a result of contributions primarily from groundwater and to a lesser extent from dissolution of solids from crushed kimberlite, and use of chloride-containing settling agents. Concentrations have increased from less than detection (<0.5 mg/L) to, in some cases, greater than 150 mg/L in receiving water bodies. Modeling of the discharge and receiving environment water, through the remainder of the mine life and into the closure period, has indicated the potential for the concentrations to continue to increase. Consequently, establishing water quality objectives for chloride for application at this site is a matter of interest.

Water quality guidelines for chloride are typically derived on the basis of toxicity tests using sodium chloride, because this cationic counter-ion contributes less toxicity than other major cations, such as K, Mg, and Ca [8]. Thus, the Na salt provides the most accurate measure for the toxicity of chloride itself by minimizing the toxicity contributed by the counter cation. The United States Environmental Protection Agency (U.S. EPA) published water quality criteria for chloride based on data for sodium chloride in 1988. The final acute value for chloride was 1,720 mg/L and the chronic criterion was 230 mg/L [9]. The chronic toxicity test data available were insufficient to calculate a chronic criterion directly and, consequently, the chronic value was calculated by dividing the final acute value by an acute-to-chronic ratio (ACR) of 7.594. This ACR was calculated as the geometric mean of ACR values from tests with three species: rainbow trout (7.308), fathead minnows (15.17), and *Daphnia pulex* (3.951). These individual estimates varied by more than

fourfold, resulting in uncertainty in the final ACR estimate, particularly considering the small number of datapoints on which it was based.

No Canadian water quality guidelines for chloride presently exist; however, an evaluation conducted by Environment Canada has calculated a concentration of 212.6 mg/L chloride that is expected to be protective of at least 95% of species in long-term exposures [10]. This estimate was made using a species sensitivity distribution (SSD) approach using acute toxicity data, divided by the ACR value reported by U.S. EPA [9], and was performed as part of an evaluation of risk associated with application of road salts for control of snow and ice [7,10].

Considerable data are available on the acute toxicity of sodium chloride to aquatic organisms [7,9]; however, a general lack of chronic toxicity data exists for this anion. Consequently, guideline derivation and risk assessments for chloride have estimated effects thresholds for long-term exposure by applying an ACR to results from acute toxicity tests to derive a long-term exposure guideline [7,9,10]. However, this approach relies heavily on the accuracy of the ACR employed. The objectives of the present study were to develop additional acute and chronic toxicity data to derive a more robust estimate of the ACR, as well as obtain sufficient chronic data to calculate a chronic guideline directly. In addition, because increasing concentrations of chloride at EKATI are associated with increases in concentrations of other major ions, such as Ca, Mg, K, carbonate, and sulfate, the present study was also designed to evaluate whether increases in ionic strength modify the toxicity of chloride. Water hardness was used as a proxy for increased concentrations of other ions.

The present study was designed to provide information necessary to establish safe levels of chloride in the receiving environment at EKATI. However, the results of the testing conducted here are broadly applicable.

METHODS

Test species were chosen on the basis of providing a suitable representation of invertebrate and fish species for which both acute and chronic exposures could be conducted in the laboratory following standardized procedures. Additional considerations for species selection were: inclusion of organisms that have previously been shown to be sensitive to chloride (e.g., cladocerans and fathead minnows [9]); selection of species that the laboratory had previous experience working with and that were available; selection of invertebrate species that would occur in planktonic (e.g., cladocerans and rotifers) and benthic habitats (e.g., amphipods, chironomids, and oligochates); and selection of species that were either resident, or were suitable surrogates for species that occur in subarctic lakes. Algal species were not tested because toxicity test data were already available for a number of these species, and they had generally exhibited a low degree of sensitivity to this anion [10].

Acute and chronic toxicity tests were conducted using two cladocerans (*Ceriodaphnia dubia* and *Daphnia magna*), two oligochaetes (*Lumbriculus variegatus* and *Tubifex tubifex*), a chironomid (*Chironomus dilutus*), an amphipod (*Hyalella azteca*), a rotifer (*Brachionus calyciflorus*), and two fish (rainbow trout, *Oncorhynchus mykiss*, and fathead minnows, *Pimephales promelas*). The tests followed standardized methods published by the U.S. EPA [11–13], Environment Canada [14,15], American Society for Testing Materials (ASTM) [16–19], or American Public Health Association (APHA) Standard Methods [20], with the exception of the test using *Lumbriculus variegatus*, which was adapted from a U.S. EPA method designed for evaluation of bioaccumulation with this species [13] to incorporate a growth (biomass) endpoint. Test durations, endpoints, and references to the methods followed are provided in Table 1.

Exposures were conducted in constant environment rooms that maintained temperature within 1 °C of the target temperature. Water used in the tests was prepared by supplementing deionized water with reagent grade salts according to procedures specified by U.S. EPA [12], to achieve a hardness of between 80 and 100 mg/L, as $CaCO_3$, with the exception of the rainbow trout tests which were conducted using dechlorinated municipal tapwater, supplemented with salts in the ratios specified by U.S. EPA [12] for hardness adjustment, to a hardness of approximately 40 mg/L, as $CaCO_3$. Test solutions incorporated five concentrations, in addition to the control, following a 0.5-fold dilution series, and were prepared by addition of sodium chloride. The highest test concentration in the tests was 16 g/L as NaCl for acute tests and 8 g/L as NaCl for chronic tests, with the exception of chronic tests using *C. dubia*, *D. magna*, and *B. calyciflorus* which used 3, 15, and 16 mg/L NaCl, respectively, as the highest test concentration.

Chloride concentrations were measured on subsamples from the test solutions. Subsamples were collected at the beginning and end of each of the tests, with the exception of tests using *B. calyciflorus*, which was only subsampled at test initiation, as well as at intermediate intervals during the longer-term chronic toxicity tests, typically at weekly intervals. Concentrations of chloride were averaged for each test solution and the mean measured chloride concentration was used for calculation of the test endpoints.

Chronic toxicity tests using *Tubifex*, *Lumbriculus*, *Hyalella*, and *Chironomus* were performed using clean sediment comprised of a beach-collected sand that was rinsed with laboratory control water and supplemented with peat at a rate of 2% by

Table 1. Duration and endpoints of toxicity tests used to determine acute to chronic ratios for chloride

Species	Common name	Acute test duration	Method	Chronic test duration	Method	Chronic test endpoints
Ceriodaphnia dubia	Water flea	48 h	[12]	7 ± 1 d	[14]	Survival, reproduction
Daphnia magna	Water flea	48 h	[12]	21 d	[19]	Survival, reproduction
Oncorhynchus mykiss	Rainbow trout	96 h	[12]	54 d	[15]	Survival, development, biomass
Pimephales promelas	Fathead minnow	96 h	[12]	33 d	[11]	Survival, development, biomass
Lumbriculus variegatus	California blackworm	96 h	[16]	28 d	[13]	Survival, reproduction
Tubifex tubifex	Sludge worm	96 h	[16]	28 d	[18]	Survival, reproduction
Chironomus dilutus[a]	Midge	96 h	[16]	20 d	[13]	Survival, biomass
Hyallela azteca	Amphipod	96 h	[16]	28 d	[13]	Survival, weight
Brachionus calyciflorus	Rotifer	24 h	[17]	48 h	[20]	Survival, reproduction

weight. Test solutions were renewed daily three times a week throughout exposure with freshly prepared chloride-spiked water, at which time Tetramin (for *Chironomus, Lumbriculus,* and *Tubifex*) or digested yeast, cerophyll, and trout chow (YCT) (for *Hyalella*) was added as food. These tests were conducted using four replicates per concentration in glass jars containing 100 ml of sediment and filled to 275 ml with the test solutions. The exposures were conducted at 23 ± 1°C with a 16:8 h light:dark photoperiod. *Lumbriculus* and *Tubifex* tests were conducted using 5 test organisms per replicate, whereas *Hyalella* and *Chironomus* tests used 10 and 12 organisms per replicate, respectively. *Hyalella* tests were initiated with 7- to 8-d-old amphipods, *Chironomus* tests with <24-h posthatch organisms; both of these test species were obtained from Aquatic Biosystems. *Tubifex* and *Lumbriculus* tests were initiated with adults obtained from Aquatic Research Organisms.

Chronic toxicity tests using *Ceriodaphnia* were conduced in 10-ml volumes in 15-ml glass test tubes. Each concentration comprised 10 replicates, each containing a single <24-h-old daphnid obtained from in-house cultures. Solutions were renewed daily, at which time they were fed with a mixture of *Pseudokirchneriella* cells and YCT. Exposures were conducted at 25°C under a 16:8 h light:dark photoperiod. Survival and reproductive output were recorded daily for the three brood, 7 ± 1-d test. Tests with this species were performed regularly as a reference toxicant test and, consequently, the long-term geometric mean (and 2 SD range) from 20 separate tests was used for this water type, because this reflects a more robust approach than using a single test, although these reference toxicant tests did not have analytical confirmation of chloride concentrations.

Daphnia magna tests were conducted in 100-ml volumes in 250-ml glass beakers. Exposures were initiated with <24-h-old organisms obtained from in-house cultures, with one daphnid in each of 10 replicates. Solutions were renewed three times per week, at which time the organisms were fed with a mixture of *Pseudokirchneriella* cells and YCT. Exposures were conducted at 20°C under a 16:8 h light:dark photoperiod. Survival and reproductive output recorded daily for the 21-d duration of the test.

Brachionus calyciflorus were exposed for 48 h in a culture plate using a 0.5-ml exposure volume and eight replicates per concentration, each containing one rotifer. The test was initiated with organisms that were <4-h posthatch, and the solutions were supplemented with *Pseudokirchneriella* as food at test initiation. Exposures were conducted at 25°C in the dark. This test was considered to be a chronic test despite its relatively short duration because of the short life-history of this organism and the fact that the method incorporated a reproductive endpoint within this timeframe. Rotifer cysts were supplied by Micro Bio Tests, and were hatched in control water prior to test initiation.

Chronic toxicity tests with rainbow trout and fathead minnows were initiated with embryo-stage fish; rainbow trout gametes were obtained from Trout Lodge and dry fertilized in the laboratory prior to initiation of exposure, and fathead minnow embryos were obtained from Aquatic Biosystems. In the case of rainbow trout, the exposures were initiated within 30 min, and for fathead minnows, within 36 h of fertilization. Rainbow trout were exposed at 14°C using four replicates of 30 organisms in 500-ml volumes. Once the fish reached the swim-up stage, the number of fish was thinned to 10 per replicate, the exposure volume was increased to 2 L, and the fish were fed daily with *Artemia* nauplii. Fathead minnows were exposed at 25°C using five replicates with 15 organisms per replicate and using 100-ml exposure volumes for the first week, 250-ml for the next two weeks, and 500-ml for the remainder of the exposure period. Fathead minnows were fed twice daily with *Artemia* following hatch.

In general, acute toxicity tests were conducted under the same exposure regime and initiated with the same lifestage as described for the chronic tests, with the exception of the following: Acute tests on sediment-dwelling species were conducted in the absence of sediment; acute tests with *Ceriodaphnia* and *Daphnia* were conducted using five organisms per replicate; and acute tests using rainbow trout and fathead minnows were initiated using juvenile fish. Acute toxicity tests were conducted using four replicates and were performed under static conditions for 96 h, with the exception of tests using *Daphnia* and *Ceriodaphnia*, which were exposed for 48 h, and *Brachionus* which was exposed for 24 h. Acute tests were conducted without feeding, with the exception of the *Hyalella* test, which was fed with YCT after 48 h of exposure.

In addition, a series of toxicity tests were conducted using *C. dubia* to evaluate the relationship between water hardness and chloride toxicity using 7-d survival and reproduction tests. In advance of the tests, the organisms were cultured in water with hardnesses of 10, 20, 40, 80, 160, and 320 mg/L, as $CaCO_3$, for a minimum of two generations (more than two weeks) in order for the cladocerans to acclimate to the water hardness. Test water was prepared by addition of reagent grade salts to deionized water to achieve the target hardnesses; characteristics of the water types are summarized in Table 2. After the acclimation period, toxicity tests using sodium chloride were conducted with waters at each hardness using the organisms acclimated to the corresponding hardness (i.e., 10, 20, 40, 80, 160, and 320 mg/L). The tests were conducted according to the procedures outlined previously for chronic toxicity tests with chloride-spiked water using this species. *Ceriodaphnia dubia* was selected for this evaluation because this species was among the most sensitive to chloride, and could be acclimated to the range of required water hardnesses, and because of its relatively short test duration (~7 d) which enabled acclimation and testing within a reasonable period.

Statistical analyses were conducted using Comprehensive Environmental Toxicity Information System (CETIS) statistical

Table 2. Characteristics of waters used to evaluate the effect of hardness on toxicity of chloride to *Ceriodaphnia dubia*[a]

Hardness (mg/L as $CaCO_3$)	pH	Chloride (mg/L)	Sulfate (mg/L)	Sodium (mg/L)	Potassium (mg/L)	Calcium (mg/L)	Magnesium (mg/L)
10	6.8	0.2	11.3	3.3	0.3	2.2	1.5
20	7.0	0.5	22.6	6.6	0.5	4.4	3.0
40	7.2	1.0	45.1	13.1	1.0	8.8	6.1

software package (Tidepool Scientific Software) on the basis of measured concentrations of chloride. Analyses followed procedures recommended by U.S. EPA for statistical analyses of toxicological data [11,12]. Median lethal concentration (LC50) estimates were calculated using Probit regression or, if assumptions for this method were not met, with Trimmed Spearman–Karber. Inhibition concentration values (IC*x*) associated with 10, 25, and 50% responses from chronic toxicity tests were calculated using linear interpolation. ACR values were calculated by dividing the IC25 from the chronic test by the LC50 from the acute test with the same species.

An SSD was calculated for chloride according to procedures specified by Environment Canada [21]. This procedure involves calculating toxicological thresholds for available data, and plotting a cumulative distribution of the dataset. No-observed-effect concentration (NOEC) values have often been used in constructing SSDs [22]; however, these values are subject to constraints associated with statistical power of the tests and use of these endpoints has been criticized [23]. Thus, consistent with Environment Canada guidelines [21], toxicological thresholds were defined as the most appropriate IC*x* value reflecting the threshold for toxicity in the test. Ideally, the IC10 was considered to be the toxicological threshold; however, if the IC10 value was lower than the NOEC, the test was not considered to be sufficiently robust to provide a reasonable estimate of the IC10, in which case, the IC25 was used as the toxicological threshold. In the event that suitable point estimates were not available for a given test, the next most appropriate endpoint was selected based on the following order of preference: maximum-acceptable-toxicant concentration (MATC) > NOEC > lowest-observed-effect concentration (LOEC) > median effect concentration (EC50). Only the most sensitive endpoint from long-term tests (e.g., reproduction, growth) was included in the distribution. In cases where multiple endpoints were available from different studies, a geometric mean of the values was used in the distribution.

Nonlinear regression was conducted using CETIS to model the distribution and calculate the 5th percentile of the distribution; this value, referred to as the HC5, is considered by Environment Canada to be protective of overall ecosystem health and function [21]. Models tested included normal, log normal, logistic, log logistic, log Gompertz and Weibull; relative fit of the models was evaluated on the basis of corrected second order Akaike information criteria (AIC), and the fit of individual candidate models with the smallest and similar AIC values were inspected to select the curve that best described the distribution, with particular attention to the lower tail of the distribution where the HC5 is located. Normal distribution of the dataset was tested using a Shapiro–Wilk test for normality ($p < 0.01$).

RESULTS AND DISCUSSION

All of the acute and chronic toxicity tests conducted in the present study met control performance requirements, with the exception of the chronic test with *Hyalella*, which had 62.5% survival and was lower than the control acceptance criterion of 80% survival. Survival in the three lowest test concentrations in this test was consistent with the control performance, ranging from 62.5 to 75% and a typical dose–response curve was obtained with the entire dataset. Consequently, the data from this test appear to provide useful information, despite not meeting the control performance specifications of the method. Interestingly, the chronic test using *Hyalella* was less sensitive to chloride than the acute test with this species, suggesting that the presence of control sediment and peat may ameliorate the toxicity of chloride; organic carbon influences the toxicity of a number of metals [24,25], but it is not known if this might explain decreased toxicity in this case.

Results of the chronic toxicity tests are presented in Table 3, and acute and chronic toxicity test data and calculated ACR values for nine species tested in this investigation are summarized in Table 4. The ACRs calculated in the present study include a second measure of the ACR for each of the three genera that were previously used in the development of the U.S. EPA chloride water quality guideline. The values used by U.S. EPA are also provided in Table 4. The genus mean ACRs were recalculated for each of these three genera, on the basis of the geometric mean of the two values. The overall ACR, calculated as the geometric mean of the ACR values for all nine species, was 3.50. Thus, the results of these tests suggest that the estimate for the ACR provided in the U.S. EPA guideline (7.59) likely overestimated the actual value by approximately twofold. Since this ACR value was employed by both the U.S. EPA in deriving the 1988 chronic guideline for chloride and by Environment Canada in conducting a risk assessment for road salts, these studies likely resulted in benchmarks that were unnecessarily conservative to be protective of long-term ecosystem health.

Where sufficient data exist, it is preferable to calculate long-term exposure guidelines directly on the basis of chronic toxicity test results, rather than relying on use of an ACR to calculate this value. As a result of the toxicity testing conducted here, a number of additional chronic toxicity values are now

Table 3. Results of sublethal toxicity tests[a]

Species	Endpoint	IC10[b]	IC25[b]	IC50[b]	NOEC	LOEC
Ceriodaphnia dubia	Reproduction	NR	454 (251–819)[c]	697 (540–901)[c]	NC	NC
Daphnia magna	Reproduction	NR	421 (262–825)	1,037 (684–1,491)	<506	506
Oncorhynchus mykiss	Biomass	NR	1,174 (733–1,344)	1,559 (1,362–1,679)	1,104	2,327
Pimephales promelas	Biomass	NR	704 (486–973)	958 (700–1,582)	558	1,058
Lumbriculus variegatus	Biomass	NR	825 (549–1,256)	1,366 (1,199–1,541)	<366	366
Tubifex tubifex	Reproduction	519 (235–529)	606 (391–632)	752 (628–803)	462	964
Chironomus dilutus	Biomass	2,316 (NC)	2,590 (2,118–2,590)	3,047 (2,732–3,047)	2,133	3,960
Hyallela azteca	Biomass	NR	1,705 (440–1,907)	2,298 (1,852–2,937)	2,210	4,237
Brachionus calyciflorus	Reproduction	1,241 (211–1,345)	1,505 (540–1,670)	1,945 (1,631–2,263)	1,120	2,330

[a] NOEC = no-observed-effect concentration; LOEC = lowest-observed-effect concentration; NR = not reported, because the IC10 was lower than the NOEC. Thus, the test data were not considered sufficiently robust to calculate an IC10; NC = not calculated, since these point estimate data were derived from multiple tests (i.e., 20).

[b] IC = inhibition concentration values (IC*x*) associated with 10, 25, and 50%.

[c] Mean (±two standard deviations) for 20 tests conducted as reference toxicant tests.

Table 4. Results of toxicity tests and acute-to-chronic ratio calculations[a]

Genus	Acute test LC50 (mg/L Cl)	Chronic test IC25 (mg/L Cl)	Acute–chronic ratio from the present study	Acute–chronic ratio from U.S. EPA [9]	Combined acute–chronic ratio
Ceriodaphnia	1,068 (603–1,533)[b]	454 (251–819)[b]	2.35	NC	2.35
Daphnia	3,630 (3,172–4,154)	421 (262–825)	8.62	3.95	5.84
Oncorhynchus	6,030 (5,916–6,145)	1,174 (733–1,344)	5.14	7.31	6.13
Pimephales	4,079 (3,644–4,565)	704 (486–973)	5.80	15.17	9.38
Lumbriculus	3,100 (2,759–3,483)	825 (549–1,256)	3.76	NC	3.76
Tubifex	5,648 (5,219–6,111)	606 (391–632)	9.31	NC	9.31
Chironomus	5,867 (5,452–6,313)	2,590 (2,118–2,590)	2.27	NC	2.27
Hyalella	1,382 (1,276–1,496)	1,186 (693–1,516)[c]	1.17	NC	1.17
Brachionus	1,645 (1,588–1,703)	1,505 (540–1,670)	1.09	NC	1.09
Geometric mean acute-to-chronic ratio			3.40	7.59	3.50

[a] LC50 = median lethal concentration; IC25 = 25% inhibition concentration; NC = not calculated by the U.S. EPA [9].
[b] Mean (±2 SD) for 20 tests conducted as reference toxicant tests.
[c] The chronic test for *Hyalella* was less sensitive than the acute test and, consequently, for calculation of the acute-to-chronic ratio, the chronic test value was assumed to be the LC25 (25% lethal concentration) from the acute test. The actual IC25 for biomass of *Hyalella* was 1,705 mg/L.

available for the toxicity of chloride; these values, combined with those from the literature, provide sufficient data to calculate a long-term exposure guideline directly using an SSD approach. Additional data using in the SSD include data that were reported in the U.S. EPA water quality guideline for *D. pulex* [26], *P. promelas* [26], *Nitzschia linearis* [27], *Chlamydomonas reinhardtii* [28], and *Chlorella emersonii* [29], as well as other data from the literature for *Lemna minor* [30] and *Stenonema modestum* [31]. To meet the recommendations of Environment Canada [21], point estimates from these studies (i.e., IC10 or IC25 values) were used where possible; sufficient data were present in one of these documents to recalculate the threshold using point estimates, rather than relying on the hypothesis tests that were reported in that study [26]. The data used in calculation of the SSD are shown in Table 5.

A subset of data points that were used in the U.S. EPA water quality guideline development were excluded here. For example, data for rainbow trout, attributed to Spehar and cited by U.S. EPA [9], were not available for review because this study was apparently not published. In addition, data for the sensitivity of a number of unicellular freshwater algae were excluded from the SSD because these papers only reported tolerance to chloride, rather than evaluating inhibition of growth compared to control performance [32,33].

Differing opinions have been expressed in the literature on the number of species required to construct an SSD, with as few as six [21], and up to 15 to 55 species being considered ideal to achieve an HC5 estimate with minimal variance [34]. In addition, the composition of the species assemblage reflected in the dataset can alter the outcome, particularly in cases where the toxicological mode-of-action varies between species, and the dataset needs to reflect the ecosystem being protected [35]. The dataset shown here has 15 data points, including nine invertebrates, two fish, two algae, one plant, and one diatom. The cumulative distribution appears to fit a single distribution, without any indication of a bimodal distribution (Fig. 1). Furthermore, a Shapiro–Wilk test for normality demonstrated that the dataset was normally distributed ($p = 0.55$), indicating that no unusual patterns in the data occurred. Thus, it appears that the species reflected in the dataset provide a reasonable distribution from which to calculate an HC5.

The HC5 was calculated using a Weibull distribution to model the SSD dataset using nonlinear regression. Log logistic and log normal models produced a similar fit to the Weibull

Table 5. Chronic toxicity test data used for calculation of the species sensitivity distribution[a]

Species	Category	Threshold value (mg/L Cl)		Source

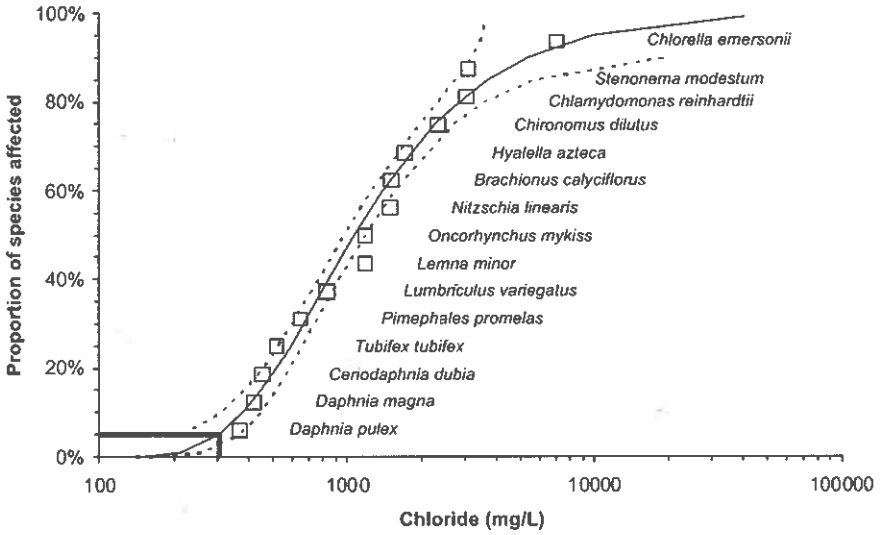

Fig. 1. Species sensitivity distribution for chronic toxicity test data using chloride. The squares represent the empirical data, the solid line represents the modeled distribution, and the dashed lines represent the 95% confidence limits.

distribution (i.e., produced similar AIC values); however, the Weibull model was selected because it provided a closer fit to the data in the lower tail of the distribution, by inspection. The HC5 (and 95% confidence intervals) calculated on this basis was 307 (217 to 369) mg/L (Fig. 1). This value is lower than all of the thresholds reported in Table 4 and appears to be appropriately protective to apply as a long-term objective for chloride, at least under moderately hard conditions.

The results of toxicity tests using *C. dubia* conducted at various hardnesses are provided in Table 6. A clear decrease in the toxicity of chloride was observed with increasing hardness across the range of 10 to 160 mg/L hardness. Lasier et al. [36] also reported lower chronic toxicity of chloride in higher hardness water with this species, and Mount et al. [8] reported decreased acute toxicity of chloride to *C. dubia* when tested as a combination of sodium chloride and calcium chloride (resulting in higher hardness), compared with sodium chloride alone. Interestingly, these authors also reported that the toxicity of the combined salts was lower than calcium chloride alone, which would be even higher in hardness than the mixture. These data suggest that decreased toxicity corresponding to increasing hardness may relate to maintenance of a tolerable balance in molar ratios of cations, rather than a mechanistic effect of hardness (i.e., Ca or Mg ions) itself. Regardless, the data presented here demonstrate a clear reduction in toxicity of sodium chloride in solutions with higher hardness, with water hardness potentially being a proxy for higher overall ionic strength or more balanced ionic ratios of major ions.

Table 6. Results of *Ceriodaphnia dubia* chronic toxicity tests conducted across a range of hardnesses[a]

Hardness (mg/L as $CaCO_3$)	Chloride toxicity endpoints (mg/L Cl)		
	Ceriodaphnia reproduction (IC25 [95% CL])	*Ceriodaphnia* reproduction (IC50 [95% CL])	*Ceriodaphnia* survival (LC50 [95% CL])
10	117 (94–169)	161 (126–211)	132 (107–161)
20	264 (104–280)	301 (275–362)	316 (268–373)
40	146 (82–277)	481 (207–541)	540 (460–633)
80	454 (251–819)[b]	697.4 (540–901)[b]	1,134 (858–1,410)[b]
160	580 (210–733)	895 (706–1,177)	1,240 (1,025–1,501)
320	521 (361–588)	700 (613–784)	1,303 (1,019–1,665)

[a] IC = inhibition concentration values (ICx) associated with 25 and 50%; CL = confidence limits; LC50 = median lethal concentration.
[b] Mean and 2 SD range of 20 data points for chronic toxicity tests using chloride.

A logarithmic regression of the data for hardnesses of 10 through 160 mg/L resulted in R^2 values of 0.95, 0.99, and 0.78 for LC50, IC50, and IC25 values, respectively, indicating a strong positive relationship between these parameters (Fig. 2). Above a hardness of 160 mg/L, an additional reduction in toxicity was not as apparent, with generally similar values for sensitivity to chloride at hardnesses of 160 and 320 mg/L.

The majority of toxicity data used to establish the SSD value of 307 mg/L were derived from toxicity tests conducted under moderately hard water conditions (80 to 100 mg/L, as $CaCO_3$). Consequently, this value may not be sufficiently conservative for soft-water conditions, and appears to be unnecessarily conservative at hardnesses exceeding 100 mg/L. Using the slope of the hardness toxicity relationship shown in Figure 2, the results from the SSD can be hardness-adjusted to accommodate this relationship in a similar manner to water quality guidelines for metals such as Zn, Cu, Cd, and Ni.

The relationship between IC25 values and hardness across a range of 10 to 160 mg/L resulted in a logarithmic trendline described by Equation 1.

$$IC25_{(\text{hardness } x)} = [161 \cdot \ln_{(\text{hardness } x)}] - 281.73 \quad (1)$$

Thus, using the water quality benchmark of 307 derived from the SSD for a hardness of 80 mg/L, and the IC25 for *C. dubia* of 423.78 mg/L chloride (calculated from Eqn. 1, for a hardness of 80 mg/L), the objective can be linked to hardness by incorporating this equation into Equation 2.

$$\begin{aligned} WQO_{(\text{hardness } x)} &= [WQO_{(\text{hardness } 80)}/IC25_{(\text{hardness } 80)}] \\ &\cdot [161 \cdot \ln_{(\text{hardness})} - 281.73] = (307/423.78) \\ &\cdot [161 \cdot \ln(\text{hardness}) - 281.73] \\ &= [116.63 \cdot \ln(\text{hardness})] - 204.09 \end{aligned} \quad (2)$$

Electronic Filing: Received, Clerk's Office 3/14/2019

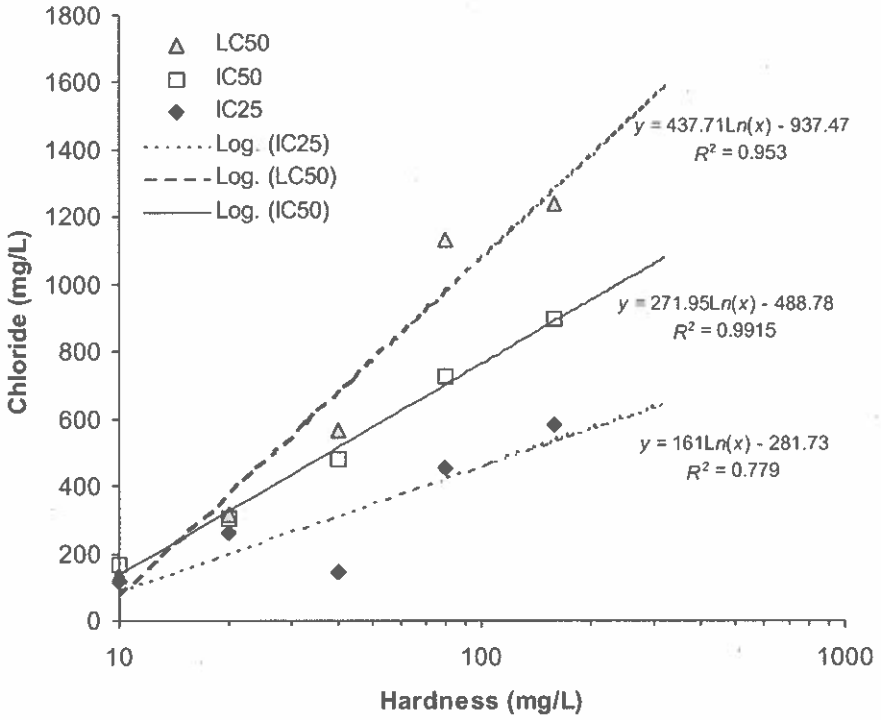

Fig. 2. Relationship between hardness and sensitivity to chloride for reproduction (IC25 and IC50 inhibition concentrations) and survival median lethal concentration (LC50) endpoints.

where: $WQO_{(hardness\ x)}$ = Water quality objective for chloride at hardness (x);

$WQO_{(hardness\ 80)}$ = Water quality objective for chloride at hardness 80 mg/L (i.e., the HC5 from the SSD); $IC25_{(hardness\ 80)}$ = Concentration resulting in a 25% reduction in reproduction of *C. dubia* at hardness 80 mg/L $CaCO_3$.

Thus, the hardness-specific WQO for chloride across a range of 10 to 160 mg/L hardness is established as

$$WQO = [116.63 \cdot \ln(\text{hardness})] - 204.09$$

Using the water quality benchmarks provided in Table 7should provide sufficient protection against adverse effects in receiving environments impacted by chloride.

Although data relating water hardness to the toxicity of chloride are only available for one species (i.e., *C. dubia*), it appears reasonable to assume that a similar response would also occur with other cladocerans, and potentially with other species as well, although uncertainly exists as to the extent to which that would be the case. Regardless, the range of water quality guidelines proposed in Table 7 (i.e., 64 to 388 for hardnesses ranging from 10 to 160 mg/L) is lower than the threshold for toxicity to any non-cladoceran species reported in Table 4. Thus, even if this phenomenon was limited to the cladocera, incorporation of hardness into a guideline would not appear to result in risk to other taxa, and takes account of the higher sensitivity of cladocerans to chloride under low hardness conditions.

Table 7. Hardness-dependent water quality benchmarks for chloride, calculated on the basis of application of the relationship between IC25 (inhibition concentration value associated with 25%) for *Ceriodaphnia dubia* reproduction and water hardness to the 5th percentile of the species sensitivity distribution (HC5)

Water hardness (mg/L $CaCO_3$)	Water quality objective for chloride $WQO_{(hardness\ x)}$ (mg/L)

40	226
60	273
80	307
100	333
120	354
140	372
160	388
>160	Not established

The results presented here suggest that current U.S. EPA water quality guidelines for chloride may not be sufficiently protective of aquatic life under soft-water conditions. This finding has particular significance in areas of road salt use, because snow-melt runoff is very low in hardness and can contain significant concentrations of chloride. Use of road salt formulations that combine calcium chloride with sodium chloride would appear to result in lower risk for adverse effects in the environment because this would confer an increased hardness to runoff and, consequently, lower risk of adverse effects. Conversely, the data presented here suggest that current water quality guidelines for chloride may be unnecessarily conservative in waters with moderate or high hardness.

Assessing the toxicity of sodium chloride to the glochidia of freshwater mussels: Implications for salinization of surface waters

Patricia L. Gillis

National Water Research Institute, Environment Canada, 867 Lakeshore Road, Burlington, ON L7R-4A6, Canada

Freshwater mussel larvae were acutely sensitive to sodium chloride, such that chloride levels in some Canadian rivers may pose a threat to the survival of this early life stage.

Glochidia

ABSTRACT

Chloride concentrations in surface waters have increased significantly, a rise attributed to road salt use. In Canada, this may be a concern for endangered freshwater mussels, many with ranges limited to southern Ontario, Canada's most road-dense region. The acute toxicity of NaCl was determined for glochidia, the mussel's larval stage. The 24 h EC50s of four (including two Canadian endangered) species ranged from 113–1430 mg Cl L^{-1} (reconstituted water, 100 mg $CaCO_3$ L^{-1}). To determine how mussels would respond to a chloride pulse, natural river water (hardness 278–322 mg $CaCO_3$ L^{-1}) was augmented with salt. *Lampsilis fasciola* glochidia were significantly less sensitive to salt in natural water (EC50s 1265–1559 mg Cl L^{-1}) than in reconstituted water (EC50 285 mg L^{-1}). Chloride data from mussel habitats revealed chloride reaches levels acutely toxic to glochidia (1300 mg L^{-1}). The increased salinization of freshwater could negatively impact freshwater mussels, including numerous species at risk.

1. Introduction

The increase in the chloride concentration of North American surface waters over the past 30 years has been correlated with the increased application of de-icing salts on paved surfaces (Kaushal et al., 2005; Jackson and Jobbágy, 2005). Kaushal et al. (2005) demonstrated that chloride levels in rivers and streams were correlated with the percentage of impermeable surfaces in the watershed. This increased salinization of freshwater has implications for both human and ecosystem health. Chloride concentrations in some drinking water reservoirs now exceed the level for potable water (Kaushal et al., 2005) and numerous urban streams frequently exceed the levels considered harmful to aquatic life (Evans and Frick, 2001; Trowbridge et al., 2010). In addition to the seasonal influx of salt in snowmelt and runoff, groundwater (Howard and Haynes, 1993; Kelly et al., 2008; Roy and Bickerton, 2010) and soils (Kincaid and Findlay, 2009) can also act as reservoirs releasing chloride throughout the year. Therefore, it is quite probable that the full impact of freshwater salinization has yet to be realized, not only because millions of tons of road salt are applied each year (Environment Canada and Health Canada, 2001), but also because delayed and longer-term inputs of chloride from contaminated soils and groundwater are expected (Kelly et al., 2008; Kincaid and Findlay, 2009). Kaushal et al., (2005) suggested that baseline salinity in the Northeastern United States is approaching levels where significant changes in ecological communities and ecosystem function are expected. Recent studies suggest that such shifts may in fact already be occurring for some contaminant sensitive groups. For example, Collins and Russell (2009) concluded that exposure to road salt affects amphibian community structure and species richness by excluding salt-sensitive species from high chloride environments.

Freshwater mussels, one of the most imperiled groups of organisms (Ricciardi and Rasmussen, 1999; Lydeard et al., 2004), are also known to be particularly sensitive to some waterborne contaminants. In fact environmental pollution is considered to be one of the factors responsible for their decline (Strayer et al., 2004; Lydeard et al., 2004). Nearly 70% of North American freshwater mussels are designated as either threatened, endangered, or in decline (Williams et al., 1993; Neves et al., 1997). Recent studies have reported that for some contaminants, freshwater mussel larvae and juveniles are much more sensitive than standard test organisms, leading to concerns that water quality regulations may not protect freshwater mussels (Augspurger et al., 2003; Wang et al., 2007, 2009; March et al., 2007). In Canada, the geographical distribution of freshwater mussels is thought to be limited by temperature, either because the mussels themselves or their fish hosts reach their lower limit of thermal tolerance (Metcalfe-Smith et al., 1998). Many species reach the northern limit of their range in

the lower Great Lakes Basin, with 40 of Canada's 53 freshwater mussels species found in this area (Metcalfe-Smith et al., 1998). Of particular concern is that the range of eight Canadian mussel species classified as federally endangered are limited to the heavily populated and road dense southern Ontario. However, it is unknown whether the contamination of mussel habitats by chloride will affect the mussels, particularly their sensitive early life stages. The parasitic larvae of freshwater mussels, called glochidia, are released from the brooding chambers (marsupia) in the female's gills into the water column in order to make contact with fish hosts. In Canada, most glochidia are released between May and October, depending upon species specific temperature cues for release. Fortunately, the typical release period does not coincide with the seasonal influx of chloride associated with snowmelt runoff, but the steady increase in baseline chloride levels along with periodic summer chloride pulses from stormwater runoff and groundwater upwelling (Howard and Haynes, 1993; Kincaid and Findlay, 2009) may pose a risk to this imperiled, but ecologically significant group of animals.

This study examined acute sodium chloride (NaCl) toxicity in glochidia and compared median effective concentrations (EC50s) to chloride concentrations in the mussel's natural habitat. Specifically, sensitivity was determined for five species of mussels, three of which are designated as federally endangered in Canada. Toxicity tests with glochidia and NaCl were conducted in both standard reconstituted waters and natural waters. Reconstituted water exposures were used to determine the sensitivity of glochidia to chloride in relation to other aquatic organisms and the effect of water hardness on chloride toxicity. Natural water exposures employed water collected from four southern Ontario rivers that support diverse mussel populations (9–34 species). The aim of the natural water exposures was to determine how glochidia would respond to an episodic pulse of chloride in their habitat.

2. Materials and methods

2.1. Mussel collection and laboratory care

Gravid female mussels were collected from streams and rivers in southern Ontario. The period of gravidity varied with species such that *Lampsilis siliquoidea* (Barnes 1823) (fatmucket) and *Lampsilis cardium* (Rafinesque 1820) (plain pocketbook) were collected in May, *Lampsilis fasciola* (Rafinesque 1820) (wavy-rayed lampmussel) in mid-July, and *Epioblasma torulosa rangiana* (Lea 1838) (northern riffleshell) and *Ptychobranchus fasciolaris* (Rafinesque 1820) (kidneyshell) in early September. The endangered *L. fasciola*, *P. fasciolaris* and *E. torulosa rangiana* were collected under Canadian Species at Risk Permits (SECT 08 SCI 007, SECT 73 SARA C&A 09-012). Because the availability of gravid females varied each year, toxicity tests were conducted over two field seasons (2008–2009). In addition, acute chloride sensitivity of *L. siliquoidea* glochidia was assessed using gravid females collected from two different watersheds (one in each of 2008 and 2009) and toxicity tests with *L. fasciola* were also conducted in both years but using different gravid females collected from the same field site. Although mussels for this study were collected in Ontario, all species examined are also found in the U.S. (Parmalee and Bogan, 1998).

Gravid mussels were held at the University of Guelph's Aqualab facility and maintained in a flow-through system with well water held at 10 ± 2 °C (to prevent the glochidia release). Mussels were fed approximately 1.2×10^{10} algae cells per mussel per day with a commercial shellfish diet (Instant Algae Shellfish Diet 1800®, Richmond Hill, ON). Glochidia for testing were collected by flushing the marsupia (i.e., brooding chambers) with a water-filled syringe. The viability of each mussel's glochidia was assessed (described below) prior to use. Prior to initiating an exposure, glochidia collected from gravid mussels held at 10 °C, were gradually (over 2–3 h) acclimated to the exposure temperature (21 °C) through dilutions with room temperature reconstituted water. Glochidia were pooled from a minimum of three gravid females for each experiment. For the endangered species, glochidia were only collected from one marsupium gill, and each mussel was returned to the location from which they were collected to facilitate the release of remaining glochidia in their natural habitat.

2.2. Toxicity testing

Acute toxicity tests with glochidia were modeled after the American Society for Testing and Materials' method for conducting toxicity tests with the early life stages of freshwater mussels (ASTM, 2006). Briefly, the viability of glochidia were evaluated after exposure to waterborne contaminants. In order to parasitize fish, glochidia must be viable, which means they must be able to close their valves and clamp down on a fish's gill in order to encyst. Glochidia viability (i.e., ability to close valves) was assessed prior to exposure and after 24 h of exposure in a sub-sample (100–200) of the glochidia (500–1000) through the addition of a saturated salt solution (NaCl 240 g L^{-1}). Viability was calculated using the following equation: Percent Viability = 100 × (Number of closed glochidia after NaCl addition − Number of closed glochidia before NaCl addition)/(Number of closed glochidia after NaCl addition + Number of open glochidia after NaCl addition). Results are expressed as (chloride) effective median concentrations (EC50) rather than median lethal concentrations (LC50), but as they are obligatory parasites, for practical purposes non-viable glochidia should be considered 'dead' because they would be unable to attach to a host fish and complete their life cycle.

The ASTM (2006) method indicates that glochidia control survival remain above 90%. Therefore, for toxicity tests conducted in reconstituted water, pre-exposure ($t = 0$) and post-exposure ($t = 24$ h) control survival (i.e. viability) were determined. In addition, for toxicity tests conducted in natural waters, 24 h control survival in each river water (without salt augmentation) was determined.

An aqueous stock made from certified ACS grade (Fisher Scientific) sodium chloride (NaCl) was used to create exposure solutions. Waters (reconstituted or field-collected) were spiked with NaCl (nominal, 0–10 g NaCl L^{-1}) and held in the dark at 4 °C for 48 h before initiation of an exposure. Exposures were conducted in 250 mL glass beakers, under a 16:8 light:dark cycle at 21 ± 2 °C. Water quality including dissolved oxygen (DO), pH, alkalinity, dissolved organic carbon (DOC), water hardness as well as the concentration of major ions (Na, K, Ca) and trace metals were assessed at exposure initiation. DO, pH and Cl were also measured upon completion of an exposure. Water analysis was conducted by the Canadian National Laboratory for Environmental Testing (Environment Canada, Burlington, ON). Chloride was measured by Ion Chromatography (detection limit (DL) 0.02 mg L^{-1}). Mean chloride recovery was 100.4% (STD 0.36) using the National Water Research Institute's (NWRI) certified reference material ION-915. Metals, including copper, were measured by ICP-SFMS (copper DL 0.02 µg L^{-1}). Mean copper recovery was 100% (STD 0.16) using the National Research Council of Canada's certified reference material SLRS-4. DOC (DL 0.1 mg L^{-1}) was measured by a UV Persulfate Total Organic Carbon Analyzer. Mean DOC recovery was 95.5% (STD 0.2) using NWRI's certified reference material WINN-02. Major ions (e.g. potassium, DL 0.01 mg L^{-1}) were analyzed by Atomic Absorption Spectrometry. Mean potassium recovery was 99.4% (STD 0.4) using VHG Labs (New Hampshire) certified reference material QWSMIN. Glassware was acid washed with 10% nitric acid (Reagent Grade, Fisher Scientific) prior to use and solutions were made with Millipore™ water.

2.3. Chloride sensitivity in reconstituted waters

A series of toxicity tests were conducted with NaCl and reconstituted waters (ASTM, 2003). For each species studied at least one acute toxicity test was conducted in moderately-hard reconstituted water (95–115 mg $CaCO_3$ L^{-1}). In addition, a series of exposures were conducted in reconstituted waters of varying hardness (range 47–322 mg $CaCO_3$ L^{-1}) using *L. siliquoidea* glochidia.

2.4. Chloride sensitivity in natural waters

A series of toxicity tests were conducted with water collected from four significant mussel habitats in southern Ontario (Table 1). River water (10 L) was collected just below the surface where the water was visibly flowing. Water samples were held in the dark at 4 °C until used in an exposure (maximum one week). Acute exposures in NaCl-spiked natural waters were conducted with *L. fasciola* glochidia as described above.

In addition to the *L. fasciola* natural water exposures, another natural water test was conducted with *P. fasciolaris* glochidia. Unlike the other species examined which release free glochidia, *P. fasciolaris* produces conglutinates. These small packets of glochidia (100–200) resemble fish prey and serve to enhance infection of host fish. Two intact conglutinates were used in each replicate test concentration. One conglutinate was opened (by gently tearing casing with fine forceps) after 24 h and the other after 48 h of exposure to assess the viability of the encased glochidia (24 h data shown). Because the number of conglutinates was limited, an exposure with chloride-spiked natural water was selected as the most ecologically relevant test to conduct with this endangered species.

2.5. Statistical analysis

Chloride EC50s and EC20s were determined by Probit Analysis (Statistical Package for the Social Sciences (SPSS)) version 11.0 using measured chloride concentrations and presented with 95% confidence intervals (CI) (e.g. EC50 (95% CI). EC50s and EC20s were considered to be significantly different when their 95% CI did not overlap (Environment Canada, 2005). Linear regression analysis was conducted (SigmaStat version 3.2) to examine the relationship between water hardness and chloride toxicity (EC50s). Note: Although EC50s and EC20s are reported with respect to the chloride component of NaCl, no attempt was made to determine the toxic

mode of action of NaCl in glochidia, therefore this study cannot distinguish whether glochidia are responding to the chloride ion or the sodium ion.

2.6. Chloride concentrations and mussel distribution data in southern Ontario

To assess the potential threat that chloride poses to freshwater mussels, the chloride levels in key mussel habitats in southern Ontario were examined. In Ontario, watersheds are managed locally by Conservation Authorities. The Canadian Department of Fisheries and Oceans has produced distribution lists of endangered mussels and fish species for each Conservation Authority (CA). Therefore, mussel distribution data and chloride concentrations are presented according to CA. Four CAs were selected for in-depth analysis of field-measured chloride levels and laboratory toxicity tests with waters from these habitats. The CAs selected along with their main mussel habitat (i.e. river) were the Grand River CA (Grand River), St. Clair Region CA (Sydenham River), Maitland Valley CA (Maitland River), and Upper Thames River and Lower Thames Valley CAs (Thames River). For the purposes of this summary, data from the Upper and Lower Thames CAs were combined. Chloride concentrations measured from 1998 to 2008 at 105 sites across the CAs were determined by the (Ontario) Provincial Water Quality Monitoring Network (PWQMN) and provided by the Ontario Ministry of the Environment (PWQMN, 2009).

Individual chloride concentrations at each site were averaged over time. These 'site averages' were then averaged to determine an overall mean for each CA, referred herein to as a "CA Mean". Site averages, rather than individual readings were used to calculate each CA Mean to prevent skewing of the mean by differences in sampling frequency or extreme readings. The 'CA Range' demonstrates the maximum and minimum individual chloride concentrations across the CA over the 10 years examined. The number of endangered mussel species reported for each CA was obtained from Canadian Department of Fisheries and Oceans (DFO) maps (DFO, 2010).

3. Results

3.1. Chloride sensitivity in reconstituted waters

Glochidia control survival (24 h) for the four mussel species employed in NaCl exposures with moderately-hard reconstituted water is presented in Table 2. With one exception (*L. siliquoidea*, 2008), all tests met the ASTM (2006) requirement of less than 10% drop in control survival. The 24 h chloride EC50s ranged from 113 mg Cl L^{-1} for *L. fasciola* (2008) to 1430 mg Cl L^{-1} for *L. siliquoidea* (2009) (Fig. 1). In addition to interspecific variation, *L. siliquoidea* glochidia collected from different water bodies exhibited significantly different EC50s. Those collected from Cox Creek (2008) produced an EC50 of 168 (135–198) mg Cl L^{-1}, while those collected from the Maitland River (2009) produced an EC50 of 1430 (1350–2953) mg Cl L^{-1}. In contrast, both tests (2008, 2009) of *L. fasciola* glochidia from a single field site produced relatively similar EC50s (113 (63–163), 285 (163–451) mg Cl L^{-1}, respectively).

A series of exposures with *L. siliquoidea* glochidia demonstrated that chloride sensitivity is influenced by water hardness (Table 3). A linear relationship between the 24 h chloride EC50s and water hardness ($r^2 = 0.97$) was observed for water hardness between 47 and 172 mg $CaCO_3$ L^{-1}, but no further protection was afforded when hardness increased to 322 mg $CaCO_3$ L^{-1}.

Table 2
Pre-exposure ($t = 0$) viability and post-exposure ($t = 24$ h) control survival for freshwater mussel glochidia as well as observed 24 h chloride EC50s (95% confidence intervals) from sodium chloride exposures conducted in reconstituted water.

Mussel species	% Viability ($t = 0$)	% Viability ($t = 24$)	EC50 (95% CI) ($mg\,Cl\,L^{-1}$)
Lampsilis siliquoidea[a] (2008)	91.3	77.4	168 (135–189)
Lampsilis siliquoidea (2009)	93.4	93.2	1430 (1350–2953)
Lampsilis cardium	91.1	88.3	817 (770–869)
Lampsilis fasciola[b] (2008)	91.9	92.2	113 (63–163)
Lampsilis fasciola (2009)	93.8	91.4	285 (163–451)
Epioblasma torulosa rangiana	95.2	91.3	244 (230–260)

[a] Gravid *L. siliquoidea* were collected from different water bodies in 2008 and 2009.
[b] Gravid *L. fasciola* were collected from the same site in 2008 and 2009.

3.2. Chloride sensitivity in natural waters

Control survival of *L. fasciola* glochidia in the field-collected waters was more variable (78–93%) than in reconstituted water (87–92%) (Table 1). The 24 h chloride EC50 values for *L. fasciola* glochidia were similar across the natural waters tested (1265–1559 mg Cl L^{-1}) (Table 4), but all were significantly higher than the EC50 (285 (163–451) mg Cl L^{-1}) produced in reconstituted water with glochidia from the same gravid females. The 24 h natural water control survival for *P. fasciolaris*'s conglutinate encased glochidia was 95% and the EC50 was 3416 (3059–3835) mg Cl L^{-1}.

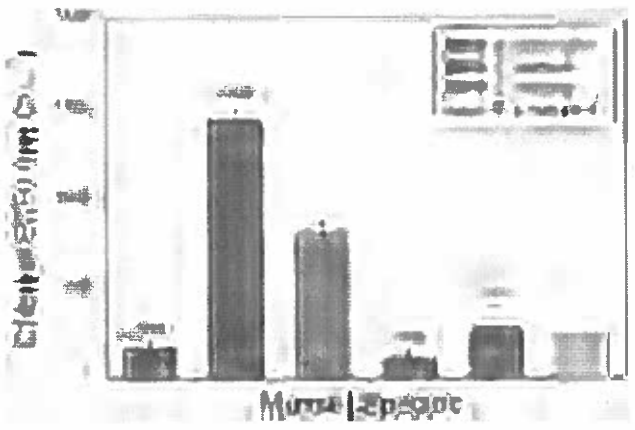

Fig. 1. Chloride EC50s (24 h) for glochidia (larvae) of four species of freshwater mussels. Exposures were conducted in reconstituted moderately-hard water (95–115 mg $CaCO_3$ $mg\,L^{-1}$). Error bars represent 95% confidence intervals around the EC50. Asterisks indicate Canadian endangered species. Toxicity tests with *Lampsilis siliquoidea* and *Lampsilis fasciola* were conducted in both 2008 and 2009. *L. siliquoidea* were collected from different water bodies. *L. fasciola* were collected from the same field site both years.

3.3. Chloride concentrations and mussel distribution in southern Ontario

A summary of chloride concentrations in four rivers in southern Ontario, along with the number of mussels species found in each habitat is presented in Table 4. Water hardness for the selected rivers ranged from 278 to 322 mg $CaCO_3$ L^{-1}. Although the range in mean chloride concentration was narrow (38–58 mg Cl L^{-1}), the range of individual measured chloride concentrations over the 10 years examined was much broader, covering 2–1300 mg L^{-1}.

4. Discussion

4.1. Chloride sensitivity in reconstituted waters

Acute toxicity testing in reconstituted water revealed that glochidia were sensitive to chloride, although significant interspecific and in one case intraspecific variation was observed. The EC50 values for free glochidia of the four mussel species tested ranged from 113 to 1430 mg Cl L^{-1} (Fig. 1). This 13 fold difference in chloride sensitivity between mussel species was not unlike the variation observed by Wang et al. (2007) (12 fold for 9 species) and Gillis et al. (2008) (5 fold for 8 species) in the acute sensitivity of glochidia to copper. Although chloride toxicity data for glochidia is limited, NaCl has been used as a reference toxicant for glochidia toxicity tests. Bringolf et al. (2007) reported EC50s from 0.55 to 3.3 g NaCl L^{-1} (334–2008 mg Cl L^{-1}) for five species of mussel glochidia, Valenti et al. (2007) reported EC50s from 2.68 to 3.08 g NaCl L^{-1} (1625–1868 mg Cl L^{-1}) for three species, and finally Cope et al. (2008) reported EC50s of 2.0 and 2.7 g NaCl L^{-1} (1213–1638 mg Cl L^{-1}) for *L. siliquoidea* glochidia. In this study there also appears to be intraspecific variation in chloride sensitivity. Although *L. fasciola* collected from the same site (Grand River, ON) on two different occasions produced somewhat similar EC50s (113 and 285 mg Cl L^{-1}), *L. siliquoidea* glochidia from two separate water bodies produced EC50s that varied by eight fold (Maitland River, 1430 mg L^{-1}; Cox Creek 168 mg L^{-1}). Perhaps the discrepancy is simply due to the fact that one batch of glochidia was healthier (Maitland River, control survival 93.2%) than the other (Cox Creek, control survival 77.4%) or perhaps prior exposure or even acquired tolerance may alter the response of glochidia to contaminants. But regardless, these data indicate that mussels from different water bodies may respond differently to chloride. While this observation was only based on the chloride sensitivity of one mussel species from two watersheds, possible differences in contaminant sensitivity across watersheds should be considered when selecting gravid females for toxicity testing with glochidia.

Even taking the variability between species into account, glochidia are still notably more sensitive to chloride than most previously tested aquatic organisms. While a full review of chloride toxicity in freshwater organisms is beyond the scope of this paper, Table 5 illustrates that compared to other groups, freshwater mussel larvae, were more sensitive to chloride. Particularly interesting is that some species of mussel glochidia (Fig. 1) experience chloride toxicity at a fraction of the concentration required to kill *Daphnia* (Mount et al., 1997; Harmon et al., 2003), a standard test organism often used to assess the toxicity of chemicals and effluents. Implications of this sensitivity for natural populations of freshwater mussels are discussed below.

4.2. Effect of water hardness

Water hardness had a significant effect on the sensitivity of glochidia to chloride. A two fold increase in the EC50 was observed when hardness increased from 47 to 99 mg $CaCO_3$ L^{-1}, but further increases in hardness were less effective at protecting glochidia (Table 3). The ameliorating effect of water hardness on chloride toxicity has been previously documented, in fact the state of Iowa has recently (2009) updated water quality criteria for chloride to adjust for water hardness (Iowa Department of Natural Resources,

Table 4
Summary of chloride concentrations in four significant mussel habitats in southern Ontario, the total number of mussel species and species at risk found in each habitat, as well as the observed 24 h chloride EC50s and EC20s for *Lampsilis fasciola* glochidia in toxicity tests conducted with salt-spiked samples of those waters.

Conservation authority	CA mean chloride (mg L^{-1})	CA range chloride (mg L^{-1})	Observed EC50 (mg L^{-1})	Observed EC20 (mg L^{-1})	Total mussel species	Mussels species at risk[a,b]

2009). The protection provided by hard water is beneficial for the freshwater mussels of southern Ontario as many key mussel habitats have very hard water (Table 1).

4.3. Chloride sensitivity in natural waters

L. fasciola glochidia were significantly less sensitive to salt in natural water than in reconstituted water. Some of the discrepancy can be explained by difference in water hardness because all of the natural waters tested were much harder (278–322 mg $CaCO_3$ L^{-1}) than the moderately-hard reconstituted water (100 $CaCO_3$ L^{-1}) used in the *L. fasciola* exposures. However, the four fold difference in EC50s is much larger than would be expected based solely on the difference in hardness because the *L. siliquoidea* exposures with a similar increase (100–322 mg $CaCO_3$ L^{-1}) produced less than a 30% difference in the chloride EC50. These data suggest that in addition to the protection provided by elevated water hardness that other water chemistry factors contributed to the reduced toxicity of chloride in natural waters.

The EC50 (3416 mg Cl L^{-1}) of conglutinate encased *P. fasciolaris* glochidia exposed to the salt-augmented water of the Grand River is nearly three times that of *L. fasciola* glochidia in the same water. This could simply be another example of intraspecific variation in glochidia contaminant sensitivity, or it could indicate that the life history strategy of encasing glochidia in conglutinates not only facilitates host transfer, but may also provide protection for the encased glochidia from chloride and potentially other ionic waterborne contaminants. For the current study it is not possible to determine the reason for the higher EC50 in conglutinate encased glochidia, although a previous study demonstrated that *P. fasciolaris* conglutinate encased glochidia were four fold less sensitive to copper than glochidia released from their conglutinate (Gillis et al., 2008).

The advantage of using reconstituted waters in toxicity tests is that they provide consistency and permit comparison between studies and between species; the disadvantage is that EC50s produced in reconstituted water may not necessarily predict how an organism will respond to that contaminant in its natural environment. On the other hand, one disadvantage of natural water exposures is that other contaminants may be present which can contribute to toxicity. Perhaps the variable (78–93%) control survival in the natural waters examined was due to other contaminants. One such contaminant of concern is potassium which is much more toxic than chloride. Imlay (1973) observed that only 2 of 10 rivers in the United States with potassium concentrations greater than 4 mg L^{-1} supported freshwater mussels, whereas 28 of 39 rivers with levels less than 4 mg L^{-1} were found to support mussels. All four natural waters tested were at or near this apparent threshold (Table 1). Moreover, preliminary data (Gillis unpublished) indicate that glochidia are sensitivity to potassium (*L. fasciola* 24 h moderately-hard reconstituted water LC50, 10 mg K L^{-1}). The potential effect of elevated potassium on freshwater mussel recovery requires further study especially because potassium chloride is currently being used as an alternative to sodium chloride for winter road maintenance (Evans and Frick, 2001). There have also been concerns that in some water bodies copper may be negatively impacting freshwater mussels (March et al., 2007; Ward et al., 2007). Background copper levels in the natural waters tested ranged from 5 to 6 μg L^{-1} (Table 1), but considering the level of DOC in these waters (>4 mg C L^{-1}) it is unlikely that copper contributed to the observed toxicity (Gillis et al., 2010; Wang et al., 2009). Unfortunately no comment can be made on the potential contribution of organic contaminants (such as pesticides) to the variation in control survival because these water samples were not analyzed for organics.

4.4. Implications for native populations of mussels

The rivers and streams of the lower Great Lakes Basin contain the richest assemblage of freshwater mussels in Canada (Metcalfe-Smith et al., 1998). After surveying historic (pre-1960) and more recent (up to 1996) mussel distribution data for southern Ontario, Metcalfe-Smith et al. (1998) concluded that significant species losses (15–30%) had already occurred, thereby verifying that the freshwater mussel decline documented in the U.S. (Neves et al., 1997) is also occurring in Canada. Although, many factors from exotic species to habitat loss (Williams et al., 1993; Bogan, 1993; Gillis and Mackie, 1994) are thought to have contributed to the decline of freshwater mussels, the role of waterborne contaminants remains uncertain. The chloride levels in the mussel habitats examined along with the heightened sensitivity of glochidia to NaCl suggest that chloride may in fact be impacting freshwater mussels in the lower Great Lake Basin. Even though the 'Mean' chloride concentrations (10–50 mg Cl L^{-1}) indicate that during the majority of the year, chloride levels are below the EC50, there are many documented instances where chloride concentrations would be toxic to glochidia. Even considering the higher EC50s produced in field-collected water (1265–1559 mg Cl L^{-1}), some rivers such as the Thames River, a habitat that supports eleven federally endangered species of mussels can exceed (1300 mg L^{-1}) the level found to be toxic to 50% of the glochidia.

Based on the results of this study, it is clear that even short-term spikes in chloride during the period of glochidia release would have

Electronic Filing: Received, Clerk's Office 3/14/2019

a negative impact on the successful reproduction of freshwater mussels. Fortunately for most species, timing appears to be in the glochidia's favor, because the largest chloride spikes typically coincide with snowmelt (PWQMN, 2009), months before glochidia are released into the water column. However, many mussel species are referred to as long term brooders. This means that glochidia are held in the marsupial gills throughout the winter and released the following spring (Barnhart et al., 2008). Although there is evidence that brooding glochidia are less sensitive to waterborne copper than those released to the water column (Jacobson et al., 1997), it is unknown whether brooding glochidia are affected by the chloride laden waters their mothers are exposed to in early spring. While glochidia are only present in the water column during the spring and summer months, juvenile mussels, which have also been shown to be sensitive to some waterborne contaminants (Wang et al., 2007) would be exposed to chloride throughout the year. Another potential and likely year-round source of chloride is contaminated groundwater (Kincaid and Findlay, 2009). Juvenile mussels, because they remain burrowed in the sediment for their first few years of life, would be most at risk from elevated chloride from groundwater upwelling. Although the present study examined the potential risk of chloride toxicity in lotic habitats of freshwater mussels, urban basin analysis suggests the potential for chloride toxicity may be even greater in lentic habitats. Chloride contributes to densimetric stratification of receiving waters (Marsalek, 2003; Eyles and Meriano, 2010) which results in higher chloride concentrations just above the sediment-water interface in static or slow moving water bodies. Such stratification could exacerbate the risk of acute chloride toxicity for freshwater mussels living in embayments and lakes subjected to road salt runoff.

5. Conclusion

This study has demonstrated that compared to most other aquatic organisms that glochidia are very sensitive to chloride. It has also been demonstrated that increased water hardness and natural river water offer 'protection' from acute chloride toxicity. But even considering these ameliorating factors, the level of chloride, likely from road salt runoff, in key mussel habitats in the lower Great Lakes Basin, may pose a threat to the successful reproduction and thus recovery of endangered freshwater mussels in this area.

Temperature affects acute mayfly responses to elevated salinity: implications for toxicity of road de-icing salts

John K. Jackson and David H. Funk

Stroud Water Research Center, 970 Spencer Road, Avondale, PA 19311, USA

Salinity in freshwater ecosystems has increased significantly at numerous locations throughout the world, and this increase often reflects the use or production of salts from road de-icing, mining/oil and gas drilling activities, or agricultural production. When related to de-icing salts, highest salinity often occurs in winter when water temperature is often low relative to mean annual temperature at a site. Our study examined acute (96 h) responses to elevated salinity (NaCl) concentrations at five to seven temperature treatments (5–25°C) for four mayfly species (Baetidae: *Neocloeon triangulifer*, *Procloeon fragile*; Heptageniidae: *Maccaffertium modestum*; Leptophlebiidae: *Leptophlebia cupida*) that are widely distributed across eastern North America. Based on acute LC50s at 20°C, *P. fragile* was most sensitive (LC50 = 767 mg l^{-1}, 1447 µS cm^{-1}), followed by *N. triangulifer* (2755 mg l^{-1}, 5104 µS cm^{-1}), *M. modestum* (2760 mg l^{-1}, 5118 µS cm^{-1}) and *L. cupida* (4588 mg l^{-1}, 8485 µS cm^{-1}). Acute LC50s decreased as temperature increased for all four species (n = 5–7, R^2 = 0.65–0.88, p = 0.052–0.002). Thus, acute salt toxicity is strongly temperature dependent for the mayfly species we tested, which suggests that brief periods of elevated salinity during cold seasons or in colder locations may be ecologically less toxic than predicted by standard 20 or 25°C laboratory bioassays.

This article is part of the theme issue 'Salt in freshwaters: causes, ecological consequences and future prospects'.

1. Introduction

Salinity in fresh waters is naturally variable, primarily reflecting differences in concentrations of dissolved inorganic cations calcium, magnesium and sodium, and anions carbonate, sulfate and chloride [1,2]. The differences in ion concentrations among fresh waters primarily reflect the weathering of soil and bedrock underlying a watershed, atmospheric deposition, and the evaporation–precipitation cycle. Sodium is generally less common than calcium and magnesium, and chloride is generally less common than carbonate or sulfate in natural waters. Elevated Na and Cl concentrations have been observed in effluents from wastewater treatment plants that reflect use of water softeners, table salt in the human diet, and disinfection before discharge [3,4], in wastewaters from some industrial, coal mining, and oil and gas production activities [5–7], in runoff and groundwater associated with various agricultural practices [8], and in road runoff following applications of de-icing products such as rock salt and anti-icing brines [9–13]. Recent analyses of multi-year data have found that sodium and chloride concentrations in surface waters have been increasing over the last two to five decades, at multiple locations (e.g. [14–18], and more recently [19–21]). This increase in sodium and chloride is part of a worldwide trend for increasing salinity along with pH and alkalinity [22–27], which was recently labelled the Freshwater Salinization Syndrome [28,29].

With these increases in ambient salinity, there has been renewed interest in the toxicity of salt in our aquatic ecosystems. Building on early toxicity tests [30], researchers have again begun examining salt toxicity by focusing on specific ions such as sodium, magnesium, chloride, carbonate, and sulfate (e.g. delivered as NaCl, $MgCl_2$, Na_2SO_4) for a variety of aquatic algae [31], insects and other macroinvertebrates [32–41], mussels [42–46], zooplankton [47,48], amphibians [49,50], and fish [32,51–53]. Other researchers have approached salt toxicity as a function of total salinity (as salt concentration or electrical conductivity), rather than as an ion-specific issue (e.g. [54–57]). The challenge in both cases is general applicability of findings as it is well known that ion composition is important to overall salt toxicity [30,58–62]. Additional references can be found in review articles [63–69]. Salt toxicity has been found to vary greatly among aquatic species, with recent data showing that some mayflies and juvenile mussels are among the most sensitive species tested [34,52,56,70]. The combination of salt sensitivity and elevated ambient salinity suggests that, at least at times, salt may reach levels that may have a negative affect on aquatic organisms [10,31,71–76].

There are two challenges in understanding the potential salinity toxicity under field conditions in colder climates where de-icing salts can increase salinity dramatically during snow/ice storms. First, most salt toxicity studies have been conducted at constant 17–25°C, which are the recommended test temperatures for standard acute and chronic toxicity tests for many species, [77,78]. However, in colder climates where de-icing salts are frequently used, water temperature can vary naturally across seasons, with winter lows of 0–10°C versus summer highs of 20–30°C (e.g. figure 1). In addition, there can be significant differences among years (e.g. an interannual range of 10°C or more; figure 1). It has been found that temperature can affect toxicity of many chemicals [79–86]. For most toxins and species, the relationship between temperature and toxicity is positive—increases in temperature result in increased toxicity (i.e. a lower LC50). Mayer & Ellersieck [80] summarized the relationship as a 10°C increase in temperature results in a two- to fourfold decrease in the LC50. Second, streams and rivers that exhibit a long-term increase in Na and Cl concentrations also often exhibit a strong seasonal cycle that includes frequent, short-term snow and ice events when salinity can be many times greater than at base flow (figure 2) [87,88]. This is a sharp contrast to streams with little urbanization (e.g. figure 1 and [88]). Unfortunately, the magnitude and duration of these events are often not well quantified in the historic data because these data are primarily periodic grab samples while snow and ice events are better described with a continuously recording sensor. While the recent studies of salt toxicity have addressed the range of conditions needed to set regulatory limits [47,89], they have not included seasonal temperature variation as part of their analyses.

This paper describes a series of experiments that examine lethal responses of mayfly (Ephemeroptera) larvae in acute (96 h) exposures to elevated salinity (i.e. NaCl added to moderately hard source water) at five to seven different temperatures. The results show how understanding the experimental relationship between temperature and salt toxicity can provide important insight into the toxicity of ambient salt concentrations, especially those originating from winter de-icing programmes.

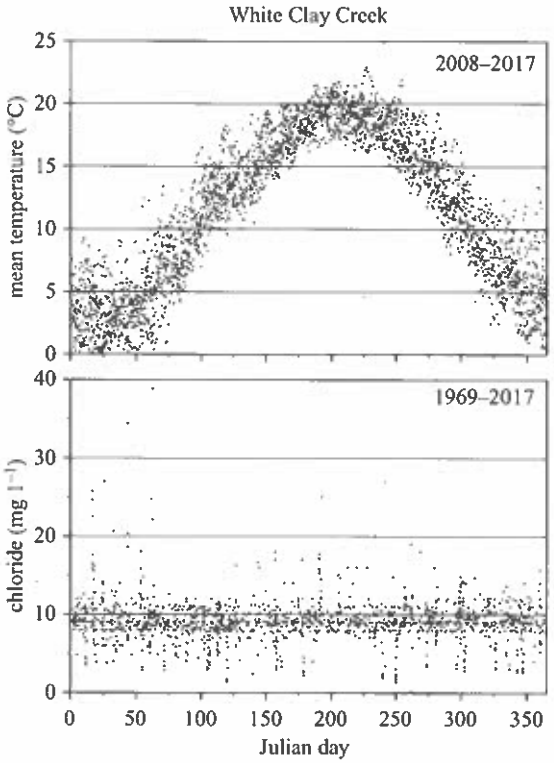

Figure 1. Long-term seasonal variation (date plotted as Julian day) in water temperature (mean daily from various continuous recorders, 2008–2017) and chloride concentration (from grab samples, 1969–2017) for White Clay Creek at the Stroud Water Research Center, 39°51′38.41″ N, 75°47′01.96″ W. Values greater than 20 mg Cl l^{-1} are presumably evidence of local de-icing efforts during winter. (Online version in colour.)

2. Methods

(a) Source water

Water for all tests was collected from White Clay Creek at the Stroud Water Research Center (39°51′38.41″ N, 75°47′01.96″ W), Chester Co. Pennsylvania, a limestone-influenced, headwater stream that drains a 7 km^2, rural (less than 0.5% developed) watershed and is moderately hard (mean 97 mg CO_3^{2-} l^{-1}) with relatively low salinity (143.8 mg l^{-1}, table 1). Seasonal patterns in temperature and chloride (as an indicator of de-icing salts affecting background salinity) from long-term data for White Clay Creek are shown in figure 1. The temperature treatments (see below) are representative of the range of conditions these test mayfly populations have experienced for generations in White Clay Creek. In contrast, the relatively low salinity in the historic data suggests that these wild mayfly populations from White Clay Creek have not been exposed to sodium or chloride concentrations similar to those in our experimental treatments in the last 50 years. Background concentrations on four dates when water was collected for laboratory bioassays averaged 6.6 mg l^{-1} for sodium and 12.3 mg l^{-1} for chloride (table 1).

To provide context for laboratory results, field data were collected every 5 min (30 Mar 2017–1 May 2018) with a Decagon CTD-10 (electrical conductivity or specific conductance corrected to 25°C, temperature, depth) sensor in Rocky Run, First State National Historic Park, New Castle County, Delaware, USA (39°49′00.45″ N and 75°33′02.84″ W), which drains a highly urbanized (60% developed), 2 km^2 watershed about 20 km from the Stroud Water Research Center. Salinity for Rocky Run was estimated from the conductivity : salinity relationship used in our experiments with White Clay Creek water, where salinity =

(b) Study species

Mayflies were chosen for this study because Ephemeroptera are ecologically significant in most streams and rivers, and they are considered pollution sensitive and have historically played important roles in water quality monitoring programmes [90–92]. We quantified acute responses to short-term (96 h) chloride exposures for four mayfly species that are common in White Clay Creek (where test species were collected) and widely distributed in eastern North America. *Neocloeon triangulifer* (McDunnough 1931) was until recently called *Centroptilum triangulifer* [93] and before that *Cloeon triangulifer* [94]. It is a parthenogenetic (clonal) mayfly species [95,96] that is most abundant during summer, when it has a relatively rapid larval development (egg hatch to adult in 25–30 days at 20°C). We worked with Stroud Water Research Center (SWRC) Clone WCC-2®, which occurs in low larval numbers during the winter, with minimal growth below 9.6°C. This specific clone has also been recently used in a number of experiments examining the toxic effects of cadmium, mercury, selenium and zinc [97–102], and chloride and sulfate salts [34,36,38–40]. *Procloeon fragile* (McDunnough 1923) was for many years called *Centroptilum fragile* [94]. It is a sexual mayfly species that exhibits a life history similar to that of *N. triangulifer* except that it has a winter egg diapause. *Maccaffertium modestum* (Banks, 1910) was long known as *Stenonema modestum*, but was recently reclassified [103]. It is a sexual

species that exhibits a bivoltine or multivoltine life history at White Clay Creek, with larval development of about 80 days at 20°C. *Leptophlebia cupida* (Say 1923) is a sexual mayfly species that exhibits a univoltine life history that begins with eggs hatching in mid-June and adult emergence the following April.

(i) Experimental treatments

We quantified acute responses of four mayfly species in short-term (96 h) exposures to elevated NaCl (A.C.S. reagent; J.T. Baker 33624-05). NaCl was chosen for these experiments because it represents 90–98% of the rock salt (halite) used for de-icing roads [104]. We conducted 100 temperature-specific acute tests (each test had one replicate of 20 individuals for each salinity treatment), with 20 newly hatched 1st instar larvae for *N. triangulifer*, *P. fragile*, *L. cupida* or *M. modestum* placed in a 30 ml beaker containing 15 ml of treatment solution. Newly hatched larvae were chosen because younger/smaller individuals are often more sensitive than older/larger individuals of the same species [55,105–107].

Each toxicity test had six treatments: a control (0 mg NaCl l^{-1} added to White Clay water) and five elevated salinity treatments that represented a 50% dilution series (i.e. 412, 824, 1649, 3297, 6594 mg NaCl l^{-1} added to White Clay water for *N. triangulifer* and *P. fragile*, and 824, 1649, 3297, 6594, 13 188 mg NaCl l^{-1} added to White Clay water for *L. cupida* and *M. modestum*). These were static (no renewal) experiments, conducted at five to seven constant (±0.1°C) temperature treatments (i.e. 10, 12.5, 15, 20, 25°C for all species, with the addition of a 7.5°C treatment for *M. modestum* and 5 and 7.5°C treatments for *N. triangulifer* and *L. cupida*). A diatom slurry (i.e. *ca* 20 µl of biofilm scrapings suspended in White Clay water) was provided as food in each test vessel for *N. triangulifer* and *P. fragile*. Food was not provided in *L. cupida* and *M. modestum* tests. Four replicate tests were run for each temperature treatment. Photoperiod (light : dark) was 16 : 8 h during the tests. Temperature in the rearing system was recorded every 5 min, and calibrated with a certified thermometer. Salinity across treatments was monitored with a calibrated conductivity meter.

Mayfly response was reported as survivorship after 96 h, and summarized as the lethal salinity associated with 50% mortality (or LC50) estimated using the nonparametric trimmed-Spearman–Karber method [76,108] of test population at a specific temperature. The relationship between temperature and LC50 for each species was assessed with a simple linear regression of geometric means. Linear regressions were used because it was a simple assessment of the relationship between five to seven temperature treatments and salinity toxicity, and because regression slope was consistent across the temperature range, which facilitates interpretation and incorporation into regulatory standards.

3. Results and discussion

(a) Interspecific differences in mayfly sensitivity to elevated salinity

Control survival was greater than 90% in most of the acute toxicity tests reported for *P. fragile*, *N. triangulifer* and *L. cupida*, and those tests with slightly higher control mortality were still included in these analyses as their dose-responses were similar to other tests. Survival was less than 90% for many tests with *M. modestum* (suggesting this species should be fed during 96 h tests), but the response to temperature was similar to the other mayfly species and is included in this report. However, because of low control survival, the LC50s for *M. modestum* should be used with caution until further verification.

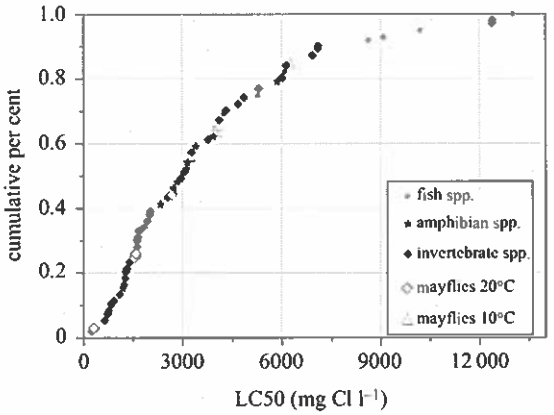

Figure 3. Relative sensitivities for the mayflies *N. triangulifer*, *P. fragile*, *M. modestum*, and *L. cupida* based on LC50s (expressed as mg Cl l^{-1}, electronic supplementary material, table S1) for 10 and 20°C (table 2) plotted with fish, amphibian and invertebrate data included in fig. 3 from [52].

Mean LC50s estimated by the nonparametric trimmed-Spearman–Karber method are expressed as salinity (mg l^{-1}) and electrical conductance (µS cm^{-1}) in table 2. We prefer to compare toxicities among mayflies at 20°C because it appears in some mayfly species we have examined that 25°C is physiologically stressful, independent of the chemical stressor being evaluated. Based on acute LC50s at 20°C, *P. fragile* was most sensitive (LC50 = 767 mg l^{-1}, 1447 µS cm^{-1}), followed by *N. triangulifer* (2755 mg l^{-1}, 5104 µS cm^{-1}) and *M. modestum* (2760 mg l^{-1}, 5118 µS cm^{-1}), and finally *L. cupida* (4588 mg l^{-1}, 8485 µS cm^{-1}) (table 2). NaCl toxicity for *N. triangulifer* has been examined in earlier studies [34,36,39], but all at 25°C. The acute LC50 for *N. triangulifer* at 25°C in our study was markedly lower than LC50 we observed at 20°C as well as the LC50s estimated by Soucek & Dickinson [34], Struewing *et al.* [36], and Soucek *et al.* [39]. Our LC50s for 25°C for all four mayfly species were not out of line with LC50s from colder temperature treatments, and the temperature versus LC50 regressions fitted the data relatively well (see below), so we do not currently have an explanation for differences observed among the studies of *N. triangulifer*. When salinity was expressed as electrical conductivity (µS cm^{-1} or mS cm^{-1}), the LC50s we observed for the baetids *P. fragile* and *N. triangulifer* (1447–5104 µS cm^{-1}) were similar to those observed for the baetid *Centroptilum* sp. (1.8–5.6 mS cm^{-1} in [59], and 10 mS cm^{-1} in [57]), and less than was observed for the baetid *Cloeon* sp. (21 mS cm^{-1} in [57]).

Mayflies are generally considered pollution sensitive, and are important contributors to metrics used to assess pollution impacts [90–92]. When we compared the LC50s for our mayflies at 20°C (expressed as mg Cl l^{-1}, electronic supplementary material, table S1) relative to the acute LC50s included in fig. 3 of [52], *P. fragile* was among the most sensitive species, *M. modestum* and *N. triangulifer* was moderately sensitive (*ca* 25th percentile) and *L. cupida* was average (45th percentile) (figure 3). Relative sensitivity for mayflies in our study would be even higher if we used LC50s from the common test temperature of 25°C (table 2)—*P. fragile*, *N. triangulifer* and *M. modestum* would be among the most sensitive, and *L. cupida* would be moderately sensitive.

Electronic Filing: Received, Clerk's Office 3/14/2019

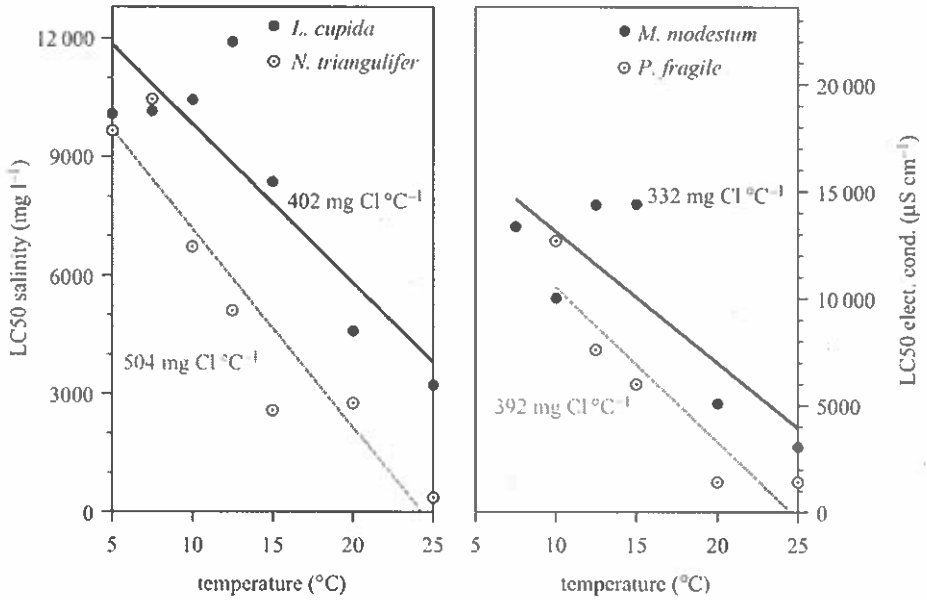

Figure 4. Simple linear regressions describing the relationship between temperature and acute salinity LC50s for the mayflies *L. cupida*, *N. triangulifer*, *M. modestum* and *P. fragile*.

Table 3. Simple linear regression results for figure 4 describing the relationship between temperature and acute salinity toxicity expressed as LC50 (geometric means, mg l^{-1}).

species	*N*	Pr > F	R^2	intercept	slope
N. triangulifer	7	0.002	0.881	12 211.2	−503.7
P. fragile	5	0.026	0.850	9616.0	−391.8
L. cupida	7	0.011	0.756	13 851.5	−402.2
M. modestum	6	0.052	0.653	10 425.3	−331.9

Conversely, the mayflies in our study would not be considered sensitive if we used LC50s from the 10°C test temperature (figure 3) We saw similar relative sensitivity when our study mayflies were compared to the mayflies and other macroinvertebrates presented in Wang *et al.* [70], and in the broader global survey of salinity sensitivity for mayflies and other macroinvertebrates in Kefford *et al.* [56].

The four mayfly species included in our study were not selected based on presumed or known pollution sensitivity. In fact, it is possible there are mayfly species that are as or more sensitive to elevated salinity than the species we examined. Our data, in combination with other published observations such as Wang *et al.* [70] and Kefford *et al.* [56], support the general belief that mayflies as a group are relatively sensitive to elevated salinity, although the physiological mechanisms surrounding mayfly sensitivity to salt remain to be determined [109]. Cormier *et al.* [110] defined a maximum acute benchmark of 680µS cm^{-1} for salinity derived from field observations of occurrence for 142 stream macroinvertebrate genera and annual chemistry data. While this hypothetical benchmark might not be directly comparable with our laboratory studies (Cormier *et al.* [110] eliminated several sites with high chloride), 680 µS cm^{-1} (=369 mg l^{-1} in our study) would appear to be over-protective for all species based on the LC50s at 5–10°C, and protective for *N. triangulifer*, *M. modestum* and *L. cupida*, and possibly *P. fragile*, based on the LC50s at 20°C. The benchmark might not be protective for *P. fragile* and *N. triangulifer* based on the LC50s at 25°C.

It is important to note that salinity toxicity is known to vary among salts and dilution waters tested [30,39,41,47,58–61], so our toxicities for elevated salinity that is predominately NaCl must be used with caution when referring to other de-icing and anti-icing salts such as $MgCl_2$, $CaCl_2$, KCl or calcium magnesium acetate ($CaMg_2(CH_3COO)_6$), to the 'chemical cocktail' that characterizes the Freshwater Salinization Syndrome [29], or to ambient waters with natural salinities that are markedly lower or higher than in White Clay Creek (e.g. a soft-water stream or a limestone stream).

(b) Changes in salinity toxicity in response to temperature

The relationship between salinity toxicity and temperature is important because, in regions where de-icing salts are frequently used, water temperature can change significantly with seasons (figure 1). Moreover, salinity from de-icing efforts peaks following snow and ice events when stream temperature is often nearest its lowest level, and well below the 20 or 25°C temperature used in standard bioassays (figure 2). We observed a significant or nearly significant ($n = 5–7$, $R^2 = 0.65–0.88$, $p = 0.052–0.002$) decrease in toxicity (i.e. acute LC50s increased) as temperature decreased for all four species (figure 4 and table 3). Based on the

Electronic Filing: Received, Clerk's Office 3/14/2019

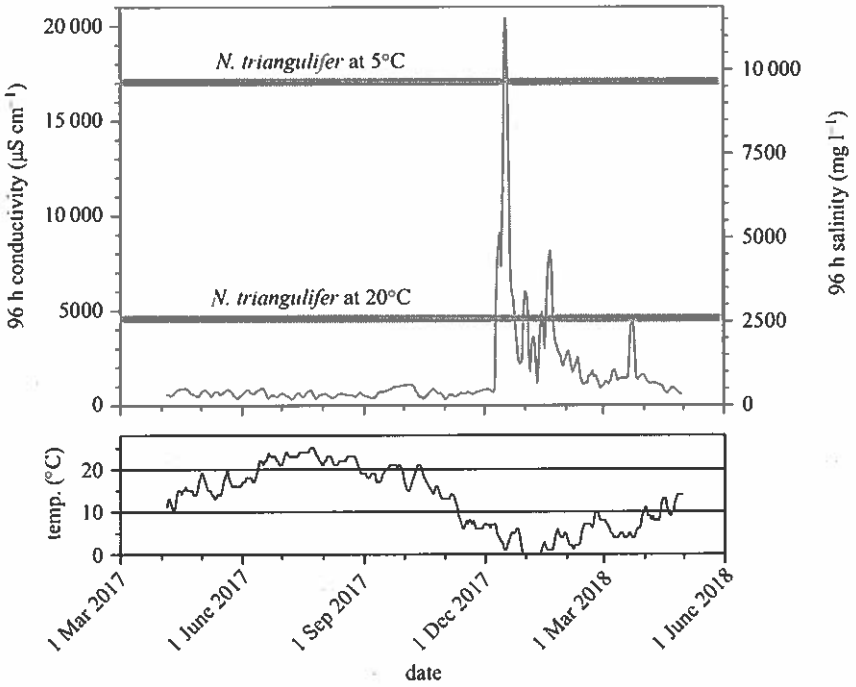

Figure 5. Plot showing mean 96 h LC50 for *N. triangulifer* at 5 and 20°C with seasonal variation (from 30 March 2017 to 1 May 2018) in 96 h running salinity as conductivity (µS cm^{-1}) and mg l^{-1}, and 96 h mean running daily temperature (°C) for Rocky Run, First State National Historic Park, New Castle County, Delaware, USA. (Online version in colour.)

regression slopes, the rate of change was similar for *P. fragile*, *M. modestum* and *L. cupida*. Their LC50s decreased between 332 and 402 mg l^{-1} for each 1°C increase in temperature. The response for *N. triangulifer* was somewhat stronger and its LC50s decreased 504 mg l^{-1} for each 1°C increase in temperature. The LC50s for *L. cupida* and *M. modestum* increased 1.7–1.9-fold for each 10°C decrease in temperature while the LC50s for *N. triangulifer* and *P. fragile* increased 3.5–3.6-fold for each 10°C decrease. This difference between *L. cupida* and *M. modestum* versus *P. fragile* reflects the estimated LC50s relative to the rate of change per °C. The species with lowest LC50 (*P. fragile*) increased proportionally more per °C than species with higher LC50s (*L. cupida* and *M. modestum*). The higher proportional change for *N. triangulifer* reflects a moderately low LC50 with a higher rate of change per °C. Our results almost match the summarization by Mayer & Ellersieck [80] that a 10°C increase in temperature results in a two- to fourfold decrease in the LC50. There are a few studies where reduced salt toxicity has been observed at lower versus higher temperature [73,111,112], but the relationship between acute salt toxicity and temperature has not been quantified in a manner that can be applied to water quality criteria (table 3).

To illustrate how the interaction between temperature and salinity toxicity provides important perspective to understanding aquatic ecosystems receiving de-icing salts, we took the raw data used to generate figure 2 and calculated 96 h (i.e. the duration of the acute toxicity tests) running mean values for conductivity, salinity (from conductivity) and temperature (figure 5). We then added the LC50 for *N. triangulifer* at 5°C and 20°C to figure 5. Based on the LC50 at 20°C, there were 21 dates that were preceded by 96 h with an average salinity that exceeded the LC50 at 20°C. In contrast, based on the LC50 at 5°C (which is more representative of thermal conditions at the time of elevated salinity), there were only two dates that were preceded by 96 h with an average salinity that exceeded the LC50 at 5°C. Thus, accounting for lower salt toxicity for an acute exposure at low temperature can change one's perspective on the apparent toxicity of ambient conditions during winter. However, it is important to note that, even after accounting for lower toxicity at 5–10°C, salinity in Rocky Run still appears to have been acutely toxic (i.e. ≥50% mortality in a 96 h period) for all four mayflies we examined. This suggests that elevated salinity (e.g. averaging 9500–11 500 mg l^{-1} for 96 h) during winter when snow and ice management programmes are being implemented may contribute to the overall impairment of the macroinvertebrate assemblage in Rocky Run, and probably other small urban streams that receive salt-laden runoff from roads, car parks and pavements. However, this is not to suggest that elevated (but not peak) salt concentrations during winter are not contributing to overall impairment. These non-peak exposures are more frequent (i.e. exposure time can be longer), and based on results for polar marine invertebrates, exposure time must be considered in the evaluation and interpretation of potential impact of toxicants at cold temperature [113,114].

(c) Regulatory and management implications of the relationship between salinity toxicity and temperature

As salinization of freshwater ecosystems resulting from de-icing and anti-icing salts continues, the regulatory and management challenge for winter road maintenance programmes will be to balance the need to protect public safety and reduce the economic costs of winter storms with the need to protect environmental health and infrastructure integrity related to excess salt, and to address potential drinking water/public health related to increased dietary intake of

Electronic Filing: Received, Clerk's Office 3/14/2019

sodium [4,21,115,116]. Our study found low temperature can reduce the frequency or intensity of salt-related toxic events expected based on winter de-icing activities that increase NaCl concentrations. But it also shows that NaCl concentrations during winter can be so high that NaCl-related toxic events may still occur even after accounting for low temperature. Our results can also be applied to other activities that result in acute exposure to elevated salt. For example, spills or discharges of high salinity wastewaters such as oil and gas brine [6,7] may have more of an impact in summer, when both the stored wastewater and receiving stream water are seasonally warmer, than in winter, when both are cool. The negative relationship between temperature and salt toxicity we observed highlights the potential importance in considering water temperature when interpreting current environmental conditions or events, or setting regulatory standards for salinity or NaCl.

Abstract: The ions Na^+, K^+, Ca^{2+}, Mg^{2+}, Cl^-, SO_4^{2-}, and HCO_3^-/CO_3^{2-} (referred to in the present study as "major ions") are present in all freshwaters and physiologically required by aquatic organisms but can increase to harmful levels from a variety of anthropogenic activities. It is also known that the toxicities of major ion salts can vary depending on the concentrations of other ions, and understanding these relationships is key to establishing appropriate environmental limits. The authors present a series of experiments with *Ceriodaphnia dubia* to evaluate the acute toxicity of 12 major ion salts and to determine how toxicity of these salts varies as a function of background water chemistry. All salts except $CaSO_4$ and $CaCO_3$ were acutely toxic below saturation, with the lowest median lethal concentrations found for K salts. All 10 salts that showed toxicity also showed some degree of reduced toxicity as the ionic content of the background water increased. Experiments that independently varied Ca:Mg ratio, Na:K ratio, Cl:SO_4 ratio, and alkalinity/pH demonstrated that Ca concentration was the primary factor influencing the toxicities of Na and Mg salts, whereas the toxicities of K salts were primarily influenced by the concentration of Na. These experiments also indicated multiple mechanisms of toxicity and suggested important aspects of dosimetry; the toxicities of K, Mg, and Ca salts were best related to the chemical activity of the cation, whereas the toxicities of Na salts also reflected an influence of the anions and were well correlated with osmolarity. Understanding these relationships between major ion toxicity and background water chemistry should aid in the development of sensible risk-assessments and regulatory standards. *Environ Toxicol Chem* 2016;35:3039–3057. INTRODUCTION

Inorganic ions generally present at the highest concentrations in freshwaters are Na^+, K^+, Ca^{2+}, Mg^{2+}, Cl^-, SO_4^{2-}, and HCO_3^-/CO_3^{2-} (referred to as "major ions" herein) and are used to describe the basic chemistry of natural waters [1]. All have physiological roles and are actively regulated by aquatic organisms [2] but can also cause toxicity when present in sufficient excess [3]. Concentrations in natural waters are governed by a variety of atmospheric, geochemical, and biological processes [1], but these natural concentrations can be greatly increased by a wide variety of anthropogenic influences, such as mineral mining, oil and gas extraction, irrigation, road deicing, water softening, and wastewaters from various industrial processes.

A variety of studies have shown or implicated major ions as causes of aquatic toxicity in surface waters, with sources such as oil and/or gas production [4,5], irrigation return flows [6,7], mining [8,9], road salt [10], and industrial wastewater [11]. In fact, toxicity identification studies on industrial and municipal effluents have shown major ions to be among the more common causes of effluent toxicity [12]. Field studies in Appalachian streams have also found associations between changes in macrobenthic communities and increased major ion concentrations from mining activities [13–15].

Understanding the aquatic hazards posed by increased major ion concentrations presents a number of challenges. First, concentrations of major ions cannot be manipulated individually because charge balance demands that increased concentrations of any ion be offset by equal and opposite charge from other ions, making it more difficult to infer the effects of individual ions. Second, the relative concentrations of major ions vary widely across watersheds and anthropogenic inputs, and such differences are known to influence aquatic toxicity. For example, based on total salt concentration, a 1:1 mixture (by mass) of NaCl and $CaCl_2$ has substantially lower acute toxicity to *Ceriodaphnia dubia* than either salt alone [3], indicating that toxicity of this salt mixture is not simply additive. Third, the toxicity of a single salt can vary based on the characteristics of the water to which it is added, such as water hardness [16–20] and, more specifically, Ca [21]. Although relationships between water hardness and the toxicity of various other chemicals are often attributed, explicitly or implicitly, to the Ca and Mg ions that comprise most hardness, more detailed studies sometimes show that the concentrations of other ions covarying with hardness are playing important roles. For example, though "hardness" was long reported to influence toxicity of metals such as copper, later research demonstrated more detailed roles of specific ions; this enhanced understanding was incorporated into a more refined toxicity model, the biotic ligand model [22].

In previous work, Mount et al. [3] approached the toxicity of major ion mixtures by developing a multivariate regression model based on a large number of acute toxicity tests conducted with many different combinations of major ion salts. The resulting models predict the survival of 3 test species,

cladocerans *Ceriodaphnia dubia* and *Daphnia magna*, and the fathead minnow (*Pimephales promelas*) based on concentrations of the 7 major ions. Although this model represented a step forward in addressing the complexities of evaluating ion mixtures and showed effectiveness as a predictive tool [5,23], there are important aspects of major ion toxicity that were not fully addressed. Notable among these was that all of the ion solutions tested were created by adding ions to a single base water. This issue underlies the failure of the model to represent some influences of background water chemistry on ion toxicity, such as the reduction of NaCl and Na_2SO_4 toxicity afforded by adding hardness within ranges common to natural waters [16–21]. Other aspects of the interactions among the ions (e.g., independent vs additive toxicity) also are incompletely addressed by this regression model.

The present study is the first of 3 articles that establish a better foundation for predicting the acute toxicity of elevated major ion concentrations to *C. dubia*. The present study describes a comprehensive study of the influence of background water chemistry that extends earlier work on hardness effects [16–21] to more water chemistry factors and to more major ion salts. Toxicities of major ion salts were evaluated using a wide range of dilution waters; some mimicked natural waters, while others were designed specifically to isolate different components of background water chemistry to better understand their roles in influencing major ion toxicity and thereby determine what is important to risk assessment of ions in natural systems.

These experiments also allowed preliminary consideration of exposure metrics that more effectively describe major ion toxicity to *C. dubia* than total salt concentration. For example, are there different toxicity mechanisms among the salts that need to be addressed? Should the toxicity of a salt be related to an individual ion or both ions, and how should concentrations of multiple ions be combined? Should reductions in toxicity attributable to the formation of complexes between ions and to the general effects of high ion concentrations on chemical reactivity be addressed?

The second article will present results of mixture tests with pairs of salts to more rigorously address the preceding questions. The third will address how the information from the other articles can be incorporated into a mathematical model applicable to any ion mixture and will test the predictions of that model for more complex mixtures relevant to field exposures.

The acute toxicity to *C. dubia* was selected as the endpoint for these efforts because this is a widely distributed organism with considerable sensitivity to ions and for which it was practical to conduct the large number of tests needed to adequately address the multiple factors and interactions of interest. The knowledge gained from the present study with *C. dubia* supports more informed testing and model development for other endpoints and species, which are now under way and will be the subject of additional publications. When combined with the efforts of other investigators, this body of information will support better assessment of the risks of major ions to aquatic communities.

MATERIALS AND METHODS

Test water composition and study design

Twenty-six experiments were conducted on the acute toxicity of individual major ion salts to *C. dubia*. Each experiment consisted of 3 to 8 simultaneous toxicity tests with different combinations of dilution waters and toxicants, for a total of 149 median lethal concentration (LC50) determinations. Test waters were developed from deionized water, sand-filtered and ultraviolet light-treated Lake Superior water (LSW), or a combination of both. Deionized water was produced from a Millipore Super-Q system configured as specified by the US Environmental Protection Agency (USEPA) [24]. Lake Superior water was obtained from an intake located offshore from our laboratory at 46.840°N, 92.004°W; typical hardness and alkalinity are 47 mg/L and 43 mg/L as $CaCO_3$, respectively, with conductivity of 104 µS/cm and pH approximately 7.5. The full ionic composition of LSW is provided in Table 1.

Table 1. Composition of dilution waters

Dilution water description	Abbreviation	Base water	Na (mg/L)	K (mg/L)	Ca (mg/L)	Mg (mg/L)	Cl (mg/L)	SO_4 (mg/L)	Alkalinity (mg $CaCO_3$/L)	Hardness (mg $CaCO_3$/L)

[a]Organisms from both amended ALSW cultures also tested in 1× ALSW.
[b]Organisms from both cultures also tested in 1× MHRW.
[c]Duplicate tests conducted which also included 1× ALSW.
ALSW = amended Lake Superior water; MHRW = moderately hard reconstituted water.

Some test waters were based on the commonly used reconstituted water formulas given by the USEPA [24] and originally proposed by Marking and Dawson [25], specifically the formula for "moderately hard reconstituted water" (MHRW), which was also used by Mount et al. [3]. While commonly used, MHRW (and other reconstituted waters based on this formula) has a chemistry (Table 1) that is atypical for surface waters of the United States: the Ca:Mg ratio is low, the $Cl:SO_4$ ratio is very low, and the Na concentration is extremely high relative to hardness. The high Na concentration is a consequence of using $NaHCO_3$ to impart alkalinity; in nature, alkalinity generally comes from dissolution of carbonate minerals of Ca and Mg, but these have solubilities and dissolution rates that are inconveniently low for water preparation in the laboratory. The low Ca:Mg and $Cl:SO_4$ ratios in MHRW are not a practical requirement, and the reason for their original selection is not clear.

To design a dilution water with chemistry more like natural waters, we analyzed data from the US Geological Survey national stream water-quality monitoring networks [26]. Data records were obtained for 425 sites in operation from 1983 to 1992. Records ($n = 32\,895$) were used that had 1) measurements for all major ions, 2) a charge imbalance of no more than 10%, 3) a hardness ≥ 10 and ≤ 400 mg/L as $CaCO_3$, and 4) pH no lower than 6.0. These data were subjected to regression analyses using Sigmaplot (v11.0; Systat Software) to establish relationships between log(hardness) and the logarithms of various other ion concentrations and ratios. A formula was then developed for an "amended Lake Superior water" (ALSW; Table 1) consistent with these relationships. Salts were added to LSW to increase hardness to the estimated geometric average (53.3 mg $CaCO_3$/L) in the US Geological Survey data for the alkalinity of LSW (43.0 mg $CaCO_3$/L) and to increase other ions to average values for this hardness. Benefits of modifying LSW to create this test dilution water, rather than creating a completely synthetic water from deionized water, are that it provides alkalinity without having to dissolve carbonate salts or add excessive Na and that it will contain trace constituents from the source water that make the water more realistic and possibly beneficial to the test organisms.

The present study was organized into 12 sets of 1 to 4 experiments addressing different aspects of dilution water chemistry or experimental procedure. These sets of experiments and the toxicants that were tested are summarized in Table 2, and the chemistries of the various dilution waters are provided in Table 1. The purpose and design of each experimental set were as follows.

Sets 1 and 2: Effects of acclimation to dilution water. Some previous studies of the effect of dilution water on major ion toxicity to *C. dubia* used organisms that were cultured in the dilution water prior to testing [16–20]. This was not done routinely in the present study because the logistics involved in culturing organisms in so many different dilution waters (Table 1) were prohibitive. However, because a preliminary comparison of NaCl toxicity in MHRW and MHRW diluted by a factor of 3 (1/3× MHRW) showed much less of an impact of this dilution than the 1×, 1/2×, 1/4×, and 1/8× MHRW series tested by Elphick et al. [19], we conducted experiments to determine whether observed salt toxicity in waters more dilute than MHRW or ALSW varied significantly depending on whether the organisms were cultured in these dilute test waters or in the standard-strength water formulations. Initially, organisms from our primary culture (in 1× MHRW) were used to create secondary cultures in 1× MHRW, 1/3× MHRW,

R04563

 Electronic Filing: Received, Clerk's Office 3/14/2019

1× ALSW, and 1/3× ALSW, which were maintained for a minimum of 2 generations before being used in tests. The toxicities of NaCl and $MgCl_2$ in 1/3× MHRW and 1/3× ALSW were simultaneously tested using the cultures from both the dilute water and the corresponding full-strength water (Table 2, set 1). For NaCl, tests were also conducted in 1x ALSW using both the 1× ALSW and 1/3× ALSW cultures. To further explore this issue, we conducted additional acclimation studies (Table 2, set 2) comparing the toxicity of several salts in 1/8× MHRW using *C. dubia* cultured in MHRW and in 1/8× MHRW (the same composition as the 10 and 80 hardness waters in the Elphick et al. [19] study). For NaCl, tests were also conducted in 1× MHRW using both cultures.

Set 3: Salt toxicity in MHRW versus ALSW. Because ALSW was developed in response to concerns about the composition of MHRW and because much existing ion toxicity information was conducted in MHRW or similar waters, comparative toxicities in these 2 waters were of interest. Therefore, a set of experiments (Table 2, set 3) compared the toxicity of all major ion salts in MHRW and ALSW, except for $CaSO_4$ and $CaCO_3$, for which preliminary experiments showed no toxicity at saturation in these waters.

Set 4: Salt toxicity in different strengths of ALSW. Natural waters vary widely in total ion concentration, the 10th and 90th percentiles in our analysis of US Geological Survey data being approximately 1.5 mEq/L and 16 mEq/L for the sum of major cations and anions. To determine the effect of varying overall ion concentrations, another set of experiments (Table 2, set 4) compared toxicities of 9 salts in dilution waters that had one-third and 3 times the ion concentrations of ALSW (1/3× ALSW and 3× ALSW; Table 1). We note that, in natural waters, average concentrations of the various ions do not vary exactly in proportion with total ion concentrations, so 1/3× ALSW and 3× ALSW do not match our estimated field water averages at the same hardnesses, which are also provided in Table 1 for comparison purposes. We elected not to match the field chemistry so that all ions would be in the same proportions across the 1/3×, 1×, and 3× ALSW series but the ion ratios would still be well within the ranges observed in the US Geological Survey data.

The results of these tests were combined with separate data for 1× ALSW (from set 3) to compare across a 1/3×, 1×, and 3× ALSW dilution water series; for NaCl and Na_2SO_4 an additional experiment simultaneously tested this entire series to verify results. Preparation of 1/3× ALSW was simply by dilution of ALSW with deionized water. Creating the 3× ALSW chemistry required dissolution of $CaCO_3$ to provide higher alkalinity while maintaining the desired cation ratios, in addition to adding other more soluble salts. This was accomplished by adding the appropriate amounts of the various salts to LSW in a large graduated cylinder and bubbling CO_2 gas through the solution until pH stabilized near 5.0 and all salts were dissolved. The solution was then aerated with ambient air until pH was approximately 7.8.

Sets 5–7: Effects of modifying specific ion ratios. Most previous work on the effects of dilution water chemistry on major ion toxicity to daphnids has focused on water hardness [16–20] as a generalized parameter without parsing the influence of other ions that covaried with the hardness, although Davies and Hall [21] did identify Ca as being more important than Mg for the effects of hardness on Na_2SO_4 toxicity. Regarding other ions in dilution water, Soucek [17] reported an ameliorative effect of low concentrations of added NaCl on the toxicity of Na_2SO_4 to *Hyalella azteca* (attributed to the chloride requirements for this species) but no such effect on *C. dubia*. At higher NaCl concentrations, there was an exacerbation of Na_2SO_4 toxicity for both species, attributed to additive toxicity of the 2 salts. Soucek et al. [18] also reported a small increase in apparent NaCl toxicity when Na_2SO_4 was added, again attributed to additive toxicity of the 2 salts.

To more completely evaluate the influence of particular dilution water characteristics on the toxicity of major ion salts, we tested selected salts in ALSW modified to provide different ratios of certain ion pairs, based on the tails of the distributions of these ratios in our analysis of US Geological Survey data. Waters with high Ca:Mg (13.6 by mass) and low Ca:Mg (0.27) ratios (Table 2, set 5) were created by changing the salts added to LSW to achieve the target ratios without altering concentrations of any other ions in the water (Table 1). Similar approaches were used to create waters with high and low $Cl:SO_4$ ratios (4.2 and 0.072 by mass; Table 2, set 6) and high and low Na:K ratios (38 and 0.19 by mass; Table 2, set 7). Some of these waters required that LSW be initially diluted with deionized water to lower the concentrations of a target ion to its lowest value, followed by addition of salts to match the ALSW chemistry except for the ion pair being manipulated (Table 1). Where required, the CO_2-aided dissolution of $CaCO_3$ was used to restore alkalinity to waters based on diluted LSW.

Sets 8 and 9: Effects of manipulating alkalinity and pH. The effects of pH and alkalinity were evaluated in 2 ways. First, the alkalinity of ALSW was reduced to 10 mg $CaCO_3$/L and raised to 90 mg $CaCO_3$/L (resulting, respectively, in pHs of 7.3–7.5 and 8.1–8.3; Table 2, set 8). Alkalinity was raised simply by adding $NaHCO_3$, whereas it was lowered by diluting LSW and adding salts to restore all cations and Cl to their same values as in the high-alkalinity water, with SO_4 replacing the alkalinity (Table 1). Second, pH was reduced to approximately 6.8 and raised to approximately 8.5 (Table 2, set 9) without altering alkalinity or other ions by bubbling the ALSW used in test solution preparation with air containing 1% CO_2 and 0% CO_2, respectively, and enclosing test vessels in sealed chambers containing these same CO_2 concentrations [27].

Set 10: Effect of sodium on potassium toxicity. Based on the results of the tests contrasting MHRW and ALSW (set 3), we hypothesized that the toxicity of K salts was dependent on the Na concentration in the dilution water. To evaluate this hypothesis, the toxicity of KCl was tested in 6 different dilution waters with Na ranging from 1.6 mg/L to 300 mg/L (Table 2, set 10). Test waters were prepared by modifying the formulation of ALSW to have no added Na and Cl, then adding NaCl to achieve the desired levels of Na (Table 1).

Set 11: Effects of time-dependent calcium precipitation. Testing of the toxicity of $NaHCO_3$ and $MgCO_3$ resulted in oversaturation of $CaCO_3$ and possible loss of Ca from solution, which would affect toxicity given the established ameliorative effect of Ca. Although Ca was monitored in these tests, the sampling was too limited to precisely determine the Ca concentration to associate with the LC50. Therefore, an additional experiment was conducted to more thoroughly characterize the dependence of any Ca loss on time and test salt concentration. This was a 2 × 2 × 2 factorial experiment, the 3 factors being test salt ($NaHCO_3$, $MgCO_3$), dilution water (1× ALSW, 3× ALSW), and solution age (freshly prepared vs aged for 48 h before introducing test organisms; Table 2, set 11). Extra replicate test cups were prepared to allow sampling of Ca at multiple times and treatment concentrations. This experiment provided not only $NaHCO_3$ and $MgCO_3$ LC50s from tests that

R04564

Electronic Filing: Received, Clerk's Office 3/14/2019

were monitored better but also data with which to better estimate Ca concentrations at the LC50 in other CO_3/HCO_3 salt tests.

Set 12: Toxicities of gluconate salts and mannitol. Charge balance requires including both cations and anions in any testing of ion toxicity, making it more difficult to infer the relative toxicities of the individual ions. In addition, results of other experiments in the present study led us to hypothesize that the toxicity of some salts might be related to their effect on the osmolarity of the test solution and thus on the osmotic gradient the organism experiences. To provide more information on the role of the individual cations, we tested the toxicity of the gluconate salts of Na, Ca, and Mg (Table 2, set 12). Gluconate is an organic ion that is not expected to be absorbed appreciably and, thus, should act only through its effect on osmotic potential or on charge gradients, providing an informative contrast to Cl, SO_4, and HCO_3/CO_3. This experiment also evaluated the toxicity of mannitol, a sugar alcohol also not expected to be appreciably absorbed, enabling us to manipulate the external osmolarity without adding any ions. NaCl was also included as a reference major ion salt.

Toxicity test procedures

Salts for all 12 combinations of the 4 major cations and 3 major anions; gluconate salts of Na, Ca, and Mg; and mannitol were obtained from Sigma-Aldrich or Fisher Scientific. All chemicals were American Chemical Society reagent grade or better, with the exception of $MgCO_3$ which was specified as meeting US Pharmacopeia requirements. The certificate of analysis for this salt was used to determine the ratio of $MgCO_3$ to total salt weight for computing nominal $MgCO_3$ concentrations. This certificate of analysis also specified the Ca content to be 0.73% of the Mg content, enough to appreciably affect the background Ca; this was used to adjust the nominal Ca background concentration for tests on the toxicity of $MgCO_3$.

Test organisms were <24-h-old *C. dubia* obtained from in-house cultures. Most test organisms were cultured in MHRW, but organisms for testing the effects of acclimation were also cultured in the dilution waters for the tests (for a least 2 wk prior to the tests); and some tests late in the present study were conducted with organisms cultured in ALSW after a switch of our culture to this water. The culture water for each toxicity test is indicated in Table 3. General culture procedures followed those described by the USEPA [24].

Static 48-h toxicity tests were conducted in 30-mL plastic cups (Berry Plastics) filled with 10 mL test solution and held in polystyrene boards with holes sized to the cups. These boards were floated in a temperature-controlled water bath with a glass sheet covering all test cups. Because preliminary studies indicated that the response curves for major ion salts were quite steep, we used closely spaced exposure concentrations, with each test concentration being approximately 80% of the next higher. Test solutions were prepared by combining the applicable salt and dilution water to achieve the highest test concentration (100%). From this, 2 additional solutions, 80% and 64%, were prepared by dilution of the first; then, each of these 3 solutions was serially diluted by 0.5× to produce a total of 9 to 12 exposure concentrations, plus a dilution water control. The highest salt concentration in each test varied according to its expected toxicity (based on a combination of preliminary testing, any preceding experiments, and literature values), but all tests used the same relative dilution spacing. Most experiments were structured to compare toxicity under 2 related conditions (e.g., high and low Ca:Mg); tests were assigned to experiments such that both conditions would be tested simultaneously for a particular salt, using the same preparation of dilution water and the same cohort of test organisms.

All salts except $CaCO_3$, $MgCO_3$, and $CaSO_4$ could be easily dissolved at concentrations high enough to cause mortality. For $CaCO_3$ and $MgCO_3$, the CO_2 procedure in the description of set 4 was used to dissolve the salts. After adjusting to pH 7.8, $MgCO_3$ solutions so prepared were stable for 48 h at lethal concentrations, thereby allowing for testing as for other salts. However, a 15 mM (1500 mg/L) $CaCO_3$ solution dissolved in ALSW using CO_2 showed substantial precipitation and settling once the pH was raised, with the total concentration being only 6.5 mM at test start and dropping to 2.4 mM (2.2 mM dissolved) after 24 h and to 1.2 mM after 48 h, with no mortality observed. For $CaSO_4$, consistent with the findings of Mount et al. [3], a saturated solution at 16.2 mM (2200 mg $CaSO_4$/L) was not acutely toxic to *C. dubia* in MHRW or ALSW. Based on these results, no further testing was conducted with $CaSO_4$ or $CaCO_3$.

Test cups were usually prepared in duplicate, but in a few tests with CO_3/HCO_3 salts more replicates were used to provide test solution for more monitoring of alkalinity or Ca than in other tests. Each cup received food in the form of 100 μL of a 50:50 mixture of yeast, cereal leaves, and trout chow [24] and algae (*Pseudokirchneriella subcapitata* at 3.5×10^7 cells/mL). Food was added based on previous work indicating that it had minimal effect on toxicity of major ions [3] and to avoid possible stress. Test temperature was 25 ± 1 °C with fluorescent lighting on a 16:8-h light: dark photoperiod. Five *C. dubia* neonates were added to each cup, and survival was determined after 24 h and 48 h of exposure; death was defined as no visible movement after gentle prodding and at least 10 s of observation.

Exposure monitoring

Temperature was monitored daily in test cups from each simultaneous test and continuously in the surrounding water bath. Hardness and alkalinity of dilution waters in every test were measured by titration [28]. For tests with $MgCO_3$ and $NaHCO_3$, alkalinity was also measured in the highest test concentration. Conductivity was used to verify that dilution of the salt solutions was done properly and was measured (model 2052; Amber Science) in each treatment at the start of the exposure, in every treatment that had 100% mortality after 24 h, and in all remaining treatments at 48 h. The pH was measured (PH150 with A57198 probe; Beckman Coulter) at the start of each test in the highest concentration and control (in all concentrations for tests with CO_3/HCO_3 salts), in every concentration that had 100% mortality at 24 h, and in all remaining treatments at 48 h. Dissolved oxygen was measured (model 58; Yellow Springs Instruments) in the highest concentration and control at the start of the test, in the highest and lowest concentrations with 100% mortality at 24 h, and in 2 arbitrarily selected treatments at 48 h.

Because of the large number of exposure treatments (~1500), it was not practical to measure major ion concentrations in every treatment. Instead, the analytical sampling program was structured with 2 primary purposes: 1) to verify that the dilution waters and highest concentrations were prepared properly and 2) to verify the exposure concentrations near the LC50. Accordingly, analytical samples were collected at the start of exposure from each dilution water and from the highest concentration of each salt in each dilution water. In addition, analytical samples were collected from each exposure series after 24 h in the lowest concentration with 100% mortality and at 48 h from the concentration nearest the LC50. Beyond this routine sampling program, some tests included additional

Table 3. Results of tests on the acute toxicity of major ion salts, gluconate salts, and mannitol to *Ceriodaphnia dubia* in various tests waters[a]

[a]See text for designations and formulations for test and culture waters; horizontal gaps delineate experiments and horizontal lines delineate experimental sets. For median lethal concentrations (LC50s), "Probit" denotes exposure-effects curve calculation by probit method; "Midpoint" denotes geometric mean of confidence limits; parentheses denote confidence limits; see text for methodology. Except where noted, LC50s and component concentrations are nominal, and expected to be within +/–10% based on analysis of subset of test solutions.

[b]Ca concentrations are an extrapolation of Ca measurements to median lethal concentration based on model for time dependence of Ca as a function of alkalinity; see Supplemental Data for more information.

[c]Ca concentrations are a weighted average of measurements and 24 and 48 hours that bracket the median lethal concentration.

ALSW = amended Lake Superior water; LC50 = median lethal concentration; MHRW = moderately hard reconstituted water.

sampling from intermediate treatments at the beginning and end of exposure to verify that exposure concentrations were stable over the course of the exposure. Every dilution water was analyzed for all 4 cations plus Cl and SO_4. Because cation analysis was more time-efficient than anion analysis, exposure concentrations of the salt tested were verified by analyzing for its cation. For tests of the toxicity of CO_3/HCO_3 salts, which caused oversaturation of $CaCO_3$ even at the low Ca concentrations in dilution water, Ca concentrations were also measured. In the Ca precipitation experiment with $NaHCO_3$ and $MgCO_3$ (set 11), extra test chambers were used to monitor Ca at 0 h, 24 h, and 48 h at the 25%, 50%, and 100% treatment concentrations, in addition to the cation samples normally taken.

For cation analysis, filtered (0.45-μm nylon syringe filter; Grainger) and unfiltered samples were collected in early experiments; but these analyses consistently showed no significant difference between the 2, so later cation samples were not filtered, except for tests with $NaHCO_3$ and $MgCO_3$ in which $CaCO_3$ precipitation was a concern. Samples for cation analysis were acidified by adding 0.2% (v/v) concentrated HNO_3 and held at room temperature; for tests with $NaHCO_3$ and $MgCO_3$, this amount of acid was increased by an amount calculated to neutralize the extra alkalinity. Cation measurements were made using an Agilent 240 FS flame atomic absorption spectrophotometer (Agilent Technologies), calibrated with a blank and a series of 5 standards, and verified with a quality control standard and an independent calibration standard at both the beginning and the end of the run.

Concentrations of Cl and SO_4 were determined on samples filtered into a polypropylene centrifuge tube, stored under refrigeration, and analyzed within 28 d. Quantifications were made using a Dionex DX600 Ion Chromatograph with an AS50 autosampler, an LC25 chromatography oven, an ED50 electrochemical detector, and a GP50 gradient pump (Thermo Fisher Scientific). A typical instrument run included a blank, a series of 8 standards, a blank spike, and a quality control standard analyzed at both the beginning and the end of the run. Thirteen percent of all ion analyses were run in duplicate; the average relative percentage difference was 1.6% (maximum 8%, standard deviation 1.6%).

Across all test solutions (i.e., samples other than controls) of the 10 major ion salts for which LC50s were determined, comparison of measured and nominal cation concentrations averaged 98.7% with a standard deviation of 4.9% ($n = 329$). Individual results ranged from 83% to 116% of nominal, and 95% fell between 90% and 110% of nominal. Conductivity measurements on all treatments confirmed that the intended gradient of exposure existed among samples not sampled for cation analysis. Based on these results, and the complexity of estimating concentrations in test solutions that were not directly measured, nominal exposure concentrations were used for calculating LC50 values.

Analysis of dilution waters yielded a similarly high average agreement between the measured cation concentrations and nominal values based on past reported measurements (99.3%, $n = 313$) but a higher standard deviation of 10.2%; 97% of values fell between 80% and 120% of nominal and 79% of samples fell between 90% and 110% of nominal. This higher variability is associated with the much lower ion concentrations in control waters, which can inflate percentage error values; in the more dilute waters, K in particular was at very low concentrations, sometimes lower than can be confidently quantified by the methods used (e.g., <0.5 mg/L). Wherever measured concentrations deviated more than 20% from nominal ($n = 8$), all data from that test were reviewed; and in each instance, the information suggested the large deviation was likely spurious (e.g., concentrations of all other ions measured in the same water were close to nominal). Accordingly, ion concentrations in dilution water were also assumed to be equal to nominal in the data analyses, except for Ca concentrations in tests on the toxicity of CO_3/HCO_3 salts, in which case Ca was based on measured concentrations. Because these Ca concentrations varied with time and added salt concentration, this involved interpolation of Ca measurements, which is further discussed in the Supplemental Data.

Data analysis

Concentration–response curves were extremely steep, so that even with the closely spaced exposure concentrations (0.8×), it was common for there to be only 1 (or no) exposure treatment with partial survival less than that attributable to background (control) mortality. For such tests, continuous concentration–effect models cannot be fit to provide point estimates for LC50s. Consequently, a tiered approach was used, based on the type of calculation the data would support. For each test, a background mortality range was defined as all treatments up to the highest concentration at which the fraction of mortality was no greater than at any lower concentration. The number of treatments with partial mortality (i.e., above this background mortality range and below the lowest treatment with complete mortality) was then determined and used to select the type of analysis.

For tests with at least 2 partial mortalities that increased with concentration, a tolerance distribution analysis was conducted, using a 3-parameter model that included a background survival parameter and assumed a log-normal distribution for the lethal concentrations. Parameters were estimated by maximum likelihood analysis using custom software written with Intel Professional Fortran Composer XE 2011. Of the 149 LC50s reported in the present study, 82 supported calculation of such "probit LC50s." The 95% confidence limits were calculated using the likelihood ratio method [29]. Statistical significance of LC50 differences between treatments within an experiment was assessed based on these confidence limits not overlapping, so that such differences have a significance level of at least 95%.

For tests with insufficient partial mortalities for this probit LC50 analysis, the same likelihood ratio method was used to calculate confidence limits for the LC50 (such confidence limits can be assigned even when a unique point estimate for the LC50 cannot be calculated). For these tests, we assigned the geometric mean of these confidence limits to be the point estimate for the LC50 ("midpoint LC50s"). For cases in which there were no partial mortalities, these confidence limits are the bracketing concentrations (the upper end of the background mortality range and the lowest treatment with complete mortality) and the LC50 is equivalent to linear interpolation of survival versus log concentration between these 2 concentrations. To test the performance of this methodology when tolerance distribution assumptions are met, it was applied to simulated data sets generated based on the range of observed parameters, which demonstrated the bias for LC50 estimation to be <1% and the confidence limits to equal or exceed 95%.

These LC50 calculations were based on the nominal concentration of added salt, without consideration of background ion concentrations, because different ion ratios in the dilution water and the added salt make it impossible to express total ion concentrations as an equivalent concentration of salt. Initial comparisons of how dilution water differences affect salt toxicity are also on the basis of added salt for the same reason.

Electronic Filing: Received, Clerk's Office 3/14/2019

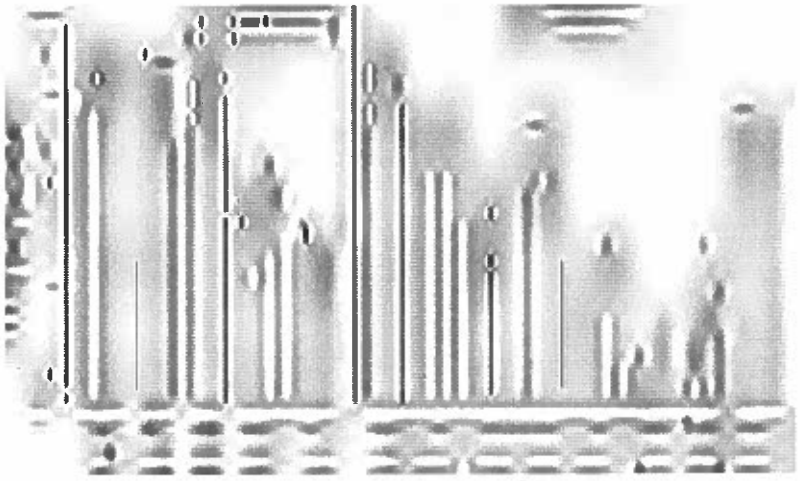

Figure 1. Effects of culturing and testing organisms in different strengths of amended Lake Superior water and moderately hard reconstituted water on median lethal concentrations for selected major ion salts to *Ceriodaphnia dubia*. Error bars denote upper 95% confidence limits, and asterisks denote where confidence limits do not overlap. ALSW = amended Lake Superior water; LC50 = 48-h median lethal concentration; MHRW = moderately hard reconstituted water.

Background concentrations of the component ions of the test salt were <5% in all but 6 tests and never >10%; these had negligible impact on comparisons based on added salt except as noted in *Results and Discussion*. However, for further analyses of the aggregated data, exposure metrics included both background and added ions.

Although test preparation and chemical analysis were based on weight of the salts and the various ions, this is not a good basis for comparing the relative toxicity of the individual salts and ions because the toxic action of these ions should be related to their molarity, not their mass. As such, salt and ion concentrations were converted to molarity, which is the primary basis for toxicity comparisons of the added salts. In addition, evaluation of the dosimetry at these elevated ion concentrations should consider formation of complexes between the various cations and anions, which would affect their chemical reactivities and thus their toxicities. It should also consider that the high ionic strength of these solutions will reduce the reactivity of the ions, as represented in lower activity coefficients, and that exposure metrics thus would be best expressed as chemical activity rather than molarity. To this end, the ion composition at each LC50 was analyzed using the chemical speciation program Visual MINTEQ (Ver 3.0) to estimate chemical speciation and the chemical activity of each chemical species. The osmolarity of each LC50 solution was also calculated based on these MINTEQ activity estimates using the method described by Robinson and Stokes [30].

RESULTS AND DISCUSSION

For each test ($n = 149$), added-salt LC50 values with confidence limits are provided in Table 3, as both milligrams per liter and millimolarity, along with total ion concentrations and osmolarities at these LC50s. The pH associated with each LC50 at the end of exposure is also provided based on measurements in treatments bracketing the LC50. All reported tests had conductivity measurements that varied across treatments in a manner consistent with the intended exposure concentrations, and LC50s directly based on these conductivities are also provided in Table 3. Dissolved oxygen was always above 7.5 mg/L, and temperature was always within 1 °C of 25 °C. Measurements made at the beginning and end of experiments indicated that evapoconcentration during the experiment was low (<5%). Over the background mortality range, as defined in *Data analysis*, survival was ≥90% in all toxicity tests and averaged 98% overall.

Effects of acclimation to dilution water

Figure 1 compares LC50s for *C. dubia* cultured in dilute solutions to those from our standard culture waters. Culturing organisms in 1/3× ALSW or 1/3× MHRW had no significant effect on the toxicities of NaCl and $MgCl_2$, either in test waters at these dilutions or (for NaCl only) in 1× ALSW, the LC50 estimates differing by 20% or less. Culturing organisms in 1/8× MHRW also had no effect on the toxicities of NaCl, $NaHCO_3$, and $CaCl_2$, the LC50s differing by no more than 10%. However, for Na_2SO_4, KCl, $MgCl_2$, and $MgSO_4$, LC50s for 1/8× MHRW test water are 20% to 45% lower for organisms cultured in 1/8× MHRW than those cultured in 1× MHRW, these differences being statistically significant except for $MgCl_2$, for which the LC50 is uncertain because of highly variable responses in this dilute test water.

Thus, "acclimation" to 1/8× MHRW resulted in *C. dubia* being more, rather than less, sensitive to some salts when tested in this dilute solution. Although both we and Elphick et al. [19] established successful cultures in this water, based on our experience with *C. dubia*, such a dilute solution appears to be stressful, an indication of this being the greater variability of organism response to salt toxicity. It is not clear whether this should be considered an artificial stress created by manipulating organisms long adapted to laboratory waters with higher ion concentrations, or a natural consequence for a species not adapted to and not endemic to such dilute waters.

These acclimation experiments were prompted by the work of Elphick et al. [19], who acclimated cultures to dilutions waters (for 2 generations or more) and found that, relative to 1× MHRW, the 7-d NaCl LC50 for *C. dubia* decreased by 2.1-fold in 1/2× MHRW, 3.6-fold in 1/4× MHRW, and 8.4-fold in 1/8× MHRW. In contrast, for organisms both cultured and tested in the waters, we found only a 9% decrease in the NaCl LC50 between 1× MHRW and 1/3× MHRW and only a 1.9-fold decrease between MHRW and 1/8× MHRW (Figure 1). The lack of culture water effect on our LC50s for NaCl suggests that these differences between the 2 studies resulted from other

R04571

 Electronic Filing: Received, Clerk's Office 3/14/2019

factors, such as the longer duration in Elphick et al. [19] or a variability associated with culturing and/or testing *C. dubia* in such dilute waters. More recent communication with J. Elphick has indicated that they have observed variability in NaCl LC50s for *C. dubia* in very dilute test waters (D.R. Mount, personal communication).

Overall, we concluded that the absence of dilution water-specific culturing was not a substantial factor for most of our experiments but that data for the 1/8× MHRW waters should be interpreted with caution. The results presented hereafter will be only for organisms from our standard culture waters and will consider LC50s for the most dilute test waters to be more useful for qualitative insights into ion toxicity rather than establishing quantitative relationships. Any quantitative uncertainties of LC50s for such dilute waters are probably of limited practical concern because few unimpacted surface waters will likely experience elevations of a single salt to toxic levels while other ions remain at such low levels.

Our culture experiments only addressed more dilute waters than our standard culture water because discrepancies of our results from that of Elphick et al. [19] were noted for those waters. Although we did not evaluate effects of culturing at higher ion concentrations, the relationship of our NaCl LC50s to Ca concentration shows good agreement with that of Soucek et al. [18] and Elphick et al. [19], who did culture organisms in their different test waters. Also, Soucek and Kennedy [16] reported only small and statistically nonsignificant differences among Na_2SO_4 LC50s in MHRW for *C. dubia* cultured in MHRW versus MHRW with elevated Na_2SO_4 levels. This suggests that acclimation to higher ion concentrations may not be a significant factor, but more study would be needed to reach a definitive conclusion.

Salt toxicity in MHRW versus ALSW

Figure 2 compares LC50s for 10 major ion salts tested in both ALSW and MHRW. For NaCl, $MgCl_2$, $CaCl_2$, Na_2SO_4, $MgSO_4$, and $MgCO_3$, LC50 differences are <15% and not statistically significant. For $NaHCO_3$, the LC50 is 20% lower for MHRW and is statistically significant; however, this test involved significant precipitation of Ca, and this precipitation was more pronounced in the MHRW test (Table 3). Given previous studies on the effect of hardness on salt toxicity [16–21], such a Ca difference would contribute to the observed LC50 difference. The fact that MHRW provides a higher background Na concentration and alkalinity would also contribute to the difference in LC50s expressed in terms of added $NaHCO_3$.

Only for the 3 K salts are there clear, substantial differences between the 2 dilution waters. The LC50s are 32% to 67% higher for MHRW than for ALSW, and these differences were all statistically significant. Notable compositional differences between these waters (Table 1) include 4-fold higher Na in MHRW (because of the use of $NaHCO_3$ to add alkalinity), 3-fold higher Mg in MHRW (but similar Ca), 5-fold higher SO_4, and 3-fold lower Cl. The higher Na for MHRW is of particular interest because Na and K are linked physiologically through the central role of Na K adenosine triphosphatases in ion regulation and other key cellular processes [2]. Additional information regarding this issue is provided below (see *Effects of sodium on potassium toxicity*).

Comparing the LC50s in Figure 2 across salts also supports some inferences regarding the contributions of individual ions to toxicity. On a total molarity basis, the Na salts are significantly less toxic than salts of other cations with the same anion. On a total molarity basis NaCl is also significantly less toxic than the other Na salts. For Na_2SO_4, the greater toxicity could be caused by it containing 2, instead of 1, Na atoms, in addition to any anion effects. For $NaHCO_3$, the greater toxicity should be partly the result of lower Ca concentrations (Table 3) from the $CaCO_3$ precipitation induced by this salt. These differences among Na salts will be further addressed below (see *Effects of calcium on the toxicities of sodium salts*).

The K salts are much more toxic than the corresponding salts with other cations, especially Na (Figure 2). The ratio of the Na salt LC50 to the K salt LC50 ranges across the different anions from 4.2 to 6.6 for MHRW and from 5.8 to 9.1 for ALSW, with smaller ratios for MHRW resulting from the aforementioned dilution water effect on K toxicity. These large ratios indicate that K is the principal source of toxicity for these salts because the anion concentrations at the LC50s for K salts are in all cases a small fraction of those present at the LC50s for the Na salts. The LC50 on a molarity basis for K_2SO_4 is approximately half that of KCl, consistent with toxicity being related to the molarity of K rather than the molarity of the salt. Factors controlling K salt toxicity are explored further below (see *Effects of sodium on potassium toxicity*).

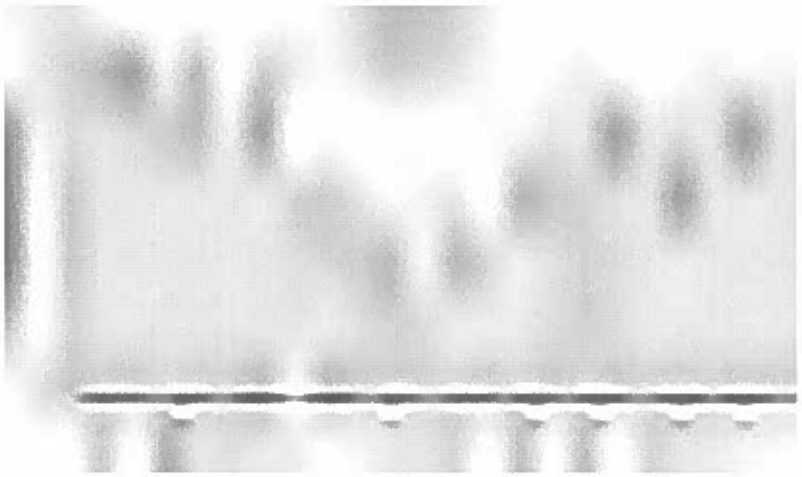

Figure 2. Median lethal concentrations for major ion salts to *Ceriodaphnia dubia* in moderately hard reconstituted water and amended Lake Superior water. Error bars denote upper 95% confidence limits, and asterisks denote where confidence limits do not overlap. R04572

Electronic Filing, Received, Clerk's Office 3/14/2019

Although less toxic than the K salts in these test waters, the Mg salts are also significantly more toxic than their corresponding Na salts (ratios of 1.4–4.4; Figure 2), suggesting that, like K, Mg is also more important to the toxicity of these salts than are the anions. On a total molarity basis, $MgSO_4$ was approximately 2-fold less toxic than $MgCl_2$. Given the same Mg stoichiometry in each salt, this suggests that the toxicity of Mg is differentially modified by the anions, perhaps by SO_4 complexing Mg and thus reducing its toxicity. Unlike for $NaHCO_3$, there was no Ca precipitation in the tests with $MgCO_3$ (Table 3; and see Supplemental Data for more information on Ca precipitation relationships), and $MgCO_3$ was only slightly less toxic than $MgCl_2$. The relationship of these toxicity differences among Mg salts to ion speciation and activity is discussed later (see *Effects of calcium on the toxicities of magnesium salts*).

For Ca, only the Cl salt was acutely toxic below its solubility. On a total molarity basis, $CaCl_2$ is more toxic (by 1.9 fold) than NaCl (Figure 2); however, because $CaCl_2$ has twice as many chlorides as NaCl, this result by itself provides no clear evidence regarding relative ion toxicities.

Salt toxicity in different strengths of ALSW

Figure 3 shows the effect of varying all ions in dilution water by comparing LC50s for 1/3×, 1×, and 3× ALSW. These comparisons were developed by combining data from simultaneous tests in 1/3× and 3× ALSW with the 1× ALSW data generated separately (Figure 2). Also, NaCl and Na_2SO_4 were evaluated in an additional experiment with all 3 waters tested simultaneously (marked "dup" in Figure 3); this was done to determine if combining data across experiments might influence conclusions. For the 3× ALSW water, ions in the dilution water equaled between 3% and 8% of the added salt LC50, so that any amelioration of toxicity in this water would be slightly underestimated when based just on the added salt.

For the K salts, there is a 2.3-fold to 2.5-fold increase in LC50s from 1/3× to 3× ALSW (Figure 3), with the LC50 for 1× ALSW being near the midpoint of these ranges. Because all ions varied proportionately between these dilution waters, the specific factors responsible for these differences are not directly identifiable. However, the decreased toxicity from 1× to 3× ALSW (entailing a 3-fold change in both Na and hardness) is similar to the change between ALSW and MHRW (Figure 2), between which Na differs 4-fold but hardness is just 1.5-fold different and Ca is virtually constant, suggesting that Na is more important than other cations to these toxicity differences.

For the Mg salts, there are substantial increases in the LC50s from 1/3× to 3× ALSW, totaling 3.4-fold, 2.5-fold, and 1.8-fold for $MgCl_2$, $MgCO_3$, and $MgSO_4$, respectively (Figure 3). For $MgCO_3$, the lack of difference between 1× and 3× ALSW is associated with substantial precipitation of $CaCO_3$ in 3× ALSW (Table 3). For $MgCl_2$ and $MgSO_4$, the LC50 increases between 1× and 3× ALSW are similar to the corresponding K salts; but because these Mg salts show no LC50 difference between ALSW and MHRW whereas the K salts do, the underlying reasons must be different. These effects of dilution water strength should reflect the effects of the anions on the speciation of Mg and Ca; whether such consideration of speciation accounts well for LC50 differences among dilution waters, and among the salts, is addressed later.

For the Na salts, LC50s show responses to ALSW strength that are different from each other and from the K and Mg salts (Figure 3). The LC50 for Na_2SO_4 increases by 1.8-fold from 1/3× to 3× ALSW in both replicate tests, similar to $MgSO_4$ and K_2SO_4; but the increase is all between 1/3× to 1× ALSW. The LC50 for NaCl increases much less from 1/3× to 3× ALSW (1.2-fold and 1.4-fold in the different replicates). For $NaHCO_3$, there is a nonsignificant but slight decrease of the LC50 from 1/3× to 3× ALSW. This is again associated with precipitation of Ca, this precipitation being more extensive in the higher ALSW strengths, leading to Ca concentrations actually being similar across these waters (Table 3) despite the original formulations being 9-fold different. Possible reasons for these LC50 differences across Na salts, including chemical speciation and the ameliorative effects of Ca, are further addressed below (see *Effects of calcium on the toxicities of sodium salts*).

For $CaCl_2$, there is an increase of only 1.2-fold in the LC50 from 1/3× to 3× ALSW of marginal statistical significance. This small dependence of Ca toxicity on ALSW strength, compared with the large dependence of Mg toxicity, results in the toxicity of $MgCl_2$ being very similar to $CaCl_2$ in 3× ALSW (a factor of 1.3 difference) and very different in 1/3× ALSW (a

factor of 3.7 difference). To the extent that the toxicity of $MgCl_2$ (or another salt) depends on Ca, judging relative potencies is best done at high, but nontoxic, Ca concentrations because any adverse consequences of low Ca cannot, by definition, affect Ca toxicity. Thus, Ca and Mg should be considered to have similar intrinsic toxicities.

Effects of manipulating specific ion ratios

To evaluate the factors behind the responses in the 1/3× versus 3× ALSW and MHRW versus ALSW, 3 sets of experiments were conducted in which the Ca:Mg, Cl:SO_4, and Na:K ratios were manipulated whereas other ions remained constant. The LC50s for $MgCl_2$, Na_2SO_4, and $MgSO_4$ are at least 2-fold greater at high Ca:Mg than low (Figure 4). Because total hardness and all other ion concentrations were the same in high Ca:Mg and low Ca:Mg waters, these differences are presumably attributable to Ca, rather than overall hardness. These same salts have large LC50 differences in the 1/3× versus 3× ALSW comparisons (Figure 3), for which Ca also changed substantially (in concert with other ions), but small LC50 differences for the MHRW versus ALSW comparisons (Figure 2), for which Ca was essentially the same but other ions varied markedly. Overall, this suggests that Ca is the important factor in differences among these various dilution waters for these salts. The LC50s of NaCl and $NaHCO_3$ had smaller (20–30%) increases at high Ca:Mg (Figure 4), but the magnitude of these effects is also consistent with the results shown in Figures 2 and 3 and their associated Ca concentrations (Table 3). In contrast, although KCl has a higher (15%) LC50 at high Ca:Mg, this is not statistically significant and is much smaller than the LC50 differences for both the MHRW and ALSW comparison (Figure 2) and the 1/3× to 3× ALSW comparison (Figure 3) for this salt. This reinforces the earlier suggestion of the importance of Na to K salt toxicity (see *Salt toxicity in MHRW versus ALSW*).

When the Cl:SO_4 ratio was altered (Figure 4), no significant differences in LC50s (<15%) exist for any of the tested salts (Table 2), indicating that these anions are not important characteristics of dilution water for major ion toxicity to *C. dubia*. When the Na:K ratio was altered (Table 3), there also are no significant effects on the LC50s of the tested salts. No K salts were included in Na:K ratio studies because the effect of Na on K salt toxicity was evaluated separately.

Effects of manipulating alkalinity and pH

Two sets of toxicity tests evaluated the effects of dilution water alkalinity and pH on salt toxicity (Figure 5). In the first set, alkalinity was decreased (by dilution, then restoring other ions) and increased (by $NaHCO_3$ addition) relative to 1× ALSW water, resulting in pHs of approximately 7.4 and 8.3 in the low-alkalinity and high-alkalinity treatments, respectively, compared with a typical pH of approximately 7.9 in ALSW. The effects of these combined changes in alkalinity and pH on LC50s are <10% and not statistically significant for NaCl, Na_2SO_4, and $MgSO_4$, but are larger and statistically significant for $MgCl_2$ and KCl. For $MgCl_2$, increasing the alkalinity decreased the LC50 by 1.4-fold. This test was repeated, yielding virtually identical results (Table 3). We initially speculated that complexation by the higher HCO_3/CO_3 decreased Ca activity and thus increased toxicity. However, to maintain a constant Na concentration in these tests, the low-alkalinity water had higher SO_4, which also complexes Ca. As a result, the calculated Ca activity in the high-alkalinity treatment is actually higher than that in the low-alkalinity treatment, so it would not explain the observed LC50 shift. We similarly have no explanation for the lower LC50 (20%) for KCl at high alkalinity. One area of needed future work is direct ion activity measurements to verify speciation model calculations before further exploring the cause of these effects.

In the second set of tests, pH was manipulated by CO_2 partial pressure, leaving alkalinity and all other ions constant as pH varied. For this experiment, pH had no effect on NaCl toxicity over the pH range 6.75 to 8.20 or on $MgCl_2$ toxicity over the pH range 6.75 to 8.50 (Figure 5). (The high pH treatment for the NaCl tests had lower pH than for the $MgCl_2$ tests because of an air leak in the chamber for the low CO_2 treatment, so that the range of tested pHs was less than intended.) This insensitivity of toxicity to pH manipulation suggests that something other than pH itself is responsible for the effects of altered alkalinity on $MgCl_2$ toxicity noted in the previous experiment. However, although these tests at different pHs and alkalinities indicate limited or no effect of these factors on the toxicity of SO_4 and Cl salts, they do not

encompass the much higher pHs and buffering levels of the tests with HCO_3/CO_3 salts. Therefore, pH might still have a role in the relative toxicity of those salts.

Effects of sodium on potassium toxicity

To evaluate the suspected effect of Na on the toxicity of K salts, 6 dilution waters were prepared, each having the composition of ALSW except that the Na^+ concentrations were varied to be 0.070 mM (background in LSW), 0.13 mM, 0.43 mM, 1.3 mM, 4.3 mM, and 13 mM (1.62 mg/L, 3 mg/L, 10 mg/L, 30 mg/L, 100 mg/L, and 300 mg/L), added as NaCl so that the anion was the same as for the toxicant, KCl. The LC50 of KCl differs consistently and substantially across these dilution waters (Figure 6), from a low of 2.05 mM (153 mg/L) at the lowest Na to a high of 10.1 mM (752 mg /L) at the highest Na. The magnitudes of these changes are consistent with the behavior observed for KCl in the MHRW versus ALSW and 1/3× versus 3× ALSW experiments (Figures 2 and 3 and included in Figure 6).

Mount et al. [3] and our initial experiments (Figure 2) demonstrated that K is the most toxic of the major ions to *C. dubia* and, as a result, the effects of K seem to greatly exceed any effect of the different anions. This is demonstrated in Figure 6, which shows agreement of other K salts and dilution waters with the experiment regarding KCl toxicity across different NaCl levels. Note that by compiling data for tests conducted across a variety of dilution water compositions, the correlation of Na with other major ions that might exist in a single experiment is reduced, strengthening the case for Na being the primary factor influencing toxicity of K salts. There might be some lesser effects of other factors, as evidenced by slightly lower LC50s (expressed as K) for $KHCO_3$ than for KCl and K_2SO_4 (Figures 2 and 6). As noted previously, the carbonate tests entailed much higher pH and buffering for which effects are uncertain. However, any such effects appear to be of less consequence than the primary effect of Na on K toxicity.

One implication of the Na dependence of K toxicity demonstrated in the present study is that the high toxicity of K in typical test waters with low Na may be of limited field relevance because K would be unlikely to be present at toxic concentrations when Na is so low. For example, the K-dominated effluent evaluated by Jop and Askew [11] had approximately 1.5 mM Na, which would put the expected acute LC50 for K at 10 mM or higher (Figure 6). This is similar to the toxicity of Mg salts and only 2-fold to 3-fold more toxic than Na salts.

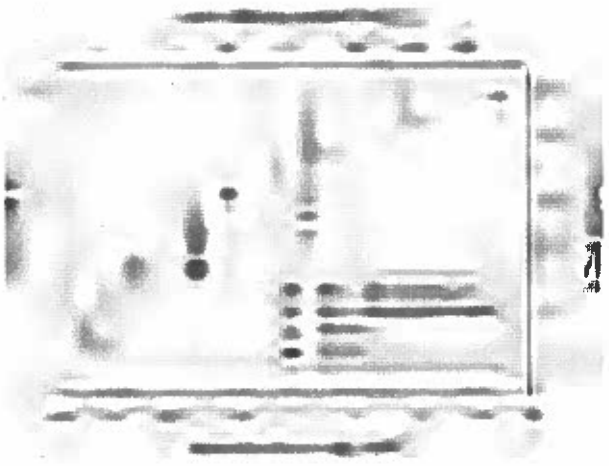

Figure 6. Effect of Na on median lethal concentrations for K salts to *Ceriodaphnia dubia*. Error bars denote 95% confidence limits. LC50 = 48-h median lethal concentration.

Effects of calcium on the toxicities of sodium salts

Aside from the effect of Na on the toxicity of K, Ca is the only other ion in the present study which exerted a substantial influence on the acute toxicity of major ion salts to *C. dubia*. Several studies have shown that hardness influences major ion toxicity to *C. dubia* [16–20], though the way in which hardness was manipulated differed across studies. Experiments by Soucek et al. [16–18] varied hardness by adding $CaCl_2 + MgCl_2$ (for NaCl toxicity tests) or $CaSO_4 + MgSO_4$ (for Na_2SO_4 toxicity tests) in fixed ratios and keeping the remaining ions constant, whereas Elphick et al. [19,20] varied all ions proportionately (as in the 1/8×, 1/3×, and 1× MHRW waters used in the present study). In the present experiments, the combination of manipulating all ions simultaneously in some tests and only specific ion pairs in others (at constant hardness) allowed us to conclude that the "hardness effect" on the toxicity of Na salts is primarily an effect of Ca, rather than total hardness or the other ions that covary with hardness. The same conclusion was reached by Davies and Hall [21], who manipulated both

total hardness and the Ca:Mg ratio to show the dominance of Ca in determining toxicity of Na_2SO_4 to *D. magna*.

Figure 7 shows the relationship of LC50s to Ca for all our Na salt toxicity tests using organisms cultured in 1× ALSW or MHRW. Each panel considers different exposure metrics for how LC50 and Ca are expressed. As a comparative performance measure for these different metrics, residual standard deviations of the logLC50s (RSD_{log}) around the mean trend of logLC50 with Ca are provided. Mean data trends were calculated by least-square regression of logLC50 versus logCa using Sigmaplot with a model for an exponential rise to a maximum. This is not intended to provide a definitive model for the relationship of toxicity to Ca but rather only an empirical description of the mean data trend suitable for calculating the RSD_{log}.

In Figure 7A, LC50s are plotted as millimolarity of added salt and Ca is plotted as total concentration (measured Ca for $NaHCO_3$ tests, nominal for others). Although the 3 inorganic salts have a similar and substantial (2-fold to 3-fold) dependence on Ca, there is an apparent difference in the relative toxicities of the salts, with LC50s being ordered NaCl ≈ Na gluconate > $NaHCO_3$ > Na_2SO_4. The RSD_{log} is 0.110, for which ±2 SDs corresponds to nearly a 3-fold range in LC50 at a fixed Ca concentration, indicative of the substantial variability among the different salts.

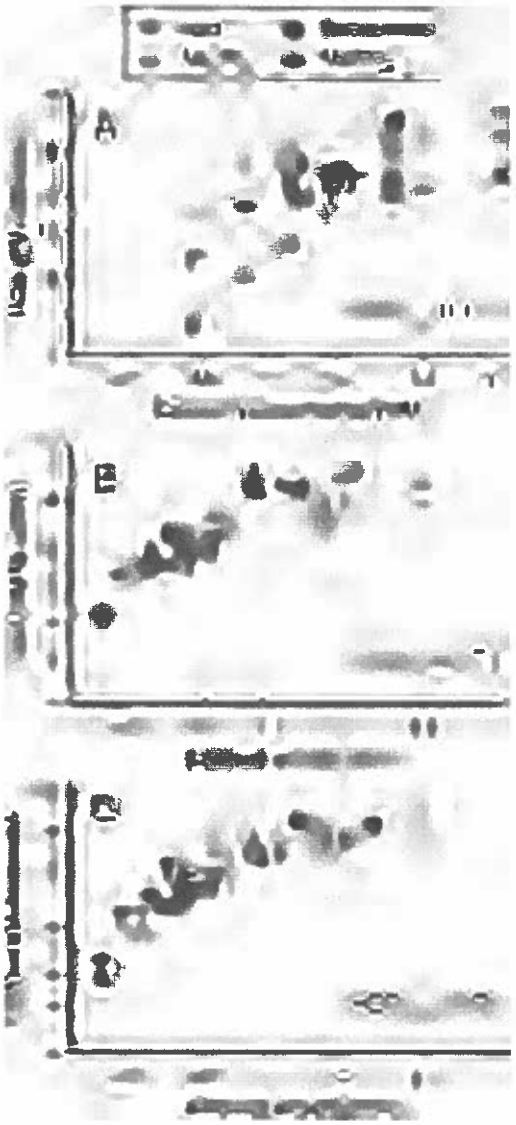

Figure 7. Effect of Ca on 48-h median lethal concentrations (LC50s) for Na salts to *Ceriodaphnia dubia* using different exposure metrics. (A) Metrics are LC50 as concentration of added salt and Ca concentration. (B) Metrics are Na and Ca activities. (C) The LC50 metric is changed to osmolarity. RSD_{log} denotes the residual standard deviation of log(LC50)s from their mean trend with Ca.

Because chemical reactions are governed by chemical activity rather than concentration, the relative toxicities of salts and their relationships to Ca should be based on chemical activities rather than total concentrations, as in Figure 7A. Activities will differ from total concentrations because of formation of chemical complexes as well as reduced activity coefficients associated with high ion concentrations (especially for the divalent Ca ion), and these factors will differ among the salts and dilution waters. Another issue for comparing toxicities across these salts is that, per mole of salt, Na_2SO_4 provides twice as many Na ions and 1.5 times as many total ions as do the other salts. To address these issues, in Figure 7B, Ca is plotted as Ca activity and the LC50s are based on the activity of Na. This results in much closer agreement among the salts, with the RSD_{log} reduced to 0.071 and the ±2 SD range for LC50 reduced to less than 2-fold; NaCl and $NaHCO_3$ now show similar toxicity because complexation of Ca by CO_3 and HCO_3 in the $NaHCO_3$ exposures causes Ca activity to be lower than that in NaCl exposures at the same total Ca concentration. Accounting for Na_2SO_4 having twice as many Na atoms as other Na salts has also made its LC50s more similar to the other salts; however, Na_2SO_4 now appears to be less, rather than more, toxic than NaCl, based on the repeated tests with Na_2SO_4 and NaCl in 1× ALSW and other waters with similar Ca concentration (i.e., the cluster of red triangles near 0.1 mM Ca activity and green circles near 0.2 mM Ca activity). This continued discrepancy between Na_2SO_4 and NaCl suggests that the anions play some role in determining toxicity beyond their effects on cation speciation.

A simple metric for expressing the aggregate effect of Na and anions is osmolarity, which reflects the combined, unweighted influence of all dissolved species. Figure 7C provides LC50s on the basis of calculated osmolarity, resulting in excellent agreement among all the tests of Na salt toxicity. The LC50s for the different salts now overlap within experimental variability; the RSD_{log} is reduced to 0.052 and the ±2 SD range to 1.6-fold. Further support for using osmolarity as an exposure metric comes from the test conducted with mannitol (black star in Figure 7C), whose LC50 is not significantly different from those of the Na salts even though its only expected effect would be on osmolarity. While this case for osmolarity is simply correlative and does not establish osmotic potential as the primary stressor, an exposure metric such as osmolarity that includes multiple ions in a nonspecific manner is indicated by these data.

Effects of calcium on magnesium toxicity

Figure 8 examines the relationship of LC50s to Ca for all our Mg salt toxicity tests using organisms cultured in 1× ALSW or MHRW. The panels address different exposure metrics parallel to those examined in Figure 7 for Na salts and include RSD_{log} as a performance measure for these different expressions of exposure.

In Figure 8A, LC50s are plotted as millimolarity of added salt and Ca is plotted as total concentration (measured Ca as appropriate for $MgCO_3$ tests, nominal for others). There is an even greater effect of Ca (~ 10-fold LC50 range over the 0.05–1.0 mM Ca range) for Mg salts than for Na salts (note scale change from Figure 7). On the basis of total added salt

R04576

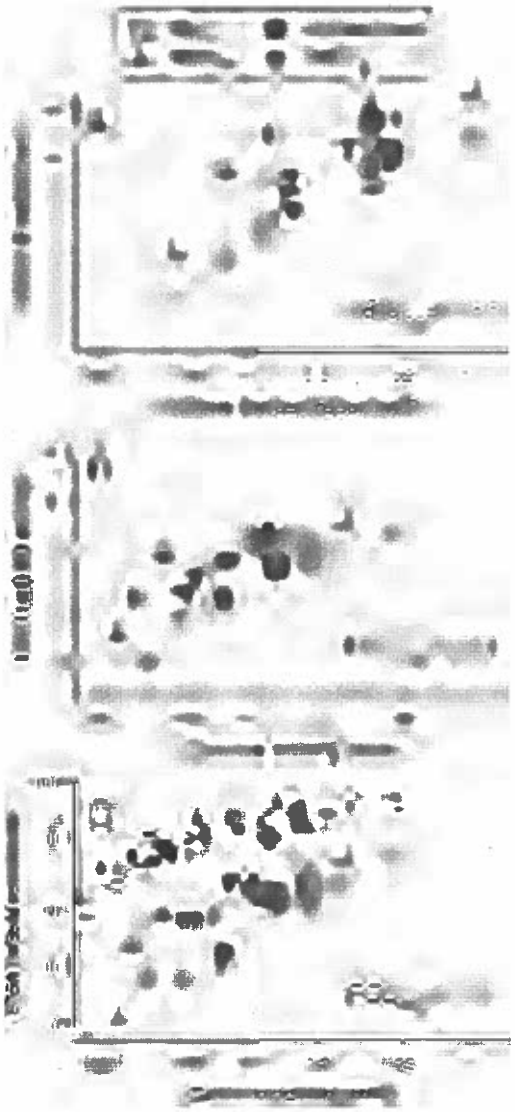

Figure 8. Effect of Ca on 48-h median lethal concentrations (LC50s) for Mg salts to *Ceriodaphnia dubia* using different exposure metrics. (**A**) Metrics are LC50 as concentration of added salt and Ca concentration. (**B**) Metrics are Mg and Ca activities. (**C**) The LC50 metric is changed to osmolarity, and black dots provide comparison to Na salt data from Figure 7C. RSD_{log} denotes the residual standard deviation of log(LC50)s from their mean trend with Ca.

concentrations, the salts have different apparent toxicities, with $MgSO_4$ and Mg gluconate being approximately 2-fold to 3-fold less toxic than $MgCl_2$ and $MgCO_3$. These differences make the RSD_{log} (0.167) even larger than for Na salts (Figure 7A), corresponding to a ±2 SD range of almost 5-fold at a fixed Ca concentration.

Expressing exposure on the basis of chemical activities of Mg and Ca (Figure 8B) reduces the residual variability and the differences between the salts because of the different degrees of complexation of both Ca and Mg by the different anions. The total range of the LC50s is also less because of a concentration dependence for complexation and activity coefficients. However, the closer agreement among the data is mainly for Ca activity >0.05 mM; at lower Ca activity, there remains considerable disparity between $MgSO_4$ and $MgCl_2$. As noted earlier (see *Effects of acclimation to dilution water*), these tests in very dilute test water raised some concerns about variable response and stresses associated with low ions, which might involve effects other than from Mg and Ca. Thus, although basing LC50s on Mg activity does provide a better metric than total Mg concentration, it does not account for all factors of significance. For all the data, the RSD_{log} is reduced to 0.123; but if only the data at Ca activity >0.05 mM are considered, the RSD_{log} is 0.102 and the ±2 SD range is then 2.5-fold, half of what is was for LC50s based on total added salt concentration.

Although osmolarity provides a possible unifying exposure metric for Na salts (Figure 7C), it is not a useful metric for Mg salt toxicity (Figure 8C). Using osmolarity to express Mg salt toxicity did not improve, but rather increased, the RSD_{log} of the data. More importantly, the osmolarities at the LC50 for Mg salts are 2-fold to 4-fold lower than those for Na salts at the same Ca activity. This indicates specific action of Mg and is incompatible with using a nonspecific, total ion metric such as osmolarity for the toxicity of Mg salts.

Our results indicate a strong effect of Ca on $MgSO_4$ and $MgCl_2$ toxicity, nearly a 10-fold change in LC50s from the Ca concentration in 1/8× MHRW (0.044 mM) to that in 1× MHRW (0.35 mM), with Figure 1 indicating even lower LC50s at 1/8× MHRW if organisms are cultured in this water. This is in contrast to results from van Dam et al. [31] for an Australian cladoceran (*Moinodaphnia macleayi*) collected from and cultured in very low ionic strength water (Ca <0.02 mM). In 6-d to 7-d reproductions tests, the $MgSO_4$ concentration reducing reproduction by 50% for *M. macleayi* was 2.6 mM in the culture water but only 2-fold higher (5.0 mM) when $CaSO_4$ was added to increase the Ca concentration by roughly 20-fold, to 0.34 mM. While there are several possible explanations for the difference in Ca effect for the 2 species, the van Dam et al. [31] study does reinforce concerns that species like *C. dubia* tested at very low ionic strength may not respond the same way as species (or strains) naturally adapted to low ionic strength water.

The toxicity of calcium

Because of solubility constraints, only limited testing of Ca salts could be conducted; and conclusions about any specific Ca toxicity could not be made based on simple comparisons of the toxicities of $CaCl_2$ and NaCl in our standard test waters. However, there are some indications that the toxicity of $CaCl_2$ is dominated by the cation, as are the toxicities of K and Mg salts. First, any comparison of the toxicity of $CaCl_2$ to NaCl should be made for NaCl tests in the dilution waters with the highest Ca. Otherwise, the comparison is confounded by the exacerbation of Na toxicity by low Ca. For the $CaCl_2$ tests (Table 3), osmolarities at the LC50s average 45 milliosmoles/L (range, 39–52), well below the average osmolarity of 76 milliosmoles/L (range, 69–83) for the NaCl tests in 3× ALSW. Unless the Cl from these 2 salts acts differently, this indicates some Ca-specific toxicity beyond the toxicity exerted by Na and the various anions (Figure 7). Second, in ALSW, the calculated Ca activity is 7.5 mM for $CaCl_2$ and 8.1 mM for Ca gluconate; such similarity would not be expected if these disparate anions were contributing to toxicity. However, the conclusion that there is some specific toxicity of Ca is tentative and will be further addressed in the next article in this series.

Relationship of toxicity to conductivity

Figure 9 replots the data from Figures 7 and 8 with LC50s based on conductivity. Given the results already presented for the toxicity of different salts, it is not surprising that these conductivity LC50s also show a strong dependence of toxicity on Ca and substantial variation across the different salts. The

R04577

 Electronic Filing: Received, Clerk's Office 3/14/2019

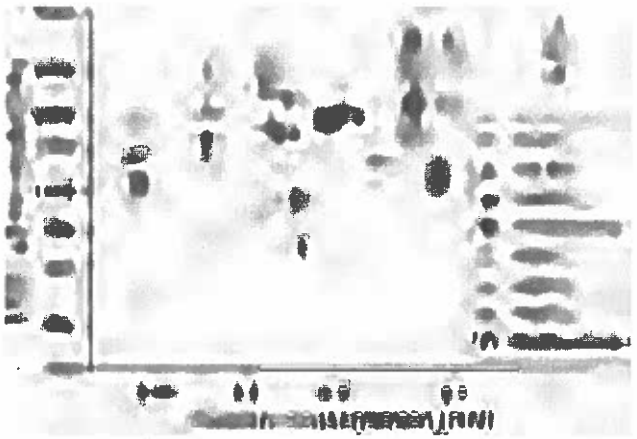

Figure 9. Median lethal concentration of Na and Mg salts expressed as conductivity. LC50 = 48-h median lethal concentration.

total range of conductivity LC50s is approximately 10-fold, with up to a 5-fold range among salts at the same Ca concentration. This indicates that assessment approaches using conductivity as an exposure metric should have a restricted scope of applicability regarding relative ion concentrations, as is the case for the conductivity benchmark of Cormier et al. [14,15].

SUMMARY AND IMPLICATIONS

In the present study, the key influences of background water chemistry on the acute toxicity of major ions salts to *C. dubia* were the effect of Na on toxicity of K salts and the effects of Ca on the toxicity of Na and Mg salts. Although the practical implications of the Na effect on K toxicity are limited because of the unlikelihood of K-dominated exposures, this result does mean that when K exposures are of concern [11] effects concentrations based on typical laboratory tests with low Na concentrations would overestimate risk. Regarding the Ca effects, although a hardness dependence of toxicity was already known for some Na and Mg salts [16–20] and Davies and Hall [21] implicated Ca as the specific factor for Na_2SO_4 toxicity, our results more thoroughly establish a role of Ca for a variety of salts. Predicting salt toxicity across waters will thus be more accurate if done on the basis of Ca rather than hardness, but the benefits of accuracy must be weighed against the availability of Ca versus hardness data. Uncertainties associated with using hardness as a surrogate for Ca can be addressed based on the regional variability of the Ca:Mg ratio, the resultant uncertainty on Ca, and the consequent uncertainty on toxicity estimated from Ca (e.g., Figures 7 and 8); in many cases, the resultant uncertainty should be limited.

An important tool in addressing the toxicity of ion mixtures has been the model of Mount et al. [3], and part of the purpose of the present study was to address some limitations of that model. The present results do indicate that not addressing the hardness (or Ca specifically) of the background water can introduce uncertainty into this model and raise questions regarding how joint toxicity across the different ions was addressed by Mount et al. [3]. However, any quantitative evaluation of that model relative to our results must wait for the alternative model to be presented in our subsequent article.

In addition to describing the dependence of major ion salt toxicities on background water chemistry, the results of the present study allowed some inferences about mechanisms and some conclusions about how salt toxicity dosimetry should be expressed. At least 3 separate mechanisms were apparent. First, a K-related mechanism is indicated by the high toxicities of K salts, the dependence of this toxicity on Na concentration, and its good correlation to K concentration. Second, a Mg-related mechanism is indicated based on the greater toxicity of Mg salts than Na salts and the correlation of Mg salt toxicity to Mg activity. Third, a mechanism related to multiple ions is indicated, based 1) on Na salts being less toxic than salts of other cations, 2) on anions affecting the toxicity of Na salts, 3) on the good correlation of this toxicity to osmolarity, and 4) on the agreement of toxicity from Na gluconate and mannitol with that of inorganic Na salts when expressed as osmolarity. Calcium salt toxicity also likely represents a mechanism different from that of Na salts because of the greater toxicity of $CaCl_2$ compared with Na salts tested at high but nontoxic Ca concentrations; however, this might be the same mechanism as Mg, which has similar toxicity to Ca when tested in waters with higher Ca background.

Regarding dosimetry, rigorously understanding and describing salt toxicity requires examining toxicity on the basis of chemical activities and consideration of various ion interactions. The cation-related mechanisms would be expected to be best related to cation activities, and the multiple ion mechanism associated with Na salts requires some measure, such as osmolarity, which addresses multiple chemical species. These conclusions regarding mechanisms and dosimetry are preliminary and will be further addressed in the subsequent articles mentioned in the *Introduction*, but it is evident that regulations based solely on a single ion may lack robustness from failing to address the relative toxicities and interactions of multiple ions.

One limitation of the present results is that they just concern the toxicities of single salts, with other ions being at low to moderate background concentrations reported for US waters. Most field situations would involve enrichment of more ions—to well above ambient levels, if not to toxic levels. For example, it would not be expected that Mg would be enriched to toxic levels while Ca stays at background levels, and the high toxicity of K salts depends on very low Na concentrations, which would be an unusual exposure scenario. The exposure metrics and relationships noted in the present study would be expected to apply to more complex mixtures (e.g., all ions contributing to osmolarity), but there is a need to better define the scope of applicability of these relationships. Their extension to more complex mixtures will be the subject of subsequent articles.

Although a complete model for the acute toxicity of major ions to *C. dubia* will be forthcoming, Figures 6 through 8 make it clear that this will be complicated, involving chemical speciation calculations, multiple toxicity mechanisms, and interactions among 7 toxicants. Any practical application will require simplifications, but we feel that the detail provided in the present study and in later articles will provide a starting point for determining what simplifications are possible and how they should be structured. Another application issue concerns the relevance of acute ion toxicity for *C. dubia* to the assessment of an entire aquatic community, especially in low-ion, lotic systems. This toxicity endpoint is the starting point for work that will address more endpoints and species. However, the relationships developed for *C. dubia* will be directly relevant to many aquatic systems and will also have value in developing and interpreting major ion toxicity data for other species.

COMMONWEALTH OF PENNSYLVANIA
DEPARTMENT OF ENVIRONMENTAL PROTECTION
BUREAU OF CLEAN WATER

TRIENNIAL REVIEW OF WATER QUALITY STANDARDS

RATIONALE FOR THE DEVELOPMENT OF AMBIENT WATER QUALITY CRITERIA FOR

CHLORIDE

PROTECTION OF AQUATIC LIFE

Introduction

Section 303(c)(1) of the Clean Water Act (33 U.S.C.A § 1313(c)(1)) requires that states periodically, but at least once every three years, review and revise as necessary their water quality standards. Water quality standards are instream water quality goals that are implemented by imposing specific regulatory requirements (such as treatment requirements and effluent limits) on individual sources of pollution. As part of the current review, the chloride criterion is being evaluated.

Chloride occurs naturally in the aquatic environment, especially in waters flowing through geologic formations of marine origin. The major anthropogenic sources of chloride include deicing salt for roads, urban and agricultural runoff, treated industrial waste, discharges from municipal wastewater plants and the drilling of oil and gas wells (EPA, 1988). Elevated levels of chloride are toxic to aquatic life in freshwater environments. A state-wide aquatic life criterion for chloride would provide an appropriate level of protection for all of Pennsylvania's waters.

Pennsylvania's existing chloride criterion was developed primarily for the protection of potable water supplies (PWS). It is not applied in all waters of this Commonwealth, but rather only at the point of water supply intake, pursuant to 25 Pa. Code § 96.3(d) (relating to water quality protection requirements). The current PWS criterion for chloride is included in Table 3 at 25 Pa. Code § 93.7 (relating to specific water quality criteria) and establishes a maximum level of 250 milligrams of chloride per liter of water, applicable only at the point of all existing or planned surface PWS withdrawals, unless otherwise specified by regulation.

The Pennsylvania Department of Environmental Protection has developed draft water quality criteria for chloride for the protection of aquatic life. The draft criterion is based on current science that shows that the water hardness and sulfate concentrations affect chloride toxicity to aquatic organisms. This relationship is incorporated into the newly developed equation used for calculating the acute and chronic numeric criteria for chloride in Pennsylvania waters. The Department is recommending that this chloride criterion be applied in all waters for the protection of aquatic life.

Electronic Filing: Received, Clerk's Office 3/14/2019

History

The U.S Environmental Protection Agency (EPA) published Ambient Water Quality Criteria (AWQC) for Chloride in February 1988, which summarized the published toxicity data that was available at that time for chlorides on freshwater plant and animal species. The acute and chronic effects of chlorides on aquatic animals were documented, along with the chronic effects of chloride on aquatic plants. The findings of 106 published scientific studies were considered in the development of the national aquatic life criteria for chloride. EPA developed the chloride criteria in 1988 for protection against adverse acute and chronic impacts on freshwater aquatic life based on the Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses, NTIS PB85-227049 (Stephan, et al., 1985). EPA determined the four-day (chronic) and one-hour acute average concentrations based upon how quickly some aquatic species reacted to higher concentrations of pollutants. The Criteria Continuous Concentration (CCC) and Criteria Maximum Concentration (CMC) values should not be exceeded more than once every three years on the average (US EPA, 1988).

The 4-day average (CCC) criterion = 230 mg/l

The 1-hour average (CMC) criterion = 860 mg/l

In 2005, the state of Iowa with the help of EPA Region 5 began an investigation into updating the existing chloride AWQC. The revised WQS was promulgated by Iowa in 2009. EPA Office of Research and Development scientists served to link the relationship of chloride toxicity to aquatic organisms with water hardness and sulfate concentration. This relationship provided the basis for the revised WQS promulgated in Iowa.

The Department has reviewed the equation-based aquatic life criteria for chloride as developed by EPA and successfully implemented in Iowa. The researchers at the Great Lakes Environmental Center (GLEC) in Columbus, OH and the Illinois Natural History Survey (INHS) in Champaign, IL worked collaboratively under a contract with the EPA to determine the toxicity of chloride in freshwater invertebrate species. The research demonstrated a strong correlation between chloride toxicity and hardness and to a lesser extent with sulfate. The final results of this toxicity testing were published in the report "Acute Toxicity of Chloride to Select Freshwater Invertebrates" US EPA, October 28, 2008. Iowa Department of Natural Resources (IDNR) selected the appropriate acute and chronic criteria equations after considering input from many sources and two equations were promulgated by Iowa. Both the one-hour acute and ninety-six hour chronic criteria values should not be exceeded more than once every three years on the average (personal communication: Connie Dou, IDNR, November 2011).

Test Compound Determination

Chloride is one of the major anions commonly found in surface and wastewater. It is a constituent of naturally occurring minerals; it readily dissolves in water, and is important to living systems. As a solid, chloride is typically found as a salt bonded with a cation such as

Electronic Filing: Received, Clerk's Office 3/14/2019

calcium, sodium, magnesium, or potassium. The salinity of a water body is measured by its total salt composition. Freshwater lakes are dominated by the cations: Ca^{2+}, Mg^{2+}, K^{+} and Na^{+} and the anions $HCO3^{-}$, SO_4^{2-} and Cl^{-}. (Wetzel, 1983) Data obtained from stream surveys of Pennsylvania waters confirmed this determination: the ionic composition is >40% $HCO3^{-}$/ Ca^{2+}, followed by SO_4^{2}, Mg^{2+}, Na^{+}, K^{+} and Cl^{-}. Pennsylvania waters are calcium/bicarbonate dominant.

Chloride toxicity tests have been conducted through the addition of chloride salts such as sodium chloride (NaCl), calcium chloride ($CaCl_2$), magnesium chloride ($MgCl_2$) and potassium chloride (KCL). Results of tests with potassium and magnesium chloride suggest toxic effects observed can be due to the potassium and magnesium cation, rather than the chloride ion. It has been observed that the toxic effects of calcium chloride and sodium chloride are due to the chloride anion. In establishing the effect concentrations of the chloride ion, exposure to KCL and $MgCl_2$ salts are lower (more toxic) than the effect concentration of the exposures to $CaCl_2$ and NaCl salts (Canadian Council of Ministers of the Environment, 2011). Therefore the approximate order of chloride salt toxicity to freshwater organisms is KCL > $MgCL_2$ > $CaCl_2$ > NaCl (Mount et al 1997). Based on this information, chloride toxicity to freshwater organisms was evaluated using tests dosed with NaCl to ensure the effect concentrations were derived from tests where effects were based on the chloride anion, not the associated cations.

Other Modifying Factors

A long term study by Elphick et al. indicates that increased hardness may have an effect on the toxicity of chloride. GLEC and INHS (2008) also conducted some short-term exposure tests indicating that a hardness-chloride toxicity relationship exists for the water flea *Ceriodahpnia dubia*, the fingernail clam *Sphaerium simile*, the Oligochaete *Tubifex tubifex* and the aquatic snail *Gyraulus parvus*. (CCME, 2011)

EPA contracted with the GLEC and the INHS (2009) to perform toxicity testing for chloride. The results showed that chloride toxicity is heavily dependent on water hardness, and to a lesser degree, sulfate levels in water. PA Department staff has been monitoring sulfate and hardness levels at Water Quality Network (WQN) stations throughout PA. This data confirms that PA source waters have a varied amount of hardness and sulfate concentrations. As an example, the Aughwick Creek watershed is located in southcentral Pennsylvania. In this single watershed, the hardness values range from 10 mg/l in the small freestone streams to 250 mg/l in areas of limestone geology. There is a full range of hardness values between the 10 mg/l and 250 mg/l as the tributaries flowing through various geologies coalesce and mix. This is not an unusual situation as there are extensive limestone deposits in the Commonwealth. Pennsylvania has a legacy of abandoned coal mines that can discharge high levels of sulfate. Instream sulfate levels are elevated where there are concentrations of these abandoned discharges. Where there is a legacy of abandoned coal mines the sulfates often range between 100 to 500 mg/l and sometimes higher. In contrast, the streams in the less affected parts of the state have sulfate values less than 50 mg/l. Urban streams often have sulfate between 50 mg/l and 100 mg/l. The variation in the hardness and sulfate concentrations throughout the state confirms that it is appropriate to develop an equation based criterion that includes a modification for hardness and sulfate.

Electronic Filing: Received, Clerk's Office 3/14/2019

PA Site Specific Research/Literature Review

The Department contracted with the Stroud Water Research Center, in Avondale, Pennsylvania to perform chloride toxicity testing. The study was designed to provide the additional information needed to support the development of a chloride criterion that is protective across the range of aquatic habitats and species found in Pennsylvania waters. Benthic macroinvertebrates were used in this eco-toxicity study of chloride because they are an ecologically important group of aquatic organisms and are common components of the Pennsylvania bio-monitoring multi-metrics used in standard water quality assessment protocols (e.g., PA IBI; PADEP 2013)

The following mayfly species were included in the study: *Neocloeon triangulifer*, previously classified as *Centroptilum* (Jacobus and Wiersema, 2014), *Anafromtilum semirufum*, *Procloeon fragile*, *Ephemerella invaria*, *Maccaffertium modestum* and *Leptophlebia cupida*. All six species were evaluated for short term (acute) exposures to chloride. Chloride sensitivities were determined using sodium chloride because sodium is known to have little effect on the toxicity of chloride (Stroud 2015). Four species (*N. triangulifer*, *A. semirufum*, *P. fragile*, *M. modestum*) were subjected to a whole-life (chronic) toxicity test. The chronic test began with newly hatched larvae and ended when all larvae had emerged as adults (i.e., 20-48 days). The development time for a complete life cycle of *M. modestum* is 60-80 days. The experiment was ended before the adult emergence; therefore the chronic study of *M. modestum* was omitted.

The acute and chronic data obtained from the Stroud study was incorporated into the data set used to determine Pennsylvania-specific chloride criteria. It has been shown that some aquatic organisms show significantly more sensitivity when tested in reconstituted laboratory water compared to natural waters (CCME, 2011). The Stroud study was conducted in water from three source water streams: Spruce Run, a soft water stream (hardness 6 mg/L) in Union County, PA; House Run, a moderately hard water stream (hardness 94 mg/L) in Greene County, PA and Cedar Run, a hard water (hardness 212 mg/L) stream in Union County, PA. The reference stream was White Clay Creek which is a moderately hard water stream (hardness 89 mg/L) located at the Stroud Water Research Center in Chester County, PA, where all the study species were originally collected. (Stroud, 2015)

Other toxics data sources used:

Toxics data that was compiled by Charles Stephan, November 06, 2007 – This document contains acceptable acute and chronic data obtained from several significant studies (Birge et al., 1985; Spehar 1987; Cowgill and Milazza 1990; and Wisloh 2007). It also contains a list of the studies reviewed previous to 2007 that were not approved and the reasons for the disapproval.

Data from Canadian Council of Minister of the Environment, 2011 – This document contained additional studies (Harmon et al 2003; Collins & Russell 2009; Gillis 2011, GLEC & INHS 2008; Elphick et al 2011; Wang and Ingersoll 2010; US EPA 2010, Valenti et al 2007; Bringolf et al 2007) In particular, the Valenti et al, Bringolf et al and Gillis studies contained valuable data on sensitive and endangered mussels. This document also contains studies that have relevant chronic toxicity data.

Electronic Filing: Received, Clerk's Office 3/14/2019

US EPA, 2015 – EPA's data set contained additional peer reviewed studies. (GLEC and INHS 2010; Wang et al 2013; Garner and Royer 2010; Soucek 2012, 2013; Environ 2009; Sanzo and Hecnar 2006; Garibay and Hall 2004).

In addition, PA DEP staff evaluated Maryland's Freshwater Chloride Development Methodology and reviewed the data used in their chloride criteria development. (MDE, 2013)

Acute criteria determination

Acute values were used from all acceptable data contained in the reports listed above. This resulted in 219 acute toxicity results for aquatic species (51 genera). The LC50's are in mg/L for all acceptable data, including Stroud mayfly data. The four genera most sensitive to acute testing were *Epioblasma* (freshwater mussel); *Sphaerium* (fingernail clam); *Neocloeon* (mayfly); and *Lampsilis* (freshwater mussel). The genus mean acute value (GMAV) for the most sensitive organism (*Epioblasma*) was 698 mg/L. This value was lower than the calculated final acute value (FAV) of 874.8 mg/L. In order to protect for this sensitive freshwater mussel, the species mean acute value (SMAV) for the *Epioblasma* (698 mg/L) was used as the FAV. The final acute value is 349 mg/L, which will be incorporated into the hardness/sulfate modifying equation to determine the final acute chloride criterion.

Chronic criteria determination

The chronic toxicity data set included 10 aquatic species. *Pimephales promelas*, *Oncorhynchus mykiss*, *Daphnia ambigua*, *Daphnia magna*, *Daphnia pulex*, *Ceriodaphnia dubia*, *Lumbriculus variegatus*, *Neocloeon triangulifer*, *Anafroptilum semirufum* and *Procloeon fragile*. The final calculated acute/chronic ratio (FACR) from the acceptable data is 6.2. The final chronic value is 112.7 mg/L (113 mg/L), which will be incorporated into the hardness/sulfate modifying equation to determine the final chronic chloride criterion.

Chloride Criteria Development

The hardness and sulfate values used to derive the appropriate chloride criteria shall be determined by instream measurements, statewide water quality network (WQN) or other values as approved by the Department. The proposed chloride criterion is calculated using the following equations that incorporate the hardness and sulfate modifiers based on the GLEC studies:

Acute Chloride Criterion Equation – One hour average concentration should not exceed

$$\text{Acute Criterion (mg/L)} = \mathbf{349}(\text{Hardness})^{0.2058}(\text{Sulfate})^{-0.0745}$$

Chronic Chloride Criterion Equation – 4 day average concentration should not exceed

$$\text{Chronic Criterion (mg/L)} = \mathbf{113}(\text{Hardness})^{0.2058}(\text{Sulfate})^{-0.0745}$$

Recommendation

On April 17, 2012 the EQB adopted a proposed rulemaking for the promulgation of an aquatic life criterion for chloride. Based on the comments received during the public comment period, which ended August 8, 2012, the Department, in this new proposed rulemaking has re-evaluated and incorporated Pennsylvania-specific data into the determination of the chloride criterion. The Department has developed a state-specific equation-based aquatic life criterion for chloride. It incorporates additional state-specific aquatic toxicity data, as related to the ion composition of our waterbodies, and the necessary adjustment for the effects of hardness and sulfate on the toxicity of chloride.

The Department recommends adopting the Pennsylvania-specific equation-based aquatic life criterion for chloride.

FULL-LIFE CHRONIC TOXICITY OF SODIUM SALTS TO THE MAYFLY *NEOCLOEON TRIANGULIFER* IN TESTS WITH LABORATORY CULTURED FOOD

DAVID J. SOUCEK* and AMY DICKINSON
Illinois Natural History Survey, Champaign, Illinois, USA

(Submitted 8 January 2015; Returned for Revision 6 February 2015; Accepted 24 April 2015)

Abstract: Although insects occur in nearly all freshwater ecosystems, few sensitive insect models exist for use in determining the toxicity of contaminants. The objectives of the present study were to adapt previously developed culturing and toxicity testing methods for the mayfly *Neocloeon triangulifer* (Ephemeroptera: Baetidae), and to further develop a method for chronic toxicity tests spanning organism ages of less than 24 h post hatch to adult emergence, using a laboratory cultured diatom diet. The authors conducted 96-h fed acute tests and full-life chronic toxicity tests with sodium chloride, sodium nitrate, and sodium sulfate. The authors generated 96-h median lethal concentrations (LC50s) of 1062 mg Cl/L (mean of 3 tests), 179 mg N-NO_3/L, and 1227 mg SO_4/L. Acute to chronic ratios ranged from 2.1 to 6.4 for chloride, 2.5 to 5.1 for nitrate, and 2.3 to 8.5 for sulfate. The endpoints related to survival and development time were consistently the most sensitive in the tests. The chronic values generated for chloride were in the same range as those generated by others using natural foods. Furthermore, our weight-versus-fecundity plots were similar to those previously published using the food culturing method on which the present authors' method was based, indicating good potential for standardization. The authors believe that the continued use of this sensitive mayfly species in laboratory studies will help to close the gap in understanding between standard laboratory toxicity test results and field-based observations of community impairment. *Environ Toxicol Chem* 2015;34:2126–2137. © 2015 SETAC

Keywords: Mayfly Toxicity testing Chronic toxicity Major ions

INTRODUCTION

Despite the fact that insects occur in nearly all freshwater ecosystems and are often the dominant class of macroinvertebrate in those systems [1], few insect models exist for use in determining the toxicity of contaminants. Among the most commonly used insect species in toxicity testing are the midges *Chironomus riparius* and *Chironomus dilutus*, which can be cultured in the laboratory but tend to be among the more insensitive invertebrates. Efforts have been made to assess the potential for use of abundant, wild-caught mayflies (Ephemeroptera) for standardized toxicity test development [2,3], but knowledge of exposure history, health, and age of test organisms before testing provides for better interlaboratory test result comparisons [4].

A major step toward the development of a sensitive insect model organism for toxicity testing was taken when Sweeney and Vannote [5] characterized the effects of several variables on life history characteristics of the parthenogenetic mayfly *Neocloeon triangulifer* McDunnough (originally described as *Cloeon triangulifer* [6], later transferred to *Centroptilum* [7], and most recently assigned to *Neocloeon* [8]). The same research group (Stroud Water Research Center) later developed a method of culturing this organism in the laboratory and using it in toxicity tests [9]. The advantage of *N. triangulifer* is that because it is parthenogenetic, it does not require a large amount of space for mating to take place; female clones can emerge into small containers (e.g., 300-mL beakers) and then deposit viable eggs. Furthermore, parthenogenic organisms in general are desirable for use in toxicity testing because being clonal eliminates genetic variability as a confounding factor. The Stroud Water Research Center group uses naturally colonized periphyton plates to feed the organisms, and this approach has now been adapted by others to conduct toxicological investigations with various contaminants [10–13].

Because food quality and quantity appear to influence the response of *N. triangulifer* to contaminants [10,11,13], developing a cultured food consisting of 1 or more diatom species is necessary to further allow standardization and more widespread use of this organism in toxicity testing. Great progress has been made toward this end by Weaver et al. [14], who developed a method of culturing 3 different diatom species (*Mayamea atomus, Nitzschia* cf. *pusilla*, and *Achnanthidium minutissimum*) in the laboratory, and then using stocks of monocultures of the species to colonize microscope slides, which are then offered to nymphs as biofilms. This approach was successfully used to culture 13 successive generations of the organisms, and both acute and short-term chronic (i.e., less than full-life) toxicity data have been generated using organisms cultured with this food [15].

Previously reported chronic toxicity tests with this species (or genus) have been conducted using wild-caught individuals [16], using cultured individuals with naturally colonized periphyton plates ([9–13,17,18]; J. Jackson, Stroud Water Research Center, Avondale, PA, USA, unpublished data), or for less than a full life cycle [15,19]. The objectives of the present study were to adapt the previously developed diatom culturing and toxicity testing methods for *N. triangulifer* [14,15] and to further develop a method for chronic toxicity tests spanning organism ages of less than 24 h post hatch to adult emergence, with the goal of producing data that are suitable for use in the development of chronic water quality criteria, as prescribed by Stephan et al. [20] (i.e., similar in scope to the daphnid and mysid life-cycle tests). We chose 3 sodium salts that are contaminants of interest in the Great Lakes region: sodium chloride, sodium nitrate, and sodium sulfate (E. Hammer, United States Environmental Protection Agency [USEPA],

Washington, DC, USA, personal communication), and conducted 96-h fed acute tests and full-life chronic toxicity tests so that acute-to-chronic ratios could be calculated.

METHODS

Culturing of test organisms and food

Mayfly and diatom biofilm culturing methods were based on those developed by Weaver et al. [14], with several modifications. As recommended [14], we initially used 3 species of diatom for feeding of mayflies, but we stopped using *Achnanthidium* sp. because it was more difficult to culture than the other diatoms, and culture results indicated that it was not necessary (DJ Soucek, personal observation). Diatoms used to feed mayflies included *Mayamea* sp. and *Nitzschia* sp. Both diatoms were obtained from Carolina Biological Supply, sold as *Navicula* sp. and *Synedra* sp., respectively. We had the genus-level identities taxonomically confirmed by an expert (S. Decelles) at USEPA-ORD, Cincinnati, Ohio, USA.

Mixed diatom stocks

To culture diatoms, we autoclaved (30 min at 121 °C, liquid cycle) a 4-L flask containing 4 L filtered (Whatman 934-AH) dechlorinated tap water and a 2-inch-long, Teflon-coated stir bar. After allowing it to cool, sterile technique was used to add 1.3 mL Kent Proculture Professional F/2 Algal culture formula A, 1.3 mL Kent Proculture Professional F/2 Algal culture formula B, 150 mg sodium metasilicate ($Na_2SiO_3 \cdot 9H_2O$), and 200 mL fresh diatom stock solution (just removed from stir-plate). Both diatom species were present in combination in stock cultures. We had initially kept the species stocks separate, but combining the species in stocks did not appear to impact the performance of the mayflies, so we adopted the combined stock approach. The flasks were placed on stir-plates with moderate to fast stirring (a large vortex was visible) in an environmental chamber set for a 16:8-h light:dark photoperiod and 25 °C. Diatom stocks were allowed to grow for 5 d, then 200 mL stock was used to seed the next flask and cages for mixed diatom slides (see below *Mixed-diatom slides*). Stocks were not refrigerated before seeding subsequent flasks or mixed-diatom slide cages.

Mixed-diatom slides

To culture mixed-diatom slides, 15 fully frosted microscope slides (catalogue no. 12-544-5CY, Fisherscience) were placed in a single layer (with frosted side facing up) on the bottom of a 7.2-L (189 mm × 297 mm × 128 mm) autoclavable polysulfone mouse cage (#PC7115HT, Ace Caging) filled with 2.5 L filtered (Whatman 934-AH) dechlorinated tap water. The container with the slides was autoclaved (30 min at 121 °C, liquid cycle) and allowed to cool. Sterile technique was used to add 1.3 mL Kent Proculture Professional F/2 Algal culture formula A, 1.3 mL Kent Proculture Professional F/2 Algal culture formula B, 150 mg sodium metasilicate ($Na_2SiO_3 \cdot 9H_2O$; dissolved in a small amount of deionized water before addition), and 200 mL fresh (never refrigerated) mixed-diatom stock. The container with slides was covered with clear plastic wrap and placed in an environmental chamber set for a 16:8-h light:dark photoperiod and 25 °C. Slides tended to have the most robust biofilms if used within approximately 6 d to 10 d after inoculation, but slides as old as 1 mo were used with success as long as most of the material appeared to be distinct round or spindle-shaped diatom cells when examined under a compound microscope. Poor-quality slides would have very few distinct cells on microscopic examination and would be mostly masses of amorphous material. If, after approximately 5 d, the biofilms appeared to be thin, we mildly aerated cages containing slides rather than adding more nutrients. We made the observation that color of the biofilm slides, as apparent to the naked eye, was not necessarily predictive of good mayfly performance. Therefore, before feeding to mayflies in toxicity tests or cultures, diatom biofilms were examined under a compound microscope to ensure that most of the biofilm material was distinct diatom cells, rather than being amorphous material.

Mayfly nymph rearing method

Mayflies (*Neocloeon triangulifer*; Stroud Water Research Center Clone #WCC-2) were reared in an environmental chamber at 25 °C, and a 16:8-h light:dark photoperiod. Culture water was a reconstituted water (hereafter referred to as Duluth 100) with a nominal hardness of 100 mg/L as $CaCO_3$, prepared according to a formula developed at the USEPA laboratory in Duluth, Minnesota, USA. To make this water, the following salt concentrations were added to deionized water from a Barnstead "E-pure" filtration system: $KHCO_3$, 10 mg/L; $NaHCO_3$, 125 mg/L; $MgSO_4$, 38 mg/L; $CaSO_4$, 40 mg/L; $CaCl_2$, 43 mg/L; NaBr, 0.05 mg/L. This water recipe was designed with the goal of better mimicking chemistry of "typical" North American freshwaters relative to other commonly used reconstituted waters (D. Mount, USEPA, Washington, DC, USA, personal communication). When eggs hatched, approximately 250 mL culture water was added to a 300-mL "I-chem" jar. All water was filtered using Whatman #934-AH glass microfiber filters. One mixed diatom slide was added to the jar. Newly hatched mayfly larvae (100–1000s) were then added to the jar, the lid was loosely placed, and the jar was covered with aluminum foil to block direct overhead lighting. When mayflies were 4 d to 8 d old (usually 6 d or 7 d), 40 individuals were placed in a 1-L beaker containing 400 mL Duluth 100 reconstituted water, and fed as described for the I-chem jar. The diatom slide was placed in the beaker before adding mayflies to avoid injury. Again, the container was covered with aluminum foil to block direct overhead lighting. When mayflies were 11 d to 12 d old, 20 individuals were transferred to a 19-cm × 24-cm × 6.5-cm Pyrex casserole dish containing 1.5 L Duluth 100 water and 5 mixed diatom slides. Slides were replaced when diatom biofilms were depleted, and water was changed twice per week or more if water appeared to be littered with loose diatoms and waste products. The container was covered loosely with foil. Using this method, aeration was not necessary at any point during mayfly culturing.

When pre-emergent nymph stages (determined by presence of black wing pads) appeared (days 20–23), they were placed in a 300-mL I-chem jar containing culture water and a mixed diatom slide. A screened cover was placed on the jar to allow for emergence of sub-imagoes and molting to imago stage (within 24 h after pre-emergent nymph stage). To induce the imago to release its eggs, we held it by the wings with forceps and touched its abdomen to culture water held in a small petri dish. This procedure was conducted with the aid of a dissecting microscope. Eggs were then pipetted into a scintillation vial; when possible, eggs of 3 females were combined in each vial. Eggs were either allowed to hatch or placed in an environmental chamber at 10 °C for later use. We observed a predictable relationship between the number of days eggs were held at 10 °C and the number of days to hatch on transfer of eggs to 25 °C (Figure 1). In some cases, eggs hatched over multiple days. For the purposes of generating a predictive equation for time to egg hatch, we used half-day intervals; for

R04592

 Electronic Filing: Received, Clerk's Office 3/14/2019

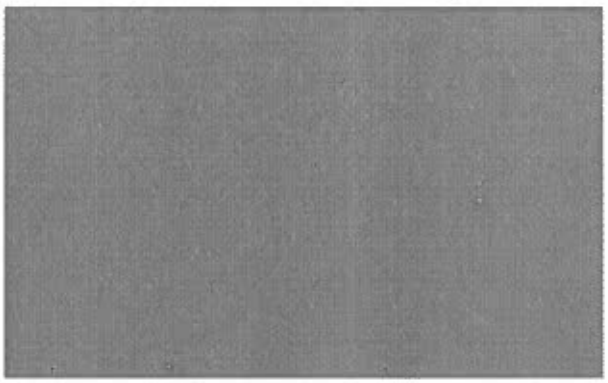

Figure 1. Predictive relationship between the number of days *Neocloeon triangulifer* eggs are held at 10 °C and number of days to hatch on moving eggs to 25 °C.

example, if approximately equal numbers of eggs hatched on days 2 and 3 after placement in 25 °C, we used 2.5 d in the regression model. The predictive model is as follows: # days to hatch on moving eggs to 25 °C = 0.0009 (# days at 10 °C)^2 − 0.1385(# days at 10 °C) + 6.809.

Test chemicals and dilution water

The nitrate, chloride, and sulfate sources for acute and chronic toxicity tests were reagent-grade sodium salts ($NaNO_3$ CAS # 7631-99-4; NaCl CAS # 7647-14-5; Na_2SO_4 CAS # 777-82-6). All acute and chronic tests were conducted in Duluth 100 hard water. As noted in the section *Mayfly nymph rearing method*, this was also the mayfly culture water, and eggs were stored in this water, so no acclimation was required.

Starvation test

To confirm previous observations that young mayflies are unable to survive extended periods without food [15], we conducted a starvation experiment in which we placed 1 <24-h-old mayfly into each of twenty 30-mL beakers containing 20 mL Duluth 100 water at 25 °C. We added no food to the beakers and observed mortality over the next 48 h. All organisms were alive at 24 h, but by the next day (48 h), survival was down to 22% (Figure 2). Based on this finding, all acute toxicity tests were fed a scraping of mixed diatom biofilm (described in *Acute test procedures*). Because all tests were conducted with sodium salts, food was not expected to impact availability of the contaminants, and analytical chemistry confirmed this (described in *Acute test procedures*).

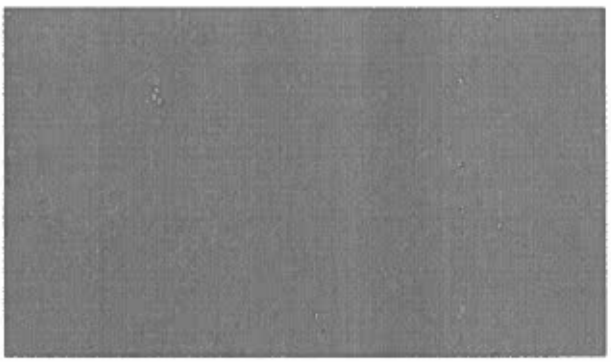

Figure 2. Percentage of survival of *Neocloeon triangulifer* larvae over time with no food. Organisms were less than 24 h old at the start of the test.

Table 1. Test conditions for acute toxicity tests with *Neocloeon triangulifer*

Condition	Value
1. Temperature (°C)	25 ± 1
2. Photoperiod (light:dark)	16:8
3. Test chamber size	30 mL
4. Test solution volume	20 mL
5. Age of organisms	<24 h
6. Dilution water	Duluth 100
7. Substrate	None
8. No. of organisms per chamber	5
9. No. of chambers/treatment	4
10. Food	Scraping of live diatom biofilm
11. Aeration	None
12. Test type	Static
13. Renewal frequency	None
14. Test duration	96 h
15. Control survival	≥90%
15. Endpoint	Survival

Acute test procedures

Static, nonrenewal, acute toxicity tests were conducted according to guidelines detailed in ASTM International E729-96 [4]. Treatments comprised a 50% dilution series. Five concentrations were tested in addition to controls. Further general details on test conditions are provided in Table 1. Organisms were less than 24 h old at the beginning of the test. Test chambers were fed by grasping a mixed diatom slide (cultured as described previously in *Mixed-diatom slides*) with a forceps, and scraping off an approximately 5-mm × 10-mm × 25-mm area of biofilm with another clean microscope slide, and releasing the biofilm into the test chamber. Chambers were fed on day 0 only, because 1 biofilm scraping was more than enough for the 96-h test duration. Mortality was assessed daily, using a dissecting microscope. Individuals were considered dead if they did not respond to gentle prodding with a blunt instrument. All median lethal concentration (LC50) values were calculated by using the trimmed Spearman-Karber method [21].

Standard water chemistry parameters were measured at both the beginning and the end of each exposure period, including temperature, pH, conductivity, and dissolved oxygen. Alkalinity and hardness were measured at the beginning of the test only. The pH measurements were made by using an Accumet (Fisher Scientific) model AB15 pH meter equipped with an Accumet gel-filled combination electrode (accuracy < ±0.05 pH at 25 °C). Dissolved oxygen was measured using an air-calibrated Yellow Springs Instruments (RDP) model 55 meter. Conductivity measurements were made using a Mettler Toledo (Fisher Scientific) model MC226 conductivity/total dissolved solids meter. Alkalinity and hardness were measured by titration [22]. Water samples from each treatment were collected at the beginning and end of acute tests and submitted to the Illinois State Water Survey analytical laboratory for measurement of nitrate, chloride, and sulfate concentrations as appropriate, using ion chromatography. Conductivity varied with salt concentration in all 3 tests. For the NaCl tests, mean (±standard deviation [SD]) temperature, pH, dissolved oxygen, alkalinity, and hardness were 25.0 ± 0.2 °C, 8.3 ± 0.1, 7.5 ± 0.3 mg/L, 84 ± 2 mg/L as $CaCO_3$, and 93 ± 1 mg/L as $CaCO_3$, respectively. For the $NaNO_3$ test, the values were 24.7 ± 0.3 °C, 8.3 ± 0.1, 7.8 ± 0.1 mg/L, 83 ± 1 mg/L as $CaCO_3$, and 99 ± 1 mg/L as $CaCO_3$, respectively. For the Na_2SO_4 test, the values were 24.8 ± 0.2 °C, 8.3 ± 0.1, 7.6 ± 0.2 mg/L, 84 ± 2 mg/L as $CaCO_3$, and 99 ± 1 mg/L as $CaCO_3$, respectively. For the NaCl test, measured chloride concentrations averaged 103%

R04593

 Electronic Filing: Received, Clerk's Office 3/14/2019

of nominal (range, 100–106%); for the $NaNO_3$ test, measured $N\text{-}NO_3$ averaged 105% of nominal (range, 103–107%); for the Na_2SO_4 test, measured sulfate averaged 107% of nominal (range, 101–110%). All reported LC50 values are based on measured concentrations.

Chronic toxicity testing procedures

For chronic toxicity tests, 6 treatments, including a control (dilution water), were tested. Nominal chloride concentrations for the treatments were as follows: 37 mg Cl^-/L (control), 70 mg Cl^-/L, 112 mg Cl^-/L, 196 mg Cl^-/L, 364 mg Cl^-/L, and 700 mg Cl^-/L. Nominal $N\text{-}NO_3$ concentrations were as follows: 0 mg $N\text{-}NO_3$/L (control), 12.5 mg $N\text{-}NO_3$/L, 25 mg $N\text{-}NO_3$/L, 50 mg $N\text{-}NO_3$/L, 100 mg $N\text{-}NO_3$/L, and 200 mg $N\text{-}NO_3$/L. Nominal SO_4^{2-} concentrations were as follows: 59 mg SO_4^{2-}/L (control), 136 mg SO_4^{2-}/L, 214 mg SO_4^{2-}/L, 369 mg SO_4^{2-}/L, 679 mg SO_4^{2-}/L, and 1300 mg SO_4^{2-}/L.

Test conditions are summarized in Table 2. In an attempt to minimize the mass of diatoms required for each test chamber, we initially used the model of the ASTM International *Ceriodaphnia dubia* chronic method [23], in which 1 organism is added per test chamber, and each treatment has 10 replicates. The NaCl and $NaNO_3$ chronic tests were conducted in this manner, but for the Na_2SO_4 chronic test, we used 2 organisms per test chamber (a total of 20 organisms per treatment) to decrease the chance of random control mortalities causing test failure. Because having 2 individuals per chamber did not require substantially higher numbers of diatom slides through the course of the test, we recommend using this organism loading rate for further tests.

Before the start of a test, a vial containing eggs from 3 females was moved from the 10 °C environmental chamber to the 25 °C chamber to encourage hatching of the eggs. The test began when sufficient numbers hatched to conduct the test; organisms were less than 24 h old at the start. Tests were conducted at 25 ± 1 °C and a 16:8-h light:dark photoperiod. All test chambers were covered with plastic wrap to minimize evaporation and with aluminum foil to eliminate direct overhead light. Light intensity in test chambers was approximately 110 lux to 160 lux. The test chambers at the beginning of the test were 30-mL glass beakers with 20 mL test water (or control). No substrate was used, but a scraping from a mixed diatom biofilm slide was added to each beaker for food as described previously in *Acute test procedures* for acute testing. Chambers were fed on day 0 and day 5, then on every water change day thereafter. Beginning on day 17 and until the end of the tests, biofilm scrapings were added to test chambers daily. Beakers were never allowed to be empty of food before the next feeding. We used scrapings of live biofilms for food, because numerous previous experiments using concentrated, refrigerated mixed diatom suspension made from concentrated stocks of freshwater diatoms, as recommended by Struewing et al. [15], resulted in lack of development of nymphs (DJ Soucek, personal observation). Water was not renewed for the first 4 d of the test, because the small size of the test organisms at that time made handling a potential source of error. Beginning on day 5 and every Monday, Wednesday, and Friday thereafter, complete water changes were conducted, with organisms being transferred to new beakers with freshly made water. Organisms were held in 30-mL beakers until day 14, when they were moved to 150-mL glass beakers with 100 mL test water. The 150-mL beakers were used until just before emergence.

Mayflies began to reach the pre-emergent nymph stage on day 20 to day 22, depending on the test. Slower developing individuals took as many as 36 d to reach this stage, but most had done so by day 25 in all 3 tests. When pre-emergent nymph stages were observed, they were transferred to 300-mL glass beakers with 125 mL appropriate test or control water and food. In early experiments to test this method, we added a clean microscope slide placed at a slant in the beaker to provide a surface for organisms to walk up and exit the water surface, but we later learned that this was not necessary. The larger beakers were used to provide more space for the flying sub-imagoes/imagoes, and they were covered individually with plastic wrap to prevent escape of the organisms. Sub-imagoes and imagoes were able to rest by clinging to the beaker wall or plastic wrap cover. For the NaCl and $NaNO_3$ tests, each organism had its own emergence chamber. In the case of the Na_2SO_4 chronic, which had 2 organisms per chamber at the beginning of the test, if both individuals reached pre-emergent nymph stage on the same day, they were placed in the same emergence chamber. Otherwise, each individual had its own emergence chamber. The pre-emergent nymph-staged nymphs were observed in the morning, and by the next morning, if successful, they had molted through the sub-imago stage to the imago stage. Imagoes then were grasped by the wings with a forceps, and weighed live to the nearest 0.001 mg by using a Cahn C-35 microbalance. Then, holding them again by the wings using a forceps, we held the ventral surface of their abdomen to Duluth 100 water held in a thick depression slide (85 mm × 14 mm × 33 mm), allowing the adult to release its eggs. When this procedure is performed under a dissecting scope, a faint yellowish coloration formed by the eggs is visible in the side of the abdomen. When all of the eggs are released, this coloration is no longer visible. In addition, we watched through the scope as the eggs were released and continued to hold the abdomen to the water for some time after eggs stopped appearing, to ensure that all eggs

Table 2. Test conditions for chronic toxicity tests with *Neocloeon triangulifer*

Condition	Value
1. Temperature (°C)	25 ± 1
2. Photoperiod (light: dark)	16:8

 Electronic Filing: Received, Clerk's Office 3/14/2019

were released. With the eggs in the depression slide, we used a dissection probe to break the surface tension, allowing the eggs to fall to the bottom of the depression. The concave nature of the depression caused eggs to gather in the bottom. We then used the probe to spread the eggs into a monolayer, and photographed the monolayer using an Olympus Q-color 3 camera mounted on a dissecting scope and QCapture Ver 2.7.3 software. The images were then printed to hard copy, and eggs were counted manually.

Standard water chemistry parameters were measured throughout the exposure period, including temperature, pH, conductivity, dissolved oxygen, alkalinity, and hardness, as detailed previously in *Acute test procedures* for acute toxicity tests. Water samples from each treatment were submitted to the Illinois State Water Survey analytical laboratory for confirmation of chloride, sulfate, or nitrate concentrations by using ion chromatography. With the exception of conductivity, which varied with salt concentration in all 3 tests, measured water quality parameters varied little in the chronic toxicity tests. For the NaCl test, mean (±SD) temperature, pH, dissolved oxygen, alkalinity, and hardness were 25.2 ± 0.5 °C, 8.3 ± 0.1 mg/L, 7.4 ± 0.4 (lowest value = 6.8) mg/L, 86 ± 4 mg/L as $CaCO_3$, and 94 ± 3 mg/L as $CaCO_3$, respectively. For the $NaNO_3$ test, the values were 25.2 ± 0.3 °C, 8.3 ± 0.1 mg/L, 7.5 ± 0.5 (lowest value = 6.6) mg/L, 85 ± 5 mg/L as $CaCO_3$, and 95 ± 7 mg/L as $CaCO_3$, respectively. For the Na_2SO_4 test, the values were 25.0 ± 0.3 °C, 8.4 ± 0.1 mg/L, 7.3 ± 0.4 (lowest value = 6.1) mg/L, 83 ± 3 mg/L as $CaCO_3$, and 95 ± 4 mg/L as $CaCO_3$, respectively. For the NaCl test, measured chloride concentrations averaged 100% of nominal (range, 92–109%); for the $NaNO_3$ test, measured $N\text{-}NO_3$ averaged 102% of nominal (range, 96–107%); for the Na_2SO_4 test, measured sulfate averaged 97% of nominal (range, 90–106%).

Endpoints measured included percentage of survival to pre-emergent nymph stage; percentage of pre-emergent nymph when controls finished (% pre-emergent nymph when controls finished, calculated as the number of individuals in a treatment that had successfully reached pre-emergent nymph stage by the day the last individual in the control reached pre-emergent nymph stage); mean number of days until pre-emergent nymph stage; percentage of emergence (calculated as the number successfully emerging to imago stage divided by the number of individuals at the start of the test), mean pre-egg-laying wet (live) weight of imago; number of eggs per female (i.e., number of eggs per emerging female, a measure of mean individual fecundity); number of eggs per original female (i.e., overall number of eggs produced in a treatment divided by the number of individuals at the start of the test). The latter endpoint is analogous to population growth rate, which would include development time as well, but because the results of the 2 calculations were highly correlated, we only included number of eggs per original female in the present study. Another endpoint reported by the Stroud Water Research Center (J. Jackson, Stroud Water Research Center, Avondale, PA, USA, unpublished data) was instantaneous growth rate, which incorporates adult and hatchling mass and development time. This endpoint was not responsive to any of the salts tested in the present study, so for the sake of brevity, we have not included it. Percentage of survival was analyzed statistically by using Fisher's exact test, and means for the remaining endpoints except for percentage of emergence and number of eggs per original female were compared by using analysis of variance with post hoc pairwise comparisons conducted using Tukey's honest significant difference. Dunnett's test was not used for post hoc tests for sublethal endpoints, because the treatments did not have equal replication because of mortality. The maximum allowable toxicant concentration was calculated as the geometric mean of the no observable effect concentration (NOEC: the highest concentration at which means were not significantly different from the control) and the least observable effect concentration: the lowest concentration at which means were significantly different from that of the control). When possible, 20% effective concentrations (EC20s) were calculated by using TRAP software (Ver 1.21A; R.J. Erickson, USEPA, MED, Duluth, MN, USA).

RESULTS

Acute toxicity tests

In the five 96-h, fed, acute toxicity tests conducted with *Neocloeon triangulifer* (3 with sodium chloride and 1 each with sodium sulfate and sodium nitrate), control survival was 100% in all cases except for the sodium sulfate test, which had 95% control survival. For the sodium chloride tests, individual 96-h LC50s (95% confidence intervals) were 1140 (994–1309) mg Cl/L, 910 (719–1153) mg Cl/L, and 1153 (96–1374) mg Cl/L. The geometric mean of these 3 tests (1062 mg Cl/L) was used to calculate the acute-to-chronic ratios for chloride. The 96-h LC50 for the nitrate test was 179 (165–205) mg $N\text{-}NO_3$/L, and the value for the sulfate test was 1227 (1073–1404) mg SO_4/L.

Chronic toxicity tests

Chloride test. Survival to pre-emergent nymph stage was high for the controls and the 3 lowest-exposure treatments (Table 3). In the 194-mg/L treatment, 1 individual was killed because of technician error, so survival was 8 of 9 individuals/replicates. The 362-mg/L and 701-mg/L treatments had significantly lower survival to pre-emergent nymph stage than the other treatments. All of the organisms in the 701-mg/L treatment were dead by day 4, and all mortality in the 362-mg/L treatment occurred on day 7 or before (Figure 3A). Percentage of pre-emergent nymph when controls finished was slightly more sensitive than the percentage of survival to pre-emergent nymph stage (20% vs 60%, respectively, in the 362 mg Cl^-/L treatment), but calculated effects levels were similar in the 2 endpoints. Controls reached the pre-emergent nymph stage by day 23 on average, as did the 70-mg/L, 112-mg/L, and 194-mg/L treatments. Organisms that survived in the 362-mg/L treatment had significantly delayed (by ~3 d) development to pre-emergent nymph stage. The percentage of emergence was relatively high in the controls, but although the highest concentration had no emergence, no dose–response relationship was observed for this endpoint. The measured maximum allowable toxicant concentration and EC20 (95% confidence interval) for percentage of pre-emergent nymph when controls finished were 265 mg Cl^-/L and 165 mg Cl^-/L (119–230 mg Cl^-/L), respectively, and for percentage of survival to pre-emergent nymph stage were 265 mg Cl^-/L and 190 mg Cl^-/L (129–280 mg Cl^-/L), respectively. We could not calculate an EC20 for number of days to pre-emergent nymph stage (as 1/mean number of days) or percentage of emergence because of insufficient slope, but the maximum allowable toxicant concentrations were 265 mg Cl^-/L and 504 mg Cl^-/L, respectively.

The sublethal endpoints of pre-egg-laying weight, number of eggs per female, and number of eggs per original female were not as sensitive as the survival-related endpoints. In fact, mean weights and number of eggs for the surviving individuals in the 362-mg Cl^-/L treatment were nominally higher than those for

MATC = maximum acceptable toxicant concentration; WCF = when controls finished; NA = not applicable; NC = not calculated (not statistically possible); EC20 = 20% effect concentration; CI = confidence interval; ACR = acute to chronic ratio.

any other treatment (Table 3). Neither maximum allowable toxicant concentrations nor EC20s could be calculated for any of these 3 endpoints. However, variability for these endpoints was relatively low, with coefficients of variation ranging from a minimum of 5 to a maximum of 17, suggesting that they may be useful endpoints for other contaminants with different modes of action.

With EC20s or maximum allowable toxicant concentrations ranging from 165 mg Cl^-/L to 504 mg Cl^-/L, and a mean 96-h LC50 of 1062 mg Cl^-/L, the acute to chronic ratios for chloride ranged from 2.1 to 6.4 (Table 3).

Nitrate test

Percentage of survival to pre-emergent nymph stage was high for the controls and up to 51 mg N-NO_3/L (Table 4). None of the mayflies in the 101-mg/L and 201-mg/L treatments survived to pre-emergent nymph stage. All of the organisms in the highest treatment were dead by day 16. In contrast to the chloride chronic test in which all mortality in the second highest exposure concentration occurred on day 7 or before, in the nitrate test, all mortality in the 101-mg/L treatment occurred on or after day 20, when organisms in other treatments were reaching the pre-emergent nymph stage (Figure 3B). Percentage of pre-emergent nymph when controls finished was more sensitive than percentage of survival to pre-emergent nymph stage, with a maximum allowable toxicant concentration of 36 mg/L compared with 72 mg/L for the latter. The EC20s could not be calculated for either of the survival endpoints because of inadequate partial effects. Controls reached the pre-emergent nymph stage by day 21 on average, and the 12.8 mg/L and 26 mg/L treatments had similar means for number of days to pre-emergent nymph stage (Table 4). Organisms in the 51-mg/L treatment reached the pre-emergent nymph stage on day 22 on average, and this mean was significantly different from that of the control. Although none of the organisms in the 101-mg N-NO_3/L treatment reached the pre-emergent nymph stage, 1 individual in this treatment was alive until day 31. Percentage of emergence was 60% in the controls but even higher in the 12.8-mg/L and 26-mg/L treatments.

As was true of the chloride chronic test, the sublethal endpoints of pre-egg-laying weight and number of eggs per

MATC = maximum acceptable toxicant concentration; NA = not applicable; NC = not calculated (not statistically possible); EC20 = 20% effect concentration; CI = confidence interval; ACR = acute to chronic ratio.

female were not as sensitive as survival or number of days to pre-emergent nymph stage (Table 4). In fact, mean weights and number of eggs for the surviving individuals in the nitrate-exposed treatments were nominally higher than those in the control. We were, however, able to calculate an EC20 for number of eggs per original female of 35 mg $N\text{-}NO_3$/L, which was the lowest chronic value obtained. Variability for pre-egg-laying weight and number of eggs per female were relatively low, with coefficients of variation ranging from 3 to 17.

With EC20s or maximum allowable toxicant concentrations ranging from 35 mg $N\text{-}NO_3$/L to 72 mg $N\text{-}NO_3$/L, and a 96-h LC50 of 179 mg $N\text{-}NO_3$/L, the acute-to-chronic ratios ranged from 2.5 to 5.1 for nitrate (Table 4).

Sulfate test

Percentage of survival to pre-emergent nymph stage was high for the controls and the 129 mg SO_4/L treatment, but was significantly reduced at 209 mg/L and above (Table 5). None of the mayflies in the 1277-mg/L treatments survived to pre-emergent nymph stage. As was the case for the nitrate test, all of the organisms in the highest treatment were dead by day 16 (Figure 3C). For the other treatments that had 60% to 70% survival to pre-emergent nymph stage, most of the mortality occurred after day 21, similar to what was observed in the nitrate test. Percentage of pre-emergent nymph when controls finished was again more sensitive than percentage of survival to pre-emergent nymph stage. Both endpoints had the same maximum allowable toxicant concentration (164 mg/L), but the EC20 for percentage of pre-emergent nymph when controls finished (170 mg/L) was substantially lower than that of the percentage of survival to pre-emergent nymph stage (289 mg/L). Controls reached the pre-emergent nymph stage by day 23 on average, and 2 treatments had significant delays in development, with the 359-mg/L treatment averaging 26 d and the 661-mg/L treatment averaging 32 d (Table 5). None of the organisms in the 1277-mg/L treatment reached the pre-emergent nymph stage. Percentage of emergence was 70% in the controls and roughly decreased with increasing sulfate dose, resulting in an EC20 of 145 mg/L (Table 5).

Again, the sublethal endpoints of pre-egg-laying weight and number of eggs were not as sensitive as survival or number of

R04597

days to pre-emergent nymph stage (Table 5), but we were able to calculate an EC20 for number of eggs per original female of 281 mg SO_4/L. Mean weights for the surviving individuals in the 661-mg/L treatment were significantly higher than those in the control, likely because of the longer development time. Again, variability for pre-egg-laying weight and number of eggs per female were relatively low, with coefficients of variation ranging from 9 to 21.

With EC20s ranging from 145 SO_4/L to 528 mg SO_4/L, and a 96-h LC50 of 1227 mg SO_4/L, the acute-to-chronic ratios ranged from 2.3 to 8.5 for sulfate (Table 5).

Relative sensitivity of endpoints

We were able to generate at least 4 acute-to-chronic ratios for each of the 3 chronic tests conducted (Table 6). To assess the relative sensitivity of the various endpoints over the 3 tests, we calculated relative acute-to-chronic ratios by dividing each individual acute-to-chronic ratio by the highest acute-to-chronic ratio for each particular test, thereby creating a ranking with a maximum of 1.00 (highest acute-to-chronic ratio) and a minimum of 0 (no acute-to-chronic ratio calculated). By taking the average relative acute-to-chronic ratio for each endpoint, we determined that percentage of pre-emergent nymph when controls finished was the most sensitive endpoint across the 3 tests, with an average relative acute-to-chronic ratio of 0.94, and pre-egg-laying weight and number of eggs per female were the least sensitive, with no acute-to-chronic ratios calculated (Table 6).

DISCUSSION

Our mean 96-h chloride LC50 of 1062 mg Cl/L at 25 °C and a hardness of 93 mg/L was higher than the 48-h LC50 of 399 mg Cl/L (calculated from the reported value for NaCl) reported by Struewing et al. [15] at the same temperature and a similar hardness. However, in the same paper, Struewing et al. [15] reported a 14-d LC50 of 505 mg Cl/L, which, being higher than their 48-h LC50, suggests that perhaps their reported acute tests were an overestimate of sensitivity. Based on results of separate experiments conducted in our laboratory (see Supplemental Data, Table S1), possibly this discrepancy is attributable to the feeding method used by the respective laboratories. The Struewing [15] study fed acute tests using a concentrated mixed diatom suspension, whereas the present study used live diatom biofilm scrapings as food. We conducted acute toxicity tests with *N. triangulifer* using both food types (refrigerated mixed diatom suspension and live biofilm scrapings) but otherwise with identical methods, and obtained substantially different LC50 values (~2-fold difference with non-overlapping confidence intervals) in the chloride salt tests (Supplemental Data, Table S1). Interestingly, although a similar difference was observed in tests with potassium chloride, the same comparisons with sulfate and nitrate salts resulted in LC50s that were quite similar between food types (Supplemental Data, Table S1), so this appears to be a phenomenon specific to chloride. At this time we are unable to speculate as to the mechanism for this difference. Our acute chloride toxicity results lie between those previously mentioned [15] and the findings of the Stroud Water Research Center (J. Jackson, Stroud Water Research Center, Avondale, PA, USA, unpublished data), who generated 48-h LC50s in tests conducted at 20 °C of 1423 mg Cl/L at a hardness of 22 to 42 (Dyberry Creek dilution water), and 2459 mg Cl/L at a hardness of approximately 100 (White Clay Creek dilution water), using naturally colonized live algal biofilm plates as food. With longer duration and a higher test temperature, believing that the Stroud Water Research Center results would be similar to ours is reasonable. All of these described tests were conducted with first instar larvae.

Our full-life chronic toxicity values for chloride, EC20s of 165 mg Cl/L to 190 mg Cl/L, and maximum allowable toxicant concentrations of 265 Cl/L to 504 mg Cl/L are similar to 14-d 25% inhibitory concentrations (IC25s) reported by Struewing et al. [15] in water with a similar hardness (~90 mg/L). Their values ranged from 139 Cl/L to 224 mg Cl/L (calculated from reported NaCl IC25s). Their acute-to-chronic ratios ranged from 0.79 to 2.9, whereas ours ranged from 2.1 to 6.4, a function of our higher LC50. Although they found weight and body length to be sensitive endpoints, our survival and development time data were more sensitive to chloride. A potential explanation for this different finding is that our weights were for egg-bearing adults that successfully emerged, whereas Struewing et al. [15] measured weight on approximately 14-d-old nymphs. Because we observed developmental delays (greater mean number of days to reach pre-emergent nymph stage at 362 mg Cl/L compared with lower treatments), we likely would have obtained similar results regarding weight if we ended the test at 14 d. Comparing endpoints is difficult because of the disparity in test duration, but another difference in the 2 test systems is that, again, Struewing et al. [15] fed their organisms a loose suspension of diatoms, whereas we fed ours live diatom biofilm scrapings. In our preliminary experiments, we were unable to bring mayflies to adulthood by using a refrigerated loose diatom suspension, even when plenty of excess food was available.

Table 6. Actual and relative acute to chronic ratios generated in the present study for three chronic toxicity tests with sodium salts[a]

Endpoint	Cl test		$N\text{-}NO_3$ test		SO_4 test		Average relative ACR
	ACR	Relative ACR	ACR	Relative ACR	ACR	Relative ACR	
% pre-emergent nymph WCF[b]	6.4	1.00	5.0	0.98	7.2	0.85	0.94
% survival to pre-emergent nymph stage	5.6	0.88	2.5	0.49	4.2	0.49	0.62
No. of days to pre-emergent nymph	4.0	0.63	5.0	0.98	2.3	0.27	0.63
% emergence	2.1	0.33	4.6	0.90	8.5	1.00	0.74
Weight[c]	NC	0	NC	0	NC	0	0
No. of eggs/female	NC	0	NC	0	NC	0	0
No. of eggs/original female	NC	0	5.1	1.00	4.4	0.52	0.51

[a]Relative acute-to-chronic ratios were calculated by dividing each individual acute-to-chronic ratio for a given test by the highest acute-to-chronic ratio for that test. A high relative acute-to-chronic ratio indicates high sensitivity (i.e., a larger difference between the chronic endpoint and the 96-h LC50).
[b]WCF = when controls finished (i.e., when the last control individual has reached pre-emergent nymph stage).
[c]Weight = pre-egg-laying live weight of adults.
ACR = acute to chronic ratio; WCF = when controls finished; NC = not calculated; LC50 = median lethal concentration.

R04598

The Stroud Water Research Center (J. Jackson, Stroud Water Research Center, Avondale, PA, USA, unpublished data) reported full-life chronic chloride toxicity to *N. triangulifer*, using naturally colonized periphyton plates as food. Their most sensitive endpoints were development time and instantaneous growth rate. Despite their testing at 20 °C, their maximum allowable toxicant concentrations in water with a similar hardness to ours (White Clay Creek) ranged from 177 Cl/L to 708 mg Cl/L. Thus, our full-life chronic method using laboratory-cultured food appears to produce chronic values similar to those produced using natural food sources.

In other chronic toxicity studies using this species or closely related mayflies with chloride dominated salts, Hassell et al. [16] obtained 21-d conductivity LC50s of 890 µS/cm to 2700 µS/cm in 2 different dilution waters at 15 °C, using wild-caught *Centroptilum* sp., and Johnson et al. [18] reported an EC20 of 672 µS/cm at 24.5 °C in a mesocosm study with *N. triangulifer*, using a combination of $CaCl_2$ and NaCl. Both of these tests were conducted with natural foods: conditioned leaves for the former and naturally colonizing periphyton for the latter. In our chloride test, we calculated a conductivity EC20 of 895 µS/cm (709–1129 µS/cm) for the most sensitive endpoint, so again, our test with cultured food can produce similar results to those with natural foods.

Other mayfly genera have been investigated for sodium chloride sensitivity in subchronic tests. For example, Diamond et al. [24] tested *Stenonema modestum* (Heptageniidae) at 12 °C in 14-d exposures. The maximum allowable toxicant concentrations for survival and molting endpoints ranged from 1410 mg Cl/L to 3798 mg Cl/L (calculated from salt concentrations). Echols et al. [3] observed a mean *Isonychia bicolor* 7-d NOEC of 855 mg Cl/L at 20 °C to 23 °C. Goetsch and Palmer [25] reported a 96-h LC50 between 1500 mg Cl/L and 2500 mg Cl/L for *Tricorythus* sp. in an unfed test at 10 °C to 16 °C. K. Allan recorded a 72-h conductivity LC50 of 12 600 µS/cm for the leptophlebiid mayfly *Nousia* sp. using sodium and chloride–dominated saline waters. A 7-d acclimation to higher salinity water did not significantly alter conductivity LC50s for that species (K. Allan, 2006, Master's thesis, University of Tasmania, Hobart, TAS, Australia). Although these effect levels are higher than those observed in our NaCl chronic test, comparisons are tenuous because of the differences in test temperatures, duration, endpoints, and the fact that all of these studies used wild-collected organisms.

Much less information is available in the literature on chronic toxicity of sulfate salts to *N. triangulifer* and related species. Kunz et al. [12] conducted static, nonrenewal exposures of first instar nymphs through adult emergence (~35 d) at ambient laboratory temperatures of 21 °C, using naturally colonized periphyton plates (from Stroud Water Research Center) as food and survival (emergence) and biomass as endpoints. They developed reconstituted waters to simulate major ion compositions typical of streams impacted by coal mining in Appalachian streams. One of the waters tested ("Upper Dempsey") was dominated by Na and SO_4, but in contrast to our findings, it did not cause significant toxicity at the highest test concentration (~640 mg SO_4/L). We observed EC20s ranging from 145 SO_4/L to 528 mg SO_4/L, but our test was conducted at a hardness of 95 mg/L, whereas the Kunz et al. [12] test was conducted at a hardness of 220 mg/L. Hardness has been shown to have a strong influence on sodium sulfate toxicity to other species [26,27]. In 2 other reconstituted waters having an ionic composition dominated by Ca, Mg, HCO_3, and SO_4, Kunz et al. [12] did observe significant toxicity to *N. triangulifer* at sulfate concentrations ranging from 386 mg/L ("Winding Shoals" water) to approximately 770 mg/L ("Boardtree" water; sulfate not measured). In terms of conductivity, the Winding Shoals and Boardtree waters were toxic to *N. triangulifer* at approximately 800 µS/cm and 1300 µS/cm, respectively [12]. We calculated a conductivity EC20 for our sodium sulfate test of 725 µS/cm.

Goetsch and Palmer [25] reported a 96-h LC50 of 532 mg SO_4/L for the mayfly *Tricorythus* sp. in sodium sulfate exposures at approximately 10 °C to 15 °C. This is substantially lower than our 96-h LC50 of 1227 mg SO_4/L, but in addition to using a different species with potentially different sensitivity to sulfate, the *Tricorythus* test was conducted at a moderately lower hardness (~70 mg/L as $CaCO_3$), and the test was not fed. Conversely, our conductivity EC20 (725 µS/cm) for *N. triangulifer* is quite similar to 7-d maximum allowable toxicant concentrations reported by Kennedy et al. [28] (737–773 µS/cm) for *Isonychia bicolor* exposed to a simulated mine effluent dominated by sodium and sulfate.

To our knowledge, these are the first acute and chronic nitrate toxicity values reported for *N. triangulifer*, but our lowest maximum allowable toxicant concentrations (36 mg N-NO_3/L) and EC20 (35 mg N-NO_3/L) are strikingly similar to a 20-d threshold effect concentration (equivalent to an maximum allowable toxicant concentration) reported for the New Zealand leptophlebiid *Deleatidium* sp. [29]. Our 96-h LC50 for *N. triangulifer* (179 mg N-NO_3/L) would place this species fifth in sensitivity among the invertebrate data previously compiled [30]. Our lowest chronic value is similar but nominally less sensitive than the mean maximum allowable toxicant concentration (22 mg N-NO_3/L, calculated from NOEC and least observable effect concentration values) reported for the water flea *Ceriodaphnia dubia* [31], but it is substantially more sensitive than *Daphnia magna* (mean maximum allowable toxicant concentration = 507 mg N-NO_3/L [31]), and the apple snail *Pomacea paludosa* (mean 14-d EC50 = 560 mg N-NO_3/L) [32].

For each of our 3 full-life chronic toxicity tests, we evaluated 7 endpoints: 2 involving survival to pre-emergent nymph stage, 1 involving development time, 1 involving adult emergence rates, and 3 involving adult weight or fecundity. Based on average relative acute-to-chronic ratio (Table 6), the most sensitive endpoints in our tests were those involved with survival, emergence, and development time. This suggests that exposure to sublethal concentrations of these sodium salts in the field may not affect somatic growth or fecundity directly, but could have phenological effects that may indirectly impact population growth. The weight and number of eggs per female endpoints were not sensitive in any of our 3 tests; however, others, using different testing scenarios, have found growth and biomass endpoints to be sensitive ([12,15,18]; J. Jackson, Stroud Water Research Center, Avondale, PA, USA, unpublished data). As stated previously, this disparity can in part be attributed to differences in when tests are ended, for example, based on our development time results (number of days to pre-emergent nymph stage), had we ended our tests at day 14 as in Struewing et al. [15], we likely would have seen differences among treatments in organism weights. Furthermore, we believe that even in a test conducted according to the method in our present study, weight and fecundity endpoints should be evaluated because chemicals with different modes of action than those tested in the present study may cause different types of effects.

In our chloride chronic test, nearly all mortality occurred by day 7, whereas in the nitrate chronic, mortality in the highest concentration occurred early in the test (beginning on day 2), but in the second highest concentration, no mortality occurred until pre-emergent nymph stages were appearing in other treatments (day 20; Figure 3). A similar pattern was observed in the sodium sulfate chronic. This suggests that the most sensitive life stage may be dependent on the contaminant, but it also supports the findings of others [19,33], who in field and laboratory studies exposing *N. triangulifer* to metals found that metamorphosis to the imago was a highly sensitive life-stage.

Based on our starvation test, acceptable control survival (≥90%) appears to not be possible in an unfed 48-h or 96-h acute toxicity test conducted at 25 °C. Similar results were reported for this species by Struewing et al. [15], who had 11% survival after 48-h in USEPA moderately hard reconstituted water with no food, and by the Stroud Water Research Center (J. Jackson, Stroud Water Research Center, Avondale, PA, USA, unpublished data), who in 4 of 5 waters tested had approximately 10% survival or less after 48 h. The ASTM International [4] method for conducting acute toxicity tests states that organisms should not be fed during acute toxicity tests, although it makes an exception for mysid shrimp, which are severely stressed if not fed. In the present study, the nature of the chemicals tested is such that the presence of food would not be expected to alter bioavailability of the contaminants, but the need to feed *N. triangulifer* in acute tests will be a factor to consider in tests with other contaminant types. Poteat and Buchwalter [34] contend that in the case of metals in particular, dietary uptake is a more ecologically valid measurement for aquatic insects than dissolved exposures, but in general, water quality criteria development still uses data from waterborne exposures, so this is an issue that may require some flexibility.

We compared the relationship between pre-egg-laying weight and the number of eggs produced per female in the present study with that reported in Weaver et al. [14], and although our fecundity numbers were consistently lower than those predicted by their equation (Figure 4), the slopes of the lines were quite similar whether we used only control data (Figure 4A) or both control and exposure data (Figure 4B). If we use our data to predict a minimum adult weight at which 1000 eggs or more would be produced in the same manner as that described in Weaver et al. [14], we obtain values of 2.95 mg for control-only data, and 2.72 for control plus exposure data. These numbers bracket the previously reported value of 2.8 mg [14]. In other words, using our "controls only" equation to predict number of eggs based on a weight of 2.0 mg results in a value that is 80% of the result using the Weaver et al. [14] equation, and at a weight of 3.8 mg (just above our maximum), our equation produced a number of eggs value that was 94% of that using the Weaver et al. [14] equation. These slight differences may be attributable to acclimation to different waters or different sources of within-laboratory error, but the overall similarity of these relationships obtained using similar methods of producing laboratory-cultured food indicates good potential for standardization.

In the process of adapting the Weaver et al. [14] method and developing our own full-life chronic toxicity method, a few of the lessons we learned are as follows. First, for culturing, we have obtained best results when seeding stocks and cages for diatom slides with fresh diatom stocks that have never been refrigerated. Second, further work should be done to specifically characterize ion and nutrient concentrations required for diatom slide and diatom stock media. We currently use dechlorinated

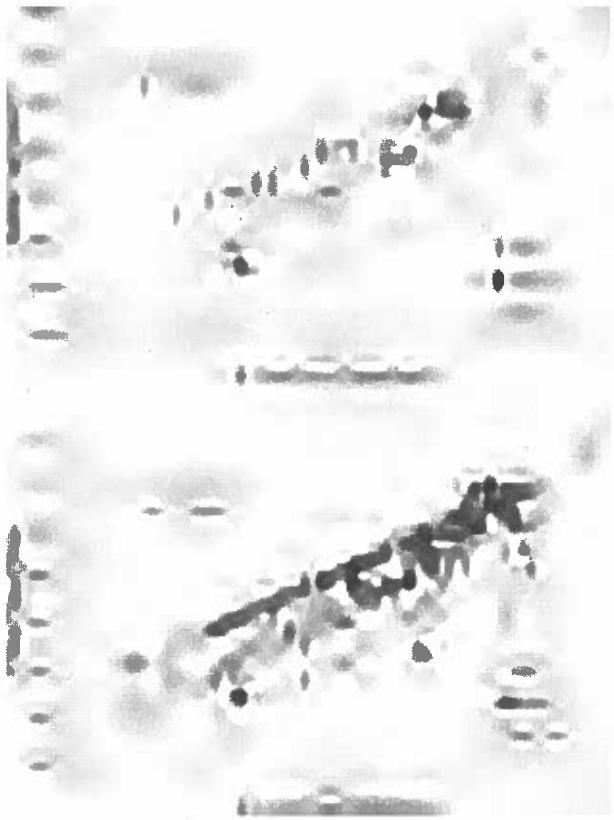

Figure 4. Relationship between pre–egg-laying wet weight of *Neocloeon triangulifer* and number of eggs produced in (A) controls only and (B) all treatments of 3 chronic toxicity tests. Asterisks are number of eggs/female predicted by the equation from Weaver et al. [1] based on our mayfly weights. Dashed lines show 95% confidence intervals for the solid line described by the equation in each panel.

tap water with an added nutrient and trace metal solution to culture diatom stocks and slides. Although we have analyzed tap water samples for ionic composition, this is likely variable over time because of the nature of municipal water supplies. One of the most variable aspects of the current method remains the quality of diatom slides, and better knowledge of specific ion requirements for diatoms will help to reduce this variability. Third, our results suggest that mayflies require live biofilms for robust development to adulthood. In numerous attempts, feeding concentrated mixed diatom suspensions that have been refrigerated did not result in development to pre-emergent nymph stage. Fourth, before feeding live biofilms to mayflies, a sample of the biofilm slide must be examined under a compound microscope to ensure that most of the cells are intact, and that the biofilm is not made up of amorphous material. Color of the biofilm does not appear to be a good predictor of food quality. Finally, having a higher percentage of emergence in controls during chronic toxicity tests would be desirable. One current thought is that because the lowest nitrate concentration had 90% emergence during that test, perhaps the addition of a low concentration of nitrate to culture medium and test dilution water would improve the food quality and therefore increase the rate of emergence.

Mayflies have received much attention recently because of their apparent sensitivity to mining influences in Appalachian headwater streams, with declines attributed to elevated conductivity, a surrogate measure of major ion concentrations of total dissolved solids [35–38]. Until recently, a disconnect

R04600

Electronic Filing: Received, Clerk's Office 3/14/2019

has been perceived between what major ion concentrations are toxic to organisms in the laboratory versus what concentrations cause impairment to endemic benthic macroinvertebrate communities. Although no laboratory exposure system can completely replicate exposure scenarios experienced by organisms in situ, our observation of effects at various life-stages and documentation of potential phenological impacts brings some environmental relevance in addition to the fact that this is an organism that better represents benthic macroinvertebrate communities than standard crustacean models. We believe that the continued use of this sensitive mayfly species in laboratory studies will help to close this gap in understanding.

SUPPLEMENTAL DATA

Table S1. (15 KB DOC).

Acknowledgment—We thank D. Funk and J. Jackson at Stroud Water Research Center for providing *Neocloeon triangulifer* eggs to begin cultures and for consultation during the present study. J. Jackson provided the unpublished Stroud Water Research Center data referred to throughout the text. Thanks also to P. Weaver and J. Lazorchak at United States Environmental Protection Agency-ORD in Cincinnati, OH, and D. Buchwalter of North Carolina State University for invaluable advice throughout the course of the present study. The present study was funded by the Great Lakes Restoration Initiative by way of a Cooperative Ecosystem Studies Unit grant from US Geological Survey, Columbia Environmental Research Center grant No. G12AC20025. M. Hung assisted with some of the toxicity tests.

Data availability—Contact David Soucek at soucek@illinois.edu for available data.

Environmental Toxicology

Influence of Dilution Water Ionic Composition on Acute Major Ion Toxicity to the Mayfly *Neocloeon triangulifer*

David J. Soucek,[a,*] David R. Mount,[b] Amy Dickinson,[a] and J. Russell Hockett[b]

[a]Illinois Natural History Survey, Champaign, Illinois, USA
[b]Mid-Continent Ecology Division, US Environmental Protection Agency, Duluth, Minnesota, USA

Abstract: Field and laboratory studies have shown that mayflies (Ephemeroptera) tend to be relatively sensitive to elevated major ion concentrations, but little is known about how ionic composition influences these responses. The present study evaluated the acute toxicity of major ion salts to the mayfly *Neocloeon triangulifer* over a range of background water quality conditions. The mayfly was particularly sensitive to Na_2SO_4, with the median lethal concentration (LC50) of 1338 mg SO_4/L being lower than LC50s reported for 7 other species at that hardness. Increasing hardness of the dilution water from 30 to 150 mg/L (as $CaCO_3$) resulted in doubling of LC50s for sodium salts, and an approximately 1.5-fold increase in LC50 for $MgSO_4$. Potassium salt toxicity was not strongly influenced by hardness, consistent with findings for other species. When hardness was held constant but the Ca to Mg ratio was manipulated, the ameliorative effect on Na_2SO_4 and NaCl did not appear as strong as when hardness was varied; but for $MgSO_4$ the amelioration relative to Ca activity was similar between the 2 experiments. The toxicity of K salts to *N. triangulifer* was similar to Na salts on a millimolar basis, which contrasts with several other species for which K salts have been much more toxic. In addition, the toxicity of KCl to *N. triangulifer* was not notably affected by Na concentration, as has been shown for *Ceriodaphnia dubia*. Finally, plotting LC50s in terms of ion activity (Cl, SO_4, Na, Mg, or K) over the range of Ca activities in dilution water resulted in significant positive relationships, with comparable slopes to those previously observed for *C. dubia* over the same range of Ca activities. *Environ Toxicol Chem* 2018;37:1330–1339. © 2018 SETAC

INTRODUCTION

The environmental impacts of elevated concentrations of major ions (i.e., Na^+, K^+, Ca^{2+}, Mg^{2+}, Cl^-, SO_4^{2-}, and HCO_3^-) have received considerable research attention in the 2 decades since it was recognized that major ion toxicity varies widely depending on the composition of the solution (Mount et al. 1997). The primary sources of elevated major ions in freshwaters were reviewed by Goodfellow et al. (2000), but much of the recent North American literature has focused on issues related to road salting and mining (Corsi et al. 2010; Palmer et al. 2010), with toxicity testing primarily focused on sodium chloride or sodium sulfate tested with standard test organisms, especially crustaceans (Soucek and Kennedy 2005; Davies and Hall 2007; Soucek 2007; Lasier and Hardin 2010; Elphick et al. 2011a, 2011b; Soucek et al. 2011; Mount et al. 2016; Wang et al. 2016).

A number of field studies have shown that mayflies (Ephemeroptera) appear to be more sensitive than other benthic macroinvertebrate taxa to elevated major ion concentrations in streams impacted by mining (Pond et al. 2008; Pond 2010; Cormier et al. 2013; Timpano et al. 2015; Boehme et al. 2016), and several recent laboratory studies have generated chronic toxicity data confirming this sensitivity (Kennedy et al. 2004; Hassell et al. 2006; Kunz et al. 2013; Johnson et al. 2015; Soucek and Dickinson 2015; Struewing et al. 2015; J. Jackson, Stroud Water Research Center, Avondale, PA, USA, personal communication). Until relatively recently, difficulties with culturing have precluded the use of mayflies as laboratory toxicity testing organisms to any great extent; however, researchers at Stroud Water Research Center developed a method for testing a parthenogenetic species (*Neocloeon triangulifer*) that readily reproduces under laboratory conditions (Sweeney et al. 1993). Furthermore, recent efforts to develop laboratory cultured diets and chronic toxicity testing methods for mayflies have been successful and will help us move toward standardization of methods for this species (Soucek and Dickinson 2015; Struewing et al. 2015; Weaver et al. 2015). In acute (96-h) exposures

reported by Soucek and Dickinson (2015), sodium chloride median lethal concentrations (LC50s) for *N. triangulifer* were approximately equal to those reported for the cladoceran *Ceriodaphnia dubia* (Mount et al. 1997), but sodium sulfate LC50s were approximately half those for *C. dubia*. In a full-life chronic toxicity test, the percentage of emergence (the most sensitive endpoint in that test) 20% effect concentration for *N. triangulifer* exposed to sodium sulfate (Soucek and Dickinson 2015) was 15 to 23% of the lowest values reported for other invertebrates including *C. dubia*, *Lampsilis abrupta*, and *Chironomus dilutus* (Wang et al. 2016). The most sensitive chronic response level of *N. triangulifer* to sodium chloride (Soucek and Dickinson 2015) was 36 to 39% of those of *C. dubia* and *Daphnia magna* (Elphick et al. 2011a) and similar to the response of the chloride-sensitive mussel *Lampsilis siliquoidea* (Wang et al. 2015).

The fact that major ion toxicity to standard laboratory test organisms like cladocerans, amphipods, and fish is dependent on the ionic composition of a water or effluent has been well established; for example, several studies have shown that the toxicity of sodium sulfate and sodium chloride decrease with increasing water hardness (Mount et al. 1997, 2016; Soucek and Kennedy 2005; Davies and Hall 2007; Soucek 2007; Elphick et al. 2011a, 2011b; Soucek et al. 2011) and, more specifically, increasing Ca concentration (Davies and Hall 2007; Mount et al. 2016). It is also known that for crustaceans and fish, solutions tend to be more toxic when dominated by particular major ions; *C. dubia* is more sensitive to solutions dominated by K^+, Mg^+, and HCO_3^- than those dominated by Na^+, Cl^-, and SO_4^{2-} (Mount et al. 1997, 2016). Furthermore, recent work has shown that sodium concentration regulates the toxicity of potassium salts to *C. dubia* (Mount et al. 2016). Very little is known about how ionic composition influences responses of *N. triangulifer* to elevated major ions, although Kunz et al. (2013) observed differences in chronic responses of this species to Na^+ and SO_4^{2-} dominated solutions compared to Ca^{2+}, Mg^{2+}, SO_4^{2-}, and HCO_3^- dominated solutions; and Stroud Water Research Center (J. Jackson, personal communication) noted differences in 48-h NaCl LC50s in 2 dilution waters with different hardnesses. Zalizniak et al. (2006) investigated the influence of ionic composition on salinity toxicity to the related Australian mayfly *Centroptilum* sp., but test concentrations were not sufficiently low to have confidence in LC50s. Because *N. triangulifer* appears to be more sensitive to some major ions than other laboratory cultured test organisms, greater knowledge of the influence of dilution water composition on major ion toxicity will be important to refining our ability to evaluate potential risks to aquatic communities.

Although most field studies (e.g., Pond et al. 2008; Cormier et al. 2013; Boehme et al. 2016) and some laboratory or mesocosm studies (Kefford et al. 2003; Hassell et al. 2006; Kunz et al. 2013; Johnson et al. 2015; Clements and Kotalik 2016) report responses to elevated major ions in terms of electrical conductivity, endpoints for major ion laboratory toxicity tests are most frequently reported in terms of anion concentrations (e.g., Soucek and Kennedy 2005; Davies and Hall 2007; Soucek 2007; Lasier and Hardin 2010; Elphick et al. 2011a, 2011b; Soucek et al. 2011; Wang et al. 2016). The focus on anions may be attributable in part to the finding of Mount et al. (1997) that Na and Ca were not significant factors in regressions used to model ion toxicity; however, more recent studies by Erickson et al. (2016) suggested that K, Mg, and Ca salt toxicities to *C. dubia* are related to the cations and that Na salt toxicity may be related to multiple ions or osmolarity (i.e., not necessarily the associated anion). These findings with *C. dubia* indicate the need to reexamine drivers of acute effects attributable to various major ion salts. In the present study, we report acute toxicity of various major ion salts in terms of both anion and cation concentrations, but a subsequent article will be devoted to more explicitly evaluating likely causes of toxicity to this species in major ion salt toxicity tests.

The primary goal of the present study was to determine how changes in ionic composition of dilution water impact responses of *N. triangulifer* to elevated major ions over a range of background water quality conditions. Building on the work of Mount et al. (2016) with *C. dubia*, we investigated how changes in hardness and, more specifically, changes in Ca impact acute toxicity of several major ion salts. We also tested the reciprocal influences of Na on KCl toxicity and K on NaCl toxicity.

METHODS

Culturing of test organisms and food

The parthenogenetic mayfly *N. triangulifer* (family Baetidae; McDunnough 1931) was originally described as *Cloeon triangulifer*, later transferred to the genus *Centroptilum* (McCafferty and Waltz 1990), and most recently assigned to *Neocloeon* (Jacobus and Wiersema 2014). The genetic strain we used was Stroud Water Research Center Clone #WCC-2™. It is reared in the laboratory on a diatom diet, and mayfly and diatom biofilm diet culturing methods were similar to those reported in Soucek and Dickinson (2015). Diatoms used to feed mayflies included *Mayamaea* sp., and *Nitzschia* sp. Both diatoms were obtained from Carolina Biological Supply, sold as *Navicula* sp. and *Synedra* sp., respectively. We had the genus-level identities taxonomically confirmed by an expert (S. Decelles) at the US Environmental Protection Agency (USEPA), Office of Research and Development (Cincinnati, OH).

Mixed diatom stocks. To culture diatoms, we autoclaved (30 min at 121 °C, liquid cycle) a 4-L flask containing 4 L of filtered (Whatman™ 934-AH) dechlorinated tap water and a 2-inch long Teflon®-coated stir bar. After allowing to cool, a sterile technique was used to add 1.3 mL of Kent®–Proculture Professional F/2 Algal culture formula A, 1.3 mL of Kent®–Proculture Professional F/2 Algal culture formula B, 150 mg of sodium metasilicate ($Na_2SiO_3 \times 9H_2O$), and 200 mL of fresh diatom stock solution (just removed from the stir plate). Both diatom species were present in combination in stock cultures. The flasks were placed on stir plates with moderate to fast stirring (a large vortex was visible) in an environmental chamber set for a 16:8-h light:dark photoperiod and 25 °C. Light intensity in the chamber varied between 800 and 1200 lux depending on position in the chamber. Diatom

R04605

stocks were allowed to grow for 5 d, then 200 mL of stock was used to seed the next flask and cages for mixed diatom slides (see *Mixed diatom slides* section). Allowing growth for much more than 5 d appeared to cause depletion of nutrients and cell death. Stocks were not refrigerated prior to seeding subsequent flasks or mixed diatom slide cages.

Mixed diatom slides. To culture mixed diatom slides, 15 fully frosted microscope slides (catalog no. 12-544-5CY, Fisher Scientific) were placed in a single layer (with frosted side facing up) on the bottom of a 7.2-L (189 × 297 × 128 mm) autoclavable polysulfone mouse cage (no. PC7115HT, Allentown, Inc., Allentown, PA) filled with 2.5 L of filtered (Whatman 934-AH) dechlorinated (carbon-filtered and aged) tap water. The container with the slides was autoclaved (30 min at 121 °C, liquid cycle) and allowed to cool. A sterile technique was used to add 1.3 mL of Kent–Proculture Professional F/2 Algal culture formula A, 1.3 mL of Kent–Proculture Professional F/2 Algal culture formula B, 150 mg of sodium metasilicate ($Na_2SiO_3 \times 9$ H_2O; dissolved in a small amount of deionized water prior to addition), and 200 mL of fresh (never refrigerated) mixed diatom stock. The container with slides was covered with clear plastic wrap and placed in an environmental chamber set for a 16:8-h light: dark photoperiod and 25 °C. Light intensity at the level of the slides varied between 300 and 100 lux, depending on position in the chamber. Growth was allowed for 6 to 10 d. Soucek and Dickinson (2015) provided further details on assessing biofilm quality prior to feeding to mayflies.

Mayfly nymph rearing method. Mayflies were reared in an environmental chamber at 25 °C, a 16:8-h light: dark photoperiod, and light intensity of approximately 200 lux. Culture water was a reconstituted water (hereafter referred to as Duluth 100) with a nominal hardness of 100 mg/L as $CaCO_3$, prepared according to a formula developed at the USEPA laboratory in Duluth, Minnesota (Supplemental Data, Tables S1 and S2). This water recipe was designed with the goal of better mimicking the chemistry of "typical" North American freshwaters relative to other commonly used reconstituted waters. When eggs hatched, approximately 250 mL of culture water were added to a 300-mL clear glass jar. All water was filtered using Whatman #934-AH glass microfiber filters. One mixed diatom slide was added to the jar. Newly hatched mayfly larvae (hundreds to thousands) were then added to the jar, the lid was loosely replaced, and the jar was covered with aluminum foil to block direct overhead lighting. When mayflies were 4 to 8 d old (usually 6 or 7 d), 40 individuals were placed in a 1-L glass beaker containing 400 mL Duluth 100 reconstituted water and fed as described for the 300-mL glass jar. The diatom slide was placed in the beaker prior to adding mayflies, to avoid injury. Again, the container was covered with aluminum foil to block direct overhead lighting. When mayflies were 11 to 12 d old, 20 individuals were transferred to a 19 × 24 × 6.5–cm Pyrex casserole dish containing 1.5 L of Duluth 100 water and 5 mixed diatom slides. Slides were replaced when diatom biofilms were depleted, and water was changed twice per week or more if water appeared to be littered with loose diatoms and waste products. The container was covered loosely with foil. Using this method, aeration was not necessary at any point during mayfly culturing.

When preemergent nymph stages (determined by the presence of black wing pads) appeared (days 20–23), they were placed in a 300-mL I-chem jar containing culture water and a mixed diatom slide. A screened cover was placed on the jar to allow for emergence of subimagoes and molting to imago stage (within 24 h after preemergent nymph stage). To induce the imago to release its eggs, we held it by the wings with forceps and touched its abdomen to water held in a small Petri dish. This procedure was conducted with the aid of a dissecting microscope. Eggs were then pipetted into a scintillation vial; when possible, eggs of 3 females were combined in each vial. Eggs were either allowed to hatch or placed in an environmental chamber at 10 °C for later use.

General acute toxicity testing procedures

Static, nonrenewal, acute toxicity tests were conducted according to guidelines detailed in ASTM International (2014). Five concentrations spaced by 50% dilution were tested in addition to controls, with the highest test concentration made by adding the salt of interest to the dilution water of interest. Further details on test conditions are provided in Supplemental Data, Table S3. Eggs were transferred to test water prior to hatching so that organisms hatched into the water in which they would be tested, and organisms were <24 h old at the beginning of a test. Test chambers were fed by grasping a mixed diatom slide (cultured as described in the section *Mixed diatom slides*) with a forceps, scraping off an area of biofilm of approximately 5 to 10 × 25 mm with another clean microscope slide, and releasing the biofilm into each replicate test chamber. Test organisms were fed because in a previous study first-instar mayflies had 22% survival after 48 h with no food (Soucek and Dickinson 2015). This has been observed by others as well (Struewing et al. 2015; J. Jackson, Stroud Water Research Center, personal communication). Because all tests were conducted with major ions, food was not expected to impact dissolved concentrations of the contaminants, and analytical chemistry confirmed this (detailed in the *Quality assurance/quality control* section). Food was added to test chambers only on day 0 because previous testing demonstrated that one biofilm scraping was more than enough for the 96-h test duration. Mortality was assessed daily using a dissecting microscope. Individuals were considered dead if they did not respond to gentle prodding with a probe.

Temperature, pH, conductivity, and dissolved oxygen were measured in all treatments at the beginning and the end of each exposure period. Alkalinity and hardness were measured in the controls and the highest test treatment at the beginning of the test only. The pH measurements were made using an Accumet® (Fisher Scientific) model AB15 pH meter equipped with an Accumet gel-filled combination electrode (accuracy <±0.05 pH at 25 °C). Dissolved oxygen was measured using an air-calibrated Yellow Springs Instruments model 55 meter. Conductivity measurements were made using a Mettler Toledo® (Fisher Scientific) model MC226 conductivity/total dissolved

solids meter. Alkalinity and hardness were measured by titration as described by the American Public Health Association (2005). Water samples from each treatment were collected at the beginning and end of tests and submitted to the Illinois State Water Survey analytical laboratory for verification of selected major ion concentrations using ion chromatography.

Experimental approach and dilution waters

We developed a testing approach that covered 3 basic objectives, which are detailed in this section. Recipes for and detailed chemistry of the 9 different dilution waters used are provided in Supplemental Data, Tables S1 and S2. Reagent-grade or certified American Chemical Society–grade salts were used to make all test waters. Solutions enriched with $MgSO_4$ were prepared using $MgSO_4 \times 7H_2O$ or $MgSO_4$ (anhydrous) but are reported as $MgSO_4$.

Hardness comparisons. The first set of tests determined the toxicity NaCl, Na_2SO_4, K_2SO_4, and $MgSO_4$ in dilution waters representing different hardnesses. Waters with nominal hardnesses of 30, 90, 150, and 210 mg/L (as $CaCO_3$) were prepared using recipes developed at the USEPA laboratory in Duluth, Minnesota, which varied all major ions to approximate average concentrations in US surface waters of a given hardness (Supplemental Data, Tables S1 and S2). These test waters differed from culture water (Duluth 100) in that $CaCO_3$ was the main source of carbonate rather than $NaHCO_3$. Carbon dioxide gas (99.9% CO_2) was bubbled through the solution (to pH ~5.2) to dissolve $CaCO_3$, then natural air was bubbled through the solution to bring the pH back to approximately 7.6 for testing.

Ca to Mg comparisons. While hardness tests evaluated the aggregate effect of varying all ions in dilution water, additional tests varying Ca to Mg ratios at constant hardness were used to evaluate the specific role of calcium. Toxicity of NaCl, Na_2SO_4, K_2SO_4, and $MgSO_4$ were tested in waters similar to Duluth 100 water but modified to "low Ca to Mg" (0.5 ratio on a mass basis) and "high Ca to Mg" (5.0 mass ratio) compositions with all other ions held constant (Supplemental Data, Tables S1 and S2). The "Ca to Mg" terminology is in reference to the original dilution water, so in the case of the Mg salt, the Ca to Mg ratio was in reality different from treatment to treatment because of the added Mg. From a practical perspective it was primarily Ca in the dilution water that was being altered.

Na/K interactions. The reciprocal influences of Na on KCl toxicity and K on NaCl toxicity were tested by comparing responses in Duluth 100 water (which served as a low-Na or low-K water) to responses in Duluth 100 water with high Na (150.3 mg Na/L added as NaCl) or high K (15.0 mg K/L added as KCl; see Supplemental Data, Table S2). These comparisons were spurred by the finding of Na-dependent toxicity of KCl in *C. dubia* (Mount et al. 2016) and K-dependent toxicity of Na_2SO_4 in fathead minnows (Wang et al. 2016).

Data analysis

For each acute toxicity test, the dominant anion concentrations were analytically verified in each treatment as described in the *General acute toxicity testing procedures* section. We calculated LC50s for each test in terms of measured dominant anion concentration (milligrams per liter) using the trimmed Spearman-Karber method (Hamilton et al. 1977). Then, based on measured anion concentration, calculated concentration of the associated cation (milligrams per liter), and nominal concentrations of other ions in the dilution water, we estimated all major ion concentrations (millimoles) at the LC50 value for each test (Table 1; Supplemental Data, Table S4). We then used Visual MINTEQ, Ver 3.0 (JP Gustafsson, Royal Institute of Technology, Department of Land and Water Resources Engineering, Stockholm, Sweden) to calculate the activity of all potential ionic species at the LC50 concentration for each test (Supplemental Data, Table S5). For activity modeling, we input fixed pH values based on the average measured pH for each test. Calcium was the most frequently manipulated major ion in dilution waters in the present study, and previous studies with *C. dubia* indicated that Ca influenced toxicity of Na and Mg salts (Mount et al. 2016). Therefore, to evaluate the influence of Ca on major ion toxicity, we created scatter plots with LC50s in terms of Cl, SO_4, Na, Mg, or K activities as dependent variables and Ca activity as the independent variable. For each dependent variable ion, we included all salts tested, for example, for SO_4 LC50s, we included K_2SO4, $MgSO_4$, and Na_2SO_4. We also plotted K salt LC50s against Na activity as the independent variable because Na regulated K salt toxicity to *C. dubia* (Mount et al. 2016).

Quality assurance/quality control

Control survival was 100% in the majority of the acute toxicity tests reported and always ≥90%.

Across all acute toxicity tests conducted, the mean (± standard deviation) overall temperature, pH, and dissolved oxygen values were 25.0 ± 0.4 °C, 8.2 ± 0.3 standard units, and 7.7 ± 1.3 mg/L, respectively. The lowest dissolved oxygen concentration observed in any test was 6.4 mg/L. Specific conductivity, alkalinity, and hardness varied depending on dilution water and test treatment but were consistent with the nominal composition of the treatment.

For the acute toxicity tests with chloride salts, measured Cl^- concentrations averaged 104% of nominal (range, 92–118%). For the acute toxicity tests with sulfate salts, measured SO_4^{2-} concentrations averaged 103% of nominal (range 87–124%). Measured concentrations were used for calculating LC50s, and reported cation concentrations were calculated proportionally based on measured concentrations of anions.

RESULTS AND DISCUSSION

Hardness comparisons

When tested across dilution waters with different hardness, NaCl, Na_2SO_4, and $MgSO_4$ all decreased in toxicity with increasing hardness, though to varying degrees (Table 1 and Figure 1). For

[a]Dilution water composition was considered in estimating cation concentration at LC50.
CI = confidence interval; LC50 = median lethal concentration.

both NaCl and Na_2SO_4, the LC50 more than doubled as hardness increased from approximately 30 to 150 mg/L (nominal hardnesses), whereas for $MgSO_4$ the increase was approximately 1.5-fold. Despite this rise, all 3 of these salts showed little difference in toxicity between 150 and 210 mg/L hardness. For K_2SO_4, the pattern was markedly different, with little difference among the 30, 90, and 150 mg/L waters. For the 210 hardness water, the initial test resulted in an LC50 of 1808 mg Cl/L, roughly 1.8 times above that in the lower 3 hardnesses. Because this pattern was unexpected, the test at 210 mg/L hardness was repeated, yielding an LC50 of 1261 mg Cl/L, much closer to the lower 3 (Table 1). Therefore, it is unclear whether K_2SO_4 toxicity is hardness-dependent, but it appears to be less so than the other 3 salts.

Hardness-dependent toxicities of NaCl and Na_2SO_4 have been reported for several other species previously. For NaCl, *C. dubia* (Soucek et al. 2011; Mount et al 2016), the snail *Gyraulus parvus* (Soucek et al. 2011), the unionid mussel *L. siliquoidea* (Gillis 2011), and the worm *Tubifex tubifex* (Soucek et al. 2011) have been observed to exhibit hardness-dependent acute sensitivity. In addition, Stroud Water Research Center (J. Jackson, personal communication) documented decreased NaCl toxicity to the mayflies *N. triangulifer*, *Procloeon rivulare*, and *Pseudocloeon frondale* in 48-h toxicity tests using a natural water with a hardness of 105 mg/L relative to a natural water with a hardness of 22 mg/L. Likewise for Na_2SO_4, hardness-dependent sensitivity has been observed for *C. dubia* (Soucek and Kennedy 2005; Mount et al. 2016), *D. magna* (Davies and Hall 2007), and *Hyalella azteca* (Davies and Hall 2007; Soucek 2007).

Ca to Mg comparisons

In the dilution waters used for hardness comparisons, all of the major ions increased with increasing hardness, not just Ca and Mg (Supplemental Data, Table S2). This was done purposefully to examine trends in waters that simulate how toxicity might vary in natural waters for which concentrations of all major ions generally covary with increasing hardness. Research on other organisms has suggested that the ameliorative effect of hardness is largely attributable to increased Ca specifically (Davies and Hall 2007; Mount et al. 2016); to evaluate this relationship for *N. triangulifer*, we tested the toxicity of the same 4 salts (NaCl, Na_2SO_4, K_2SO_4, and $MgSO_4$) in dilution waters with constant nominal hardness but different Ca to Mg ratios. Both waters had measured hardnesses of 93 to 95, but the low Ca to Mg ratio water had a Ca concentration similar to that in

FIGURE 1: Influence of Ca in dilution water on the acute toxicity of (A) NaCl, (B) Na_2SO_4, (C) K_2SO_4, and (D) $MgSO_4$ to the mayfly *Neocloeon triangulifer*. "All ions manipulation" are data from the "hardness comparisons" series of tests in the present study; Ca concentrations of 8, 25, 41, and 58 mg/L were waters with 30, 90, 150, and 210 mg/L as $CaCO_3$ nominal hardness, respectively. Error bars are 95% confidence limits. CL = confidence limits; LC50 = median lethal concentration.

the Recon 30 water (nominally 9.3 mg Ca/L), whereas Ca in the high Ca to Mg ratio water was more than 3 times higher (30.3 mg Ca/L), slightly higher than that in Recon 90 (Supplemental Data, Table S2). If the variations in LC50s in the "hardness comparisons" series were attributable only to Ca, we would expect shifts in LC50 from the Ca to Mg manipulation paralleling those in the hardness comparison studies.

In the case of the 2 sodium salts, the actual differences in LC50 from low Ca to Mg ratio to high Ca to Mg ratio were less than predicted by the "hardness comparison" tests (Table 1 and Figure 1). The fact that their LC50s increased less when manipulating only Ca to Mg rather than all ions suggests either that something aside from or in addition to calcium accounted for the decreased toxicity in the "hardness comparisons" series or that the higher overall ion concentrations in the low Ca to Mg water relative to 30 hardness water provided some benefit (Supplemental Data, Table S2). Conversely, the $MgSO_4$ results showed a similar increase in LC50 when only calcium was increased and when all ions increased proportionally as in the hardness comparison (Table 1 and Figure 1); this suggests that calcium accounted for most or all of the modification of toxicity attributable to hardness. The K_2SO_4 results were consistent with the previous tests in the hardness series, showing little, if any, effect of Ca or hardness on toxicity over the range present in the lower 3 hardness waters (Table 1 and Figure 1). The hardness/Ca dependence of toxicity for Na and Mg salts but not K salts, shown in the present study for *N. triangulifer*, is consistent with the findings of Mount et al. (2016) for *C. dubia*.

Na/K interactions

In the Na/K interactions series, we observed essentially no effect on KCl toxicity when Na varied from 34 mg/L (low Na = Duluth 100; Supplemental Data, Table S2) to 150 mg/L (high Na; Supplemental Data, Table S1 and S2), with 96-h LC50s of 1226 and 1221 mg Cl/L, respectively (Table 1). Likewise, the mean LC50 for the 2 NaCl tests conducted at low K (3.9 mg/L) was 1032 mg Cl/L, whereas the LC50 at high K (15 mg/L) was 1012 mg Cl/L (Table 1). The lack of influence of Na on the toxicity of KCl contrasts with the marked ameliorative effect of Na on KCl toxicity reported for *C. dubia* (Mount et al. 2016), whereas the lack of influence of K on toxicity of NaCl is parallel with that found for *C. dubia*.

Ion activities

For all of the tests in the present study, we calculated LC50s and dilution water compositions in terms of activity (millimoles; Supplemental Data, Table S5) to account for the fact that, in more concentrated solutions, ions behave as though their concentrations are lower than their total concentrations (Snoeyink and Jenkins 1980). The importance of considering activity in expressing exposure to major ion salts was further affirmed in analyses for *C. dubia* (Mount et al. 2016). Determining specific causes of toxicity (e.g., anions, cations, osmolarity) in major ion salt tests was beyond the scope of the present study, but Erickson et al. (2016) suggested that the toxicities of K, Mg, and Ca to *C. dubia* appear to be attributable

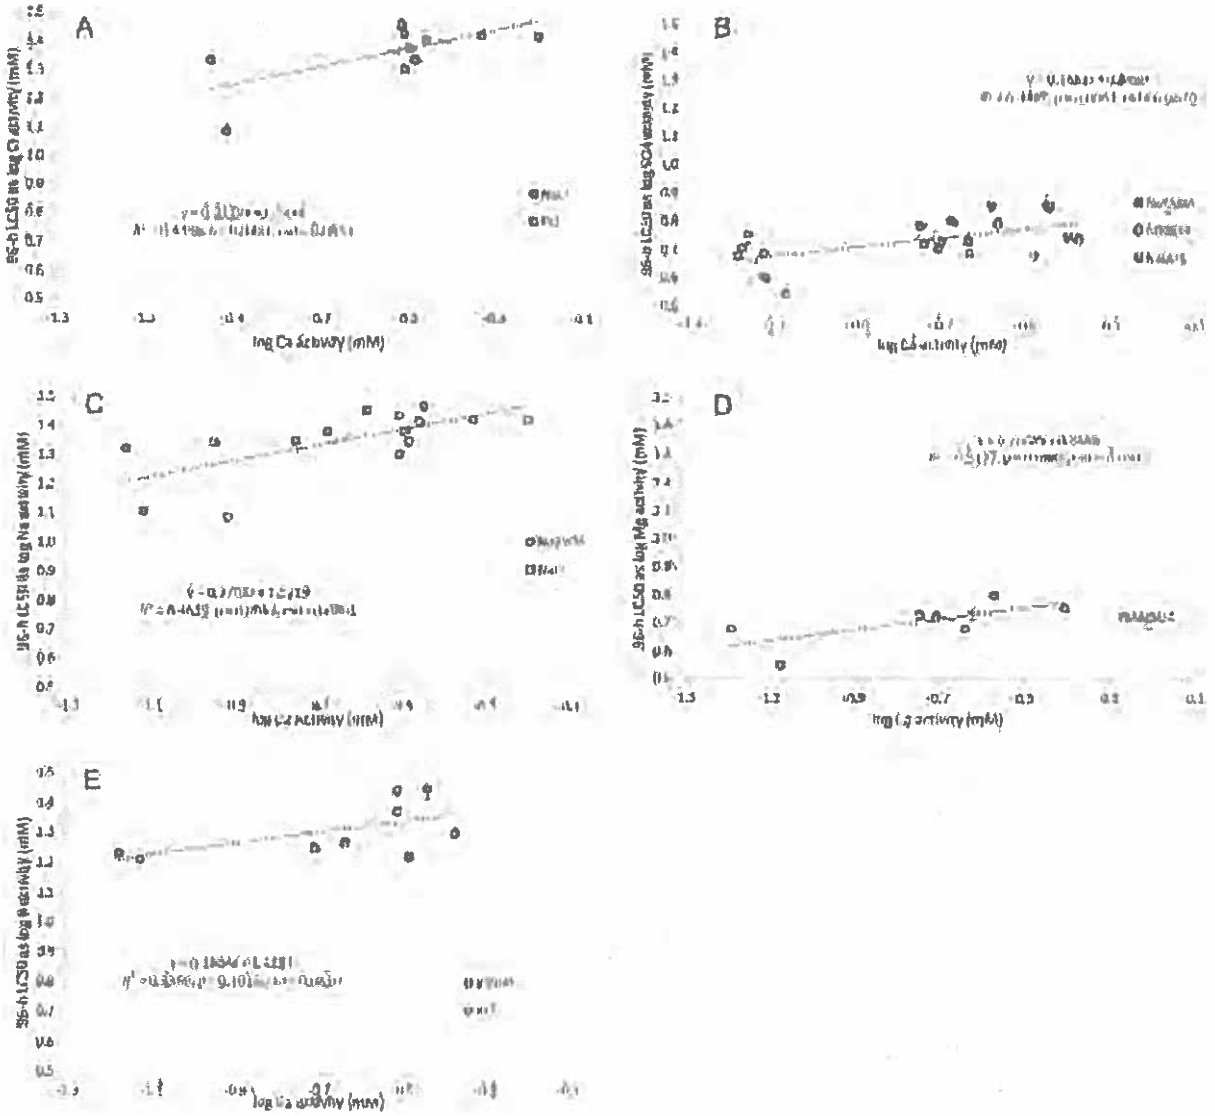

FIGURE 2: Influence of Ca activity on 96-h median lethal concentrations of various major ion salts for the mayfly *Neocloeon triangulifer* expressed as logs of (A) chloride activity, (B) sulfate activity, (C) sodium activity, (D) magnesium activity, and (E) potassium activity. LC50 = median lethal concentration; rsd = residual standard deviation.

to the cations rather than anions and that Na salt toxicity may be related to multiple ions or osmolarity (i.e., not necessarily the associated anion). We report toxicity data for the mayfly in terms of both anion and cation activities plotted against Ca activity because Ca was the most frequently manipulated major ion in dilution waters and was shown to be a primary influence on toxicity of Na and Mg salts to *C. dubia* (Mount et al. 2016).

As shown in Figure 2, the 96-h LC50s for Cl, SO_4, and Na were significantly positively correlated with Ca activity in the dilution water, whereas correlations for Mg and K with Ca were insignificant ($p > 0.05$). Although not statistically different from zero because of the inclusion of fewer tests, the slope for the Mg data was similar to those of the other ions and greater than the significantly positive slope for SO_4, which included more than double the number of tests. The chloride plot had the steepest slope, followed closely by Na. Mount et al. (2016) reported on the influence of Ca on Na salt toxicity (as Na activity) for *C. dubia* (Figure 3), but that study tested waters with substantially lower Ca concentrations than the present study did (as low as 0.04 mM compared to our lowest value of 0.2 mM). Much of the steepness in the curve in the *C. dubia* study (Mount et al. 2016) was below 0.2 mM Ca. Over the comparable range of Ca activities, the responses of the 2 organisms are similar; and if we had tested *N. triangulifer* in waters with even lower Ca concentrations, we might have observed a similarly stronger Ca dependence of Na toxicity. It is notable that in the case of the *C. dubia* data (Mount et al. 2016; Figure 3), there is distinct separation on the *y* axis between NaCl and Na_2SO_4; this was not observed for the mayfly.

Although the Ca slope for Mg activity was not statistically separable from zero, the Mg data for mayfly are generally consistent with the Ca slope found for *C. dubia* (Mount et al. 2016); and, as for the Na salts, the strongest effect of Ca on Mg salt toxicity

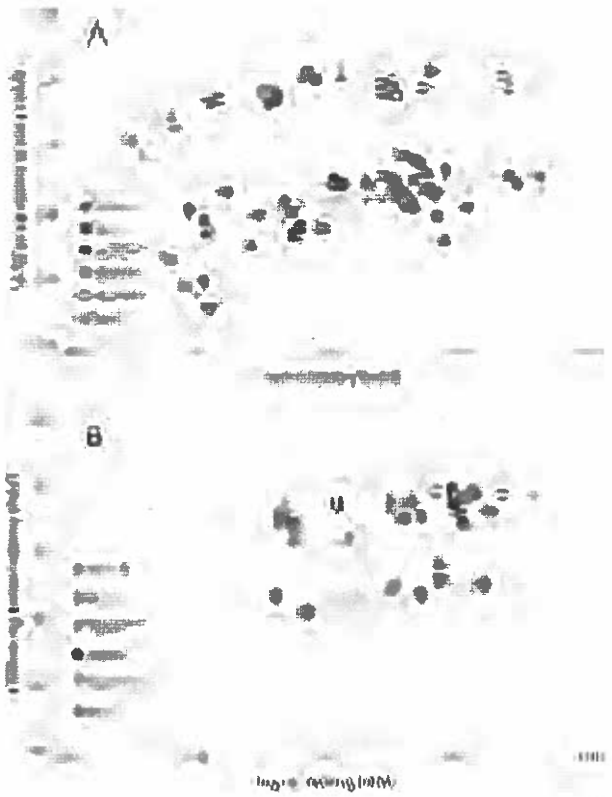

FIGURE 3: Influence of Ca activity on acute median lethal concentrations (LC50s) of various major ion salts for the (A) *Ceriodaphnia dubia* (from Mount et al. 2016) and (B) the mayfly *Neocloeon triangulifer*. All LC50s expressed in terms of cation activity for the given salt. Trendlines in (A) are linear fits for *C. dubia* data over the range of Ca activities tested with *Neocloeon*. The longer dashed yellow line fits Na_2SO_4 data, whereas the finer dotted line fits NaCl data. The same *C. dubia* trendlines are then superimposed with the *Neocloeon* data in (B).

for *C. dubia* occurred at Ca activities lower than those tested in the present study for mayfly (Figure 3). Another interesting trend apparent in Figure 3 is that the toxicities of Na and K are quite similar for *N. triangulifer* with Mg being substantially more toxic. This contrasts sharply with data for *C. dubia* and fathead minnows, for which K and Mg salts were substantially more toxic than Na salts (Mount et al. 1997, 2016). Unpublished data from C. Ivey et al. (2013, poster presented at Society of Environmental Toxicology and Chemistry) indicate an even greater disparity between Na and K toxicity to freshwater mussels, with KCl being on the order of 50-fold more toxic than NaCl on a millimolar basis.

Figure 4 in addition plots K salt LC50s against Na activity in dilution water for comparison with the finding of Mount et al. (2016) that Na regulates K salt toxicity to *C. dubia*. There is little slope evident in the data for the mayfly, further confirming our conclusion that in the case of this species Na appears to have little influence on K salt toxicity.

Sensitivity of N. triangulifer *relative to other organisms*

For the sodium salts, the range of LC50s we observed for *N. triangulifer* indicate that it is acutely sensitive relative to other

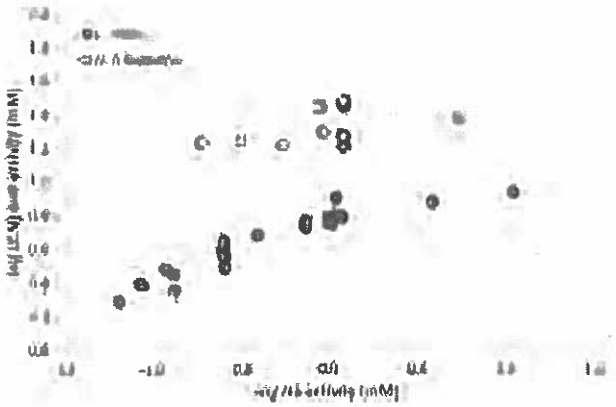

FIGURE 4: Potassium salt median lethal concentrations for the mayfly *Neocloeon triangulifer* and the cladoceran *Ceriodaphnia dubia* (from Mount et al. 2016) as a function of Na activity in dilution water. LC50 = median lethal concentration.

species. The acute toxicity of NaCl in waters of 80 to 100 mg/L hardness has been reported for many aquatic species. The chloride LC50 for *N. triangulifer* (837 mg Cl/L at nominal hardness of 90; Table 1) in the present study is lower than values for 11 other species tested in this hardness range including cladocerans (*C. dubia*, *Daphnia ambigua*, *D. magna*; Mount et al. 1997; Harmon et al. 2003; Elphicket al. 2011a; Soucek et al. 2011), a mussel (*L. siliquoidea*; Gillis 2011), a rotifer (*Brachionus calyciflorus*; Elphick et al. 2011a), an amphipod (*H. Azteca*; Elphick et al 2011a; Soucek et al. 2013), 2 worms (*Lumbriculus variegatus* and *Tubifex tubifex*; Elphick et al. 2011a; Soucek et al. 2011), an insect (*C. dilutes*; Elphick et al. 2011a), and 2 fish (*Pimephales promelas* and *Oncorhynchus mykiss*; Mount et al. 1997; Elphick et al. 2011a). Notably, the mayfly was more sensitive than *C. dubia*, for which there are a number of published LC50s in this hardness range (average LC50 ~1138 mg Cl/L; Mount et al. 1997, 2016; Harmon et al. 2003; Elphick et al. 2011a; Soucek et al. 2011). Struewing et al. (2015) and Stroud Water Research Center (J. Jackson, personal communication) have reported NaCl LC50s for *N. triangulifer* previously, but those tests were 48 h in duration compared to the 96-h tests in the present study, so comparisons of effect levels with our data are tenuous. In the present study, 48-h LC50s were consistently approximately double the corresponding 96-h LC50s (data not shown). The first molt for the organism occurs within this time frame and might account for the sharp difference in 48- and 96-h LC50s (D.J. Soucek, personal observation). The glochidia of 3 mussel species (*Lampsilis fasciola*, *Epioblasma torulosa*, and *Lampsilis cardium*) have been found to be more sensitive than *N. triangulifer* (LC50s ranging 179–817 mg Cl/L; Gillis 2011).

For Na_2SO_4, the LC50 for *N. triangulifer* at hardness 90 mg/L in the present study (1338 mg SO_4/L; Table 1) was lower than values for the 7 other species for which we found data at that approximate hardness: *H. azteca*, *Sphaerium simile*, *D. magna*, *P. promelas*, *C. dilutus*, *L. abrupta*, and *C. dubia* (Mount et al. 1997, 2016; Soucek and Kennedy 2005; Davies and Hall 2007; Soucek 2007; Wang et al. 2016). Reported LC50s for these species ranged from 1874 to 14 134 mg/L. Goetsch and Palmer (1997) generated an LC50 of 500 mg SO_4/L for the mayfly *Tricorythus* sp.

© 2018 SETAC

R04611

at a lower hardness (~69 mg/L), confirming the sensitivity of mayflies to Na_2SO_4. There is a published data point at a similar hardness for *H. azteca* of 512 mg SO_4/L (Soucek and Kennedy 2005), but the dilution water for that toxicity test had a chloride concentration lower than that considered sufficient for optimal health for that species (Soucek et al. 2015). Thus, in general, *N. triangulifer* appears to be relatively sensitive to sodium salts, especially sodium sulfate. There have been several studies published on the chronic responses of *N. triangulifer* to NaCl and Na_2SO_4 in a range of dilution waters, and these were reviewed by Soucek and Dickinson (2015).

Compared with the sodium salts, far fewer published data are available on the acute toxicity of Mg and K salts to other species (Mount et al. 1997, 2016; Van Dam et al. 2010). The Mg salt toxicity data for *C. dubia*, *D. magna*, and *P. promelas* reported by Mount et al. (1997), with LC50s ranging from 224 to 569 mg Mg/L, are similar to those reported in the present study for the mayfly at a similar hardness (224–411 mg Mg/L at hardness ~90 mg/L; Table 1). Conversely, *N. triangulifer* was substantially less sensitive to K than the 3 species tested by Mount et al. (1997), the former having LC50s ranging from 785 to 1326 mg K/L at hardness ~90 mg/L (Table 1) and the latter having LC50s of <305 to 462 mg K/L. Van Dam et al. (2010) tested the responses of a variety of Australian freshwater species from an area with background water containing extremely low Ca to $MgSO_4$, with most having median effect concentrations between 4.4 and 63 mg Mg/L (the exception being *Chlorella* at 1215 mg Mg/L). The lower values from that study are approximately an order of magnitude lower than those reported in the present study (Table 1), but the dilution water in the Van Dam et al. (2010) study had very low Ca (<0.8 mg/L), which could account for the difference given the effect of Ca on Mg toxicity observed in the present study.

CONCLUSIONS

In summary, the mayfly was in general relatively sensitive to NaCl, $MgSO_4$, and especially Na_2SO_4 compared with other species reported in the literature but relatively less so to K salts. Sodium and magnesium salt toxicity decreased with increased hardness, whereas the K salt toxicity did not, consistent with findings for other species. However, in Ca to Mg manipulations, it is not clear whether Ca activity alone can account for all of the "hardness" effect. Over the range of Ca activity tested for the mayfly, the slopes of the Ca effect on toxicity of Na and Mg salts to mayfly were similar to those reported elsewhere for *C. dubia*, though it is unclear whether the steeper slopes reported for *C. dubia* and lower Ca activities would also occur for *N. triangulifer*. Two other key differences between these 2 species were 1) that K salt toxicity to *N. triangulifer* was not modified by Na in dilution water, and 2) that K toxicity to mayflies was very similar to Na toxicity on a millimolar basis, instead of the much greater toxicity of K observed for *C. dubia*.

Calculation of Aquatic Life Criteria for Chloride

These calculations are based on "Summary of Data Concerning the Acute Toxicity of Sodium Chloride to Aquatic Animals" dated 1-15-09 and "Summary of Data Concerning the Chronic Toxicity of Sodium Chloride to Aquatic Animals" dated 1-15-09. Except as noted (for example, see footnote a), these calculations are consistent with the 1985 Guidelines. GMAVs and SMAVs are normalized to hardness = 300 mg/L and sulfate = 65 mg/L. GMAVs and SMAVs are expressed as mg chloride/L.

Rank*	GMAV	Genus	Species	SMAV	SMACR

* A "greater than" acute value for the brown trout (Salmo trutta) is not in this table because it is too low to be a useful "greater than" value.
** Name of family, not name of genus.

a. Section IV.1 of the 1985 Guidelines says: "For each species for which at least one acute value is available, the Species Mean Acute Value should be calculated as the geometric mean of the results of all flow-through tests in which the concentrations of test material were measured. For a species for which no such result is available, the SMAV should be calculated as the geometric mean of all available acute values, i.e., results of flow-through tests in which the concentrations were not measured and results of static and renewal tests based on initial concentrations (nominal concentrations are acceptable for most test materials if measured concentrations are not available) of test material." The guidance presented in section IV.1 of the 1985 Guidelines seems inappropriate for chloride because chloride is different from most pollutants for which aquatic life criteria are derived. Chloride is very soluble in water, does not oxidize or reduce, is not volatile, does not degrade, does not sorb to test chambers, test organisms, food, or waste products, is not complexed by materials that commonly occur in water, is not involved in a pH-dependent equilibrium in water, and does not precipitate in waters in which aquatic organisms commonly occur.
   i. For chloride, as long as the concentration of dissolved oxygen is sufficiently high, it seems appropriate to give static and renewal acute tests the same weight as flow-through acute tests in the derivation of the SMAV for a species.
   ii. For chloride, it seems inappropriate to give measured acute tests a weight of 1 and unmeasured acute tests a weight of 0 when both are available for the derivation of the SMAV for a species. For example, if there is a choice between one measured acute test on chloride and three unmeasured acute tests in three different laboratories, the three tests are probably preferable to the one test, but if the choice is between one measured acute test and two unmeasured acute tests in two different laboratories, the one test is probably preferable. Thus, for a species for which both measured and unmeasured acute tests are available for chloride, it seems appropriate to give measured acute tests a weight of 2.5 and unmeasured acute tests a weight of 1 when the SMAV is calculated.

   The conclusions described above concerning chloride were developed during discussions among Charles Delos, Charles Stephan, and Glen Thursby. For other pollutants, different conclusions concerning the relative merits of static, renewal, and flow-through acute toxicity tests and the relative merits of measured and unmeasured acute toxicity tests are likely to be more appropriate.

Electronic Filing: Received, Clerk's Office 3/14/2019

R04618

b. For Ceriodaphnia dubia, the acute values from Hoke et al. (1992) are considered outliers. The geometric mean is 1468.1 for Mount et al. (1997), 1790.2 for U.S. EPA (1991), 1998.2 for WISLOH (2007), and 1457.3 for GLEC and INHS (2008).
SMAV = antilog ([log 1468.1 + log 1790.2 + log 1998.2 + log 1863.6 + 2.5(log 1311.1) + 2.5(log 1457.3)]/9) = 1542.3.

c. For Daphnia magna, the values of 3815.5 (Mount et al. 1997), <2785.1, (Anderson 1946), 2439.7 (Anderson 1948), and 3025.9 and 3357.4 (Biesinger and Christensen 1972) were not used. A geometric mean of 3906.7 was calculated from the limits given by Seymour et al. (1997). The geometric mean is 3208.8 for Hoke et al. (1992) and is 4054.2 for Davies and Hall (2007). The SMAV is 3773.1, which is the geometric mean of 3208.8, 5068.2, 3906.7, 2242.3, 4749.6, 3968.5, and 4054.2.

d. Bluegill: SMAV = antilog ([2.5(log 7702.3) + log 10461.6]/3.5) = 8406.5.

e. Fathead minnow: SMAV = antilog([log 2833.9 + 2.5(log 8665.1) + 2.5(log 8225.2) + log 5112.0 + log 5226.3]/8) = 6515.3.

f. Daphnia pulex: SMAV = antilog([2.5(log 1938.8) + log 2240.3]/3.5) = 2020.5.

g. Not used in calculations because, even though the acute and chronic tests were in the same document, different dilution waters were used in the tests.

h. The SMACR for Ceriodaphnia dubia is the geometric mean of 1.508, >3.841, and 2.601.

FAV = 1205 mg chloride/L

CMC = FAV/2 = 602.5 mg chloride/L

The five SMACRs (7.308, 4.148, 1.974, 3.952, and >2.438) that are available for use in calculations result in three GMACRs:

7.308	Oncorhynchus
3.187	Daphnia
>2.470	Ceriodaphnia

The 1985 Guidelines require ACRs for species in three different families, but Daphnia and Ceriodaphnia are in the same family. However, even though the ACR for the fathead minnow should not be used in calculations because the acute and chronic tests using the fathead minnow were

Electronic Filing: Received, Clerk's Office 3/14/2019

R04619

performed in different dilution waters, the fathead minnow ACR can be considered a qualitative ACR and used to satisfy the MDRs because chloride is not likely to be complexed or sorbed or detoxified by organic or inorganic constituents of the dilution water.

The GMACRs for Oncorhynchus and Daphnia are consistent with the "greater than" GMACR for Ceriodaphnia and the GMACRs are within a factor of ten. Therefore, the Final ACR = 4.826, which is the geometric mean of the GMARCs for Oncorhynchus and Daphnia. This would give FCV = FAV/FACR = (1205 mg chloride/L)/4.826 = 249.7 mg chloride/L. However, this approach is contraindicated because the GMACRs (including the unused GMACR for Pimephales) indicate that the GMACR increases as the GMAV increases.

The GMACR for Daphnia is consistent with the "greater than" GMACR for Ceriodaphnia, so the GMACR for Daphnia can be used as the FACR. Therefore, FACR = 3.187 and FCV = FAV/FACR = (1205 mg chloride/L)/3.187 = 378.1 mg chloride/L.

CCC = FCV = 378.1 mg chloride/L.

The CMC and CCC given above are for hardness = 300 mg/L and sulfate = 65 mg/L. The equation that was used to normalize the acute values can be used to make the CMC and CCC dependent on hardness and sulfate. The resulting equations for the CMC and CCC are:

$$CMC = (602.5 \text{ mg chloride/L})\,(\text{hardness}/300)^{0.205797}\,(\text{sulfate}/65)^{-0.07452}$$
$$= (254.3 \text{ mg chloride/L})\,(\text{hardness})^{0.205797}\,(\text{sulfate})^{-0.07452}$$

At hardness = 300 mg/L and sulfate = 65 mg/L, CMC = 602.5 mg chloride/L.

$$CCC = (378.1 \text{ mg chloride/L})\,(\text{hardness}/300)^{0.205797}\,(\text{sulfate}/65)^{-0.07452}$$
$$= (159.6 \text{ mg chloride/L})\,(\text{hardness})^{0.205797}\,(\text{sulfate})^{-0.07452}$$

At hardness = 300 mg/L and sulfate = 65 mg/L, CCC = 378.1 mg chloride/L.

Electronic Filing: Received, Clerk's Office 3/14/2019

R04620

Derivation of an Alternative FCV

Even though the above derivation of FCV = 378.1 mg chloride /L follows the procedure described in the 1985 Guidelines, there is an alternative approach that is justified on the basis of the "good science" clause in section XII.B of the 1985 Guidelines. This approach is based on the fact that the four low SMACRs for chloride were obtained with invertebrates, whereas the high SMACR was obtained with a vertebrate. This can be interpreted to mean that vertebrates have a higher ACR, on the average, than invertebrates, especially because the qualitative ACR for the fathead minnow is 15.17. Therefore, a vertebrate ACR and an invertebrate ACR can be used with the GMAVs to calculate a predicted Genus Mean Chronic Value for each genus, and then a FCV can be calculated directly from the predicted GMCVs. This approach calculates and uses a predicted chronic value for each genus for which an acute value is available and probably does a better job of taking into account the chronic sensitivities of both vertebrates and invertebrates to chloride. The relevant data and calculations are presented on the next few pages.

The FACR of 3.187 derived above was derived from all of the acceptable ACRs for invertebrates. The only acceptable ACR for a vertebrate is 7.308. A predicted GMCV can be calculated from each GMAV by using 3.187 as the invertebrate ACR and using 7.308 as the vertebrate ACR.

Table of predicted GMCVs for Chloride

(GMAVs and pGMCVs are expressed as mg chloride/L)

09JanChlorideCronic.wpd DRAFT 1-15-09
C. Stephan

Summary of Data concerning the Chronic Toxicity of Sodium Chloride to Aquatic Animals

This summary is based on "Results of Literature Search concerning the Toxicity of Chloride to Aquatic Animals" dated 1-15-09. Except as noted, this summary is consistent with the 1985 Guidelines. All test results are expressed as mg chloride/L.

Fathead minnow

Birge et al. (1985) reported the results of a 33-day early life-stage test on sodium chloride in a stream water. The NOEC and LOEC were 252 and 352 mg/L, respectively, and the geometric mean was 298 mg/L. Birge et al. (1985) reported a 96-hr LC50 of 6570 mg/L, which would give an ACR of 22.05. However, it is not clear how the NOEC and LOEC were selected and the acute and chronic tests were performed in different dilution waters. The reported LOEC of 352 mg/L reduced survival by 9% compared to the control, whereas 533 mg/L reduced survival by 15%; neither concentration caused a substantial reduction in growth. It seems more appropriate to set the NOEC and LOEC at 352 and 533 mg/L, respectively, which gives a geometric mean of 433.1 mg/L. The ACR would be 15.17, but the acute and chronic tests were performed in different waters.

Diamond et al. (1992), Pickering et al. (1996) and the Wisconsin State Laboratory of Health (WISLOH 2007) performed 7-day tests on sodium chloride using the fathead minnow. Diamond et al. (1992) reported that the average geometric mean of the NOEC and LOEC was 1597 mg/L, whereas Pickering et al. (1996) reported a geometric mean subchronic value of 3458 mg/L. WISLOH (2007) reported a mean IC25 of 1752 mg/L. All three of these results are substantially higher than the geometric mean of 433.1 mg/L from Birge et al. (1985), which is not surprising because Table A19 in Birge et al. (1985) shows substantial mortality occurring between day 9 and day 33 in most of the treatments. Diamond et al. (1992) and Pickering et al. (1996) did not perform acute tests and so an ACR cannot be calculated; WISLOH (2007) obtained a mean 96-hr LC50 of 4143 mg/L, which would give an ACR of 2.365; this is substantially lower than the ACR of 15.17 from Birge et al. (1985). Although the 7-day test with the fathead minnow is not approved for use in the derivation of aquatic life criteria in the 1985 Guidelines, it could be used as a surrogate for the early life-stage test on a toxicant-specific basis if data demonstrated that the two tests give similar results. For sodium chloride, however, the data clearly indicate that the 7-day test misses much of the adverse effect observed in the 33-day early life-stage test. Because the early life-stage test is used as a surrogate for the life-cycle test, the comparison that is of most interest is a comparison of the 7-day test with the life-cycle test.

Rainbow trout

Birge et al. (1980) reported results of an early life-stage test on magnesium chloride.

Electronic Filing: Received, Clerk's Office 3/14/2019

Spehar (1986) reported the results of an 8-week exposure to NaCl that began with eggs. The highest tested concentration of 3,917 mg/L did not reduce egg hatchability, but killed all of the early juvenile fish. The next highest concentration of 1,924 mg/L did not reduce survival, but did reduce growth. Spehar (1987) reported the results of an early life-stage test on NaCl. The highest tested concentration of 2,740 mg/L killed 100%, 1,324 mg/L killed 46%, and 643 mg/L (and lower concentrations) killed less than 4%. The geometric mean of 1324 and 643 is 922.7 mg/L. The 96-hr LC50 was 6,743 mg/L and the ACR was 7.308.

Ceriodaphnia dubia

Sarma et al. (2006) reported that, on the basis of toxicity tests that studied population dynamics, all ten tested zooplankton species were adversely affected by 910 to 1820 mg/L; their data indicate that C. dubia was the most sensitive of the ten species.

Cowgill and Milazzo (1990) reported results of a life-cycle test on sodium chloride. If the geometric mean of the EC50 and the NOEC is used as the chronic value, it would be 925 mg/L, and the ACR would be 1395/925 = 1.508.

Cowgill and Milazzo (1991b) tested concentrations of chloride (as NaCl) from 8 to 283 mg/L. They found that reproduction peaked at 102 mg/L and all tested concentrations up to the maximum of 283 mg/L gave more reproduction than the control treatment.

Cowgill and Milazzo (1990) used calcium chloride extracted from a brine well to study the effect of "hardness as calcium carbonate" on C. dubia, whereas Cowgill and Milazzo (1991b) used reagent-grade calcium chloride to study the effect of "hardness as calcium carbonate" on C. dubia.

Diamond et al. (1992) reported that the average geometric mean of the NOEC and LOEC was 235 mg/L.

Wisconsin State Laboratory of Hygiene (WISLOH 2007) reported, for tests in hard reconstituted water (hardness = 169.5 mg/L and sulfate = 162.7 mg/L), a mean IC25 of 385.2 mg/L and a mean acute LC50 of 1499 mg/L. A 25% reduction is too high for a chronic value, so in hard water the chronic value is <385.2 mg/L and the ACR is >3.891. For tests in moderately hard reconstituted water (hardness = 84.8 mg/L and sulfate = 81.4 mg/L), WISLOH reported a mean IC25 of 442.2 mg/L and a mean acute LC50 of 1677 mg/L. Because a 25% reduction is too high for a chronic value, in moderately hard water the chronic value is <442.2 mg/L and the ACR is >3.792. The geometric mean ACR is >3.841.

Lasier et al. (2004) reported an IC50 of 563 mg/L and an IC25 of 340 mg/L. A 25% reduction is too high for a chronic value, so the chronic value is <340 mg/L.

Lasier et al. (2006) reported that the chronic toxicity of chloride is reduced by hardness cations, but they did not give any quantitative information.

Electronic Filing: Received, Clerk's Office 3/14/2019

From an interlaboratory study of the Ceriodaphnia dubia life-cycle test DeGraeve et al. (1992) reported that fifteen 7-day LC50s ranged from 170 to 1179 mg/L and sixteen IC50s based on reproduction ranged from 182 to 1153 mg/L. A 50% reduction is too much adverse effect to use LC50s or IC50s as chronic values, but they could be used as upper limits on chronic values.

Aragao and Pereira (2003) performed twelve 7-day life-cycle tests on NaCl; six were started with young from 16 to 24 hr old and six were started with young from 6 to 30 hr old. Of the twelve NOECs, based on reproduction, six were 303 mg/L, four were 152 mg/L, and two were <152 mg/L. The twelve 7-day IC50s based on reproduction ranged from 346 to 685 mg/L. If the geometric mean of the NOEC and the IC50 is used as the chronic value, the twelve chronic values would be:

NOEC	IC50	Chronic Value
303	685	456
303	558	411
152	455	263
303	582	420
303	667	450
303	594	424
<152	431	<256
152	412	250
152	346	229
<152	370	<237
152	437	258
303	406	351

The twelve chronic values range from <237 to 456 mg/L, and the geometric mean is <322 mg/L.

Cooney et al. (1992) performed 18 life-cycle tests on sodium chloride using C. dubia. For each of the 18 tests, the survival NOEC was 1092 mg/L and the survival LOEC was 1456 mg/L. The 18 reproduction NOECs ranged from <455 to 819 mg/L, whereas the 18 reproduction LOECs ranged from 455 to 1092 mg/L. If the geometric mean of the reproduction NOEC and the reproduction LOEC is used as the chronic value, the 18 chronic values would be:

NOEC	LOEC	Chronic Value
455	607	525
607	819	705
819	1092	946
819	1092	946
607	819	705
819	1092	946
455	607	525
819	1092	946

Electronic Filing: Received, Clerk's Office 3/14/2019

455	607	525
<455	455	<455
<455	455	<455
<455	455	<455
607	819	705
607	819	705
607	819	705
<455	455	<455
455	607	525
455	607	525

The 18 chronic values range from <455 to 946 mg/L, and the geometric mean is <629 mg/L.

Harmon et al. (2003) reported results of a life-cycle test on sodium chloride. The chronic EC20 based on reproduction was 370.6 mg/L. The ACR is 964/370.6 = 2.601.

Daphnia ambigua

Harmon et al. (2003) reported results of a life-cycle test on sodium chloride. The chronic EC20 based on reproduction was 292.4 mg/L. The ACR is 1213/292.4 = 4.148.

Daphnia magna

Leblanc and Surprenant (1984) conducted a life-cycle test on one concentration of potassium chloride and Cowgill and Milazzo (1990) conducted a life-cycle test on calcium chloride extracted from brine wells.

Biesinger and Christensen (1972) reported that 1573 mg/L caused a 50% reduction in reproduction, whereas 1049 mg/L caused a 16% reduction in reproduction in a life-cycle test. If the chronic value is set at 1111 mg/L because this is the estimated EC20, the ACR would be 2.276 using the unfed acute test and 2.526 using the fed acute test, but this is not an acceptable chronic test because the concentrations of the toxicant in the test solutions were not measured.

NOTE: Many years ago when ASTM had a task group on life-cycle tests with Daphnia magna, most of the people on the task group were having a low percentage of successful chronic tests using the Biesinger methodology because survival was too low in the control treatment. The group met in Duluth to talk to Biesinger about his methodology. When it was explained that people were having a low success rate due to low survival in the control treatment, Biesinger said that his success rate was about 50%; he would start a test on a toxicant as often as necessary in order to eventually get a successful test on that toxicant. People complained to Biesinger that he did not say this in his publication (Biesinger and Christensen 1972), and Biesinger said that he would state the success rate in a subsequent publication concerning the development of the methodology; Biesinger never published a methodology paper. A variety of people tested a variety of foods and eventually found that the success rate could be greatly increased by using a food that was better than the one that Biesinger used. This leads me to think that the

Electronic Filing: Received, Clerk's Office 3/14/2019

healthiness of the daphnids used by Biesinger and Christensen (1972) is suspect and that all of the acute and chronic data presented in Biesinger and Christensen (1972) are suspect; however, this does not mean that these test results are incorrect.

Cowgill and Milazzo (1990) reported results of a life-cycle test on sodium chloride; they reported an EC50 of 2597 mg/L and a NOEC of 2184 mg/L. If the geometric mean of the EC50 and the NOEC is used as the chronic value, it would be 2382 mg/L, and the ACR would be 4701/2382 = 1.974.

Cowgill and Milazzo (1991b) tested concentrations of chloride (as NaCl) from 8 to 283 mg/L. They found that reproduction peaked at 37 mg/L and all tested concentrations up to the maximum of 283 mg/L gave as much reproduction as the control treatment.

Cowgill and Milazzo (1990) used calcium chloride extracted from a brine well to study the effect of "hardness as calcium carbonate" on D. magna, whereas Cowgill and Milazzo (1991b) used reagent-grade calcium chloride to study the effect of "hardness as calcium carbonate" on D. magna.

Daphnia pulex

Birge et al. (1985) reported that the most sensitive adverse effect observed in a 21-day life-cycle test was a 27% reduction in reproduction at 441 mg/L, with no reduction at 314 mg/L. The chronic value was 372 mg/L (the geometric mean of 441 and 314 mg/L) and the ACR was 1470/372 = 3.952.

Stenonema modestum (a mayfly)

Diamond et al. (1992) reported that NOECs and LOECs based on survival and number of molts in 14-day tests ranged from 1213 to 4246 mg/L. These are not acceptable chronic tests, but they might be used to estimate an upper limit on the chronic value for this species.

Musculium securis (a clam)

The test results reported by Mackie (1978) are not acceptable because the treatments were prepared by adding sodium chloride to a mixture of soil, leaves, and deionized water.

Musculium transversum (a clam)

Anderson et al. (1978) reported results of chronic tests on KCl.

Rana sylvatica (a frog)

Sanzo and Hecnar (2006) reported that 625 mg/L caused a 62% reduction in the survival of wood frog tadpoles during a 90-day exposure, whereas 47 mg/L did not reduce survival. Although this is not an acceptable chronic test, 625 mg/L can be used as an upper limit on the chronic value for this species.

Gammarus pseudopinmaeus (an amphipod)

Electronic Filing: Received, Clerk's Office 3/14/2019

Williams et al. (2000) reported that neither 1000 nor 2000 mg/L reduced survival in a two-month exposure in spring water, but this is not an acceptable chronic test.

Physa sp. (a snail)

Williams et al. (2000) reported that neither 1000 nor 2000 mg/L reduced survival in a two-month exposure in spring water, but this is not an acceptable chronic test.

Orconectes limosus (a crayfish)

Boutet and Chaisemartin (1973) reported the results of unacceptable chronic tests on potassium chloride and magnesium chloride.

The acceptable chronic values available for chloride are:

Fathead minnow	433.1 mg/L	Birge et al. 1985
Rainbow trout	922.7 mg/L	Spehar 1987
Ceriodaphnia dubia	925 mg/L	Cowgill and Milazzo 1990
Ceriodaphnia dubia	235 mg/L	Diamond et al. 1992
Ceriodaphnia dubia	<442.2 mg/L	WISLOH 2007 (mod. hard water)
Ceriodaphnia dubia	<385.2 mg/L	WISLOH 2007 (hard water)
Ceriodaphnia dubia	<340 mg/L	Lasier et al. 2004
Ceriodaphnia dubia	<322 mg/L	Aragao and Pereira 2003
Ceriodaphnia dubia	<629 mg/L	Cooney et al. 1992
Ceriodaphnia dubia	370.6 mg/L	Harmon et al. 2003
Daphnia ambigua	292.4 mg/L	Harmon et al. 2003
Daphnia magna	2382 mg/L	Cowgill and Milazzo 1990
Daphnia pulex	372 mg/L	Birge et al. 1985
Rana sylvatica	<625 mg/L	Sanzo and Hecnar 2006

These result in the following Genus Mean Chronic Values:

Pimephales	433.1 mg/L
Oncorhynchus	922.7 mg/L
Ceriodaphnia	<418.7 mg/L
Daphnia	637.5 mg/L
Rana	<625 mg/L

The acceptable ACRs available for chloride are:

Rainbow trout	7.308	Spehar 1987
Ceriodaphnia dubia	1.508	Cowgill and Milazzo 1990
Ceriodaphnia dubia	>3.841	WISLOH 2007
Ceriodaphnia dubia	2.601	Harmon et al. 2003
Daphnia ambigua	4.148	Harmon et al. 2003
Daphnia magna	1.974	Cowgill and Milazzo 1990
Daphnia pulex	3.952	Birge et al. 1985

Electronic Filing: Received, Clerk's Office 3/14/2019

The following ACR is also available for chloride but it should not be used in calculations because the acute and chronic tests were performed in different waters:

Fathead minnow	15.17	Birge et al. 1985

Electronic Filing: Received, Clerk's Office 3/14/2019

09JanChlorideAcute.wpd DRAFT 1-15-09
C. Stephan

Summary of Data Concerning the Acute Toxicity of Sodium Chloride to Aquatic Animals

This summary is based on "Results of Literature Search concerning the Toxicity of Chloride to Aquatic Animals" dated 1-15-09. Except as noted, this summary is consistent with the 1985 Guidelines.

Acute Values and Normalized Acute Values are expressed as mg chloride/L. Normalized Acute Values were calculated by normalizing the Acute Values to hardness = 300 mg/L and sulfate = 65 mg/L using the following equation:

$$NAV = (AV)\ (300/Hardness)^{0.205797}\ (65/Sulfate)^{-0.07452}$$

This equation is based on the equation presented in "Multiple Regression Equation for Chloride" dated 1-15-09. The hardness of 300 mg/L and the sulfate concentration of 65 mg/L are arbitrary; any other values for hardness and sulfate would have worked equally well. NAVs could not be calculated for all AVs because assumed values were not used for hardness or sulfate. Some of the values of hardness and sulfate are nominal, not measured, values.

Species	Method	Test Material	Hardness (mg/L)	Sulfate (mg/L)	Acute Value	Normalized Acute Value	Reference
Tubificid worm, Limnodrilus hoffmeisteri	S,U	Sodium chloride	100	----	3761	------	Wurtz and Bridges 1961

a = not fed. (All tests not marked "a" or "b" were unfed tests.)
b = fed.
c = mean of at least 15 LC50s.
d = range of several toxicity tests.
e = mean of 32 tests.
f = not used because there is reason to suspect that the daphnids might have been unhealthy.
g = tables 4, 7, and 9, except for tests at 28C in table 4.
h = tables 8 and 11; Daphnia pulex tests were not used because test duration was 96 hr.
i = test duration was 64 hr.
j = no deaths in 196 hr.
k = selenium deficient.
m = selenium sufficient.
p = not used in calculation of GMAV because the species is unknown and so it is not known how to combine this acute value with the acute values for which the species are known.
q = calculated using the formula for reconstituted water and the reported average measured hardness.
r = concentrations were measured in stock solutions.
s = not acclimated to the dilution water.

Electronic Filing: Received, Clerk's Office 3/14/2019

t = might not have been acclimated to the dilution water.
v = based on analyses of samples of Lake Superior water taken in the spring and fall of 2008.

Electronic Filing: Received, Clerk's Office 3/14/2019

Supplementary information concerning the results of toxicity tests on chloride

1. The atomic weights used are those given on the website of the National Institute of Standards and Technology:
   - Calcium = 40.078
   - Carbon = 12.011
   - Chlorine = 35.453
   - Hydrogen = 1.008
   - Iron = 55.845
   - Magnesium = 24.305
   - Nitrogen = 14.007
   - Oxygen = 15.999
   - Potassium = 39.098
   - Sodium = 22.990
   - Sulfur = 32.065

2. The molecular weights used are:
   - $CaCl_2$ = 110.984 (63.89 % chloride) (36.11 % calcium) (Cl/Ca = 1.769)
   - $CaCl_2 \cdot 2H_2O$ = 147.014 (27.26 % calcium) (48.23 % chloride)
   - $CaCO_3$ = 100.086 (40.04 % calcium)
   - CaO = 56.077 (71.47 % calcium)
   - $Ca(NO_3)_2$ = 164.086 (24.42 % calcium)
   - $Ca(NO_3)_2 \cdot 4H_2O$ = 236.146 (16.97 % calcium)
   - $CaSO_4$ = 136.139 (70.56 % sulfate)
   - $CaSO_4 \cdot 2H_2O$ = 172.169 (55.79 % sulfate) (23.28 % calcium) (20.93 % water)
   - $FeCl_3 \cdot 6H_2O$ = 270.294 (39.35 % chloride)
   - H_2O = 18.015
   - KCl = 74.551 (47.56 % chloride) (52.44 % potassium) (Cl/K = 0.9068)
   - K_2SO_4 = 174.257 (55.13 % sulfate)
   - $MgCl_2$ = 95.211 (74.47 % chloride) (25.53 % magnesium) (Cl/Mg = 2.917)
   - $MgSO_4$ = 120.366 (79.81 % sulfate) (20.19 % magnesium)
   - $MgSO_4 \cdot 7H_2O$ = 246.471 (38.97 % sulfate) (9.86 % magnesium)
   - NaCl = 58.443 (60.66 % chloride) (39.34 % sodium) (Cl/Na = 1.542)
   - Na_2SO_4 = 142.041 (67.63 % sulfate)

Electronic Filing: Received, Clerk's Office 3/14/2019

$Na_2SO_4 \cdot 10H_2O = 322.191$ (29.81 % sulfate)
$SO_4 = 96.061$

3. Hardness (as $CaCO_3$) = (100.086/40.078)(Ca) + (100.086/24.305)(Mg) = 2.497(Ca) + 4.118(Mg)

4. Trama (1954), Cairns and Scheier (1959), Academy of Natural Sciences (1960), and Patrick et al. (1968) all reported results of toxicity tests that were performed at the Academy of Natural Sciences of Philadelphia with the bluegill in dilution waters that were very similar:

	mg/L
KCl	20
Na_2SiO_3	20
$NaHCO_3$	40
$MgSO_4 \cdot 7H_2O$	40
$Ca(NO_3)_2$	30*
$CaCO_3$	10
K_2HPO_4	10 or 2
Fe^{+++} (as ferric citrate)	4 or 0.4

Ca = 11.3 mg/L
Mg = 3.9 mg/L
Hardness = 44.3 mg/L as $CaCO_3$
Chloride = 9.5 mg/L
Sulfate = 15.5 mg/L

*Long after the tests of concern were performed, this was reported to be 40 mg/L of $Ca(NO_3)_2 \cdot 4H_2O$.

5. Freeman (1953), Freeman and Fowler (1953), Fairchild (1955), Dowden (1960), Dowden (1962), and Dowden and Bennett (1965) all contained information regarding toxicity tests performed at Louisiana State University in Baton Rouge, but several different dilution waters were used. Dowden and Bennett (1965) tried to clarify the most important dilution waters used, but the citations given for the waters on page 1310 need to be clarified. Reference 4 is the correct citation for "Standard Reference Water" (SRW), but the correct citation for "Reference Dilution Water" (RDW) is reference 6 (not reference 3) and reference 3 should be cited for "glass-wool filtered University Lake Water (ULW). ULW is considered an unacceptable dilution water because it is from "a small drainpipe-fed lake on the campus of Louisiana State University" (Dowden 1960). The compositions of SRW and RDW are:

SRW	mg/L
$MgSO_4 \cdot 7H_2O$	71.

Electronic Filing: Received, Clerk's Office 3/14/2019

K_2SO_4	6.5
$MnSO_4 \cdot 4H_2O$	0.2
$CaCl_2 \cdot 2H_2O$	18.6
$NaHCO_3$	25.
NH_4NO_3	3.
$K_2HPO_4 \cdot 3H_2O$	1.1
CaO	32.2
$Na_2SiO_3 \cdot 9H_2O$	62.6
$FeCl_3 \cdot 6H_2O$	1.2

Ca = 23.0 mg/L
Mg = 7.0 mg/L
Hardness = 86.2 mg/L as $CaCO_3$
Chloride = 9.4 mg/L
Sulfate = 31.2 mg/L

RDW	mg/L
$CaCl_2$	110
$NaHCO_3$	110
NaCl	100
$MgSO_4 \cdot 7H_2O$	60
KCl	20

Ca = 39.7 mg/L
Mg = 5.9 mg/L
Hardness = 123.4 mg/L as $CaCO_3$
Chloride = 140.4 mg/L
Sulfate = 23.4 mg/L

6. When known, the concentration of chloride in dilution water was negligible in tests on chloride.

7. Karraker (2007) says that "road salt" contains sodium chloride, sodium ferrocyanide, heavy metals, and often sand or cinder. Results of toxicity tests on "road salt" were not used.

Electronic Filing: Received, Clerk's Office 3/14/2019

8. Hyalella azteca appears to be especially sensitive to some pollutants when the concentration of chloride is low, e.g., lower than 25 mg/L. This should not affect the sensitivity of this species to chloride.

9. Mount et al. (1997) reported that the toxicities of sodium and calcium salts to C. dubia, D. magna, and the fathead minnow are primarily attributable to the corresponding anion.

10. Some data presented in Table 1 of USEPA (1988) have been changed:
    a. Several values differ because of roundoff differences.
    b. USEPA (1988) used results of short acute tests for the reasons given on pages 2 and 3 (see also Lowell et al. 1995), but results of short tests are not used here because short acute tests sometimes give higher LC50s than standard tests.
    c. Data from Dowden (1961, which should be 1960) and Kostecki and Jones (1983) are not used here because of the dilution water used in the tests.
    d. The test results from Trama (1954) are also given in Academy of Natural Sciences (1960) and Patrick et al. (1968).
    e. Hamilton et al. (1975) did not adequately acclimate the midges.
    f. Fed acute tests were not used in USEPA (1988), but fed acute tests are used here and are given preference over unfed acute tests when the test organisms are cladocerans.

Electronic Filing: Received, Clerk's Office 3/14/2019

09JanChlorideRev.wpd DRAFT 1-15-09
C. Stephan

Description of the Review of Results of Toxicity Tests on Chloride

Sections II.B, II.C, II.D, II.E, II.F, IV.B, IV.C, IV.D, IV.E, IV.H, VI.B, VI.C, VI.D, and VI.E of the 1985 Guidelines give reasons why some results of toxicity tests should not be used, should be rejected, or should not be used in calculations, whereas sections II.G, X, XI.C, XII.A.14, and XII.B allow the use of "questionable data" and "other data" in some situations. An easy-to-understand way of explaining the material given in the sections listed above is to say that sections II.B, II.C, II.D, II.E, II.F, IV.B, IV.C, IV.D, IV.E, IV.H, VI.B, VI.C, VI.D, and VI.E give reasons why some results of toxicity tests using aquatic animals should not be directly used in the derivation of a FAV or a FCV, whereas sections II.G, X, XI.C, XII.A.14, and XII.B describe other possible uses of test results with aquatic animals that should not be directly used in the derivation of a FAV or a FCV.

The 1985 Guidelines say the following concerning the use of results of toxicity tests using aquatic animals:

1. General guidance
   a. All data should be available in typed, dated, and signed hard copy (publication, manuscript, letter, memorandum, etc.) with enough supporting information to indicate that acceptable test procedures were used and that the results are probably reliable. (see section II.B)
   b. Information that is confidential or privileged or otherwise not available for distribution should not be used. (see section II.B)
   c. Questionable data, whether published or unpublished, should not be used. For example, a test result should usually be rejected if it is from:
      i. a test that did not contain a control treatment.
      ii. a test in which too many organisms in the control treatment died or showed signs of stress or disease.
      iii. a test in which distilled or deionized water was used as the dilution water without addition of appropriate salts.

      (see section II.C)
   d. A result of a test on technical-grade material may be used if appropriate, but a result of a test on a formulated mixture or an emulsifiable concentrate of the test material should not be used. (see section II.D)
   e. For some highly volatile, hydrolyzable, or degradable materials it is probably appropriate to use only results of flow-through tests in which the concentrations of test material in the test solutions were measured often enough using acceptable analytical methods. (see section II.E)
   f. Data should be rejected if they were obtained using:
      i. Brine shrimp
      ii. A species that does not have a reproducing wild population in North America.

Electronic Filing: Received, Clerk's Office 3/14/2019

iii. Organisms that were previously exposed to substantial concentrations of the test material or other contaminants.

(see section II.F)

2. Guidance specifically regarding results of acute tests
   g. Acute toxicity tests should have been conducted using acceptable procedures. (see section IV.B)
   h. Except for tests using saltwater annelids and mysids, results of acute tests during which the test organisms were fed should not be used, unless data indicate that the food did not affect the toxicity of the test material. (see section II.C)
   i. Results of acute tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded 5 mg/L, should not be used, unless a relationship is developed between acute toxicity and organic carbon or particulate matter or unless data show that organic carbon, particulate matter, etc., do not affect toxicity. (see section IV.D)
   j. Acute values should be based on endpoints which reflect the total severe acute adverse impact of the test material on the organisms used in the test. Therefore, only the following kinds of data on acute toxicity to aquatic animals should be used:
      1. Tests with daphnids and other cladocerans should be started with organisms less than 24 hours old and tests with midges should be started with second- or third-instar larvae. The result should be the 48-hr EC50 based on percentage of organisms immobilized plus percentage of organisms killed. If such an EC50 is not available from a test, the 48-hr LC50 should be used in place of the desired 48-hr EC50. An EC50 or LC50 of longer than 48 hr can be used as long as the animals were not fed and the control animals were acceptable at the end of the test.
      2. The result of a test with embryos and larvae of barnacles, bivalve molluscs (clams, mussels, oysters, and scallops), sea urchins, lobsters, crabs, shrimp, and abalones should be the 96-hr EC50 based on the percentage of organisms with incompletely developed shells plus the percentage of organisms killed. If such an EC50 is not available from a test, the lower of the 96-hr EC50 based on the percentage of organisms with incompletely developed shells and the 96-hr LC50 should be used in place of the desired 96-hr EC50. If the duration of the test was between 48 and 96-hr, the EC50 or LC50 at the end of the test should be used.
      3. The acute values from tests with all other freshwater and saltwater animal species and older life stages of barnacles, bivalve molluscs, sea urchins, lobsters, crabs, shrimps, and abalones should be the 96-hr EC50 based on the percentage of organisms exhibiting loss of equilibrium plus the percentage of organisms immobilized plus the percentage of organisms killed. If such an EC50 is not available from a test, the 96-hr LC50 should be used in place of the desired 96-hr EC50.
      4. Tests with single-celled organisms are not considered acute tests, even if the duration was 96 hours or less.
      5. If the tests were conducted properly, acute values reported as "greater than" values and those which are above the solubility of the test material should be used,

Electronic Filing: Received, Clerk's Office 3/14/2019

because rejection of such acute values would unnecessarily lower the Final Acute Value by eliminating acute values for resistant species.
(see section IV.E)

k. The agreement of the data within and between species should be considered. Acute values that appear to be questionable in comparison with other acute and chronic data for the same species and for other species in the same genus probably should not be used in the calculation of a SMAV. For example, if the acute values available for a species or genus differ by more than a factor of 10, some or all of the values probably should not be used in calculations. (see section IV.H)

3. Guidance specifically regarding results of chronic tests
   l. Chronic values should be based on results of flow-through (except renewal is acceptable for daphnids) chronic tests in which the concentrations of test material in the test solutions were properly measured at appropriate times during the test. (see section VI.B)
   m. Results of chronic tests in which survival, growth, or reproduction in the control treatment was unacceptably low should not be used. The limits of acceptability will depend on the species. (see section VI.C)
   n. Results of chronic tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded 5 mg/L, should not be used, unless a relationship is developed between chronic toxicity and organic carbon or particulate matter or unless data show that organic carbon, particulate matter, etc., do not affect toxicity. (see section VI.D)
   o. Chronic values should be based on endpoints and lengths of exposure appropriate to the species. Therefore, only data on chronic toxicity to aquatic animals that satisfy the species-specific requirements given in sections VI.E.1, VI.E.2, and VI.E.3 should be used.
4. Guidance regarding other possible uses of results of toxicity tests using aquatic animals
   p. Questionable data, data on formulated mixtures and emulsifiable concentrates, and data obtained with non-resident species or previously exposed organisms may be used to provide auxiliary information but should not be used in the derivation of criteria. (see section II.F)
   q. Pertinent information that could not be used in earlier sections might be available concerning adverse effects on aquatic organisms and their uses. The most important of these are data on cumulative and delayed toxicity, flavor impairment, reduction in survival, growth, or reproduction, or any other adverse effect that has been shown to be biologically important. Especially important are data for species for which no other data are available. Data from behavioral, biochemical, physiological, microcosm, and field studies might also be available. Data might be available from tests conducted in unusual dilution water, from chronic tests in which the concentrations were not measured, from tests with previously exposed organisms, and from tests on formulated mixtures or emulsifiable concentrates. Such data might affect a criterion if the data were obtained with an important species, the test concentrations were measured, and the endpoint was biologically important. (see section X)

Electronic Filing: Received, Clerk's Office 3/14/2019

r. The CCC is equal to the lowest of the FCV, FPV, and FRV, unless other data show that a lower value should be used. (see section XI.C)
s. Are any of the other data important? (see section XII.A.14)
t. On the basis of all available pertinent laboratory and field information, determine if the criterion is consistent with sound scientific information. If it is not, another criterion, either higher or lower, should be derived using appropriate modifications of these Guidelines. (see section XII.B)

In addition, the following aquatic life criteria documents published by U.S. EPA in 1985, 1986, 1987, and 1988 gave a variety of reasons for classifying specific test results as "unused":

U.S. EPA. 1985. Ambient Water Quality Criteria for Cadmium - 1984. EPA 440/5-84-032. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1985. Ambient Water Quality Criteria for Chlorine - 1984. EPA 440/5-84-030. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1985. Ambient Water Quality Criteria for Copper - 1984. EPA 440/5-84-031. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1985. Ambient Water Quality Criteria for Lead - 1984. EPA 440/5-84-027. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1985. Ambient Water Quality Criteria for Mercury - 1984. EPA 440/5-84-026. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1986. Ambient Water Quality Criteria for Chlorpyrifos - 1986. EPA 440/5-86-005. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1986. Ambient Water Quality Criteria for Parathion - 1986. EPA 440/5-86-007. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1986. Ambient Water Quality Criteria for Pentachlorophenol - 1986. EPA 440/5-86-009. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1986. Ambient Water Quality Criteria for Toxaphene - 1986. EPA 440/5-86-006. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1987. Ambient Water Quality Criteria for Selenium - 1987. EPA 440/5-87-006. U.S. Environmental Protection Agency, Washington, DC.

U.S. EPA. 1987. Ambient Water Quality Criteria for Zinc - 1987. EPA 440/5-87-003. U.S. Environmental Protection Agency, Washington, DC.

Electronic Filing: Received, Clerk's Office 3/14/2019

U.S. EPA. 1988. Ambient Water Quality Criteria for Chloride - 1988. EPA 440/5-88-001. U.S. Environmental Protection Agency, Washington, DC.

The following is a compilation of the reasons, although some have been paraphrased. Most of these reasons can be considered to be based on items a through o listed above.

1. The document is a secondary publication of the test result.
2. The test procedures, test material, dilution water, and/or results were not adequately described.
3. The test species is not resident in North America.
4. The test species was not obtained in North America and was not identified well enough to determine whether it is resident in North America.
5. The test organisms were not identified beyond, for example, "crayfish" or "minnows."
6. There is reason to believe that the test organisms were possibly stressed by disease or parasites.
7. The test organisms were exposed to elevated concentrations of the test material before the test and/or the control organisms contained high concentrations of the test material.
8. The test organisms were obtained from a sewage oxidation pond.
9. By the end of the test, the test organisms had not been fed for too long a period of time.
10. The water quality varied too much during the test.
11. The test was conducted with brine shrimp, which species are from a unique saltwater environment.
12. The exposed biological material was an enzyme, excised or homogenized tissue, tissue extract, plasma, or cell culture.
13. The test organisms were not acclimated to the dilution water for a sufficiently long time.
14. The test organisms were exposed to the test material via gavage, injection, or food.
15. There is reason to believe that the test organisms were probably crowded during the test.
16. The test organisms reproduced during an acute test and the young could not be distinguished from the old at the end of the test.
17. The test material was a component of a mixture, effluent, fly ash, sediment, drilling mud, sludge, or formulation.
18. In a test on zinc, the dilution water contained a phosphate buffer.
19. The test material was chlorine and it was not measured acceptably during the test.
20. The test chamber contained sediment.
21. The test was conducted in plastic test chambers without measurement of the test material.
22. The test was a field study and the concentration of test material was not measured adequately.
23. A known volume of stock solution was placed on a wall of the test chamber and evaporated and then dilution water was placed in the test chamber; the investigators assumed that all of the test material dissolved in the dilution water, but the concentrations of the test material in the test solutions were not measured.
24. The test only studied metabolism of the test material.
25. The only effects studied were biochemical, histological, and/or physiological.
26. The data concerned the selection, adaptation, or acclimation of organisms for increased resistance to the test material.

Electronic Filing: Received, Clerk's Office 3/14/2019

27. The percent survival in the control treatment was too low.
28. The concentration of solvent in some or all of the test solutions was too high.
29. The study was a microcosm study.
30. The concentration of test material fluctuated too much during the exposure.
31. Too few test organisms were used in the test.
32. The dilution factor was ten.
33. There was no control treatment.
34. The pH was below 6.5.
35. The dilution water was chlorinated or "tap" water.
36. The dilution water contained an excessive amount of a chelating agent such as EDTA or other organic matter.
37. The acceptability of the dilution water is questionable because of its origin or content.
38. The dilution water was distilled or deionized water without addition of appropriate salts.
39. The measured test temperature fluctuated too much.
40. Neither raw data nor a clearly defined endpoint was reported.
41. The results were not adequately presented or could not be interpreted.
42. The results were only presented graphically.
43. The test was a chronic test and the concentration of test material was not measured.

Nevertheless, the things that the 1985 Guidelines say regarding other possible uses of test results with aquatic animals that should not be directly used in the derivation of a FAV or a FCV makes it clear that "unused" test results can be used in a criteria document, if appropriate. They should not be directly used in the derivation of a FAV or a FCV, but they can be used in other ways in some situations.

Further, several additional considerations were taken into account when results of aquatic toxicity tests on chloride were reviewed:

a. Review of results of toxicity tests on such pollutants as chloride should take additional considerations into account because chloride is different from most pollutants for which aquatic life criteria are derived. Chloride is very soluble in water, does not oxidize or reduce, is not volatile, does not degrade, does not sorb to test chambers, test organisms, food, or waste products, is not complexed by materials that commonly occur in water, is not involved in a pH-dependent equilibrium in water, and does not precipitate in waters in which aquatic organisms commonly occur. Toxicity tests on most pollutants are subject to one or more of these potential complications and so it is more important to be concerned about test methodology when considering other pollutants.
b. Section IV.C of the 1985 Guidelines says: "Except for tests with saltwater annelids and mysids, results of acute tests during which the test organisms were fed should not be used, unless data indicate that the food did not affect the toxicity of the test material." Section XII.B of the 1985 Guidelines says: "On the basis of all available pertinent laboratory and field information, determine if the criterion is consistent with sound scientific evidence. If it is not, another criterion, either higher or lower, should be derived using appropriate modifications of these Guidelines." Appendix 1 below demonstrates that (i) results of acute toxicity tests on chloride should not be rejected just because the test organisms were fed

Electronic Filing: Received, Clerk's Office 3/14/2019

during the tests and (ii) results of fed acute tests should be given preference over results of unfed acute tests when the test organisms are cladocerans.

c. If tests in a document using some species had acceptable control mortalities but other tests in the same document using other species had unacceptable control mortalities, the tests using species with unacceptable control mortalities were not used. The general policy is that tests in a document using different species should be evaluated on a species-by-species basis, not on a document-by-document basis.

d. Results of 96-hr toxicity tests using juvenile freshwater mussels were used if the methodology, etc., were acceptable, but results of tests using glochidia of freshwater mussels were not used. Acute (e.g., 96-h) toxicity tests using juvenile freshwater mussels are rather standard acute toxicity tests and can be evaluated using, for example, ASTM Standard E729. In contrast, acute toxicity tests using glochidia of freshwater mussels require special consideration because free-living glochidia must attach to a host in order to survive, and they typically attach within seconds to days. In addition, for a specific species and a specific toxicant, the glochidia 6-h EC50 might be substantially higher than the glochidia 24-h EC50. It is known that free-living glochidia of several species can remain viable for up to about ten days, depending on the species and on the percent viability that is considered acceptable. However, it is not known how fast glochidia of individual species usually attach to a host, and this is important because the glochidia EC50 for some toxicants and species is quite dependent on the duration of the toxicity test. Thus, a very important question is "What species-specific toxicity-test duration is ecologically relevant for glochidia?"

e. USEPA is tending more toward a weight-of-evidence approach to the derivation of aquatic life criteria than when the 1985 Guidelines were written. The 1985 Guidelines provided very little guidance concerning a variety of issues regarding the review of test results and a weight-of-evidence approach benefits from the consideration of more data; early rejection of test results is not a good idea when a weight-of-evidence approach is used.

f. When a potential problem is identified regarding the quality of the result of a toxicity test, it usually means that the test result is questionable, not that it is incorrect. It is certainly appropriate to note test results that are questionable, but is not necessarily appropriate to immediately reject a test result that is questionable.

g. There is uncertainty regarding the results of all scientific studies. Even detailed reports of the results of toxicity tests do not necessarily allow the identification of all potential problems, as demonstrated by the range of results that is sometimes found in round-robin tests. For example, the quality of food is usually unknown, regardless of what information is given regarding the food used. (Even humans occasionally receive unhealthy food from grocery stores and restaurants.)

h. The most important issue regarding the quality of the result of a toxicity test is replication. Questions concerning the validity of a test result are best addressed by repeating the test, especially if the test is repeated in a different laboratory.

i. Test results should be rejected only for sound scientific reasons, not merely on the basis of suspicions or concerns.

j. If a test result is rejected, there is little impetus for anybody to repeat the test.

Electronic Filing: Received, Clerk's Office 3/14/2019

Appendix 1: Fed and Unfed Acute Tests on Chloride Salts

The table on the last page of this attachment compares the results of fed and unfed acute toxicity tests on NaCl, $CaCl_2$, $MgCl_2$, and KCl. The table contains all of the sets of data from each document that contained comparable acute toxicity data regarding three or more of the four salts listed above.

It is quite possible that different ions, especially chloride and potassium, have different modes of action, have different relative toxicities to different species, and possibly are affected differently by an increase in hardness, calcium, and/or magnesium. (It is possible to obtain an LC50 for NaCl or KCl in soft water, but it is not possible to obtain an LC50 for $CaCl_2$ or $MgCl_2$ in soft water because the test material increases hardness.)

The Mount et al. fed tests with C. dubia and D. magna are at the top of the table with the Biesinger and Christensen D. magna fed tests. The two fed tests with D. magna agree very well for NaCl and for $MgCl_2$ and are almost within a factor of two for $CaCl_2$ and KCl. For all four salts the B&C fed tests gave lower values than the Mount et al. fed tests. Also for all four salts, the B&C unfed tests gave lower results than the B&C fed tests. This might indicate that Mount et al. used a better food than B&C.

For all four salts C. dubia was more sensitive than D. magna in the Mount et al. fed tests. The five ratios are similar for C. dubia and D. magna, but the C. dubia ratio is always equal to or higher than the D. magna ratio. The ratios from the Mount et al. fed tests with C. dubia and D. magna are similar to the ratios from fed and unfed tests using the three species of fish at the bottom of the table:

Ca/Na (n=5): from 0.57 to 0.98 (High/Low = 1.7)
Mg/Na (n = 3): from 0.34 to 0.55 (H/L = 1.6)
K/Na (n = 5): from 0.11 to 0.25 (H/L = 2.3)
Ca/K (n = 5): from >2.19 to 7.12 (H/L = <3.25)
Ca/Mg (n = 3): from 1.78 to 1.87 (H/L = 1.1)

It is interesting that the five ratios are very similar for cladocerans and fishes. It is also interesting that there is no overlap among the Ca/Na, Mg/Na, and K/Na ratios and there is no overlap among the Ca/Na, Ca/K, and Ca/Mg ratios. The apparent toxicity of chloride depends on the other ions that are in the test solutions in a quite reproducible manner.

These data clearly indicate that results of fed tests on these four salts should not be rejected just because the test organisms were fed during the tests. In addition, the best data regarding D. magna are probably from the Mount et al. fed tests. The fed-unfed comparisons by Biesinger and Christensen and Mount et al. demonstrate that either better foods should be developed for cladocerans and/or cladocerans should be fed during all acute tests. If cladocerans are fed during acute toxicity tests, it is possible that the duration of the tests could be increased from 48 hr to 96 hr.

Electronic Filing: Received, Clerk's Office 3/14/2019

There are several considerations regarding the feeding of cladocerans during acute toxicity tests on NaCl, $CaCl_2$, $MgCl_2$, and KCl:

1. The better the food used, the more healthy the organisms will be at the beginning of the test.
2. Feeding during the test will reduce the possibility of stress due to lack of food.
3. Lower quality organisms and stressed organisms might be more sensitive to these four salts.
4. Because these four salts are not very toxic, the concentrations used in toxicity tests are so high that contamination by one or more heavy metals might be sufficient to stress or kill cladocerans during acute toxicity tests. If contamination by one or more metals causes stress or death, food might sorb or complex the metals and reduce their toxicities.
   a. Cladocerans are more sensitive to some metals than fathead minnows, bluegills, and mosquitofish.
   b. EDTA will complex and detoxify several heavy metals.
5. If food affects the results of acute toxicity tests, it also affects the acute-chronic ratio.
6. All species are fed during chronic toxicity tests.
7. Chloride is not likely to be sorbed or complexed by food.

Electronic Filing: Received, Clerk's Office 3/14/2019

	Acute Value (mg chloride/L)				Ratio of Acute Values				
	NaCl	CaCl2	MgCl2	KCl	Ca/Na	Mg/Na	K/Na	Ca/K	Ca/Mg
C. dubia Mount fed	1189	1169	655	300	0.98	0.55	0.25	3.90	1.78
D. magna Mount fed	2893	1770	990	314	0.61	0.34	0.11	5.64	1.78
D. magna B&C fed	2806	821	939	150	0.29	0.33	0.05	5.47	0.87

* This acute value for NaCl is unusually low compared to the other acute values for D. magna.

** These results were considered not acceptable because test temperature was high and the acute value for D. magna in the same water was unusually low.

Electronic Filing: Received, Clerk's Office 3/14/2019

09JanChlorideAcute.wpd DRAFT 1-15-09
C. Stephan

Summary of Data Concerning the Acute Toxicity of Sodium Chloride to Aquatic Animals

This summary is based on "Results of Literature Search concerning the Toxicity of Chloride to Aquatic Animals" dated 1-15-09. Except as noted, this summary is consistent with the 1985 Guidelines.

Acute Values and Normalized Acute Values are expressed as mg chloride/L. Normalized Acute Values were calculated by normalizing the Acute Values to hardness = 300 mg/L and sulfate = 65 mg/L using the following equation:

$$NAV = (AV)\ (300/Hardness)^{0.205797}\ (65/Sulfate)^{-0.07452}$$

This equation is based on the equation presented in "Multiple Regression Equation for Chloride" dated 1-15-09. The hardness of 300 mg/L and the sulfate concentration of 65 mg/L are arbitrary; any other values for hardness and sulfate would have worked equally well. NAVs could not be calculated for all AVs because assumed values were not used for hardness or sulfate. Some of the values of hardness and sulfate are nominal, not measured, values.

Species	Method	Test Material	Hardness (mg/L)	Sulfate (mg/L)	Acute Value	Normalized Acute Value	Reference
Tubificid worm, Limnodrilus hoffmeisteri	S,U	Sodium chloride	100	----	3761	------	Wurtz and Bridges 1961

a = not fed. (All tests not marked "a" or "b" were unfed tests.)
b = fed.
c = mean of at least 15 LC50s.
d = range of several toxicity tests.
e = mean of 32 tests.
f = not used because there is reason to suspect that the daphnids might have been unhealthy.
g = tables 4, 7, and 9, except for tests at 28C in table 4.
h = tables 8 and 11; Daphnia pulex tests were not used because test duration was 96 hr.
i = test duration was 64 hr.
j = no deaths in 196 hr.
k = selenium deficient.
m = selenium sufficient.
p = not used in calculation of GMAV because the species is unknown and so it is not known how to combine this acute value with the acute values for which the species are known.
q = calculated using the formula for reconstituted water and the reported average measured hardness.
r = concentrations were measured in stock solutions.
s = not acclimated to the dilution water.

Electronic Filing: Received, Clerk's Office 3/14/2019

t = might not have been acclimated to the dilution water.
v = based on analyses of samples of Lake Superior water taken in the spring and fall of 2008.

Electronic Filing: Received, Clerk's Office 3/14/2019

Supplementary information concerning the results of toxicity tests on chloride

1. The atomic weights used are those given on the website of the National Institute of Standards and Technology:
   - Calcium = 40.078
   - Carbon = 12.011
   - Chlorine = 35.453
   - Hydrogen = 1.008
   - Iron = 55.845
   - Magnesium = 24.305
   - Nitrogen = 14.007
   - Oxygen = 15.999
   - Potassium = 39.098
   - Sodium = 22.990
   - Sulfur = 32.065

2. The molecular weights used are:
   - $CaCl_2$ = 110.984 (63.89 % chloride) (36.11 % calcium) (Cl/Ca = 1.769)
   - $CaCl_2 \cdot 2H_2O$ = 147.014 (27.26 % calcium) (48.23 % chloride)
   - $CaCO_3$ = 100.086 (40.04 % calcium)
   - CaO = 56.077 (71.47 % calcium)
   - $Ca(NO_3)_2$ = 164.086 (24.42 % calcium)
   - $Ca(NO_3)_2 \cdot 4H_2O$ = 236.146 (16.97 % calcium)
   - $CaSO_3$ = 136.139 (70.56 % sulfate)
   - $CaSO_4 \cdot 2H_2O$ = 172.169 (55.79 % sulfate) (23.28 % calcium) (20.93 % water)
   - $FeCl_3 \cdot 6H_2O$ = 270.294 (39.35 % chloride)
   - H_2O = 18.015
   - KCl = 74.551 (47.56 % chloride) (52.44 % potassium) (Cl/K = 0.9068)
   - K_2SO_4 = 174.257 (55.13 % sulfate)
   - $MgCl_2$ = 95.211 (74.47 % chloride) (25.53 % magnesium) (Cl/Mg = 2.917)
   - $MgSO_4$ = 120.366 (79.81 % sulfate) (20.19 % magnesium)
   - $MgSO_4 \cdot 7H_2O$ = 246.471 (38.97 % sulfate) (9.86 % magnesium)
   - NaCl = 58.443 (60.66 % chloride) (39.34 % sodium) (Cl/Na = 1.542)
   - Na_2SO_4 = 142.041 (67.63 % sulfate)

Electronic Filing: Received, Clerk's Office 3/14/2019

$Na_2SO_4 \cdot 10H_2O = 322.191$ (29.81 % sulfate)
$SO_4 = 96.061$

3. Hardness (as $CaCO_3$) = (100.086/40.078)(Ca) + (100.086/24.305)(Mg) = 2.497(Ca) + 4.118(Mg)

4. Trama (1954), Cairns and Scheier (1959), Academy of Natural Sciences (1960), and Patrick et al. (1968) all reported results of toxicity tests that were performed at the Academy of Natural Sciences of Philadelphia with the bluegill in dilution waters that were very similar:

	mg/L
KCl	20
Na_2SiO_3	20
$NaHCO_3$	40
$MgSO_4 \cdot 7H_2O$	40
$Ca(NO_3)_2$	30*
$CaCO_3$	10
K_2HPO_4	10 or 2
Fe^{+++} (as ferric citrate)	4 or 0.4

Ca = 11.3 mg/L
Mg = 3.9 mg/L
Hardness = 44.3 mg/L as $CaCO_3$
Chloride = 9.5 mg/L
Sulfate = 15.5 mg/L

*Long after the tests of concern were performed, this was reported to be 40 mg/L of $Ca(NO_3)_2 \cdot 4H_20$.

5. Freeman (1953), Freeman and Fowler (1953), Fairchild (1955), Dowden (1960), Dowden (1962), and Dowden and Bennett (1965) all contained information regarding toxicity tests performed at Louisiana State University in Baton Rouge, but several different dilution waters were used. Dowden and Bennett (1965) tried to clarify the most important dilution waters used, but the citations given for the waters on page 1310 need to be clarified. Reference 4 is the correct citation for "Standard Reference Water" (SRW), but the correct citation for "Reference Dilution Water" (RDW) is reference 6 (not reference 3) and reference 3 should be cited for "glass-wool filtered University Lake Water (ULW). ULW is considered an unacceptable dilution water because it is from "a small drainpipe-fed lake on the campus of Louisiana State University" (Dowden 1960). The compositions of SRW and RDW are:

SRW	mg/L
$MgSO_4 \cdot 7H_2O$	71.

Electronic Filing: Received, Clerk's Office 3/14/2019

K_2SO_4	6.5
$MnSO_4 \cdot 4H_2O$	0.2
$CaCl_2 \cdot 2H_2O$	18.6
$NaHCO_3$	25.
NH_4NO_3	3.
$K_2HPO_4 \cdot 3H_2O$	1.1
CaO	32.2
$Na_2SiO_3 \cdot 9H_2O$	62.6
$FeCl_3 \cdot 6H_2O$	1.2

Ca = 23.0 mg/L
Mg = 7.0 mg/L
Hardness = 86.2 mg/L as $CaCO_3$
Chloride = 9.4 mg/L
Sulfate = 31.2 mg/L

RDW	mg/L
$CaCl_2$	110
$NaHCO_3$	110
NaCl	100
$MgSO_4 \cdot 7H_2O$	60
KCl	20

Ca = 39.7 mg/L
Mg = 5.9 mg/L
Hardness = 123.4 mg/L as $CaCO_3$
Chloride = 140.4 mg/L
Sulfate = 23.4 mg/L

6. When known, the concentration of chloride in dilution water was negligible in tests on chloride.

7. Karraker (2007) says that "road salt" contains sodium chloride, sodium ferrocyanide, heavy metals, and often sand or cinder. Results of toxicity tests on "road salt" were not used.

Electronic Filing: Received, Clerk's Office 3/14/2019

8. Hyalella azteca appears to be especially sensitive to some pollutants when the concentration of chloride is low, e.g., lower than 25 mg/L. This should not affect the sensitivity of this species to chloride.

9. Mount et al. (1997) reported that the toxicities of sodium and calcium salts to C. dubia, D. magna, and the fathead minnow are primarily attributable to the corresponding anion.

10. Some data presented in Table 1 of USEPA (1988) have been changed:
    a. Several values differ because of roundoff differences.
    b. USEPA (1988) used results of short acute tests for the reasons given on pages 2 and 3 (see also Lowell et al. 1995), but results of short tests are not used here because short acute tests sometimes give higher LC50s than standard tests.
    c. Data from Dowden (1961, which should be 1960) and Kostecki and Jones (1983) are not used here because of the dilution water used in the tests.
    d. The test results from Trama (1954) are also given in Academy of Natural Sciences (1960) and Patrick et al. (1968).
    e. Hamilton et al. (1975) did not adequately acclimate the midges.
    f. Fed acute tests were not used in USEPA (1988), but fed acute tests are used here and are given preference over unfed acute tests when the test organisms are cladocerans.

C. Stephan

Multiple Regression Equation for Chloride

Grizzle and Mauldin (1995; 24-hr tests using striped bass) and Lasier et al. (2006; 7-day survival tests using Ceriodaphnia dubia) reported that calcium and/or magnesium reduced the toxicity of chloride, whereas MacGregor et al. (1986) reported that the toxicity of NaCl was not significantly affected by hardness. Davies and Hall (2007) reported that the Ca-Mg ratio did not affect the toxicity of either NaCl or KCl to D. magna. Because of these incomplete and potentially conflicting reports, U.S. EPA hired the Great Lakes Environmental Center (GLEC) and the Illinois Natural History Survey (INHS) to perform toxicity tests concerning the effect of hardness and sulfate on the toxicity of chloride to selected aquatic animals.

The equations presented in Figures 1 through 7 of the GLEC and INHS (2008) report can be used to make the aquatic life criterion for chloride dependent on both hardness and sulfate. However, although the LC50s used in Figures 1 through 7 are based on measured concentrations of chloride, the hardnesses and the concentrations of sulfate are nominal, not measured, values. Nevertheless, for Ceriodaphnia dubia Figure 3 shows that a log-log plot gives a straighter line than the plots given in Figures 1 and 2. A straight line fits the sulfate data in Figures 4, 5, and 6 equally well. Because a log-log plot will be used for the hardness data, a log-log plot will be used for the sulfate data.

Figure 7 gives log-log hardness equations for three other species, based on nominal hardnesses. The intercepts of the four log-log hardness equations differ because the species have different sensitivities. For the purpose of making a chloride criterion dependent on hardness, the important differences between the four equations are the exponents.

C. dubia	0.2144
S. simile	0.286
G. parvus	-0.0164
T. tubifex	0.245

The exponent for C. dubia is based on seven LC50s from GLEC and seven LC50s from INHS, whereas each of the other exponents is based on two LC50s from one laboratory. In addition, the exponent for C. dubia is close to the mean of the other three exponents. Therefore, it seems reasonable to set the chloride hardness exponent equal to the chloride hardness exponent obtained with C. dubia.

Multiple regression was performed on the data presented on pages 29 and 36 of GLEC and INHS (2008) concerning the effects of hardness and sulfate on the toxicity of chloride to C. dubia. The analysis was performed using the natural logs of the hardnesses, concentrations of sulfate, and LC50s and using the assumption that the effects of hardness and sulfate on the toxicity of chloride are proportional effects, not additive effects. The following hardnesses, concentrations of sulfate, and LC50s were used:

Electronic Filing: Received, Clerk's Office 3/14/2019

Hardness	Sulfate	LC50
30	78.7	947
44	75.9	955
96	73.7	1130
180	67.7	1609
400	78.7	1491
570	76.2	1907
800	75.5	1764
25	69.9	1007
49	67.8	767
95	70.3	1369
194	69.9	1195
375	68.9	1687
560	68.3	1652
792	70.9	1909
280	28.1	1400
280	59.6	1720
280	117	1394
280	239	1500
280	482	1109
280	729	1206
279	22.9	1311
276	49.7	1258
283	107	1240
281	229	1214
290	461	1199
278	694	1179

The resulting equation for C. dubia is:

$$LC50 = (616.67 \text{ mg chloride/L})(\text{hardness})^{0.205797}(\text{sulfate})^{0.07452}$$

where the units are:

LC50: mg chloride/L
hardness: mg $CaCO_3$/L
sulfate: mg sulfate/L.

As noted above, the C. dubia data concerning the effect of hardness on the chloride LC50 are supported by data in GLEC and INHS (2008) for three other species: a fingernail clam (Sphaerium simile), a tubificid worm (Tubifex tubifex), and a snail (Gryaulus parvus). However, no data for other species were presented in GLEC and INHS (2008) supporting the C. dubia data concerning the effect of sulfate on the chloride LC50.

WISLOH (2007) and USEPA (1991) present the following chloride LC50s in low-hardness, low-sulfate dilution water and in high-hardness, high-sulfate dilution water for C. dubia and for the fathead minnow (see "Summary of Data concerning the Acute Toxicity of Sodium Chloride to Aquatic Animals" dated 1-15-09):

Electronic Filing: Received, Clerk's Office 3/14/2019

Species	Hardness (mg/L)	Sulfate (mg/L)	Acute Value (mg Cl/L)	Reference
Cladoceran	39.2	4.6	1395	USEPA 1991
C. dubia	39.2	4.6	1638	
	39.2	4.6	1274	
	39.2	4.6	1395	
	339.0	325.4	1698	
Cladoceran	84.8	81.4	1677	WISLOH 2007
C. dubia	169.5	162.7	1499	
Fathead minnow	39.2	4.6	2790	USEPA 1991
P. promelas	39.2	4.6	2123	
	339.0	325.4	2244	
Fathead minnow	84.8	81.4	4167	WISLOH 2007
P. promelas	169.5	162.7	4127	

To facilitate use of these data, geometric mean LC50s were calculated from replicate LC50s.

If the multiple-regression equation based on the C. dubia data in GLEC and INHS (2008) is used to adjust the low-hardness, low-sulfate LC50 to the corresponding high hardness and high concentration of sulfate, the results are:

	Predicted LC50	Measured LC50	M - P*	Percent Difference**
C. dubia				
WISLOH (2007):	1837	1499	-338	-20.3%
USEPA (1991):	1612	1698	+ 86	5.2%
Fathead minnow				
WISLOH (2007):	4563	4127	-436	-10.0%
USEPA (1991):	2762	2244	-518	-20.7%

* M - P = (Measured LC50) - (Predicted LC50)

** Percent Difference = 100 (Measured - Predicted)/([Measured + Predicted]/2)

Each predicted LC50 is within a factor of two of the corresponding measured LC50 and so all four differences could be due to experimental variation. However, three of the four differences are in the same direction and the difference in the other direction is smaller.

Electronic Filing: Received, Clerk's Office 3/14/2019

There is a more direct way to relate the WISLOH (2007) and USEPA (1991) data for C. dubia and the fathead minnow to the multiple-regression equation. The relationship regarding the effect of hardness on the chloride LC50 is supported by data for four species, so it is reasonable to use this relationship to adjust the low-hardness LC50 to the high hardness. Because the low-hardness LC50 is at low sulfate, the predicted high-hardness LC50 is also at low sulfate. Therefore, the predicted high hardness, low sulfate LC50 and the measured high hardness, high sulfate LC50 can be used to calculate an exponent for sulfate. (An exponent in an arithmetic equation is a slope in a log-log plot.) The resulting sulfate exponents are:

C. dubia
WISLOH (2007): sulfate exponent = -0.368
USEPA (1991): sulfate exponent = -0.062

Fathead minnow
WISLOH (2007): sulfate exponent = -0.220
USEPA (1991): sulfate exponent = -0.123

The sulfate exponent from the multiple-regression analysis of the GLEC and INHS (2008) C. dubia data was -0.07452. This is in the range of the new C. dubia exponents, but is substantially lower than one of the new C. dubia exponents and is lower than both of the new fathead minnow exponents; the mean of the four new exponents is -0.193. Charlie Delos and Chuck Stephan interpret these exponents to mean that WISLOH (2007) and USEPA (1991) provide data for both C. dubia and the fathead minnow that support the concepts that (i) 0.205797 is a reasonable value for the hardness exponent, (ii) an increase in the concentration of sulfate causes a decrease in the chloride LC50 and (iii) the sulfate exponent might be more negative than indicated by the GLEC and INHS (2008) data.

The above calculations use multiple regression; covariance analysis is not used for several reasons. Data are available for C. dubia from two labs whereas data are available for the other three species from only one lab. Covariance analysis would do a good job of weighting the data by species, but it is not clear that it would do a good job of taking into account the fact that data for C. dubia are available from two labs. Also, many more data points are available for C. dubia than for all of the other species combined, so covariance analysis would give much more weight to C. dubia than to the other three species, which is what the above calculations do. Further, the exponent for C. dubia is close to the mean of the exponents for the other three species. For these reasons it is likely that covariance analysis would give a pooled exponent that is close to the exponent for C. dubia. In addition, data concerning sulfate are available only for C. dubia, so it seems desirable to do multiple regression of the C. dubia data rather than doing covariance analysis of the hardness data and then trying to find a way to integrate the sulfate exponent with the hardness exponent. It is possible that multiple regression and covariance analysis could be used together, but a better approach might be to use GLM or GLiM. However, it is possible that the available data do not satisfy the assumptions of any of these techniques.

Calculation of Aquatic Life Criteria for Chloride

These calculations are based on "Summary of Data Concerning the Acute Toxicity of Sodium Chloride to Aquatic Animals" dated 1-15-09 and "Summary of Data Concerning the Chronic Toxicity of Sodium Chloride to Aquatic Animals" dated 1-15-09. Except as noted (for example, see footnote a), these calculations are consistent with the 1985 Guidelines. GMAVs and SMAVs are normalized to hardness = 300 mg/L and sulfate = 65 mg/L. GMAVs and SMAVs are expressed as mg chloride/L.

* A "greater than" acute value for the brown trout (Salmo trutta) is not in this table because it is too low to be a useful "greater than" value.
** Name of family, not name of genus.

a. Section IV.I of the 1985 Guidelines says: "For each species for which at least one acute value is available, the Species Mean Acute Value should be calculated as the geometric mean of the results of all flow-through tests in which the concentrations of test material were measured. For a species for which no such result is available, the SMAV should be calculated as the geometric mean of all available acute values, i.e., results of flow-through tests in which the concentrations were not measured and results of static and renewal tests based on initial concentrations (nominal concentrations are acceptable for most test materials if measured concentrations are not available) of test material." The guidance presented in section IV.I of the 1985 Guidelines seems inappropriate for chloride because chloride is different from most pollutants for which aquatic life criteria are derived. Chloride is very soluble in water, does not oxidize or reduce, is not volatile, does not degrade, does not sorb to test chambers, test organisms, food, or waste products, is not complexed by materials that commonly occur in water, is not involved in a pH-dependent equilibrium in water, and does not precipitate in waters in which aquatic organisms commonly occur.
   i. For chloride, as long as the concentration of dissolved oxygen is sufficiently high, it seems appropriate to give static and renewal acute tests the same weight as flow-through acute tests in the derivation of the SMAV for a species.
   ii. For chloride, it seems inappropriate to give measured acute tests a weight of 1 and unmeasured acute tests a weight of 0 when both are available for the derivation of the SMAV for a species. For example, if there is a choice between one measured acute test on chloride and three unmeasured acute tests in three different laboratories, the three tests are probably preferable to the one test, but if the choice is between one measured acute test and two unmeasured acute tests in two different laboratories, the one test is probably preferable. Thus, for a species for which both measured and unmeasured acute tests are available for chloride, it seems appropriate to give measured acute tests a weight of 2.5 and unmeasured acute tests a weight of 1 when the SMAV is calculated.

   The conclusions described above concerning chloride were developed during discussions among Charles Delos, Charles Stephan, and Glen Thursby. For other pollutants, different conclusions concerning the relative merits of static, renewal, and flow-through acute toxicity tests and the relative merits of measured and unmeasured acute toxicity tests are likely to be more appropriate.

Electronic Filing: Received, Clerk's Office 3/14/2019

R04679

b. For Ceriodaphnia dubia, the acute values from Hoke et al. (1992) are considered outliers. The geometric mean is 1468.1 for Mount et al. (1997), 1790.2 for U.S. EPA (1991), 1998.2 for WISLOH (2007), and 1457.3 for GLEC and INHS (2008).
SMAV = antilog ([log 1468.1 + log 1790.2 + log 1998.2 + log 1863.6 + 2.5(log 1311.1) + 2.5(log 1457.3)]/9) = 1542.3.

c. For Daphnia magna, the values of 3815.5 (Mount et al. 1997), <2785.1, (Anderson 1946), 2439.7 (Anderson 1948), and 3025.9 and 3357.4 (Biesinger and Christensen 1972) were not used. A geometric mean of 3906.7 was calculated from the limits given by Seymour et al. (1997). The geometric mean is 3208.8 for Hoke et al. (1992) and is 4054.2 for Davies and Hall (2007). The SMAV is 3773.1, which is the geometric mean of 3208.8, 5068.2, 3906.7, 2242.3, 4749.6, 3968.5, and 4054.2.

d. Bluegill: SMAV = antilog ([2.5(log 7702.3) + log 10461.6]/3.5) = 8406.5.

e. Fathead minnow: SMAV = antilog([log 2833.9 + 2.5(log 8665.1) + 2.5(log 8225.2) + log 5112.0 + log 5226.3]/8) = 6515.3.

f. Daphnia pulex: SMAV = antilog([2.5(log 1938.8) + log 2240.3]/3.5) = 2020.5.

g. Not used in calculations because, even though the acute and chronic tests were in the same document, different dilution waters were used in the tests.

h. The SMACR for Ceriodaphnia dubia is the geometric mean of 1.508, >3.841, and 2.601.

FAV = 1205 mg chloride/L

CMC = FAV/2 = 602.5 mg chloride/L

The five SMACRs (7.308, 4.148, 1.974, 3.952, and >2.438) that are available for use in calculations result in three GMACRs:

7.308	Oncorhynchus
3.187	Daphnia
>2.470	Ceriodaphnia

The 1985 Guidelines require ACRs for species in three different families, but Daphnia and Ceriodaphnia are in the same family. However, even though the ACR for the fathead minnow should not be used in calculations because the acute and chronic tests using the fathead minnow were

Electronic Filing: Received, Clerk's Office 3/14/2019

R04680

performed in different dilution waters, the fathead minnow ACR can be considered a qualitative ACR and used to satisfy the MDRs because chloride is not likely to be complexed or sorbed or detoxified by organic or inorganic constituents of the dilution water.

The GMACRs for Oncorhynchus and Daphnia are consistent with the "greater than" GMACR for Ceriodaphnia and the GMACRs are within a factor of ten. Therefore, the Final ACR = 4.826, which is the geometric mean of the GMARCs for Oncorhynchus and Daphnia. This would give FCV = FAV/FACR = (1205 mg chloride/L)/4.826 = 249.7 mg chloride/L. However, this approach is contraindicated because the GMACRs (including the unused GMACR for Pimephales) indicate that the GMACR increases as the GMAV increases.

The GMACR for Daphnia is consistent with the "greater than" GMACR for Ceriodaphnia, so the GMACR for Daphnia can be used as the FACR. Therefore, FACR = 3.187 and FCV = FAV/FACR = (1205 mg chloride/L)/3.187 = 378.1 mg chloride/L.

CCC = FCV = 378.1 mg chloride/L.

The CMC and CCC given above are for hardness = 300 mg/L and sulfate = 65 mg/L. The equation that was used to normalize the acute values can be used to make the CMC and CCC dependent on hardness and sulfate. The resulting equations for the CMC and CCC are:

$$CMC = (602.5 \text{ mg chloride/L})\,(\text{hardness}/300)^{0.205797}\,(\text{sulfate}/65)^{-0.07452}$$
$$= (254.3 \text{ mg chloride/L})\,(\text{hardness})^{0.205797}\,(\text{sulfate})^{-0.07452}$$

At hardness = 300 mg/L and sulfate = 65 mg/L, CMC = 602.5 mg chloride/L.

$$CCC = (378.1 \text{ mg chloride/L})\,(\text{hardness}/300)^{0.205797}\,(\text{sulfate}/65)^{-0.07452}$$
$$= (159.6 \text{ mg chloride/L})\,(\text{hardness})^{0.205797}\,(\text{sulfate})^{-0.07452}$$

At hardness = 300 mg/L and sulfate = 65 mg/L, CCC = 378.1 mg chloride/L.

Electronic Filing: Received, Clerk's Office 3/14/2019

R04681

Derivation of an Alternative FCV

Even though the above derivation of FCV = 378.1 mg chloride /L follows the procedure described in the 1985 Guidelines, there is an alternative approach that is justified on the basis of the "good science" clause in section XII.B of the 1985 Guidelines. This approach is based on the fact that the four low SMACRs for chloride were obtained with invertebrates, whereas the high SMACR was obtained with a vertebrate. This can be interpreted to mean that vertebrates have a higher ACR, on the average, than invertebrates, especially because the qualitative ACR for the fathead minnow is 15.17. Therefore, a vertebrate ACR and an invertebrate ACR can be used with the GMAVs to calculate a predicted Genus Mean Chronic Value for each genus, and then a FCV can be calculated directly from the predicted GMCVs. This approach calculates and uses a predicted chronic value for each genus for which an acute value is available and probably does a better job of taking into account the chronic sensitivities of both vertebrates and invertebrates to chloride. The relevant data and calculations are presented on the next few pages.

The FACR of 3.187 derived above was derived from all of the acceptable ACRs for invertebrates. The only acceptable ACR for a vertebrate is 7.308. A predicted GMCV can be calculated from each GMAV by using 3.187 as the invertebrate ACR and using 7.308 as the vertebrate ACR.

Environmental Toxicology

Acute toxicity of sodium chloride and potassium chloride to a unionid mussel (*Lampsilis siliquoidea*) in water exposures

Abstract

Freshwater mussels (order Unionoida) are one of the most imperiled groups of animals in the world. However, many ambient water quality criteria and other environmental guideline values do not include data for freshwater mussels, in part because mussel toxicity test methods are comparatively new and data may not have been available when criteria and guidelines were derived. The objectives of the present study were to evaluate the acute toxicity of sodium chloride (NaCl) and potassium chloride (KCl) to larvae (glochidia) and/or juveniles of a unionid mussel (fatmucket, *Lampsilis siliquoidea*) and to determine the potential influences of water hardness (50, 100, 200, and 300 mg/L as $CaCO_3$) and other major ions (Ca, K, SO_4, or HCO_3) on the acute toxicity of NaCl to the mussels. From the KCl test, the 50% effect concentration (EC50) for fatmucket glochidia was 30 mg K/L, similar to or slightly lower than the EC50s for juvenile fatmucket (37–46 mg K/L) tested previously in our laboratory. From the NaCl tests, the EC50s for glochidia increased from 441 to 1597 mg Cl/L and the EC50s for juvenile mussels increased from 911 to 3092 mg Cl/L with increasing water hardness from 50 to 300 mg/L. Increasing K from 0.4 to 1.9 mg/L, SO_4 from 13 to 40 mg/L, or HCO_3 from 44 to 200 mg/L in the 50 mg/L hardness water did not substantially change the NaCl EC50s for juvenile mussels, whereas increasing Ca from 9.9 to 42 mg/L increased the EC50s by a factor of 2. The overall results indicate that glochidia were equally or more sensitive to NaCl and KCl compared with juvenile mussels and that the increased water hardness ameliorated the acute toxicity of NaCl to glochidia and juveniles. These responses rank fatmucket among the most acutely sensitive freshwater organisms to NaCl and KCl. *Environ Toxicol Chem* 2018;37:3041–3049. © 2018 SETAC. Table S1. Summary of test conditions for conducting chronic toxicity tests with fatmucket (*Lampsilis siliquoidea*) in basic accordance with ASTM (2017)

Parameter	Conditions
Test chemical	KCl or NaCl
Test type	Flow through
Test Duration	4, 8, or 12 weeks
Temperature	20°C (2012 NaCl test only) or 23°C (see text)
Light	Ambient laboratory light; about 500 lux; 16L:8D
Test chamber	300-ml beaker with 200 mL of water (5 ml of sand in exposures with sand; see text)
Water renewal	125 ml of additional water/4 h
Age of test organism	About 1-week, 1-month, or 2-month-old juveniles (see text)
Organisms/chamber	10
Replicates/conc.	4 or 8
Feeding	2 mL of algal mixture 2 to 6 times daily (see text)
Dilution water	Diluted well water (see text)
Test concentrations	5 concentrations plus control; 50% serial dilution (see text)
Chemical analyses	Water samples for Cl or K analyses at the beginning and end of the test and once every week (Cl) or once every 2 weeks (K)
Water quality	Dissolved oxygen, pH, conductivity, hardness, and alkalinity measured weekly in the control, medium, and/or high exposure concentrations. Major cations and anions in control waters measured periodically (see text)
Endpoint	Survival, length, dry weight, biomass
Test acceptability criteria	≥ 80% control survival

Table S2. Mean measured water quality characteristics (standard deviation in parenthesis)[a] in a chronic 4-week KCl test and 4 chronic 4- to 12-week NaCl toxicity tests with different ages of juvenile fatmucket (*Lampsilis siliquoidea*), feeding, and with or without a sand substrate

			Water quality						Major cations and anions (mg/L)						
Test	Test duration (week)	Sand	Number of samples	Dissolved oxygen (mg/L)	pH	Hardness (mg/L as $CaCO_3$)	Alkalinity (mg/L as $CaCO_3$)	Total ammonia (mg N/L)	Number of samples	Ca	K	Mg	Na	Cl	SO_4

Supplemental Data, Section S1

REFINING METHODS FOR CONDUCTING CHRONIC TOXICITY TESTS WITH FRESHWATER MUSSELS IN WATER EXPOSURES

BACKGROUND

The ASTM International standard for conducting chronic toxicity testing with mussels was first published in 2005 (ASTM 2017) and is in need of refinement (Wang et al. 2011). Although the survival of mussels in controls in previous chronic tests typically exceeded the test acceptability criterion of ≥80% survival (ASTM 2017), the growth of the control mussels has been inconsistent among chronic toxicity tests (Ingersoll et al. 2015). Further studies are necessary to optimize feeding and other test conditions for assessing the mussel growth endpoint (Wang et al. 2011, Ingersoll et al. 2015). The objective of the present study was to evaluate survival and growth of juvenile mussels (Fatmucket, *Lampsilis siliquoidea*) in 4- to 12 week water exposures under control conditions (1) with and without a sand substrate, (2) with or without sand and test chamber replacement every 2 weeks, (3) with different feeding levels and frequencies of algal mixture, or with an addition of food to algal mixture, and (4) with different water renewal types (static renewal vs flow through). The results of this study are useful to refine test conditions to maximize control survival and growth of juvenile mussels in long-term exposures and to revise the ASTM (2017) methods for conducting chronic water-only toxicity tests with juvenile mussels.

MATERIALS AND METHODS

Brooding female fatmucket were collected in February 2014 from the Silver Fork of Perche Creek (Boone County, MO) and shipped to Missouri State University, Springfield, MO for production of juvenile mussels. Newly metamorphosed juveniles (<5 d old) were shipped overnight to the Columbia Environmental Research Center (CERC), Columbia, MO and cultured for 2 months in a recirculating mussel culture system (Barnhart 2006) before the feeding study. The mussels were fed once every hour automatically with an algal mixture to maintain a concentration of 2 nL cell volume/mL in the culture system (see the algal source, food preparation, and other details in main text of this manuscript). The culture water was the same water used in the feeding treatments and prepared by diluting the CERC well water (a hardness of ~300 mg/L as $CaCO_3$) with deionized water to a hardness of 100 mg/L as $CaCO_3$. Water

Electronic Filing: Received, Clerk's Office 3/14/2019

temperature of 23±1°C and ambient laboratory light of 500 lux with 16:8 h light:dark photoperiod were maintained during the mussel culture and feeding treatments.

The feeding study started in July 2014 with 13 treatments for a test duration of 4 weeks, and 6 treatments for 12 weeks (Session 1-Table 1). Specific details are provided below.

Effects of beaker replacement and sand substrate under flow-through conditions. A previous 12-week NaCl toxicity test conducted in our laboratory failed because the control survival in exposures were below 80% after 8 weeks (unpublished data). A difficulty during chronic toxicity testing with mussels was cleaning debris in water-only beakers. Unconsumed food, mussel excreta, and, sometimes, fungi or algae accumulated and stuck on test beakers and mussel shells. Recent studies in our laboratory (unpublished data) have shown that periodic beaker replacement or placing a thin layer of silica sand in the beaker appeared to enhance hygiene (less fungi or algae growing on mussel shells). Four treatments were designed to confirm the effects of beaker replacement and sand substrate on survival and growth of juvenile fatmucket under the flow-through condition with a routine feeding level of 2 ml of algal mixture, which was prepared daily before morning feeding by adding 1 mL of Nanno 3600® and 2 mL of Shellfish Diet 1800® into 1.8 L of test water (algal concentration ~510 nl cell volume/ml; Wang et al. 2007):

Treatment 1: No substrate and no beaker replacement: This treatment was the same as that used in our previous chronic toxicity tests with juvenile mussels (e.g., Wang et al. 2007, 2010, 2011; Besser et al. 2013) and was considered as a control to determine the amount of improvement of mussel survival and growth in other treatments. Test duration was 4 weeks.

Treatment 2: No substrate but beaker replacement: Test beakers were replaced every 2 weeks. For the beaker replacement, the mussels in each replicate beaker were rinsed into a 200-mL glass dish with test water for survival determination. Surviving mussels (see details below) were transferred into new beakers. Test durations were 4 and 12 weeks.

Treatment 3: Sand substrate addition but no beaker replacement: 5 mL of silica sand (~100 to 400-µm particles; Granusil #5010, Unimin Corporation, New Canaan, CT, USA), which had been held in control water for 24 h prior to the treatment, was added to each replicate beaker at the beginning of the treatment. Test duration was 4 weeks.

Electronic Filing: Received, Clerk's Office 3/14/2019

Treatment 4: Beaker and sand replacement: Sand was placed in beakers at the beginning of the treatments. The sand and beakers were replaced every 2 weeks. Test durations were 4 and 12 weeks.

Effects of feeding under flow-through condition. The routine feeding rate of 2 ml of algal mixture twice daily used in our previous studies (Wang et al. 2007, 2010, 2011) was based on a mussel feeding study in water-only (no substrate) beakers at 20°C (Wang et al. 2007). Recent studies have indicated that juvenile fatmucket grew faster at 23°C than 20°C in the culture and testing (J.M. Kunz; C.M. Barnhart of Missouri State University, unpublished data). In addition to the routine feeding (2 mL of algal mixture twice daily in Treatment 4), 4 treatments were designed to determine the optimum feeding levels of algal mixtures for the growth of juvenile fatmucket at 23°C in test beakers containing sand substrate and with beaker and sand replacement once every other week:

Treatment 5: 3 mL of algal mixture twice daily manually in the early morning and late afternoon. Test durations were 4 and 12 weeks.

Treatment 6: 2 mL of algal mixture 3 times daily manually in the early morning, noon, and late afternoon. Test durations were 4 and 12 weeks.

Treatment 7: 1 mL of algal mixture 6 times daily. The food was delivered by a Hamilton syringe pump automatically every 4 hours. Test durations were 4 and 12 weeks.

Treatment 8: 2 mL of algal mixture 6 times daily. The food was delivered by a Hamilton syringe pumps automatically every 4 hours. Test durations were 4 and 12 weeks.

Effects of the addition of other food to algal mixture under flow-through condition. Klaine et al (1997) reported that a diet with alga *Selenastrum capricornutum* and combined yeast-cerophyl-trout chow (YCT) was the best food among several potential diets for the growth of juvenile mussels (*Utterbackia imbecillis*). However, yeast globules formed on mussel shells and could not be rinsed or removed without potentially damaging the juvenile shell (Klaine et al. 1997). Our design with sand substrate under flow-through conditions might help reduce globule formation. In addition, Eybe et al. (2013) found that including a protein-containing additive (crushed red bloodworms) with the algae improved survival and growth of juvenile freshwater pearl mussel

Electronic Filing: Received, Clerk's Office 3/14/2019

(*Margaritifera margaritifera*). A commercially available food Oyster-feast® (Reed Mariculture, Campbell, CA) was used for the present study. Oyster-feast® is a food mixture of oyster eggs and ovarian tissue for the culture of corals, other invertebrates, and fish, and contains high protein and omega-3 fatty acids (http://reefnutrition.com/oyster_feast.php). Three treatments were designed to evaluate the effects of the addition of YCT or Oyster-feast® to the algal mixture on survival and growth of juvenile fatmucket at 23°C in test beakers containing sand substrate and with beaker and sand replacement once every other week:

Treatment 9: 2 mL of algal mixture twice daily + 0.25 mL of YCT (1,800 mg/L stock; USEPA 2000) once daily. Test duration was 4 weeks.

Treatment 10: 2 mL of algal mixture twice daily + 0.5 mL of YCT once daily. Test duration was 4 weeks.

Treatment 11: 2 mL of algal mixture twice daily + 5 µL concentrate of Oyster-Feast® once daily (1/2 of the maximum amount recommended by the food provider). Test duration was 4 weeks.

Effects of feeding under static-renewal conditions. Limited chronic toxicity tests with juvenile mussels have been conducted under static-renewal conditions in our laboratory unpublished data, James Kunz) and previous studies (Bringolf et al. 2007). A static-renewal test may be useful when a flow-through system (e.g. diluter) is not available or the volume of test solution is limited for a flow-through test (e.g., effluent). A recent 28-d static-renewal effluent test with juvenile fatmucket indicated frequent beaker replacement (once every week) improved survival and growth (unpublished data, James Kunz). The present study further determined the optimum feeding rate under static-renewal conditions. All test conditions were the same as Treatment 4 in flow-through conditions, except that the treatments were conducted for 4 weeks and about 70% of the water was renewed on Mondays, Wednesdays, and Fridays, and beakers and sand were replaced once every week. Two feeding levels of algal mixture were used:

Treatment 12: 2 mL of algal mixture twice daily in the early morning and late afternoon. Test duration was 4 weeks.

Electronic Filing: Received, Clerk's Office 3/14/2019

Treatment 13: 3 mL of algal mixture twice daily in the early morning and late afternoon. Test duration was 4 weeks.

All experiments were conducted concurrently in 3 intermittent flow-through proportional diluter systems modified from Mount and Brungs (1967, Wang et al. 2007). For the treatments with a 4-week test duration, 4 replicate glass beakers per treatment were placed in a water bath of the diluter. For the treatments with the 4- and 12-week test durations, 8 replicate beakers were placed in the bath (4 replicates for sampling survival and growth data at week 4, and 4 replicates for sampling at week 12). Test water was maintained at 23±1°C. Each beaker (300 mL) had a 2.5-cm hole in the side covered with 50-mesh (279-µm width opening) stainless-steel screen and held 200 ml of water. For the experiments under flow-through condition, the diluter provided 125 ml of water to each replicate beaker every 4 h (3.6 water volume additions per day). At the start of the experiments, 10 juvenile mussels (starting age ~60 d old) exhibiting foot movement were impartially transferred into each beaker. Additionally, 4 replicates of 10 mussels per replicate were preserved in 70% ethanol for the measurements of initial length and dry weight. Algal mixture was prepared daily before morning feeding by adding 1 mL of Nanno 3600® and 2 mL of Shellfish Diet 1800® (Reed Mariculture, Campbell, CA) into 1.8 L of test water (algal concentration ~510 nl cell volume/ml; Wang et al. 2007) and kept in a refrigerator at <4°C for the feeding in the rest of the day. For the auto-feeding treatments, a stock of the algal mixture was maintained in an aerated cooler with ice packs and changed daily, and 3 syringe pumps (Hamilton, Reno, NV, USA) automatically delivered the targeted amount of algal mixture to exposure mixing chambers of the diluter right before each water cycling (Wang et al. 2011). In the treatments with a longer-term duration of 12 weeks, feeding levels were increased 50% every 4 weeks.

Water quality (dissolved oxygen, pH, conductivity, hardness, alkalinity, and ammonia) were determined using standard methods (Eaton et al. 2005) on composite water samples collected from the replicates at least every 2 weeks. At the end of the 4- or 12-week study, mussels in each replicate beaker was examined for survival under a dissecting microscope. Mussels with an empty shell or with a gaped shell containing decomposed tissue were classified as dead. Surviving mussels in each replicate were counted and preserved in 70% ethanol for subsequent dry weight measurements. Dry weight of pooled mussels per replicate was determined by drying

Electronic Filing: Received, Clerk's Office 3/14/2019

the mussels at 60°C for 48 h. The differences in mean weight increases (calculated as final weight/starting weight) among each of the 4 4-week treatment groups and among the 6 12-week treatments were determined using ANOVA and Duncan's multiple range test using SAS/STAT version 9.4, SAS Institute). The level of statistical significance was set at $p \leq 0.05$.

RESULTS AND DISCUSSION

Water quality

Measured water quality characteristics are summarized in Session S1-Table 2. Mean measured concentrations of dissolved oxygen were ≥ 7.6 mg/L. Mean measured concentrations of total ammonia nitrogen ranged from 0.04 to 0.08 mg N/L in Treatments 1 to 11 under flow-through conditions and were 0.10 and 0.16 mg N/L in Treatments 12 and 13 under static-renewal conditions. Mean measured conductivity, pH, hardness, and alkalinity were similar within a treatment and among different treatments (conductivity 253 to 265 µS/cm, pH 8.0 to 8.3, alkalinity 91 to 102 mg/L as $CaCO_3$, hardness 101 to 106 mg/L as $CaCO_3$; Session S1-Table 2).

4-week treatments

Mean survival was similar among the 13 treatments, ranging from 95 to 100% (Session S1-Table 1). Under flow-through conditions, the mean weight increase in Treatment 1 conducted under traditional conditions (i.e., no sand and no beaker replacement, fed 2 mL algal mixture 2 times daily; ASTM 2017) was about 3 fold of the starting weight, whereas the other 10 treatments exhibited about 5- to 13-fold weight increase (Session S1-Figure 1ABC). Specifically, under the same feeding of 2 mL algal mixture 2 times daily, Treatments 2 (with beaker replacement every 2 weeks), Treatment 3 (with sand addition but no beaker and sand replacement), and Treatment 4 (with sand addition plus sand and beaker replacement every 2 weeks) had significantly greater weight increase than Treatment 1(Session S1-Figure 1A). The results indicate that replacing beakers every 2 weeks or adding sand substrate improved mussel growth.

Among Treatments 4 to 8, all with sand and beaker replacement but at different feeding rates and frequencies of algal mixture, Treatment 8 with the auto-feeding 6 times 2 mL algal mixture had significantly greater weight increase than the other 4 treatments (Session S1-Figure 1B). The weight increases among the 3 treatments with manual feeding (Treatments 4, 5, and 6) were not

Electronic Filing: Received, Clerk's Office 3/14/2019

significantly different although Treatment 6 with the 3 times 2 mL algal mixture showed a slightly higher weight increase with less variability than Treatment 4 (2 times 2 mL) and Treatment 5 (2 times 3 mL; Session S1-Figure 1B). The weight increase in Treatment 7 with the auto-feeding 6 times 1 mL algal mixture was relatively low although the daily total amount of food was designed to be equal to or more than the 3 manual feeding treatments. It is likely that a portion of food had been lost when the diluter delivered the water (mixed with the food) to replicate beakers and the excess water, and potentially food, flowed out through the side screen. Therefore, the increased feeding rate and frequency of the auto-feeding 6 times 2 mL algal mixture supports the best growth.

The mean weight increases of mussels fed algae plus the 2 levels of YCT (Treatments 9 and 10) and fed algae plus Oyster-feast® were similar; however, the variation among replicates in Treatment 10 (algae plus high YCT treatment was much lower (Session S1-Figure 1C). The growth of mussels in these 3 treatments with additional food to the algal mixture were not significantly different from the growth of mussels only fed algal mixture 2 times daily in Treatment 4 (Session S1-Figure 1C). Notably, the mean weight increase in Treatment 10 with the additional 0.5 mL YCT was 27% greater than the weight increase in the algal feeding-only treatment, indicating the mussels may have benefited some from the YCT. Further studies need to confirm the effect of YCT on mussel growth. However, increasing YCT amount may likely cause elevated ammonia (e.g., Wang et al. 2013, to which juvenile mussels are highly sensitive (Wang et al. 2007, 2011).

Under static-renewal conditions, the weight increases in Treatments 12 and 13 with 2 different feeding rates were not significantly different (Session S1-Figure 1D). Surprisingly, the mussels under static-renewal conditions grew much faster (>70%) than the mussels fed similarly under flow-through conditions (Treatments 4 and 5). A possible reason was higher food availability in the static-renewal treatments, where the water in test chambers was renewed once Mondays, Wednesdays, and Fridays, compared to the flow-through condition, where each water addition every 4 h flushed away some remaining food in test chambers. This speculation appeared to be supported by the fact that increasing food availability by auto-feeding with each water addition in the flow-through Treatment 8 (Session S1-Figure 1B) substantially improved the growth of mussels, and the mussels grew as fast as those under static-renewal conditions (Session S1-

Electronic Filing: Received, Clerk's Office 3/14/2019

Figure 1D). The high survival and growth of mussels in the static-renewal treatments indicated that chronic toxicity tests with juvenile mussels can be successfully completed under static-renewal conditions, with a minimum water renewal on Mondays, Wednesdays, and Fridays, and sand and beaker replacement every week. The static-renewal test is useful when a flow-through system is not available or there is limited solution (e.g., effluent) for testing. However, mean concentrations of ammonia of 0.10 and 0.16 mg N/L in the 2 static-renewal treatments (Treatments 12 and 13) were 2- or 3-fold higher than those with similar feeding rates but under flow-through conditions (Treatments 4 and 5; Table Session S1-Table 2), indicating the potential problem of water quality. In a previous 4-week ammonia toxicity test with test water and pH (8.2) similar to those in the present study, the lowest effect concentration to juvenile fatmucket was as low as 0.26 mg N/L (Wang et al. 2011). Increasing water renewal (e.g., once daily, rather than once on Mondays, Wednesdays, and Fridays in the present study) may keep the ammonia below 0.1 mg N/L at a feeding rate that results in good growth of the mussels.

12-week treatments

Mean survival ranged from 78 to 98% at the end of the 6 12-week treatments (Session S1-Table 1). In Treatments 5, 6, and 7, one replicate had much lower survival (40 or 50%) compared to the other 3 replicates (typically 90 or 100%). This replicate effect has been found in previous chronic 4-week toxicity testing (e.g., Wang et al. 2016) and more often in our longer-term (e.g., 2 months) mussel culture (unpublished data). The mean weight increase ranged from 31 to 60 fold among the 6 12-week treatments, and, as observed in the 4-week study, the growth in Treatment 8 with the auto-feeding 6 times 2 mL algal mixture was significantly greater than the growth in the other 5 treatments (Session S1-Figure 2). Although the growth rates among the 5 treatments were not significantly different, the mussels in Treatment 6 with the 3 times 2 mL algal mixture had the highest weight increase (Session S1-Figure 2), which was consistent with the results obtained in the 4-week study (Session S1-Figure 1B). The results indicate that a long-term 12-week toxicity test can be successfully completed starting with 2-month-old juvenile mussels under flow-through condition with beaker replacement every 2 weeks. Adding a sand substrate may have kept food more dispersed and limited the growth of fungi or algae on the mussel shell. Increasing feeding frequency improved the mussel growth. The results of the overall feeding

Electronic Filing: Received, Clerk's Office 3/14/2019

study can be useful for the revision of the ASTM standard for conducting chronic toxicity test with juvenile mussels (ASTM 2017).

Session S1-Table 1. Summary of 13 treatments with different feeding and holding conditions and mean survival (n=4; standard deviation in parentheses) in the 4- or 12-week study conducted at 23°C in 2014

Study goal	Treat.[a]	Description[b]	Survival (%)	
			4 weeks	12 weeks
Effects of sand presence or sand and beaker replacement under flow-through condition, with a routine feeding of algal mixture (Wang et al. 2007)	1	2X2 mL algal mixture, no substrate, and no beaker replacement as recommended in ASTM (2017). The treatment served as a control to evaluate the improvement of mussel growth in other treatments	98 (5.0)	NA
	2*	2X2 mL algal mixture, no substrate, with beaker replacement after 2 weeks	100 (0)	95 (10)
	3	2X2 mL algal mixture, no beaker replacement, with 5 mL of sand	98 (5.0)	NA
	4*	2X2 mL algal mixture, with sand and beaker replacement after 2 weeks	98 (5.0)	88 (5.0)
Effects of feeding levels under flow-through condition, with sand and beaker replacement	5*	2X3 mL algal mixture (one in the morning and another in the afternoon)	100 (0)	83 (29)
	6*	3X2 mL algal mixture (morning, noon, and afternoon)	100 (0)	78 (22)
	7*	6X1 mL algal mixture (once every 4 h automatically; see text)	100 (0)	88 (25)
	8*	6X2 mL algal mixture (once every 4 h automatically; see text)	100 (0)	98 (5.0)
Effects of a food addition to algae under flow-through condition, with sand and beaker replacement	9	2X2 mL algal mixture + 1X0.25 mL of yeast-cerophyl-trout chow	100 (0)	NA
	10	2X2 mL algal mixture + 1X0.50 mL of yeast-cerophyl-trout chow	95 (5.8)	NA
	11	2X2 mL algal mixture + 1X5 µL concentrate of Oyster-Feast® (1/2 of the maximum amount recommended by the food provider)	98 (5.0)	NA
Effects of feeding under static-renewal condition	12	2X2 mL algal mixture, sand and beaker replacement once per week	98 (5.0)	NA
	13	2X3 mL algal mixture, sand and beaker replacement once per week	100 (0)	NA

[a] All 13 treatments were conducted for 4 weeks, of which 6 treatments indicated with an asterisk (*) had additional replicates for an extended study period to 12 weeks.

[b] 2X, 3X, or 6X indicates 2, 3, or 6 time feeding per day, respectively.

NA = Not applicable.

Session S1-Figure 1. The fold increases in dry weight of juvenile fatmucket (*Lampsilis siliquoidea*) in 13 treatments with different feeding and holding conditions over a 4-week period. The boundary of the box indicates the 25th and 75th percentiles, and the error bars indicate 10th and 90th percentiles (n=4). A thin black line within the box marks the median and a thick red line shows a mean. Means with a same letter above the bars within each of 4 treatment groups (panel A, B, C, and D) are not significantly different (Duncan's multiple range test, $p>0.05$).

Session S1-Figure 2. The fold increases in dry weight of juvenile fatmucket (*Lampsilis siliquoidea*) in 6 treatments with different feeding over a 12-week period. The boundary of the box indicates the 25th and 75th percentiles, and the error bars indicate 10th and 90th percentiles (n=4). A thin black line within the box marks the median and a thick red line shows a mean. Means with a same letter above the bars are not significantly different (Duncan's multiple range test, $p>0.05$). Note that feeding rates were increased 50% every 4 weeks.

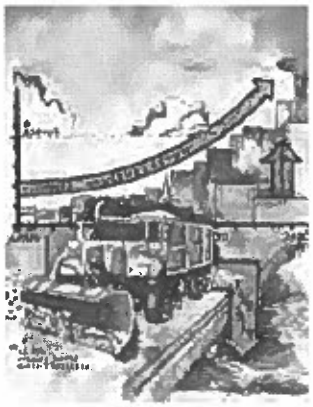
River chloride trends in snow-affected urban watersheds: increasing concentrations outpace urban growth rate and are common among all seasons



Steven R. Corsi [a,*], Laura A. De Cicco [a], Michelle A. Lutz [a], Robert M. Hirsch [b]

[a] U.S. Geological Survey, Wisconsin Water Science Center, 8505 Research Way, Middleton, WI 53562, United States
[b] U.S. Geological Survey, 432 National Center, Reston, VA 20192, United States

HIGHLIGHTS

- Chloride trends in northern U.S. urban streams are computed.
- The rate of chloride concentration increase outpaced urbanization from 1990 to 2011.
- The greatest chloride concentration increase was during the winter.
- Increasing chloride concentration trends were observed in all seasons.
- Chronic water quality criteria for chloride were exceeded for extended durations.

ABSTRACT

Chloride concentrations in northern U.S. included in this study have increased substantially over time with average concentrations approximately doubling from 1990 to 2011, outpacing the rate of urbanization in the northern U.S. Historical data were examined for 30 monitoring sites on 19 streams that had chloride concentration and flow records of 18 to 49 years. Chloride concentrations in most studied streams increased in all seasons (13 of 19 in all seasons; 16 of 19 during winter); maximum concentrations occurred during winter. Increasing concentrations during non-deicing periods suggest that chloride was stored in hydrologic reservoirs, such as the shallow groundwater system, during the winter and slowly released in baseflow throughout the year. Streamflow dependency was also observed with chloride concentrations increasing as streamflow decreased, a result of dilution during rainfall- and snowmelt-induced high-flow periods. The influence of chloride on aquatic life increased with time; 29% of sites studied exceeded the concentration for the USEPA chronic water quality criteria of 230 mg/L by an average of more than 100 individual days per year during 2006–2011. The rapid rate of chloride concentration increase in these streams is likely due to a combination of possible increased road salt application rates, increased baseline concentrations, and greater snowfall in the Midwestern U.S. during the latter portion of the study period.

1. Introduction

The impact of road salt on aquatic ecosystems continues to increase as urban development and subsequent road salt applications increase with time. Substantial application of road salt in the U.S. began in the 1940s increasing to an annual average of 9.6 million metric tons/yr of NaCl-based road salt in the 1980s and 19.5 million metric tons/yr in the last 5 years reported, ending in 2011 (Kelly and Matos, 2013). Increasing trends in chloride concentrations have been observed in water bodies of the U.S. and attributed, at least in part, to road salt influence. These trends have included rivers (Godwin et al., 2003; Interlandi and Crockett, 2003; Thunqvist, 2004; Kaushal et al., 2005; Kelly et al., 2012a), groundwater (Reisch and Toran, 2013; Kelly, 2008; Perera et al., 2009; Cassanelli and Robbins, 2013), inland lakes (Ramstack et al., 2004; Novotny and Stefan, 2010; Müller and Gächter, 2012), and even water bodies as large as the Laurentian Great Lakes (Chapra et al., 2009, 2012).

Elevated salt concentrations in surface waters can exert an adverse effect on aquatic organisms (Cañedo-Argüelles et al., 2013). The U.S. Environmental Protection Agency (USEPA) ambient water quality criteria for chloride (when associated with sodium) defines the chronic criterion as a 4-day average concentration exceeding 230 mg/L and the acute criterion as a 1-h average concentration exceeding 860 mg/L (U.S. Environmental Protection Agency, 1988). Given the sensitivity of freshwater organisms to chloride, exceedances of these criteria have the potential to affect a substantial number of species (U.S. Environmental Protection Agency, 1988). In a thorough assessment of the environmental impacts of road salt, Environment Canada estimated that 5% of aquatic species would be affected at chloride concentrations of 210 mg/L and 10% of aquatic species would be affected at chloride concentrations of 240 mg/L for chronic exposures (Environment Canada, 2001). Multiple studies have observed chloride concentrations greater than these benchmark concentrations in streams as a result of road salt runoff. These studies have included local (Ruth, 2003; Trowbridge et al., 2010; Allert et al., 2012; Morgan et al., 2012), regional (Kelly et al., 2012b), and national geographic scopes (Corsi et al., 2010).

Urban land cover in the U.S. has also increased over time from an estimated 61,000 km^2 in 1945 to 247,000 km^2 in 2007 (Nickerson et al., 2011). With urban land cover projected to continue increasing (Alig et al., 2004), applications of road salt for deicing impervious surfaces are also likely to increase. Adding to the current and past water quality issues resulting from the salinization of streams, including road salt runoff, an analysis of water quality in the northeastern U.S. predicted that many surface waters in that area of the country would not be potable for human consumption and would become toxic to freshwater life within the next century (Kaushal et al., 2005).

The primary objectives of this study were to define temporal trends in chloride concentrations in the context of chloride dependency on streamflow rates, compare temporal chloride trends among seasons, and compare these trends to changes in urban land cover, aquatic life criteria, and road salt sales patterns. Trend analysis was done using the modern water quality trend modeling technique that controlled for streamflow rate and season to help avoid confounding results due to natural variability (Hirsch et al., 2010).

2. Methods

2.1. Site selection

An initial focus for 14 sites on 3 streams in the Milwaukee metropolitan area was conducted. To assess the broader geographic impact, 11 additional streams in urban areas of the northern U.S. were studied, 4 streams in northern areas with little urban impact were studied, and one stream in an urban area of the southern U.S. was studied as a warm-climate reference.

Sites were initially chosen based on proximity to areas of urban influence in the northern U.S. (Fig. 1, Table 1). Three sites with a low degree of urbanization in northeast Wisconsin and one site in Oregon were included to evaluate non-urban influence, and the Trinity River in Texas was also examined as a non-deicing reference site in an urban area. Second, adequate data availability for modeling was necessary. Most sites had 200 or more chloride observations and 20 or more years of record with no significant gaps in data collection (i.e., larger than 5 years), and sample representation during all seasons throughout the water quality record (Table S1). The exceptions include five sites that had between 151 and 194 observations, and one site that had a 6-yr gap. These sites were included to maintain adequate geographic representation of sites (Table S1). Sites located within or just downstream from large lakes or impoundments were omitted. A continuous record of streamflow data concurrent with the chloride record was required at the selected site or at a nearby site on the same stream. Sites selected in the Milwaukee metropolitan area were chosen from a dense network of available sites in an effort to adequately represent changes in the Milwaukee, Menomonee, and Kinnickinnic Rivers.

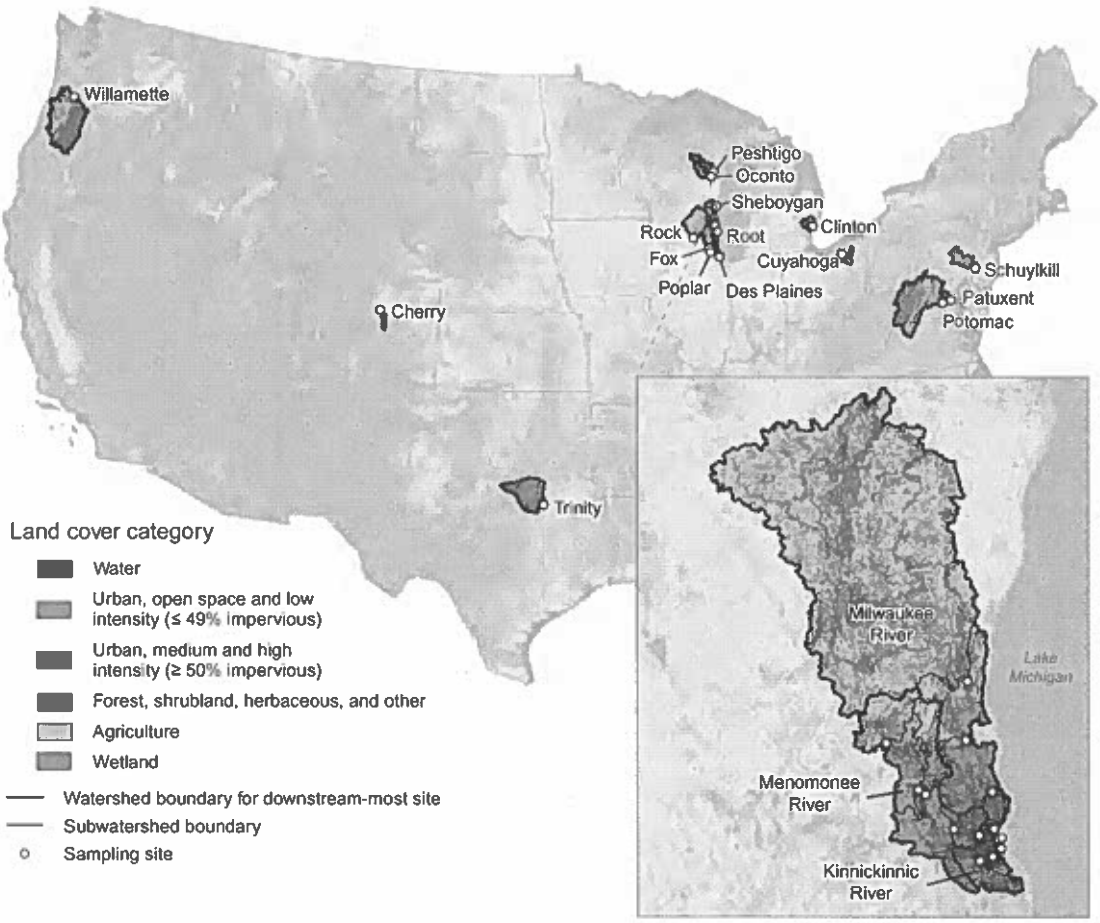
2.2. Data sources

Chloride data were obtained from the Milwaukee Metropolitan Sewerage District (MMSD), the Wisconsin Department of Natural Resources (WDNR), and the Water Quality Portal (WQ portal; http://www.waterqualitydata.us/), which includes data from the USGS National Water Information System (NWIS) and EPA STOrage and RETrieval Data Warehouse (STORET). Coordinate bounding boxes were used to query the WQ Portal to locate streams in metropolitan areas of primarily the northern U.S. with sufficient data (Fig. 1). Where data from different sources overlapped at common sites, data were combined except for one site where data from one of the sources were not considered valuable due to many duplicate data points and data differences that called into question analytical results.

If available, streamflow data from the USGS National Water Information System (http://waterdata.usgs.gov/nwis) were retrieved from the same location where chloride samples were collected; otherwise, data from a nearby location(s) on the same stream were scaled by drainage area to estimate streamflow at the chloride sampling location. In two cases, there were data gaps in streamflow that were estimated using an ordinary least squares regression with streamflow data from a nearby site (Meno 70th, $R^2 = 0.65$; Milw Cedarburg, $R^2 = 0.95$).

Road salt sales data were compiled from an annual reporting of Historical Statistics for Mineral and Material Commodities in the United States (Kelly and Matos, 2013) and used as a proxy for assessing overall road salt applications in the studied watersheds. Road salt sales were used in place of actual application numbers due to the complicated nature of gathering road salt application data from all municipalities and private applicators on the scale of this study.

Daily snowfall data for eight weather stations in the U.S. were retrieved from the National Climate Data Center (http://www.ncdc.noaa.gov/cdo-web/) for evaluation of snowfall changes throughout the study period (Table S2). Stations were chosen based on proximity of chloride study sites and availability of data during the study period.



Land cover composition and other watershed characteristics were determined from several published GIS datasets and provided in Table 1, and methods are described in Supplemental Information.

2.3. Data analysis

Data analysis included water quality trend modeling, graphical analysis of trends, and exploration of modeling results in comparison to land use, the USEPA water quality criterion, and road salt sales in the U.S.

2.3.1. Rationale for water quality modeling technique

Chloride concentrations in streams have the potential to vary depending on several factors that all arise from the nature of the contamination sources, transport characteristics, and hydrologic characteristics of a given watershed. Considerations when attempting to understand these influential factors are very similar to those outlined previously describing potentially influential factors in stream nutrient concentrations and fluxes (Hirsch et al., 2010). The primary considerations are as follows: As urban development continues, sources of nonpoint pollution such as road salt application tend to increase as well, so it is logical to expect chloride concentrations in streams to change with time. Given that road salt is applied only during cold-weather periods, seasonal differences in chloride concentrations are also expected. The nature of road salt transport to surface waters causes chloride concentrations to change with streamflow. For example, when road salt melts ice and snow during periods of low streamflow, stream chloride concentrations can become very high, but when road salt runoff periods are coincident with high-streamflow periods resulting from snowmelt or rainfall events, chloride concentrations are likely to be lower due to the larger amounts of water available to dilute the road salt.

Long-term changes in chloride concentrations from road salt can follow a variety of temporal patterns responding to factors such as: the rate of urban development, changes in road salt application practices, long-term storage and release processes from large water bodies and groundwater, and changing climate conditions. Other major sources include treated wastewater as well as fertilizer and livestock, with other minor sources also contributing (Kelly et al., 2012b). These influences led to the use of WRTDS, a data analysis technique that can describe long-term change in a flexible manner (not simply as linear or quadratic time trends) and account for the seasonal- and streamflow-related dependencies which may, themselves, be changing over a period of many years or decades (Hirsch et al., 2010). The WRTDS analysis used here is implemented within the EGRET package (Hirsch and De Cicco, 2014) in the R statistical language (R Development Core Team, 2008).

2.3.2. Modeling water quality changes

The WRTDS method is based on weighted linear regression to estimate daily concentration throughout time, discharge (streamflow), and seasonal dimensions of the data used to calibrate the model. For any given estimation point in the data domain (where the point is defined by year, season and streamflow) the model gives increased weight to values similar in time, streamflow, and season to the estimation point. For example, concentrations of samples collected in year two of a sample period will have little influence on model estimates for year 10, concentrations of samples collected during low flow periods will have little influence on model estimates for high flow, and concentrations of samples collected during summer will have little influence on model estimates for winter periods. Weighting for proximity of the estimation point to the observed data by time (the time distance),

[a] Watershed urban, agriculture, and forest/other percentages for 2006 were determined from the National Land Cover Database 2006 Land Cover dataset (Fry et al., 2011).
[b] Watershed impervious percentages for 2006 were determined from the National Land Cover Database 2006 Percent Developed Imperviousness dataset (Fry et al., 2011).
[c] Watershed urban, agriculture, and forest/other percentages for 1992 were determined from the National Land Cover Database 1992/2001 Retrofit Land Cover Change dataset (Fry et al., 2009).

streamflow (the discharge distance), and season (the seasonal distance) are assigned using a tricube weight function with half-window widths of 10 years, 2 natural log units, and 0.5 years in the time, streamflow, and seasonal dimensions respectively. These values were chosen after experimentation of the smallest values that did not cause unrealistic oscillations. The overall weight on any given observation is the product of the three weights. Estimation by the WRTDS model was performed using measured chloride and corresponding daily streamflow values. This tool has not previously been used to examine chloride trends, but applications using WRTDS have primarily been used for examination of nutrients (Hirsch et al., 2010; Medalie et al., 2012; Green et al., 2014).

2.3.3. Examination of water quality changes

One type of output produced using WRTDS for each of the study locations was graphics showing estimated concentrations for three levels of streamflow (the 10, 50, and 90 percentile points on the daily streamflow frequency distribution), four seasons of the year (centered on February 15 [winter], May 15 [spring], August 15 [summer], and November 15 [fall]), and each year of the period of record. Another type of output is a contour plot of the differences in estimated chloride concentration between the years 1981 and 2010 as a function of time-of-year and streamflow. WRTDS was also used to compute flow-normalized annual chloride concentrations over the period of record. Flow-normalization is a technique that removes the effect of year-to-year variations in streamflow (but not seasonal variations) on average chloride concentrations (Hirsch et al., 2010).

Linear regression was used to explore the response of flow-normalized annual chloride concentrations as well as the number of individual days that these concentrations exceeded the USEPA water quality (exceedance days) to the percent of urban land cover in the watershed. Linear temporal regression was also used to compare the change in national road salt sales in the U.S. to the change in urban land cover in the northern U.S. to coincide with the location of most road salt sales in the U.S. The calculation of expected number of exceedance days was determined using logistic regression based on the output of the WRTDS model for the two periods 1990–1994 and 2006–2010. These dates were chosen based on the inclusion of at least 20 years, while minimizing the number of sites that had to be excluded due to missing data. The non-deicing reference site (Trinity River) and seiche-affected sites (Milw Jones, KK 1st, KK Jones) were not used in these analyses. The period of record did not have sufficient data between 1990 and 2011 for the Clinton, Cuyahoga, and Fox River, so these sites were not included in these analyses. Dates for the Schuylkill and Des Plaines Rivers did not match perfectly, but were near enough to provide an estimate for the later time period. The WRTDS method has been extended here to estimate the daily probability of exceedance of a threshold. Because the WRTDS model provides a conditional mean and conditional variance of concentration for each day as a function of streamflow, time of year, and year (trend) it is possible to compute a conditional probability of

Electronic Filing: Received, Clerk's Office 3/14/2019

exceedance of the threshold under the assumption that the conditional distribution of concentration is log-normal. Using these results from all of the sites, logistic regressions were fit for each of the two 5-year time periods. These logistic regression models estimate the daily probability of exceedance at a site as a function the square root of the percent of the watershed that was urbanized during that time period. The number of predicted exceedances per year was then determined by summing these probabilities for the year. These calculations were implemented in R using the betareg function. Pseudo R-squared values for both models were approximately 0.83.

3. Results

Three major watersheds cover the bulk of the Milwaukee metropolitan area: the Milwaukee River, the Menomonee River, and the Kinnickinnic River. These three watersheds have all experienced increased chloride concentrations from 1980 to 2010 during winter, spring, summer, and fall (Fig. 2). The greatest increases in chloride concentrations were in watersheds with the greatest urban land cover percentage. Concentrations for the Milwaukee study sites were greatest in the Kinnickinnic River followed by the Menomonee River and then the Milwaukee River (drainage areas of 45, 355, and 1808 km^2, with 99, 68.6, and 18.5% urban land cover respectively).

In addition, chloride concentrations increased with decreasing streamflow for all three of these watersheds in each of the four seasons. The mean chloride concentration in the Milwaukee River exceeded 140 mg/L during winter low flow periods and was approaching 100 mg/L during summer low-flow periods toward the end of the study period. Mean chloride concentrations in the Menomonee and Kinnickinnic Rivers exceeded the USEPA chronic water quality criteria of 230 mg/L during the winter and spring at all three flow rates in the latter years of the study, and exceeded 100 mg/L during summer and fall periods at all three streamflow rates toward the end of the study duration.

Similar four-season graphs illustrating streamflow dependency for all remaining study sites except those impacted by backwater influences from Lake Michigan (hereafter referred to as seiche) are provided in the supporting information (Figs. S1–S25). Chloride concentrations also increased over all four seasons and decreased with streamflow at all of these additional sites except three with a few notable exceptions: Chloride concentrations at the Peshtigo River had increasing trends over the course of the study period, but concentrations did not increase with decreasing flow; concentrations were relatively constant in the Willamette River. Both of these sites have primarily forested land cover and little urban influence. With these watershed conditions, there is likely to be low road salt application and this is confirmed by very low chloride concentrations (less than 10 mg/L). Chloride concentrations in the Kinnickinnic River at 7th St. did not vary substantially with flow, but did have a slightly increasing relation with increasing streamflow during winter due to samples with high concentrations during high flow periods in the winter. Changes in concentrations with respect to streamflow at the southern urban reference site (Trinity River) were not consistent through the study period.

The change in concentration over time at three different locations within the Milwaukee River watershed is another illustration of increasing road salt effect with urban land cover. These three monitoring sites increased in downstream order from 11% to 17.5% to 18.5% urban land cover (Fig. 3, top to bottom panels, respectively; NLCD 2006 (Fry et al., 2011)). Even with these relatively minor differences in urban land cover, the effect on chloride concentration changes from 1981 to 2010 is apparent in the Milwaukee River with the Wells St. results indicating higher concentrations during winter than the two upstream sites. The greatest increase in chloride concentrations occurred during winter low-flow periods at all three sites, with greater changes as urban influence in the watershed increased. Although the greatest concentration increase was seen during these low flow winter events, substantial increases in chloride concentration also occurred during higher flow periods and extended throughout the year.

Flow-normalized concentrations estimated from 1980 to 2010 for 30 selected sites on 19 streams indicated that concentrations increased for the majority of the sites (Fig. 4). For the more urban watersheds, increases in concentration were greatest in winter periods, but summer periods also experienced increasing chloride concentrations. For the less urban watersheds, there were increasing trends over time (winter and summer slopes were similar) and the concentrations during winter were greater than or similar to concentrations during the summer. The magnitude of chloride concentrations as well as the slope of concentration change increased as the impervious land cover in the watershed increased. For example, the highest chloride concentrations and the greatest change (increase) in chloride concentration over this time period were sites with the highest degree of impervious area including those in Milwaukee, Chicago, Detroit, Cleveland, and Racine metropolitan areas (Fig. 4, top three rows, Table 1). Chloride concentrations generally decreased with decreasing impervious area in the bottom four rows of Fig. 4. The two exceptions are the sites in Portland (Willamette River) and Dallas (Trinity River) which show little or no trend in chloride concentration over the study period. Land cover in the Willamette River had 72% forest and natural area in the watershed, road salt was not commonly used in Oregon during the study period, and the climate

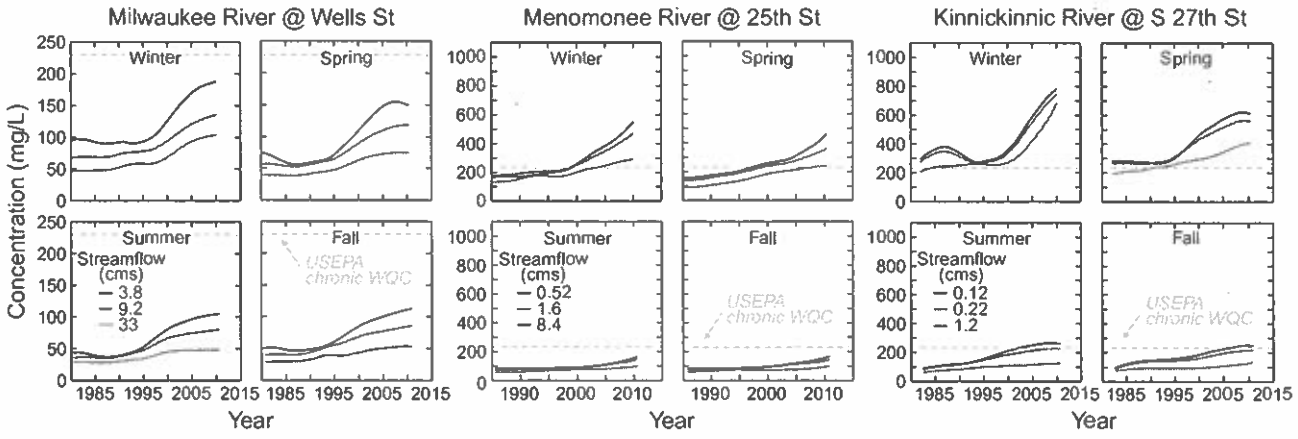

Fig. 2. Chloride concentration estimates at 10, 50, and 90 percentile flow rates from the WRTDS model over time and grouped by season for three Milwaukee streams. Graphs are presented in order of decreasing watershed size and increasing urban land cover from left to right. Streamflow is expressed in cubic meters per second (cms). Dashed line for USEPA chronic water quality criteria represents 230 mg/L.

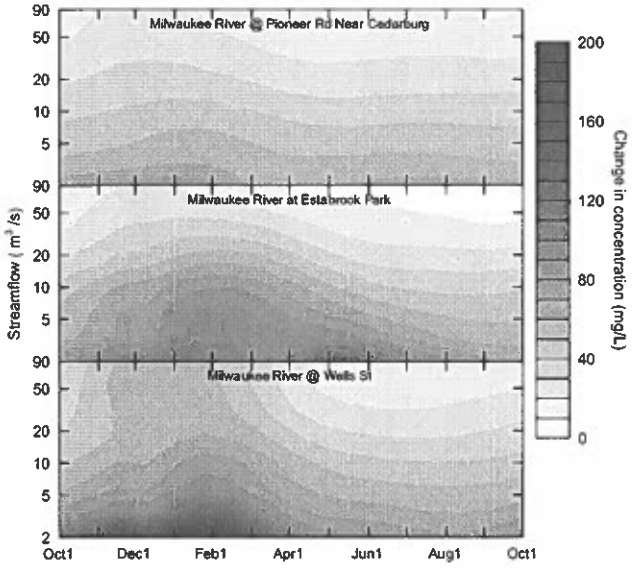

Fig. 3. Contour map of the change in chloride concentration by streamflow and time of year between 1981 and 2010 on the Milwaukee River. Sites are ordered from top to bottom with increasing urban land cover in the watershed. The color legend indicates change in concentration in mg/L.

in the Trinity River is warm enough that road salt application is not common.

Notable differences were observed among sites with low watershed imperviousness in the Midwest U.S. (Rock River; Milwaukee River at Cedarburg, which is upstream from the Milwaukee metropolitan area; and the Sheboygan River) versus those outside of the Midwest (Potomac and Willamette Rivers).

Sites with low imperviousness in the Midwest have higher chloride concentrations, when compared with sites in other areas of the country. Sites with low imperviousness in these different regions also show notable differences in non-urban land cover types; whereas the Midwest sites have large proportions of agricultural land, sites in other regions were dominated by forest and natural areas (Table 1). Concentrations at seiche-affected sites on the Milwaukee and Kinnickinnic Rivers also increased, but the magnitude of these trends was typically muted in comparison with upstream, non-seiche affected sites. Chloride concentrations were lower at study sites with the lowest percent impervious watersheds (less than 0.5%), but increasing trends were still apparent in winter and summer seasons.

Flow-normalized chloride concentration estimates from the WRTDS model were compared with urban land cover in the contributing watershed as 5-yr means for 1990–1994 and 2006–2010 (Fig. 5-A). There was a linear relation between mean concentration and percent urban land cover for both time periods, but regression slopes indicated a change in this relation over time with slopes for these regression equations indicating an increase in chloride concentration of 2.9 and 5.8 mg/L/% urban land cover for the 1990–94 and 2006–10 time periods respectively. Concentrations from 2006 to 2010 were approximately double the concentrations for 1990–1994 for the same percentage of urban land cover.

The logistic models for the probability of water quality criteria exceedance as a function of the square root of the percent of urban land cover in the watershed were significantly different ($p < 0.001$) between the two periods (1990–1994 and 2006–2010; Fig. 5-B). For a watershed with 25% urban area, the expected number of days exceeding 230 mg/L per year increased from 5 to 14, and for a watershed with 90% urban area, it increased from 95 to 231 days per year. An expected value of 17 days exceeding 230 mg/L per year decreased from 50% to 29% urban land cover, and an expected value of 95 exceedance days per year decreased from 95% to 63% urban land cover. About 29% of sites studied exceeded the concentration for the USEPA chronic water quality criteria of 230 mg/L by an average of more than 100 individual days per year during 2006–2011. All regression slopes in Fig. 5 were significant with $p < 0.001$, and R^2 values for all regressions ranged between 0.83 and 0.99. Slopes were significantly different in each of the analyses represented in Fig. 5 ($p < 0.001$ for panels A and B and $p < 0.05$ for panel C).

Beginning in 1987 and ending in 2010, road salt sales in the U.S. increased at an average rate of 3.9%/yr, and urban land cover in the northern part of the U.S. increased at a rate of 2.8%/yr (Fig. 5-C). These trends indicate that road salt usage increased at a rate 40% greater than the increase in urban land cover in the northern U.S. during this period.

4. Discussion

4.1. Temporal trends and relation with land use

Results of the present research indicate that chloride concentrations increased with time in most streams studied in the northern U.S. throughout the study period. While there were trends present in streams with watersheds dominated by urban, agriculture, and forest/natural areas alike, there was a clear increase in concentration as urban land cover (and impervious surfaces) in the watershed increased.

The concentration increase in watersheds with relatively small amounts of urban land use may be influenced by road salt, but may also be a result of other sources such as agricultural runoff which is another potentially important source of chlorides in rural watersheds (Mullaney et al., 2009). Still, the greater winter concentrations suggest that road salt was an important factor in observed trends in the rural watersheds. In contrast with the Midwest sites, which are more highly developed for agriculture, requiring a more extensive road network, the Potomac and Willamette River watersheds have larger percent forest and natural areas (60% and 72% respectively). A detailed watershed-specific investigation would be needed to better understand relative contributions in these rural sites.

The rate of chloride concentration increase outpaced that of urbanization for this study, so urban land cover information alone cannot account for these chloride trends. This changing relation of chloride with urban land cover over time (Fig. 5-A) may be attributed to several potential factors. First, it is possible that more salt was applied per unit urban area during the latter portion of the study period than during the early portion. This appears likely given that road salt sales in the northern U.S. outpaced the rate of increase in urban land cover by 40% during the study period (Fig. 5-C). More salt could be applied per unit area due to three primary reasons: 1) the application rate could have increased as an attempt to maintain more ice-free conditions; 2) the density of impervious area per unit urban area could have increased, thereby increasing the need for road salt, or 3) the difference in weather conditions between the early and latter portions of the study could have warranted different application rates.

Second, the baseline concentrations have been increasing over time due to continued road salt input to the shallow groundwater system and inability of the system to recover to true background concentrations before the next deicing season begins. The result is an increase in baseline concentrations from shallow groundwater discharge to the stream during low flow, as indicated by increasing summer concentrations. Since baseline concentrations increased with time over the course of the study, less additional road salt runoff was needed to reach concentrations of concern in the later years of the study than in the early years, effectively changing the slope of the chloride to urban land cover relation. With baseline concentrations governed by groundwater discharges in many instances, this finding is consistent with other research that has observed elevated chloride concentrations in groundwater which has caused elevated stream concentrations (Kelly, 2008; Eyles et al., 2013).

To explore the possibility of changing weather patterns as potential explanation of increased salt application, snowfall data were examined

for nine National Weather Service monitoring stations ranging geographically from Washington, D.C., to Denver, Colorado (Table S2, supporting information). For each station, the average total annual snowfall and the average annual number of individual days with snow exceeding 20 mm were computed as a measure of potential for road salt application. An increase in the annual number of days with snow exceeding 20 mm was observed at five stations, and a decrease was observed at four stations. An increase in annual snowfall was observed at six stations, and a decrease was observed at three stations. These data indicated a potentially mixed influence of weather on road salt applications among chloride monitoring sites. Given that 23 of the 30 stream sites were located in the Midwest, the result that data from all four weather stations in the Midwest had increased annual snowfall (average increase of 16%) and days with greater than 20 mm of snow (average increase of 13%) indicated a potential for road salt application increase due to snowfall conditions. In contrast, two of four weather stations in the eastern part of the country had decreased annual snowfall (average overall decrease of 11%) and three of four weather stations had decreased days with greater than 20 mm of snow (average overall decrease of 23%) indicating a potential for road salt application decrease due to snowfall conditions. Snowfall (annual depth and days with greater than 20 mm) in Denver, Colorado decreased by more than 40%. Despite the mixed trends in snow records, stream chloride concentrations increased in each of these three areas of the country, suggesting that increasing baseline concentrations and possible increasing application rates due to factors other than snow cover contribute to the changing relation of chloride with urban land cover over time. Since weather patterns and road salt application methods are locally variable, it would be valuable to extend this study in future research by examining the overall concentrations and the baseline concentrations with respect to precipitation and total salt application on an individual watershed basis.

Given the increasing road salt sales per unit area of urban land cover in the U.S., the increasing baseline chloride concentrations during summer periods, and the difference in snow conditions, it appears multiple factors could plausibly be contributors to the changing relation between average chloride concentrations and urban land cover within the watershed.

4.2. Seasonality

Increasing chloride trends were present all year, including seasons that do not require deicer application; however, the highest concentrations occurred during winter periods. A similar year-round influence has been noted multiple times in previous research (Williams et al., 2000; Kelly, 2008; Perera et al., 2013). This non-deicing season effect has been attributed to salt infiltrating into the shallow groundwater system thereby serving as a "reservoir" of salt that is slowly discharged into streams as baseflow. Relatively slow travel times in the shallow groundwater system could account for the time lag between deicer applications and eventual discharge into the stream.

4.3. Streamflow dependency

Chloride concentrations commonly increased with decreasing streamflow throughout all seasons of the year in most streams studied. The same relation has previously been observed in streams of Illinois (Kelly et al., 2010) and Toronto (Meriano et al., 2009). This behavior can be explained primarily by the factors that govern hydrology throughout the year. During cold-weather months, road salt applications occur during many types of precipitation events. These include a gradient of precipitation forms ranging from purely snowfall events to mixed rainfall and snowfall events to purely rainfall events when freezing temperatures are expected. Precipitation with very little or no liquid precipitation provide little dilution of road salt as it melts snow and ice and eventually drains to nearby streams. These are also low-flow periods, so the stream itself provides little dilution. The combination of these two factors results in high chloride concentrations in the streams. Conversely, during deicing events with greater quantities of liquid precipitation, more dilution of the road salt is provided directly from the precipitation. In addition, when snow is present on the ground, melting is enhanced by contact with rainfall, streamflow is elevated, and dilution potential in the stream is greater. These high-dilution events still have elevated chloride concentrations, but not as high as the low-dilution events.

During non-deicing months, chloride concentrations also decreased with increasing streamflow. Precipitation events again serve to dilute chloride concentrations more than those during low-flow periods that are dominated by groundwater discharge, which is a substantial source of chloride during the non-deicing months.

4.4. Comparison to aquatic toxicity benchmarks

Elevated chloride concentrations resulting from road salt application and runoff in watersheds have potential impacts on aquatic organisms (U.S. Environmental Protection Agency, 1988; Environment Canada, 2001). Increasing trends over time have resulted in increasing exceedances of concentrations that are likely to be harmful to aquatic life. The current research indicates that the relation between urban land cover and the number of daily exceedances of the USEPA chronic water quality criteria concentration of 230 mg/L has changed during the study period (Fig. 5). The number of exceedances for a particular percent of urban land cover was greater during the latter portion of the study as compared to the early portion of the study. As described above for increasing concentrations, an increase in road salt application rates over time, an increase in the baseline concentrations as indicated by summer chloride trends, and changes in snowfall are likely causes of the increased water quality criterion exceedance rate.

Previous research has indicated that degradation of biological integrity is evident beginning below 1% impervious area (Stepenuck et al., 2002; Cuffney et al., 2010; King et al., 2010). Results from the present research are consistent with these findings as chloride concentrations began to increase as soon as urban land cover was present, and concentrations exceeded the chronic water quality criterion beginning at approximately 10% impervious area (approximately 25% urban land cover; Table 1, Fig. 5). A review of road salt effects conducted by Environment Canada concluded that high concentrations of chloride may have immediate or long-term effects on ecosystem populations and that lower concentrations may have adverse effects on community structure, diversity, and productivity (Environment Canada, 2001). Studies reviewed for this Environment Canada effort found that some of the biological components affected included densities of bacteria and algae, drift of stream benthic invertebrates, as well as diversity and community structure of aquatic invertebrates (Evans and Frick, 2001). Other work has determined that elevated chloride concentrations can also influence reproduction of aquatic organisms (Beggel and Geist, 2015). All of this information is primarily based on direct influence from chloride exposures, but indirect exposures caused by mobilization of heavy metals may also have impacts on aquatic organisms (Amrhein et al., 1992; Bäckström et al., 2004; Nelson et al., 2009). These chloride influences are yet another stressor in addition to those commonly thought to impact biological integrity of urban streams such as hydraulic and hydrologic factors, degraded water quality from point and non-point source runoff, and altered habitat and stream channels (Walsh et al., 2005; Steuer et al., 2010).

The multi-season impacts presented in this research suggest the possibility of extended-duration, high-concentration exposure to chloride in urban streams of the northern U.S. This possibility appears credible given that extended-duration (multiple months), high-concentration exposures to chlorides have previously been documented in urban streams receiving road salt runoff (Corsi et al., 2010; Baldwin et al., 2012; Kelly et al., 2012b). Further work to define concentration–duration relations is warranted given that the current USEPA chronic water quality criterion is designed for a 4-day exposure period, and it appears that exposures have

Electronic Filing: Received, Clerk's Office 3/14/2019

potential to be much longer than 4 days. Longer-duration exposures may result in additional impacts on the full life-cycle of aquatic organisms that may not be evident with common evaluation methods.

4.5. Salt management and alternatives

The nature of salt presence in environmental waters makes this issue very difficult to address with common stormwater management practices that rely most commonly on settling or filtration of particulate matter (Waschbusch, 1999; Greb et al., 2000; Horwatich et al., 2011). Since salt dissolves readily in water, these types of management practices will not remove salt from runoff. The only reliable way to reduce the impact of road salt on receiving streams is to reduce applications. There are a host of techniques that have been identified and documented for reduction of road salt application. For example, many municipalities have salt management plans that include a strategy for minimizing road salt usage. Some of these practices include training programs for most effective use, pre-wetting of granular salt to maximize salt retention on paved surfaces, applicators that are calibrated and vary by groundspeed, anti-icing that reduces bonding between snow and pavement and makes plowing more effective, and more efficient predictions of icing conditions to inform deicing activities (Kramberger and Zerovnik, 2008; Fay et al., 2013). In addition, there are a number of alternative chemicals that have been used. These alternative chemicals commonly include other chloride-containing salts such as magnesium chloride or calcium chloride, organic salts such as calcium magnesium acetate, potassium acetate, or sodium acetate, different variations of salt brines, and organic deicers such as glycols. Unfortunately, none of these options are without potential environmental impact as well. All of these alternative deicers have varying degrees of associated aquatic toxicity (Environment Canada, 2001). In addition, organic chemicals used as deicers have an additional impact from increased biochemical oxygen demand (Corsi et al., 2012) and excessive biofilm growth (Mericas et al., 2014). Still, road salt is more common than the alternatives due to the performance effectiveness and relatively low cost compared to alternatives.

5. Conclusions

The U.S. is an urbanizing nation, and with increasing development, previous data and results from this research indicate that road salt applications, chloride concentrations, and resulting adverse impacts on aquatic organisms in streams are likely to increase along with urban development. This research indicates that chloride concentrations in urban streams of the northern U.S. and resulting water quality criteria exceedances have increased at a greater rate than the rate of urban development. In addition, elevated chloride concentrations in these streams through all seasons have implications on long-term exposures to chloride for aquatic organisms. Results of this research provide verification that chloride concentrations in urban streams continue to increase, influencing the potential for aquatic life in affected streams.

Acknowledgments

Support for this research was provided by the Milwaukee Metropolitan Sewerage District (MMSD; 11E4WI24910031) and the U.S. Geological Survey. We thank Christopher Magruder, Matthew Magruder, Bre McDonald of MMSD and the many people who collected chloride data for MMSD. We thank the Wisconsin Department of Natural Resources and multiple Water Science Centers in the U.S. Geological Survey for providing chloride and streamflow data. We also thank Benjamin Sleeter of the USGS for providing national land cover change data, and Benjamin Siebers for providing original artwork for the Table of Contents. ATTACHMENT 5

TOLLWAY OFFSET PROGRAM

Electronic Filing: Received, Clerk's Office 3/14/2019

Wood Dale Chloride Offset

INTERGOVERNMENTAL AGREEMENT BETWEEN
THE ILLINOIS STATE TOLL HIGHWAY AUTHORITY
AND
THE CITY OF WOOD DALE
FOR
CHLORIDE OFFSET PROGRAM

This INTERGOVERNMENTAL AGREEMENT ("AGREEMENT") is entered into this 13TH day of JUNE, 2017, by and between The Illinois State Toll Highway Authority, an instrumentality and administrative agency of the State of Illinois, hereinafter called the "ILLINOIS TOLLWAY", and The City of Wood Dale, a municipal corporation of the State of Illinois, hereinafter called the "CITY", individually referred to as "PARTY", and collectively referred to as "PARTIES".

WITNESSETH:

WHEREAS, the ILLINOIS TOLLWAY in order to facilitate the free flow of traffic and ensure safety to the motoring public, intends to improve the existing Elgin O'Hare Expressway, extend the expressway from its eastern terminus at Rohlwing Road (Illinois Route 53) to O'Hare International Airport (ORD) to be known entirely as Illinois Route 390, and construct the Western Access connecting the Jane Addams Memorial Tollway (I-90) with the Tri-State Tollway (I-294) (hereinafter sometimes referred to as the Elgin O'Hare Western Access "EOWA"), and included in multiple ILLINOIS TOLLWAY construction contracts. The ILLINOIS TOLLWAY will implement, operate and maintain the mainline improvements as tolled facilities (hereinafter sometimes referred to as "Toll Highway"); and

WHEREAS, highway de-icing practices during winter months commonly use de-icing salts to provide for safe vehicular travel and winter maintenance for the EOWA will require the use of chlorides; and

WHEREAS, studies acknowledged the potential for the addition of chloride concentrations in area streams and as the EOWA project is advancing in implementation, permits for Section 404 and Section 401 of the Clean Water Act (CWA) have been secured from the United States Army Corp of Engineers (USACE) and the Illinois Environmental Protection Agency (IEPA); and

WHEREAS, conditions established within the ILLINOIS TOLLWAY's CWA Section 401 permit require the implementation of a "Chloride Offset Program" (hereinafter called the "PROGRAM") to mitigate for increased chloride loading in the Total Maximum Daily Loading (TMDL) watersheds throughout the EOWA project area; and

Electronic Filing: Received, Clerk's Office 3/14/2019

WHEREAS, a Memorandum of Understanding (MOU) between the ILLINOIS TOLLWAY and DuPage River Salt Creek Workgroup (DRSCW) was executed October 31, 2013 to outline the PROGRAM, which is attached hereto as "Exhibit A" and incorporated by reference; and

WHEREAS, per the MOU, it was agreed that the entirety of the offset will occur within the impacted areas and be tailored to individual receiving stream segments to the maximum extent possible. As such, local watershed communities and agencies participating in the PROGRAM will be responsible for winter operations on the land surfaces that drain to those segments and are herein referred to as "TIER 1 COMMUNITY" or "TIER 1 COMMUNITIES"; and

WHEREAS, the CITY has been identified as a TIER 1 COMMUNITY and has, in coordination with the DRSCW, conducted a review of their snow and ice operations in an effort to identify areas of operational improvements relating to efficiency gains in winter chloride usage, and per the CITY'S review, it is believed that an effective reduction in chloride usage can be attained, as part of the PROGRAM through the upgrading of equipment utilized for winter operations by the CITY; and

WHEREAS, the PARTIES mutually agree to review winter operation policies and procedures and work in coordination with the DRSCW to monitor the administration and progress of the PROGRAM; and

WHEREAS, the ILLINOIS TOLLWAY by virtue of its powers as set forth in the "Toll Highway Act," 605 ILCS 10/1 *et seq.* is authorized to enter into this AGREEMENT; and

WHEREAS, the CITY by virtue of its powers as set forth in the "Illinois Municipal Code," 65 ILCS 5/1-1-1 *et seq.* is authorized to enter into this AGREEMENT; and

WHEREAS, a cooperative Intergovernmental Agreement is appropriate and such an Agreement is authorized by Article VII, Section 10 of the Illinois Constitution and the "Intergovernmental Cooperation Act", 5 ILCS 220/1 *et seq.*

WHEREAS for recording purposes this AGREEMENT shall be known as #004685.

NOW, THEREFORE, in consideration of the aforementioned recitals and the mutual covenants contained herein, the PARTIES hereto agree to the following summary of the responsibilities and participation of each PARTY in the implementation of the PROGRAM.

Electronic Filing: Received, Clerk's Office 3/14/2019

I. PURPOSE and SCOPE

A. The PROGRAM established a projected increase over existing conditions or baseline for the EOWA of 3,888 tons of salt per year, per a baseline 39.7 tons/lane mile/year application rate. The goal of the offset program will be to reduce salt usage in roadway applications in the project related watersheds by the amount of the increase (3,888 tons per year) plus a margin of safety of 25 percent or a total reduction of 4,860 tons per year.

B. The ILLINOIS TOLLWAY, as part of the PROGRAM, has established a rate reduction goal of 20% from the EOWA's established baseline salt application rate of 39.7 tons/lane mile/year, thereby accounting for 972 tons per year of the 4,860 tons per year of salt required to be reduced, as part of the PROGRAM.

C. The CITY, as part of the PROGRAM and per this AGREEMENT, has established a rate reduction goal of 17.5% from its established baseline application salt application rate of 12.3 tons/lane mile/year, thereby accounting for 204 tons per year of the 4,860 tons per year of salt required to be reduced, as part of the PROGRAM.

D. Both structural and non-structural practices will comprise the PROGRAM to provide the needed improvements in water quality but it is understood that offset reductions can only be accounted for through non-structural practices.

II. STRUCTURAL BEST MANAGEMENT PRACTICES

A. Grass swales, bio-swales, infiltration basins, and other designs will be incorporated by the ILLINOIS TOLLWAY into the EOWA projects in order to minimize the effects of roadway runoff and improve the quality of roadway runoff discharged to receiving waters and/or nearby wetlands.

III. NON-STRUCTURAL BEST MANAGEMENT PRACTICES

A. A salt reduction goal has been established by the ILLINOIS TOLLWAY and DRSCW for the PROGRAM through the analysis of existing conditions, existing practices in the affected watersheds, and planned highway improvements. Offsets will include both the adoption of salt reduction strategies implemented by the ILLINOIS TOLLWAY and providing salt application data to DRSCW, including but not limited to their application rates for each lane mile, as well as financial and other support to other mutually agreed upon partners.

Electronic Filing: Received, Clerk's Office 3/14/2019

B. The ILLINOIS TOLLWAY recognizes that meeting the objectives of the Total Maximum Daily Loads ("TMDL's") will require reductions in area chloride loading above those set out in the PROGRAM and agrees to review its practices at an agency wide scale and to actively partner with the DRSCW, its members or successors, in working for PROGRAM area chloride reductions beyond the life of the PROGRAM with the goal of meeting the applicable water quality standard.

IV. RESPONSIBILITIES

A. Pursuant to EXHIBIT A, a guideline for monitoring and reporting chloride offsets has been established. Both PARTIES agree that the requirements embodied in Clean Water Act Section 401 certification(s) or Section 404 or NPDES permit(s), are the sole responsibility of the ILLINOIS TOLLWAY, and that the CITY is not responsible in any way for the ILLINOIS TOLLWAY's failure to comply with such requirements.

B. The CITY shall provide the ILLINOIS TOLLWAY a summary raw data report that includes the following data for the most recent winter season for a minimum of five consecutive winter seasons, post equipment purchase and installation; 1) total lane miles maintained, 2) actual road salt usage in tons per lane mile, 3) baseline road salt usage in tons per lane mile, 4) target road salt usage in tons per lane mile, 5) total winter season precipitation events requiring deicing efforts, 6) average precipitation in inches of snow, ice and liquid form of winter season precipitation per precipitation event, 7) duration of each operator deicing efficiency training session and number of operators attending, 8) new equipment installation and new practices implemented and identification and practices planned and 9) the completed DRSCW's Winter Public Agency Deicing Questionnaire.

C. The PARTIES agree that the PROGRAM may require several years of monitoring and reporting from PROGRAM partners.

D. The PARTIES will develop and maintain a guidance document for the PROGRAM which will at minimum detail the methods for calculating the build scenario non-PROGRAM increase, the needed offset, BMP's the monitoring PROGRAM and reporting baseline requirements. The document will be updated by agreement between the PARTIES as the PROGRAM advances.

V. DELIVERABLES

A. The deliverables will be transmitted to the ILLINOIS TOLLWAY, by the CITY and include written reports documenting, as defined in Article IV, Paragraph B. of this AGREEMENT by June 1st pertaining to the preceding winter season.

B. The ILLINOIS TOLLWAY maintains its responsibility to remain compliant with the "Clean Water Act" as determined and administered by the IEPA.

VI. FINANCIAL

A. The ILLINOIS TOLLWAY as sponsor of the PROGRAM will compensate the CITY as outlined in this AGREEMENT and included in the CITY's Request for Equipment and Training "PROPOSAL".

B. The purchase of equipment identified within the CITY's PROPOSAL, as part of the PROGRAM shall be reimbursed by the ILLINOIS TOLLWAY to the CITY.

C. The CITY will be paid based upon its invoice(s) which shall include detailed receipts of purchased items in substantial conformance with the Budget included in the CITY's PROPOSAL.

D. The CITY shall certify in writing, upon presentation of each invoice hereunder, that items as invoiced have been actually purchased and installed and that the CITY is in fact complying with all other provisions of this AGREEMENT. Invoicing shall be sufficiently itemized to permit the ILLINOIS TOLLWAY or its consultant(s) or cooperating governmental unit(s) to verify performance of the work so invoiced.

E. It is mutually agreed that the estimated cost to the ILLINOIS TOLLWAY shall not exceed $139,500 for the term of this AGREEMENT through five consecutive winter seasons, beginning with the first winter season in which purchased equipment has been utilized and use data has been provided to the ILLINOIS TOLLWAY.

VII. GENERAL PROVISIONS

A. It is understood and agreed that this is an AGREEMENT between the City of Wood Dale and the Illinois State Toll Highway Authority.

B. All equipment proposed for purchase and installation, shall be done so prior to the 2018/2019 winter season but efforts will be made for purchases and installations to occur prior to the 2017/2018 winter season.

C. The term of this AGREEMENT shall extend through five consecutive winter seasons in which purchased equipment has been utilized and use data has been provided to the ILLINOIS TOLLWAY.

Electronic Filing: Received, Clerk's Office 3/14/2019

D. PARTIES agree to collaborate in effort to fulfill applicable goals of the PROGRAM as established in Section IV. of EXHIBIT A. Should the PARTIES mutually agree that the CITY did not operate in a manner demonstrating intent achieve the goal reduction of 17.5% in a PROGRAM year, the ILLINOIS TOLLWAY shall provide written notice to the CITY identifying delinquencies of agreed upon practices. Should the PARTIES mutually agree that the CITY did not operate in a manner in which to achieve the goal reduction of 17.5% for a second year during the term of this AGREEMENT, the ILLINOIS TOLLWAY and shall provide written notice to the CITY identifying delinquencies of agreed upon practices and the CITY shall provide reimbursement to the ILLINOIS TOLLWAY for all payments made by the ILLINOIS TOLLWAY associated with this agreement within 90 days of CITY's receipt of the notice.

E. Equipment purchased under this AGREEMENT by the ILLINOIS TOLLWAY on behalf of the CITY becomes the property and responsibility of the CITY and the CITY shall indemnify, hold harmless and defend the ILLINOIS TOLLWAY, its officials, directors, officers, employees, and agents from and against all liability, claims, suits, demands, proceedings and action, including costs, fees and expense of defense, arising from, growing out of, or related to, any loss, damage, injury, death, or loss or damage to property resulting from, or connected with, the CITY's negligent or willful acts, errors or omissions in its performance under this AGREEMENT, including, but not limited to, use of the equipment described herein. The CITY expressly acknowledges that the ILLINOIS TOLLWAY, through provision of funding, training, and certification under this AGREEMENT, is not intended to be a joint employer of the CITY's employees and agents and does not excerpt control over such persons in their use of the equipment that is the subject of this AGREEMENT.

F. It is understood and agreed that this AGREEMENT constitutes the complete and exclusive statement of the agreement of the PARTIES relative to the subject matter hereof and supersedes all previous oral and written proposals, negotiations, representations or understandings concerning such subject matter.

G. This AGREEMENT may be executed in two (2) or more counterparts, each of which shall be deemed an original and all of which shall be deemed one and the same instrument.

H. Under penalties of perjury, the CITY certifies that its correct Federal Tax Identification number is 36-6008547 and it is doing business as a governmental entity, whose mailing address is The City of Wood Dale, 404 North Wood Dale Road, Wood Dale, Illinois 60143.

I. The PARTIES agree to maintain books and records related to the performance of this AGREEMENT and necessary to support amounts charged to the ILLINOIS TOLLWAY and/or any of the PARTIES under the AGREEMENT for a minimum of five (5) years from the last action on the AGREEMENT. The PARTIES

Electronic Filing: Received, Clerk's Office 3/14/2019

further agree to cooperate fully with any audit and to make its books and records, and books and records within its custody or control available to the Illinois Attorney General, the Illinois Auditor General, the ILLINOIS TOLLWAY Inspector General, the ILLINOIS TOLLWAY Department of Internal Audit, the ILLINOIS TOLLWAY or any other governmental agency or agent thereof that is authorized to audit or inspect such books and records.

J. The introductory recitals included at the beginning of this AGREEMENT are agreed to and incorporated into this AGREEMENT.

(This section intentionally left blank.)

Electronic Filing: Received, Clerk's Office 3/14/2019

MEMORANDUM OF UNDERSTANDING
BETWEEN
THE ILLINOIS STATE TOLL HIGHWAY AUTHORITY
AND
THE DUPAGE RIVER SALT CREEK WORKGROUP
FOR
CHLORIDE OFFSET PROGRAM

This MEMORANDUM OF UNDERSTANDING (hereinafter referred to as the "MOU") is entered into this 31st day of October AD, 2013, by and between THE ILLINOIS STATE TOLL HIGHWAY AUTHORITY, an instrumentality and administrative agency of the State of Illinois, hereinafter called the "TOLLWAY", and THE DUPAGE RIVER SALT CREEK WORKGROUP, a group of local watershed stakeholders which include sanitary districts, municipalities, counties, forest preserve districts, state and federal agencies, and private environmental organizations of the State of Illinois, hereinafter called the "DRSCW", individually referred to as "PARTY", and collectively referred to as "PARTIES".

WITNESSETH:

WHEREAS, the TOLLWAY recently approved a 15 year Capitol Program, "Move Illinois; *The Illinois Tollway Driving the Future,*" which includes improving the Jane Addams Memorial Tollway (I-90) (hereinafter sometimes referred to as the "Toll Highway"), by reconstructing and widening from the John F. Kennedy Expressway to Interstate Route 39. The contemplated improvements are substantially included in multiple TOLLWAY construction contracts; and

WHEREAS, the TOLLWAY intends to improve the Elgin O'Hare Expressway, extending the expressway from its eastern terminus at Rohlwing Road (Illinois Route 53) to O'Hare International Airport (ORD) and constructing the Western Access connecting the Jane Addams Memorial Tollway (I-90) with the Tri-State Tollway (I-294) (hereinafter sometimes referred to as the Elgin O'Hare Western Access "EOWA"), and included in multiple TOLLWAY construction contract(s). The TOLLWAY will implement, operate and maintain the mainline improvements as tolled facilities (hereinafter sometimes referred to as the "Toll Highway"); and

WHEREAS, because the projects are in such close proximity, strategies for some aspects of environmental mitigation (i.e., water quality enhancements) are being considered collectively by the PARTIES, where feasible and practicable; and

WHEREAS, highway de-icing practices during winter months commonly use de-icing salts to provide for safe vehicular travel and winter maintenance for I-90 and the EOWA will require the use of salts; and

Electronic Filing: Received, Clerk's Office 3/14/2019

WHEREAS, studies acknowledged the potential for the addition of chloride concentrations in area streams and as the I-90 and EOWA projects are advancing to implementation, applications for Section 404 and Section 401 permits have been submitted to the United States Army Corp of Engineers (USACE) and the Illinois Environmental Protection Agency (IEPA); and

WHEREAS, the enhancement of water quality has been the focus of the DRSCW for many years, and the TOLLWAY in an effort to have the "Cleanest and Greenest" program possible is requesting that a partnership be developed between the PARTIES hereto, and a collaboration with permitting agencies, to achieve chloride offsets and reductions to enhance the water quality throughout the DRSCW's water-sheds affected by I-90 and the EOWA; and

WHEREAS, the waterways receiving storm water and snowmelt runoff from the I-90 and EOWA are on the IEPA's Section 303D List of impaired waters and thus require at a minimum no net increase in chlorides as defined in the "Clean Water Act"; and

WHEREAS, this MOU, for recording purposes shall be known as 002013-22, executed in duplicate, and has been prepared to outline the general understanding between the DRSCW and the TOLLWAY with regard to determine and establish their respective responsibilities toward a proposed "Chloride Offset Program" (hereinafter referred to as the "PROGRAM") and also serve as a basis for developing Intergovernmental Agreements with local watershed communities and agencies in the impacted area; and

WHEREAS the PARTIES agree that the entirety of the offset will occur with the impacted areas and be tailored to individual receiving stream segments to the maximum extent possible. As such local watershed communities and agencies participating in the PROGRAM will be responsible for winter operations on the land surfaces that drain to those segments and are herein referred to as "Tier 1 Communities";

NOW, THEREFORE, in consideration of the aforementioned recitals and the mutual covenants contained herein, the PARTIES hereto agree to the following summary of the responsibilities and participation of each PARTY in the implementation of the PROGRAM.

I. GOAL

A. The goal of the PROGRAM is to offset the increased chloride loadings from I-90 and the EOWA by affecting reductions in the use of winter de-icing salts from existing conditions. The TOLLWAY will reduce chloride applications in a quantifiable manner in support of the 401 Water Quality Certification process for I-90 and the EOWA projects and of local municipalities National Pollutant Discharge Elimination System Municipal Separate Storm Sewer System ("NPDES MS4") permit requirements.

Electronic Filing: Received, Clerk's Office 3/14/2019

B. The intent is to establish a partnership between the TOLLWAY and governmental bodies to achieve the chloride loading offset.

C. The partners will endeavor to achieve the offsets in communities straddling and or upstream of the I-90 and EOWA, but the TOLLWAY will expand beyond that area if needed to achieve the offset amounts.

D. Both structural and non-structural practices will comprise the PROGRAM to provide the needed improvements in water quality.

II. STRUCTURAL BEST MANAGEMENT PRACTICES

A. Grass swales, bio-swales, infiltration basins, etc. will be incorporated by TOLLWAY into the I-90 and EOWA projects in order to minimize the effects of roadway runoff and improve the quality of roadway runoff discharged to receiving waters and/or nearby wetlands.

III. NON-STRUCTURAL BEST MANAGEMENT PRACTICES

A. A salt reduction goal will be established by the TOLLWAY and DRSCW for the PROGRAM through further analysis of existing conditions, existing practices in the affected watersheds, and planned highway improvements. Offsets will include the adoption of salt reduction strategies (enhanced training, improved materials use, equipment upgrades), implemented by both the TOLLWAY and the Tier I communities. All participants will provide documentation on their salt application rates per lane mile, application totals, calibration logs and details on financial and other support to other mutually agreed upon partners.

B. The TOLLWAY recognizes that meeting the objectives of the Total Maximum Daily Loads ("TMDL's") will require reductions in area chloride loading above those set out in the PROGRAM and agrees to review its practices at an agency wide scale and to actively partner with the DRSCW, its members or successors, in working for PROGRAM area chloride reductions beyond the life of the PROGRAM with the goal of meeting the applicable water quality standard.

IV. TOLLWAY AND DRSCW RESPONSIBILITIES

A. Both PARTIES agree that the requirements embodied in Clean Water Act Section 401 certification(s) or Section 404 or NPDES permit(s), are the sole responsibility of the TOLLWAY, and that the DRSCW or participating agencies cannot be held liable in any way for failure to comply with such requirements.

B. The DRSCW will endeavor to unify stakeholders in the project areas with the common goal of improving chloride water quality. It is recognized that participating communities are voluntary agents and neither they nor the DRSCW can be held liable in any way for failure to collaborate in the plan.

Electronic Filing: Received, Clerk's Office 3/14/2019

C. The DRSCW will determine the baseline conditions through appropriate studies with stakeholders and other environmental evaluation which shall include sampling and analyses, as well as flow evaluation.

D. The DRSCW will determine the opportunities for improving de-icing practices through surveys and interviews with stakeholders.

E. The DRSCW and the TOLLWAY will set priorities, tracking offset progress, and the timeframe for achievement with concurrence from the IEPA.

F. The TOLLWAY will provide ongoing financial assistance supporting capital investments of alternative de-icing methods potentially for municipalities and agencies that are participating in the PROGRAM until such time as the PROGRAM objectives are met.

G. The TOLLWAY with the DRSCW's technical assistance will establish training and certifications for operators that would enhance awareness of best practices for snow and ice management operations.

H. The TOLLWAY with the DRSCW will establish data sites/sources for weather data and other information helpful in managing roadway de-icing.

I. The DRSCW with the support of the TOLLWAY will conduct long term monitoring that records salt usage and stream conditions. Evaluation of future operating conditions will be compared to baseline conditions.

J. The TOLLWAY and the DRSCW will report annually by July 1st to the IEPA the resulting efforts and success of the PROGRAM on an annual basis beginning in July of 2014. Success will be measured primarily by the application rate and totals reported with consideration given to the ambient monitoring system.

K. The TOLLWAY and the DRSCW will collaborate to put in place an ambient monitoring system that will be part of the PROGRAM monitoring and evaluation, and will document pre and post PROGRAM chloride conditions in the receiving streams. A monitoring plan will be developed through input from both PARTIES with the intent of conducting stream monitoring on Addison Creek, Salt Creek mainstem, Spring Brook, Meacham Creek and West Branch mainstem. The pre and post conditions will be synthesized in a report and submitted to IEPA on an annual basis along with other reporting data. The system would assist in evaluating the success of the PROGRAM in meeting the TMLD's goals and will be funded wholly by the TOLLWAY.

L. The PARTIES agree that the PROGRAM may require several years of monitoring and reporting from PROGRAM partners.

Electronic Filing: Received, Clerk's Office 3/14/2019

M. The PARTIES will develop and maintain a guidance document for the PROGRAM which will at minimum detail the methods for calculating the build scenario non-PROGRAM increase, the needed offset, BMP's the monitoring PROGRAM and reporting baseline requirements. The document will be updated by agreement between the PARTIES as the PROGRAM advances.

V. INTERGOVERNMENTAL AGREEMENTS

A. The TOLLWAY shall use its best efforts to enter into Intergovernmental Agreements prepared by the TOLLWAY and Tier 1 communities based upon this MOU to further determine and establish respective responsibilities toward financial partnerships, information sharing, and training.

B. These Intergovernmental Agreements shall not relieve the TOLLWAY of their responsibility to comply with the "Clean Water Act" as determined and enforced by the IEPA.

VI. FINANCIAL

A. The TOLLWAY will support financial partnerships through an Intergovernmental Agreement requiring cost sharing with a local partner as defined by the PROGRAM.

B. Project requests to the TOLLWAY will be subject to DRSCW and TOLLWAY approvals, to cost effectively promote salt usage reduction.

VII. TERMS OF THE MOU

A. The term of this MOU shall extend until such time that the PROGRAM offset has been achieved reductions have been demonstrated for a minimum of three (3) years. Either PARTY shall have the right to terminate this MOU at any time by providing at least ninety (90) days written notice to the other party in the event either PARTY breaches the terms and conditions of this MOU. At the end of the agreement period this document may be renewed by the mutual consent of the PARTIES.

(This space intentionally left blank)

Electronic Filing: Received, Clerk's Office 3/14/2019

Activity	Description	Municipal Estimated Grant Cost	Wood Dale Match	Estimated chloride reduction	Schedule
Staff Training	Concentrated small group training on interpreting weather forecasts, developing site specific storm management plans, and reconfiguring operations plans from updated forecasts.		$8,000.00	Cumulative 17.5%	Budgeted Item: Would be implemented this winter.
Purchase of 2.5 Ton Dump with sling host for v-box and anti-icing	This will allow the City to expand it's anti-icing program to cover the entire City and the V-Box would serve the industrial thus decreasing current number of passes required for salting creating less waste.	$139,500.00	170,500.00	Cumulative 17.5%	Budgeted Item for FY 18: Truck would be ordered as soon as confirmation of grant is received.
Total		$139,500.00	$178,500	Cumulative 17.5%	

This process is inter-dependent; one missing link will stop the effectiveness that the organizations involved are looking to accomplish.

Request $139,500.00; City investment $178,500.00

In the event that costs for equipment and training exceed the funds granted the City of Wood Dale, the City of Wood Dale will offset costs to the extent that City funds have available.

Average total salt use (2013-2014 to 2015-2016) 1,166 tons.
Average annual use per street mile (1,166 /95 = 12.3 tons per lane mile annual
Estimated Average Total Reduction is 17.5% or 204 tons

RESOLUTION NO. 21286

Background

It is in the best interest of the Illinois State Toll Highway Authority (the "Tollway") to enter into an Intergovernmental Agreement with the City of Wood Dale in connection with the construction of Illinois Route 390. In order to remain compliant with guidelines established by the Illinois Environmental Protection Agency, the Tollway and the DuPage River Salt Creek Workgroup (DRSCW) established a Chloride Offset Program to minimize chloride usage and enhance water quality throughout the DRSCW's water-sheds affected by Illinois Route 390. The Program is being implemented through partnerships with municipalities within the impacted areas by providing training to identify potential operational improvements, and the upgrading of equipment utilized for winter operations. The City of Wood Dale is an impacted municipality and requests the Illinois Tollway participate in the cost of providing training and purchasing upgraded equipment. The total estimated cost to the Tollway is not to exceed $139,500.

Resolution

The Chief Engineering Officer and the Acting General Counsel are authorized to negotiate and prepare an Intergovernmental Agreement between the Illinois State Tollway Highway Authority and the City of Wood Dale in substantially the form attached to this Resolution. The Chairman or the Executive Director is authorized to execute said agreement and the Chief Financial Officer is authorized to issue warrants in payment thereof.

Bensenville Chloride Offset

Electronic Filing: Received, Clerk's Office 3/14/2019

**INTERGOVERNMENTAL AGREEMENT BETWEEN
THE ILLINOIS STATE TOLL HIGHWAY AUTHORITY
AND
THE VILLAGE OF BENSENVILLE
FOR
CHLORIDE OFFSET PROGRAM**

This INTERGOVERNMENTAL AGREEMENT ("AGREEMENT") is entered into this 26TH day of JUNE, 2017, by and between The Illinois State Toll Highway Authority, an instrumentality and administrative agency of the State of Illinois, hereinafter called the "ILLINOIS TOLLWAY", and The Village of Bensenville, a municipal corporation of the State of Illinois, hereinafter called the "VILLAGE", individually referred to as "PARTY", and collectively referred to as "PARTIES".

WITNESSETH:

WHEREAS, the ILLINOIS TOLLWAY in order to facilitate the free flow of traffic and ensure safety to the motoring public, intends to improve the existing Elgin O'Hare Expressway, extend the expressway from its eastern terminus at Rohlwing Road (Illinois Route 53) to O'Hare International Airport (ORD) to be known entirely as Illinois Route 390, and construct the Western Access connecting the Jane Addams Memorial Tollway (I-90) with the Tri-State Tollway (I-294) (hereinafter sometimes referred to as the Elgin O'Hare Western Access "EOWA"), and included in multiple ILLINOIS TOLLWAY construction contracts. The ILLINOIS TOLLWAY will implement, operate and maintain the mainline improvements as tolled facilities (hereinafter sometimes referred to as "Toll Highway"); and

WHEREAS, highway de-icing practices during winter months commonly use de-icing salts to provide for safe vehicular travel and winter maintenance for the EOWA will require the use of chlorides; and

WHEREAS, studies acknowledged the potential for the addition of chloride concentrations in area streams and as the EOWA project is advancing in implementation, permits for Section 404 and Section 401 of the Clean Water Act (CWA) have been secured from the United States Army Corp of Engineers (USACE) and the Illinois Environmental Protection Agency (IEPA); and

WHEREAS, conditions established within the ILLINOIS TOLLWAY's CWA Section 401 permit require the implementation of a "Chloride Offset Program" (hereinafter called the "PROGRAM") to mitigate for increased chloride loading in the Total Maximum Daily Loading (TMDL) watersheds throughout the EOWA project area; and

Electronic Filing: Received, Clerk's Office 3/14/2019

WHEREAS, a Memorandum of Understanding (MOU) between the ILLINOIS TOLLWAY and DuPage River Salt Creek Workgroup (DRSCW) was executed October 31, 2013 to outline the PROGRAM, which is attached hereto as "Exhibit A" and incorporated by reference; and

WHEREAS, per the MOU, it was agreed that the entirety of the offset will occur within the impacted areas and be tailored to individual receiving stream segments to the maximum extent possible. As such, local watershed communities and agencies participating in the PROGRAM will be responsible for winter operations on the land surfaces that drain to those segments and are herein referred to as "TIER 1 COMMUNITY" or "TIER 1 COMMUNITIES"; and

WHEREAS, the VILLAGE has been identified as a TIER 1 COMMUNITY and has, in coordination with the DRSCW, conducted a review of their snow and ice operations in an effort to identify areas of operational improvements relating to efficiency gains in winter chloride usage, and per the VILLAGE'S review, it is believed that an effective reduction in chloride usage can be attained, as part of the PROGRAM through the upgrading of equipment utilized for winter operations by the VILLAGE; and

WHEREAS, the PARTIES mutually agree to review winter operation policies and procedures and work in coordination with the DRSCW to monitor the administration and progress of the PROGRAM; and

WHEREAS, the ILLINOIS TOLLWAY by virtue of its powers as set forth in the "Toll Highway Act," 605 ILCS 10/1 *et seq.* is authorized to enter into this AGREEMENT; and

WHEREAS, the VILLAGE by virtue of its powers as set forth in the "Illinois Municipal Code," 65 ILCS 5/1-1-1 *et seq.* is authorized to enter into this AGREEMENT; and

WHEREAS, a cooperative Intergovernmental Agreement is appropriate and such an Agreement is authorized by Article VII, Section 10 of the Illinois Constitution and the "Intergovernmental Cooperation Act", 5 ILCS 220/1 *et seq.*

WHEREAS for recording purposes this AGREEMENT shall be known as #004686.

NOW, THEREFORE, in consideration of the aforementioned recitals and the mutual covenants contained herein, the PARTIES hereto agree to the following summary of the responsibilities and participation of each PARTY in the implementation of the PROGRAM.

Electronic Filing: Received, Clerk's Office 3/14/2019

I. PURPOSE and SCOPE

A. The PROGRAM established a projected increase over existing conditions or baseline for the EOWA of 3,888 tons of salt per year, per a baseline 39.7 tons/lane mile/year application rate. The goal of the offset program will be to reduce salt usage in roadway applications in the project related watersheds by the amount of the increase (3,888 tons per year) plus a margin of safety of 25 percent or a total reduction of 4,860 tons per year.

B. The ILLINOIS TOLLWAY, as part of the PROGRAM, has established a rate reduction goal of 20% from the EOWA's established baseline salt application rate of 39.7 tons/lane mile/year, thereby accounting for 972 tons per year of the 4,860 tons per year of salt required to be reduced, as part of the PROGRAM.

C. The VILLAGE, as part of the PROGRAM and per this AGREEMENT, has established a rate reduction goal of 17.5% from its established baseline application salt application rate of 12.3 tons/lane mile/year, thereby accounting for 204 tons per year of the 4,860 tons per year of salt required to be reduced, as part of the PROGRAM.

D. Both structural and non-structural practices will comprise the PROGRAM to provide the needed improvements in water quality but it is understood that offset reductions can only be accounted for through non-structural practices.

II. STRUCTURAL BEST MANAGEMENT PRACTICES

A. Grass swales, bio-swales, infiltration basins, and other designs will be incorporated by the ILLINOIS TOLLWAY into the EOWA projects in order to minimize the effects of roadway runoff and improve the quality of roadway runoff discharged to receiving waters and/or nearby wetlands.

III. NON-STRUCTURAL BEST MANAGEMENT PRACTICES

A. A salt reduction goal has been established by the ILLINOIS TOLLWAY and DRSCW for the PROGRAM through the analysis of existing conditions, existing practices in the affected watersheds, and planned highway improvements. Offsets will include both the adoption of salt reduction strategies implemented by the ILLINOIS TOLLWAY and providing salt application data to DRSCW, including but not limited to their application rates for each lane mile, as well as financial and other support to other mutually agreed upon partners.

Electronic Filing: Received, Clerk's Office 3/14/2019

B. The ILLINOIS TOLLWAY recognizes that meeting the objectives of the Total Maximum Daily Loads ("TMDL's") will require reductions in area chloride loading above those set out in the PROGRAM and agrees to review its practices at an agency wide scale and to actively partner with the DRSCW, its members or successors, in working for PROGRAM area chloride reductions beyond the life of the PROGRAM with the goal of meeting the applicable water quality standard.

IV. RESPONSIBILITIES

A. Pursuant to EXHIBIT A, a guideline for monitoring and reporting chloride offsets has been established. Both PARTIES agree that the requirements embodied in Clean Water Act Section 401 certification(s) or Section 404 or NPDES permit(s), are the sole responsibility of the ILLINOIS TOLLWAY, and that the VILLAGE is not responsible in any way for the ILLINOIS TOLLWAY's failure to comply with such requirements.

B. The VILLAGE shall provide the ILLINOIS TOLLWAY a summary raw data report that includes the following data for the most recent winter season for a minimum of five consecutive winter seasons, post equipment purchase and installation; 1) total lane miles maintained, 2) actual road salt usage in tons per lane mile, 3) baseline road salt usage in tons per lane mile, 4) target road salt usage in tons per lane mile, 5) total winter season precipitation events requiring deicing efforts, 6) average precipitation in inches of snow, ice and liquid form of winter season precipitation per precipitation event, 7) duration of each operator deicing efficiency training session and number of operators attending, 8) new equipment installation and new practices implemented and identification and practices planned and 9) the completed DRSCW's Winter Public Agency Deicing Questionnaire.

C. The PARTIES agree that the PROGRAM may require several years of monitoring and reporting from PROGRAM partners.

D. The PARTIES will develop and maintain a guidance document for the PROGRAM which will at minimum detail the methods for calculating the build scenario non-PROGRAM increase, the needed offset, BMP's the monitoring PROGRAM and reporting baseline requirements. The document will be updated by agreement between the PARTIES as the PROGRAM advances.

V. DELIVERABLES

A. The deliverables will be transmitted to the ILLINOIS TOLLWAY, by the VILLAGE and include written reports documenting, as defined in Article IV,

Electronic Filing: Received, Clerk's Office 3/14/2019

Paragraph B. of this AGREEMENT by June 1st pertaining to the preceding winter season.

B. The ILLINOIS TOLLWAY maintains its responsibility to remain compliant with the "Clean Water Act" as determined and administered by the IEPA.

VI. FINANCIAL

A. The ILLINOIS TOLLWAY as sponsor of the PROGRAM will compensate the VILLAGE as outlined in this AGREEMENT and included in the VILLAGE's Request for Equipment and Training "PROPOSAL".

B. The purchase of equipment identified within the VILLAGE's PROPOSAL, as part of the PROGRAM shall be reimbursed by the ILLINOIS TOLLWAY to the VILLAGE.

C. The VILLAGE will be paid based upon its invoice(s) which shall include detailed receipts of purchased items in substantial conformance with the Budget included in the VILLAGE's PROPOSAL.

D. The VILLAGE shall certify in writing, upon presentation of each invoice hereunder, that items as invoiced have been actually purchased and installed and that the VILLAGE is in fact complying with all other provisions of this AGREEMENT. Invoicing shall be sufficiently itemized to permit the ILLINOIS TOLLWAY or its consultant(s) or cooperating governmental unit(s) to verify performance of the work so invoiced.

E. It is mutually agreed that the estimated cost to the ILLINOIS TOLLWAY shall not exceed $367,000 for the term of this AGREEMENT through five consecutive winter seasons, beginning with the first winter season in which purchased equipment has been utilized and use data has been provided to the ILLINOIS TOLLWAY.

VII. GENERAL PROVISIONS

A. It is understood and agreed that this is an AGREEMENT between the VILLAGE of Bensenville and the Illinois State Toll Highway Authority.

B. All equipment proposed for purchase and installation, shall be done so prior to the 2018/2019 winter season but efforts will be made for purchases and installations to occur prior to the 2017/2018 winter season.

Electronic Filing: Received, Clerk's Office 3/14/2019

C. The term of this AGREEMENT shall extend through five consecutive winter seasons in which purchased equipment has been utilized and use data has been provided to the ILLINOIS TOLLWAY.

D. PARTIES agree to collaborate in effort to fulfill applicable goals of the PROGRAM as established in Section IV. of EXHIBIT A. Should the PARTIES mutually agree that the VILLAGE did not operate in a manner demonstrating intent achieve the goal reduction of 17.5% in a PROGRAM year, the ILLINOIS TOLLWAY shall provide written notice to the VILLAGE identifying delinquencies of agreed upon practices. Should the PARTIES mutually agree that the VILLAGE did not operate in a manner in which to achieve the goal reduction of 17.5% for a second year during the term of this AGREEMENT, the ILLINOIS TOLLWAY and shall provide written notice to the VILLAGE identifying delinquencies of agreed upon practices and the VILLAGE shall provide reimbursement to the ILLINOIS TOLLWAY for all payments made by the ILLINOIS TOLLWAY associated with this agreement within 90 days of VILLAGE's receipt of the notice.

E. Equipment purchased under this AGREEMENT by the ILLINOIS TOLLWAY on behalf of the VILLAGE becomes the property and responsibility of the VILLAGE and the VILLAGE shall indemnify, hold harmless and defend the ILLINOIS TOLLWAY, its officials, directors, officers, employees, and agents from and against all liability, claims, suits, demands, proceedings and action, including costs, fees and expense of defense, arising from, growing out of, or related to, any loss, damage, injury, death, or loss or damage to property resulting from, or connected with, the VILLAGE's negligent or willful acts, errors or omissions in its performance under this AGREEMENT, including, but not limited to, use of the equipment described herein. The VILLAGE expressly acknowledges that the ILLINOIS TOLLWAY, through provision of funding, training, and certification under this AGREEMENT, is not intended to be a joint employer of the VILLAGE's employees and agents and does not excerpt control over such persons in their use of the equipment that is the subject of this AGREEMENT.

F. It is understood and agreed that this AGREEMENT constitutes the complete and exclusive statement of the agreement of the PARTIES relative to the subject matter hereof and supersedes all previous oral and written proposals, negotiations, representations or understandings concerning such subject matter.

G. This AGREEMENT may be executed in two (2) or more counterparts, each of which shall be deemed an original and all of which shall be deemed one and the same instrument.

H. Under penalties of perjury, the VILLAGE certifies that its correct Federal Tax Identification number is 36-6005794 and it is doing business as a governmental

Electronic Filing: Received, Clerk's Office 3/14/2019

entity, whose mailing address is The Village of Bensenville, 12 S. Center Street, Bensenville, Illinois 60106.

I. The PARTIES agree to maintain books and records related to the performance of this AGREEMENT and necessary to support amounts charged to the ILLINOIS TOLLWAY and/or any of the PARTIES under the AGREEMENT for a minimum of five (5) years from the last action on the AGREEMENT. The PARTIES further agree to cooperate fully with any audit and to make its books and records, and books and records within its custody or control available to the Illinois Attorney General, the Illinois Auditor General, the ILLINOIS TOLLWAY Inspector General, the ILLINOIS TOLLWAY Department of Internal Audit, the ILLINOIS TOLLWAY or any other governmental agency or agent thereof that is authorized to audit or inspect such books and records.

J. The introductory recitals included at the beginning of this AGREEMENT are agreed to and incorporated into this AGREEMENT.

MEMORANDUM

Elgin O'Hare Western Access and I-90 East Widening and Reconstruction: A Framework for Chloride Mitigation

PREPARED FOR: Bryan Wagner/Illinois Tollway

PREPARED BY: Larry Martin/CH2M HILL
Mark Mittag/CH2M HILL
Jim Huff/Huff and Huff

DATE: March 10, 2014

The Elgin O'Hare Western Access (EOWA) and I-90 East Widening and Reconstruction projects (Projects) are major transportation investments in the Chicagoland area located generally west of O'Hare Airport. The projects span various watersheds (see Exhibit 1). Most all the watersheds have water quality impairments ranging from low dissolved oxygen to elevated levels of total suspended solids (TSS), heavy metals, and chlorides from winter road and parking lot deicing operations. Many streams do not meet the Illinois chloride water quality standard of 500 mg/L. Because the chloride standard is exceeded in several locations, the Illinois Environmental Protection Agency (IEPA) has established Total Maximum Daily Loads (TMDLs) for the West Branch DuPage River, Salt Creek, and Addison Creek. Higgins Creek has a TMDL study underway. The allowable chloride loads require that measures be implemented to achieve the load reductions, which will be realized with more efficient winter deicing practices.

In December 2012 and February 2013, the Illinois Tollway submitted applications for Section 404 and Section 401 permits to the U.S. Army Corps of Engineers (USACE) and IEPA for the Projects. During the planning phases of the Projects, and more recently during the permitting processes, water quality has been a topic repeatedly emphasized by regulatory agencies, environmental groups, and individuals. In recent meetings with the IEPA, the agency acknowledged that the planned stormwater best management practices (BMPs) for the Projects would adequately manage the quality of the roadway runoff for TSS and heavy metals. For streams impaired for chlorides, however, IEPA indicated that there will be no net increase in chlorides with the projects to ensure compliance with the applicable regulations.

Program Organization

In response to IEPA's directives, the Illinois Tollway has developed a program for salt reduction in the EOWA project area. The Illinois Tollway has resolved that for this program to be viable it requires collaboration and participation beyond the boundaries of the Illinois Tollway organization. The framework of this program involves a strategic alliance with the DuPage River Salt Creek Workgroup (DRSCW), other strategic watershed groups, and local units of government for advancing salt reduction in streams affected by the project. Moving forward, the Illinois Tollway will administer and manage the overall salt reduction program for the project with guidance and support from the DRSCW. The partnership with the DRSCW will be formalized with a Memorandum of Understanding (MOU). Working arrangements with local units of government will be formalized with the use of an Intergovernmental Agreement (IGA). IGA's will be established with communities that are directly adjacent to the EOWA project and would include Hanover Park, Schaumburg, Roselle, Itasca, Elk Grove Village, Wood Dale, Bensenville, Des Plaines, Mount Prospect, Franklin Park, City of Chicago, North Lake, and Elmhurst. IGA's would also be established with DuPage and Cook counties, and local townships.

It is anticipated that the program duration will be permanent and will be a condition of the 401 Water Quality Certification. The program will be implemented in steps. The initial step involves developing the overall program, which is currently underway with the Illinois Tollway and the DRSCW planning the framework of the program that includes the following elements:

Electronic Filing: Received, Clerk's Office 3/14/2019

- Establishing baseline conditions (the starting point),
- Developing salt reduction goals, enlisting the municipal partners,
- Aligning the salt reducing practices that best fit community needs,
- Establishing funding needs,
- Developing training workshops, and
- Developing a monitoring and reporting program to measure progress toward stated goals.

The MOU with the DRSCW is be finalized by summer 2013. The IGA process with municipal partners will commence in the fall of 2013 and be completed by mid-2014. Funding levels required to finance the program are currently being developed. Program funding will come from a combination of Illinois Tollway, local communities, and other sources. It is anticipated that the Illlinois Tollway would contribute the majority share. Funding put forth by the Illinois Tollway would be distributed to the local units of government for equipment upgrades and would be administered through the IGA's.

The major Investment in new salt reducing practices is expected in the early years of the program to maximize benefits to water quality. The goal is to have salt reducing practices in place in the east-west corridor (~10 mile section between Gary Avenue on the west to York Road on the east) prior to the opening of new pavement in late 2015. The completion of the east-west corridor is schedule for 2018, and the completion of the Western Access is scheduled for 2025.

Program reporting will occur on an annual basis. Information will be collected on an annual basis to compare usage under the program with the current baseline conditions. Salt usage will be expressed in tons of salt applied in a deicing season per lane-mile. An end-of-season meeting of the communities and the Illinois Tollway may be sponsored to share lessons learned and consider adjustments prior to the next deicing season. Results below expectation will be assessed and adjustment made to the program approach.

Program Work Scope

The salt reduction scope of work is comprised of work tasks that are designed to achieve a "no net increase" in chloride with an added buffer of no less than 25 percent. Based on an assessment of current practices and future requirements, the program objective will be to achieve an annual reduction of 4,860 tons in watersheds affected by the EOWA project. The program consists of two elements:

- Improving current Illinois Tollway deicing practices.
- Expanding salt reduction practices to local communities within the EOWA drainage areas.

Improving Current Illinois Tollway Deicing Practices

An internal review of the Illinois Tollway's deicing practices was initiated in early 2013. In addition to the Illinois Tollway's internal staff expertise, the agency retained the services of an internationally known deicing expert, Dr. Wilfred Nixon, a professor and researcher on highway maintenance and ice engineering at the University of Iowa.

In 2013, Illinois Tollway staff and Dr. Nixon initiated a review of current Tollway winter maintenance practices and policies with the purpose of identifying the potential for more efficient ice control chemicals usage (e.g., salt and others) in winter maintenance activities, while maintaining a very high level of service and safety.

The review of current practices and policies focused on six principle areas of winter maintenance, including:

- Levels of service

Electronic Filing: Received, Clerk's Office 3/14/2019

- Performance measurement and continuous improvement
- Materials usage
- Equipment selection and operations
- Strategic operations
- Tactical operations

In the review of these practice areas, current salt loadings were obtained, detailed interviews were conducted with Illinois Tollway staff, and salt yard operations and equipment were examined. The following draft recommendations were formulated from the data, interviews, and observations:

- Pre-wetting salt solids on the truck – yields up to a 25 percent reduction in salt use.
- Use salt brine for pre-wetting regularly with periodic strategic use of calcium chloride brine.
- Optimizing salt application rates by considering pavement temperature and weather types may be able to reduce application rates from 500, 300 and 200 pounds per lane-mile to 375, 225, and 150 pounds per lane-mile. Reduction in salt application may require pilot testing to confirm application rate efficiency.
- Use direct liquid application prior to a storm to prevent bonding between the snow/ice and the pavement and reduce total chemical required during a storm event (anti-icing) – yields up to a 75 percent reduction in salt use during these events.
- Other practices that produce effective, but smaller reductions in salt use are the application of tow plows, new plow cutting edges, and communicating reduction methods with other agencies.

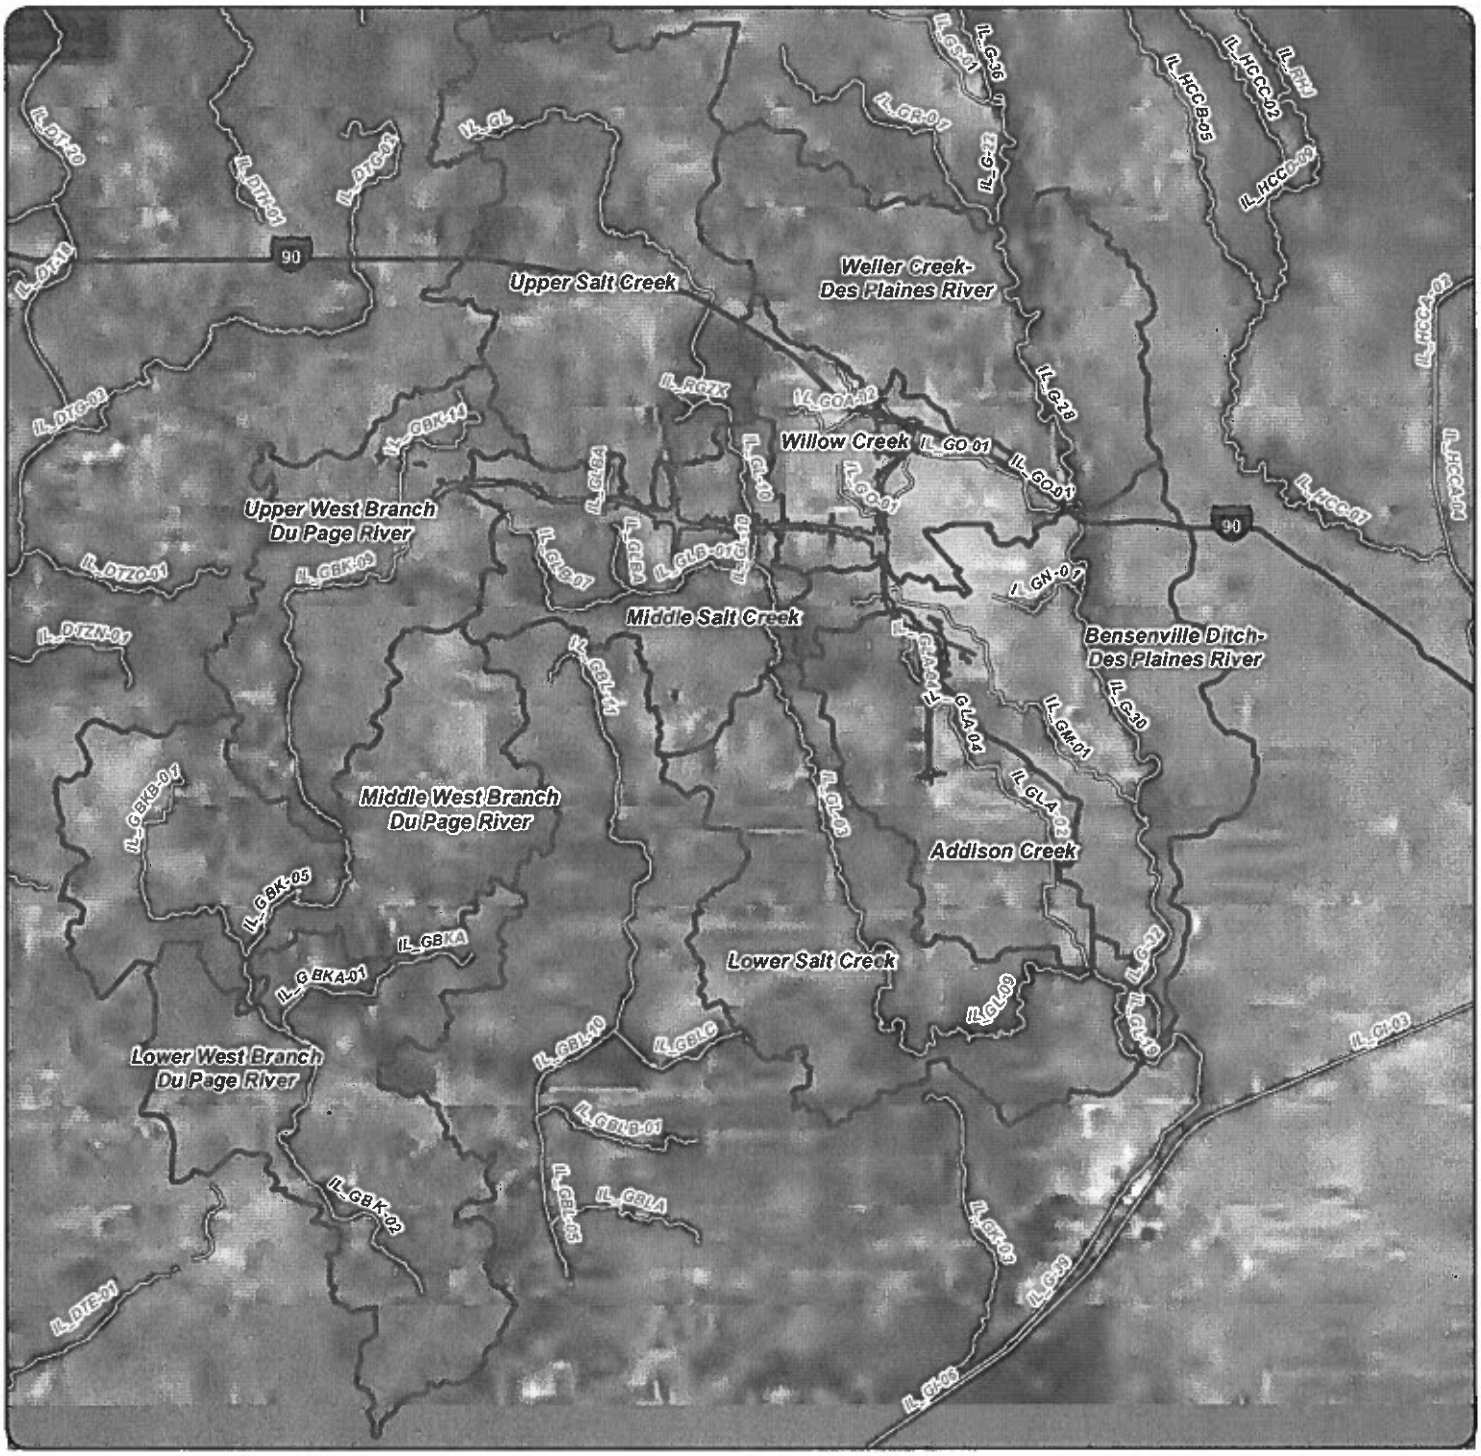
The implementation of these practices would be preceded by a review, evaluation, and approval process within the Illinois Tollway organization. As a first step, practices such as pre-wetting salt, using salt brine, adjusting salt application rates, and using direct liquid applications would be evaluated and screened based on performance, compatibility with current practice, etc. Practices that advance from the screening phase would be pilot-tested. Pilot projects would be conducted for at least one winter season, and would be pilot-tested in the region of one maintenance yard. The effectiveness, cost-savings, and comparative performance of each method would be assessed for system-wide usage. Initial pilot-testing is planned for the winter 2013-2014. The practice(s) selected for implementation and their associated reduction of salt in the project area will count towards meeting the goal of not increasing chloride discharge with the project.

Expanding Salt Reducing Practices to Local Communities - Chloride Off-Set Program

The Illinois Tollway and DRSCW have developed the Chloride Off-Set program to a concept level. It program concept provides the clarity necessary to obtain concurrence from their respective organizations to advance to program implementation. The scope of the program is described as follows.

- **Program facilitation and management.** The Illinois Tollway will manage the implementation of the salt reduction program, and be responsible to the regulatory agencies (i.e., IEPA and USACE) for compliance with the terms and conditions of the Section 404 and 401 permits. The use of IGAs would be used to formalize working arrangements with the DRSCW and local municipalities. The DRSCW will serve as a principal in the development and implementation of the program. Whereas, the DRSCW has long-term established relationships with the stakeholder communities and have been entrusted to provide guidance related to water quality issues, the DRSCW will facilitate the overall integration of the project area's salt reduction program into the water quality initiatives of the stakeholder community.

Electronic Filing: Received, Clerk's Office 3/14/2019



- **Program funding.** The funding for the program is currently under review. Funding would be directed to training, promotion of alternative deicing practices, and equipment upgrades that would provide greater efficiencies in salt usage. Funding will come from a combination of Illinois Tollway, local municipalities, and other sources. The use of IGAs will be the mechanism to enable partnership of the local communities and the funding arrangements that will affect salt reducing practices. Likely funding scenarios include the Illinois Tollway contributing the majority share, and the local communities and other sources (i.e., state and federal grant monies) comprising the remainder.
- **Assess existing practices.** Surveys and interviews are routinely conducted by the DRSCW with communities in the project area to determine current deicing practices. An additional survey will be conducted as part of this initiative to accurately define current community salt usage. This data will be used to tailor the types of salt reduction practices that would provide the best results for each community.
- **Establish baseline conditions.** The community surveys and interviews will also be used to establish baseline conditions for each potential partner. As an initial task, baseline estimates will be compiled from current practices and records, and in the absence of detailed records, a comparison to peer communities will be estimated. As a follow-on task, the collection of accurate application rates per lane-mile using existing practices will occur in Year One of the program. Standard procedures will be established to determine application rates for each community. Baseline conditions will be recorded as the rate of salt usage per lane-mile (pounds per lane-mile) under standard conditions, and total tons of salt used during the deicing season.
- **Finalize program goals and salt reduction targets.** Based on an assessment of current practices and future requirements, the program objective will be to achieve an annual reduction in tons of salt across the project area. Each partner community will be assigned a target goal wherein the combined targets of the individual communities will add to the program wide target. Individual community targets will be determined based on current practices and reasonably achievable reductions with the use of salt reducing practices.
- **Identify alternative practices best-suited to local communities.** The winter deicing practice surveys and interviews will be used to identify the types of deicing technology needed within each community for additional salt usage efficiency. The current practices will shape the menu of practices recommended for each community. Actual implementation of the new deicing practices would begin implementation in Year Two of the program.
- **Initiate training for more efficient deicing practices.** The DRSCW routinely provides training, workshops, and seminars concerning water quality practices. The organization in conjunction with the Illlinois Tollway will update training for achieving greater efficiencies in deicing practices. Appropriate training on best available deicing technologies and best practices will be shared across the partnering communities. The intent is to provide the best available information to the communities in the project area that result in salt reducing practices. Training would be initiated in Year One of the program.
- **Establish data sites (weather-related information) for managing roadway deicing.** The Illinois Tollway has a system of pavement temperature sensors and subscribes to instantaneous weather data. Data sharing with the municipal partner is contemplated and would aid local communities in making winter storm management decisions.
- **Monitor/report.** Salt use reporting will be a requirement of the program. The Tollway and each community will provide annual usage expressed as tons of salt applied per lane-mile annually. This usage rate combined with the miles of roads in the community will be used to compare progress in salt reduction and overall salt use efficiency. An end-of-season meeting will be hosted by the Illinois Tollway to share lessons learned and consider program adjustments for the next deicing season. Instreaming monitoring is planned to demonstrate that the reduction in salt use is reducing chloride

Electronic Filing: Received, Clerk's Office 3/14/2019

concentrations in receiving waters. The sampling locations and frequency of sampling is in the planning stages.

- **Reassess program objectives.** An annual assessment of the program will be conducted by the Illinois Tollway and the DRSCW. The program metrics will be evaluated to study trends, and salt reducing practices will be review to determine actual effectiveness compared to theoretical. The assessment will be documented as a report and submitted to regulatory agencies upon request. Results that are below expectations will be addressed with the necessary program revisions that produce the needed outcome

MEMORANDUM

Liquid Deicing Options and Evaluation for the Elgin O'Hare Western Access Project

PREPARED FOR: Bryan Wagner/Illinois Tollway

PREPARED BY: Steven Graziano/CH2M HILL
Mark Mittag/CH2M HILL

COPY TO: Reed Panther/Illinois Tollway
Steve McCracken/DRSCW
Illinois Environmental Protection Agency
Jim Huff/Huff and Huff
Larry Martin/CH2M HILL

DATE: July 16, 2013

As part of a chloride offset program for the Elgin O'Hare Western Access (EOWA) project, winter deicing efficiencies have been evaluated for Illinois Tollway and partnering communities. Technology experts have indicated a move towards using more liquid deicers provides efficiency in salt use. Improved efficiency results in less rock salt use. This memorandum summarizes the technology options most readily applicable to Illinois Tollway and local communities with the goal of estimating salt reduction with the implementation of more widespread use of liquid deicer.

The use of liquid brine through pre-wetting and anti-icing practices was investigated for the EOWA project. Pre-wetting involves applying salt brine directly to the surface of bulk salt solids prior to conventional deicing. The pre-wetting rapidly activates the salt melting process and reduces the degree of bounce-and-scatter of salt off the roadway surface. Anti-icing involves the application of brines or organic products to the roadway surface prior to a snow or ice event to prevent or weaken the bond between the snow or ice and the pavement surface. Preventing a bond to the pavement allows for easier and more efficient snow removal. Both practices provide considerable benefit to snow and ice management agencies.

Types of Brine

Pre-wetting and anti-icing liquid agents can be salt brines, organic agents or byproducts, or combinations of both. The focus of this general investigation involves only the use of salt brine created from bulk rock salt (sodium chloride) and water. It is assumes that brines are 23.3 percent salt by weight. Other common pre-wetting and anti-icing brines include those created from magnesium chloride and calcium chloride salts. Each salt has benefits and drawbacks and is typically appropriate for specific environmental and road conditions; however, rock salt brine is the most widely used and most affordable deicing agent. The Illinois Tollway or local communities may want to augment sodium chloride brines with calcium chloride or other liquids or mixtures based upon weather and travel conditions.

Advantages of Brine for Pre-wetting and Anti-Icing

The advantages of using brine for pre-wetting and anti-icing are listed below and are adapted from the Iowa Department of Transportation's Systems Operation Bureau, Office of Maintenance.

Pre-wetting

- Rock salt can be spread more uniformly and less is wasted on shoulders and ditches, reducing the impact to the environment.
- Materials adhere to the surface because the salt and brine mixture has a thicker consistency.
- Melting begins faster since a liquid has been introduced to the salt. It is important for salt to be in liquid form to prevent snow and ice bonding to pavement.
- Since the brine begins working and diluting as it hits the surface, it will dry much more rapidly, returning the roadway to normal winter driving conditions much sooner.

- Spreading speeds can be increased because more material stays on the roadway.
- Residual salt may remain on the road that will immediately begin working with the next storm.
- When dry materials are pre-wet with brine, the dry material application rate can actually be cut back 20 to 30 percent because more of the material remains on the roadway. In addition, the additional brine speeds the melting action.
- Can be used as a deicer on very thin layers of frost or black ice, but with caution. Salt brine is not recommended for snow pack unless it is treated regularly and frequently with a sufficient quantity of salt brine and or salt brine and rock salt. Brine alone will rapidly dilute and if an insufficient concentration is maintained and may refreeze before it can burrow through the snow or ice pack.

Anti-icing

- Application prior to a storm can help prevent snow and ice from bonding to the pavement and can help keep the roadway wet longer into a storm (or throughout the storm, if a very light precipitation event).
- Makes clean-up quicker and returns roads to normal driving conditions more rapidly.
- Reduces labor hours.
- Reduces wear on ice blades and underbody plows.

For additional information, the Iowa DOT winter maintenance website serves as a comprehensive resource and can be accessed at http://www.iowadot.gov/maintenance/materials.html.

Findings of the Nixon Report

The Illinois Tollway consulted with Dr. Nixon from the University of Iowa on a review of deicing procedures and efficiency opportunities. Dr. Nixon's report explained that approximately 30 percent of the salt spread on the road by conventional deicing methods can be expected to leave the road surface. The pre-wetting of road salt prior to spreading has shown to result in only a 4 percent loss of salt when spread on the center lane of a three lane road at vehicle speeds of 30 to 40 mph, application rates of 400 lb per lane mile, and at pre-wetting rates of 6 gallons per ton of salt applied.

As a result, a potential reduction in salt application by approximately 25 percent can be reasonably expected, meanwhile still maintaining the same level of service. Similar potential salt reductions between 20 and 30 percent have been supported by the Wisconsin Transportation Information Center, the Salt Institute's *Snowfighters Handbook*, the Iowa DOT, and the New Hampshire Department of Environmental Services. Anti-icing reductions were not explicitly stated in the Nixon Report.

Anti-icing efforts are typically more dependent on environmental conditions, road surface conditions, and on the timing of application prior to a storm or ice event. Therefore, salt savings when using anti-icing can vary but can be optimized with extensive operational experience. The *Chloride Reduction Implementation Plan for Dinsmore Brook Watershed, Windham, NH* (February 2011) from the New Hampshire Department of Environmental Services indicates that salt reductions between 10 and 30 percent can be expected when anti-icing.

Estimate of Current Salt Use and Planned Reductions with Pre-Wetting/Anti-Icing Strategies

Pre-wetting and anti-icing options were considered for communities that span the EOWA corridor. Tier 1 communities were designated as those located within the EOWA project footprint or within the USGS watersheds bordering the project footprint. Additional analysis has continued to evaluate the potential salt reduction in each community. These Tier 1 communities are located in watersheds of interest to the DuPage River Salt Creek Workgroup (DRSCW), as well as Des Plaines River watersheds, due to their proximity to the project footprint. Several communities span several watersheds. Consequently, the community salt reduction potential considers all reductions available as long as they are within the DRSCW or Des Plaines River watersheds.

The effectiveness of pre-wetting and anti-icing in the reduction of salt quantities were determined based on total lane miles present within the Tier 1 communities and typical per-lane-mile salt application rates. Total lane miles within Tier 1 communities are summarized in Table 1. Refer to Exhibits 1 and 2, which identify roadways within Tier 1 communities and watershed boundaries.

TABLE 1
Lane Miles per Jurisdiction Spanning EOWA Project Footprint

Jurisdiction[a]	DRSCW Watershed Lane Miles	Des Plaines Watershed Lane Miles	Total Lane Miles	Estimated Salt Usage, ton/yr[b]
Locally-Maintained				
Addison Township	25.4	7.2	32.6	457
Bensenville	57.6	49.2	106.7	1,494
Berkeley	21.7	0.0	21.7	304
Bloomingdale Township	7.2	0.0	7.2	101
Chicago	0.0	208.3	208.3	2,916
Elk Grove Township	14.6	6.5	21.0	295
Elk Grove Village	143.8	110.5	254.3	3,561
Elmhurst	289.1	0.0	289.1	4,047
Franklin Park	0.0	105.7	105.7	1,480

Wood Dale	46.9	37.1	84.0	1,176
Locally-Maintained Subtotal	1,289.9	581.6	1,871.5	26,202
DuPage County-Maintained	91.5	27.7	119.1	1,668
Cook County-Maintained	113.7	24.8	138.5	1,939
Total	**1,494**	**634**	**2,129**	**29,808**

[a] IDOT-maintained lane miles are excluded from these quantities. Includes locally-, DuPage Co.-, and Cook Co.-maintained lane miles.

[b] Assumed application rate: 14 tons/lane mile/year.

Note: IDOT-maintained lane miles are excluded from these quantities. Includes locally-, DuPage Co.-, and Cook Co.-maintained lane miles.

Roadway lane mile totals were based on a 2011 (latest available) Illinois Department of Transportation Roadway Data Layer GIS files (http://gis.dot.illinois.gov/gist2/), which also included jurisdictional information. The baseline road salt application rate assumed was 14 tons/lane mile/year, based on a 2007 survey conducted by the DRSCW on the average annual salt application reported by respondents located in within the Salt Creek watershed.

Electronic Filing: Received, Clerk's Office 3/14/2019

Table 2 indicates the lane miles and an estimate of added salt usage with the Initial Construction Plan (ICP) and the Full-Build phase of the Elgin O'Hare Western Access Project. Freeway/Toll road lane miles were assigned an average road salt application rate of 39.7 ton/lane mile/year based on IDOT and Illinois Tollway system-wide application rates during the 2000/2001 through 2010/2011 winter seasons. As shown in Table 2, the increase over existing conditions or baseline with the ICP is 3,888 tons per year. The goal of the offset program will be to reduce salt usage on roadway in the project related watersheds by the amount of the increase (3.888 tons per year) plus a margin of safety (MOS) of 25 percent or a total reduction of 4,860 tons per year.

TABLE 2
Salt Application Summary for EOWA Project Limits
Estimated Annual Salt Application Rates

Project Stage	Lane miles [a]	Salt Applied, ton/yr [b]	Increase from Baseline Condition, ton/yr
Existing (Baseline) Condition	159	3,959	N/A
Initial Construction Plan (ICP)	264	7,847	3,888
2040 Full Build	293	8,969	5,010

[a] Lane miles include arterial/collector and freeway lane miles located within the project limits.
[b] Considers two different salt application rates depending on the roadway class. Arterial/collector roads are loaded at 14 ton/lane mile/year. Freeways are loaded at 39.7 ton/lane mile/year.

Table 3 expands on the data provided in Table 1 and shows estimates of potential salt reductions with the use of pre-wetting or anti-icing management techniques. Overall, the use of pre-wetting and anti-icing has the potential to reduce salt use in the project watersheds by up to 40 percent or a reduction of approximately 11,900 tons per year. The combined potential of these practices to reduce salt use in the project related watersheds is far greater than the offset target of 4,860 tons per year. While unlikely, if additional offsets are needed, communities further upstream (Tier 2 communities) or downstream (Tier 3 communities) in these watersheds could be approached to achieve further reductions in salt application.

Table 4 is a breakdown of the salt reduction target (4,860 tons per year) distributed by watershed in the project area (see Exhibit 3). The breakdown is proportional to the additional miles of roadway added within each watershed.

TABLE 3
Salt Application Summary by USGS Watershed for Tier 1 Communities
Estimated Annual Salt Application Rates and Potential Reductions With Best Management Practices

USGS Watershed	Lane Miles	Salt Applied, ton/yr	Salt Reduction with Pre-Wetting, ton/yr [a]	Salt Reduction with Anti-Icing, ton/yr [b]	Potential Total Salt Reduction, ton/yr
Des Plaines River Watershed					
Addison Creek	319	4,462	1,116	669	1,785
Bensenville Ditch-Des Plaines River	435	6,085	1,521	913	2,434
Willow Creek	198	2,768	692	415	1,107
Des Plaines River Watershed Sub-total	*952*	*13,315*	*3,329*	*1,997*	*5,326*

TABLE 3

Salt Application Summary by USGS Watershed for Tier 1 Communities

Estimated Annual Salt Application Rates and Potential Reductions With Best Management Practices

USGS Watershed	Lane Miles	Salt Applied, ton/yr	Salt Reduction with Pre-Wetting, ton/yr [a]	Salt Reduction with Anti-Icing, ton/yr [b]	Potential Total Salt Reduction, ton/yr
DRSCW Watershed					
Middle Salt Creek	436	6,106	1,527	916	2,442
Upper West Branch DuPage River	329	4,603	1,151	690	1,841
DRSCW Watershed Sub-total	*756*	*10,709*	*2,678*	*1,606*	*4,283*
Grand Total	**1,717**	**24,024**	**6,007**	**3,603**	**9,609**

Note: IDOT-maintained lane miles are excluded from these quantities. Includes locally-, DuPage Co.-, and Cook Co.-maintained lane miles. Reductions were directly applied to the total annual salt usage based on an application rate of 14 tons salt/lane mile/year.

[a] Expected salt reduction attributed to pre-wetting is between 20 and 30 percent. Reduction assumed: 25 percent

[b] Expected salt reduction attributed to anti-icing is between 10 and 30 percent. Reduction assumed: 15 percent

TABLE 4

Summary by USGS Watershed for the Initial Construction Plan (ICP) EOWA Project

Estimated Annual Salt Application Rates and Increases from Existing Conditions

USGS Watershed	Reduction from Baseline Condition, ton/yr	Target Reduction with MOS, ton/yr [a]	Comparison to Local Offset Potential, ton/yr
Des Plaines River Watershed			
Addison Creek	259	324	1,785
Bensenville Ditch-Des Plaines River	645	806	2,434
Willow Creek	1,761	2,201	1,107
Des Plaines River Watershed Sub-total	*2,665*	*3,331*	*5,326*
DRSCW Watershed			
Middle Salt Creek	1,191	1,489	2,442
Upper West Branch DuPage River	32	40	1,841
DRSCW Watershed Sub-total	*1,223*	*1,529*	*4,283*
Grand Total	**3,888**	**4,860**	**9,609**

[a] Includes a margin of safety (MOS) to have 125 percent of the salt application increase for the Initial Construction Plan (ICP) condition.

Based on the estimate of current salt use in the watershed areas, the ability to offset the increased salt usage for the ICP is clearly achievable with the use of pre-wetting and anti-icing practices. With the project, the overall reduction in salt needed to achieve no net increase as well as the 25 percent margin of safety is 4,860 tons/year. The opportunity within local communities for pre-wetting and anti-icing practices to reduce salt use is far greater than the estimated offset requirement (approximately 10,000 tons/year).

Offsets will be made through a combination of Illinois Tollway reductions and partnership with local communities. For the Des Plaines River and DRSCW watersheds, the offsets available through local communities easily exceed the offset totals needed. If necessary, additional offsets can be achieved from further reductions upstream, from other Illinois Tollway operations not part of the EOWA project, other potential partners, or combinations of these options.

To track improvements in salt usage, both annual tons of salt applied and a typical storm application rate will be tracked to take into account variation in winter conditions from year to year. The implementation of these practices will be applicable to both the Illinois Tollway and local communities. The actual mix of these practices will be determined individually for each entity with the objective of tailoring salt reducing practices that best fit the community needs and yields a substantive reduction in salt use.

Major Equipment Requirements

Equipment options for pre-wetting and anti-icing operations using sodium chloride brine include:

Anti-icing

- Salt storage
- Brine production equipment (if produced onsite)
- Brine storage tank (whether purchased as bulk product or produced onsite)
- Truck-mounted brine storage, trailer brine storage, or combination storage
- Brine applicator

Pre-wetting

- Salt storage
- Brine production equipment (if produced onsite)
- Brine storage tank (whether purchased as bulk product or produced onsite)
- Truck-mounted brine and salt storage
- Brine applicator to salt

References such as the Iowa DOT Systems Operation Bureau, Office of Maintenance have additional information available on typical equipment needs. This source provides a comprehensive description of the equipment requirements and options available for anti-icing or pre-wetting programs.

Additional Ice/Snow Management Items

In addition to retrofitting fleet vehicles and constructing or purchasing brine production equipment to accommodate either anti-icing or pre-wetting practices, the following are recommendations that will further improve ice and snow removal efficiency.

- **Education and training of ice and snow management staff.** Education and training could include a one-day annual conference prior to the winter season to discuss proper operation and maintenance of ice and snow removal technologies, standards of practice, past observations, and potential solutions. This meeting would include regional ice and snow management staff.
- **Information sharing amongst members of the ice and snow management community.** This could include monthly meetings, webinars, or forums during the winter season for members to engage other municipalities or townships on the success of their deicing programs.
- **Equipment calibration program and training.** The offsets program will require that equipment is calibrated regularly and calibration documentation is provided to ensure proper and accurate salt application rates are reported annually.

Chloride Offset Program

Electronic Filing: Received, Clerk's Office 3/14/2019

MEMORANDUM OF UNDERSTANDING
BETWEEN
THE ILLINOIS STATE TOLL HIGHWAY AUTHORITY
AND
THE DUPAGE RIVER SALT CREEK WORKGROUP
FOR
CHLORIDE OFFSET PROGRAM

This MEMORANDUM OF UNDERSTANDING (hereinafter referred to as the "MOU") is entered into this 31st day of October AD, 2013, by and between THE ILLINOIS STATE TOLL HIGHWAY AUTHORITY, an instrumentality and administrative agency of the State of Illinois, hereinafter called the "TOLLWAY", and THE DUPAGE RIVER SALT CREEK WORKGROUP, a group of local watershed stakeholders which include sanitary districts, municipalities, counties, forest preserve districts, state and federal agencies, and private environmental organizations of the State of Illinois, hereinafter called the "DRSCW", individually referred to as "PARTY", and collectively referred to as "PARTIES".

WITNESSETH:

WHEREAS, the TOLLWAY recently approved a 15 year Capitol Program, "Move Illinois; *The Illinois Tollway Driving the Future,*" which includes improving the Jane Addams Memorial Tollway (I-90) (hereinafter sometimes referred to as the "Toll Highway"), by reconstructing and widening from the John F. Kennedy Expressway to Interstate Route 39. The contemplated improvements are substantially included in multiple TOLLWAY construction contracts; and

WHEREAS, the TOLLWAY intends to improve the Elgin O'Hare Expressway, extending the expressway from its eastern terminus at Rohlwing Road (Illinois Route 53) to O'Hare International Airport (ORD) and constructing the Western Access connecting the Jane Addams Memorial Tollway (I-90) with the Tri-State Tollway (I-294) (hereinafter sometimes referred to as the Elgin O'Hare Western Access "EOWA"), and included in multiple TOLLWAY construction contract(s). The TOLLWAY will implement, operate and maintain the mainline improvements as tolled facilities (hereinafter sometimes referred to as the "Toll Highway"); and

WHEREAS, because the projects are in such close proximity, strategies for some aspects of environmental mitigation (i.e., water quality enhancements) are being considered collectively by the PARTIES, where feasible and practicable; and

WHEREAS, highway de-icing practices during winter months commonly use de-icing salts to provide for safe vehicular travel and winter maintenance for I-90 and the EOWA will require the use of salts; and

Electronic Filing: Received, Clerk's Office 3/14/2019

WHEREAS, studies acknowledged the potential for the addition of chloride concentrations in area streams and as the I-90 and EOWA projects are advancing to implementation, applications for Section 404 and Section 401 permits have been submitted to the United States Army Corp of Engineers (USACE) and the Illinois Environmental Protection Agency (IEPA); and

WHEREAS, the enhancement of water quality has been the focus of the DRSCW for many years, and the TOLLWAY in an effort to have the "Cleanest and Greenest" program possible is requesting that a partnership be developed between the PARTIES hereto, and a collaboration with permitting agencies, to achieve chloride offsets and reductions to enhance the water quality throughout the DRSCW's water-sheds affected by I-90 and the EOWA; and

WHEREAS, the waterways receiving storm water and snowmelt runoff from the I-90 and EOWA are on the IEPA's Section 303D List of impaired waters and thus require at a minimum no net increase in chlorides as defined in the "Clean Water Act"; and

WHEREAS, this MOU, for recording purposes shall be known as 002013-22, executed in duplicate, and has been prepared to outline the general understanding between the DRSCW and the TOLLWAY with regard to determine and establish their respective responsibilities toward a proposed "Chloride Offset Program" (hereinafter referred to as the "PROGRAM") and also serve as a basis for developing Intergovernmental Agreements with local watershed communities and agencies in the impacted area; and

WHEREAS the PARTIES agree that the entirety of the offset will occur with the impacted areas and be tailored to individual receiving stream segments to the maximum extent possible. As such local watershed communities and agencies participating in the PROGRAM will be responsible for winter operations on the land surfaces that drain to those segments and are herein referred to as "Tier 1 Communities";

NOW, THEREFORE, in consideration of the aforementioned recitals and the mutual covenants contained herein, the PARTIES hereto agree to the following summary of the responsibilities and participation of each PARTY in the implementation of the PROGRAM.

I. GOAL

A. The goal of the PROGRAM is to offset the increased chloride loadings from I-90 and the EOWA by affecting reductions in the use of winter de-icing salts from existing conditions. The TOLLWAY will reduce chloride applications in a quantifiable manner in support of the 401 Water Quality Certification process for I-90 and the EOWA projects and of local municipalities National Pollutant Discharge Elimination System Municipal Separate Storm Sewer System ("NPDES MS4") permit requirements.

Electronic Filing: Received, Clerk's Office 3/14/2019

B. The intent is to establish a partnership between the TOLLWAY and governmental bodies to achieve the chloride loading offset.

C. The partners will endeavor to achieve the offsets in communities straddling and or upstream of the I-90 and EOWA, but the TOLLWAY will expand beyond that area if needed to achieve the offset amounts.

D. Both structural and non-structural practices will comprise the PROGRAM to provide the needed improvements in water quality.

II. STRUCTURAL BEST MANAGEMENT PRACTICES

A. Grass swales, bio-swales, infiltration basins, etc. will be incorporated by TOLLWAY into the I-90 and EOWA projects in order to minimize the effects of roadway runoff and improve the quality of roadway runoff discharged to receiving waters and/or nearby wetlands.

III. NON-STRUCTURAL BEST MANAGEMENT PRACTICES

A. A salt reduction goal will be established by the TOLLWAY and DRSCW for the PROGRAM through further analysis of existing conditions, existing practices in the affected watersheds, and planned highway improvements. Offsets will include the adoption of salt reduction strategies (enhanced training, improved materials use, equipment upgrades), implemented by both the TOLLWAY and the Tier 1 communities. All participants will provide documentation on their salt application rates per lane mile, application totals, calibration logs and details on financial and other support to other mutually agreed upon partners.

B. The TOLLWAY recognizes that meeting the objectives of the Total Maximum Daily Loads ("TMDL's") will require reductions in area chloride loading above those set out in the PROGRAM and agrees to review its practices at an agency wide scale and to actively partner with the DRSCW, its members or successors, in working for PROGRAM area chloride reductions beyond the life of the PROGRAM with the goal of meeting the applicable water quality standard.

IV. TOLLWAY AND DRSCW RESPONSIBILITIES

A. Both PARTIES agree that the requirements embodied in Clean Water Act Section 401 certification(s) or Section 404 or NPDES permit(s), are the sole responsibility of the TOLLWAY, and that the DRSCW or participating agencies cannot be held liable in any way for failure to comply with such requirements.

B. The DRSCW will endeavor to unify stakeholders in the project areas with the common goal of improving chloride water quality. It is recognized that participating communities are voluntary agents and neither they nor the DRSCW can be held liable in any way for failure to collaborate in the plan.

Electronic Filing: Received, Clerk's Office 3/14/2019

C. The DRSCW will determine the baseline conditions through appropriate studies with stakeholders and other environmental evaluation which shall include sampling and analyses, as well as flow evaluation.

D. The DRSCW will determine the opportunities for improving de-icing practices through surveys and interviews with stakeholders.

E. The DRSCW and the TOLLWAY will set priorities, tracking offset progress, and the timeframe for achievement with concurrence from the IEPA.

F. The TOLLWAY will provide ongoing financial assistance supporting capital investments of alternative de-icing methods potentially for municipalities and agencies that are participating in the PROGRAM until such time as the PROGRAM objectives are met.

G. The TOLLWAY with the DRSCW's technical assistance will establish training and certifications for operators that would enhance awareness of best practices for snow and ice management operations.

H. The TOLLWAY with the DRSCW will establish data sites/sources for weather data and other information helpful in managing roadway de-icing.

I. The DRSCW with the support of the TOLLWAY will conduct long term monitoring that records salt usage and stream conditions. Evaluation of future operating conditions will be compared to baseline conditions.

J. The TOLLWAY and the DRSCW will report annually by July 1st to the IEPA the resulting efforts and success of the PROGRAM on an annual basis beginning in July of 2014. Success will be measured primarily by the application rate and totals reported with consideration given to the ambient monitoring system.

K. The TOLLWAY and the DRSCW will collaborate to put in place an ambient monitoring system that will be part of the PROGRAM monitoring and evaluation, and will document pre and post PROGRAM chloride conditions in the receiving streams. A monitoring plan will be developed through input from both PARTIES with the intent of conducting stream monitoring on Addison Creek, Salt Creek mainstem, Spring Brook, Meacham Creek and West Branch mainstem. The pre and post conditions will be synthesized in a report and submitted to IEPA on an annual basis along with other reporting data. The system would assist in evaluating the success of the PROGRAM in meeting the TMLD's goals and will be funded wholly by the TOLLWAY.

L. The PARTIES agree that the PROGRAM may require several years of monitoring and reporting from PROGRAM partners.

Electronic Filing: Received, Clerk's Office 3/14/2019

M. The PARTIES will develop and maintain a guidance document for the PROGRAM which will at minimum detail the methods for calculating the build scenario non-PROGRAM increase, the needed offset, BMP's the monitoring PROGRAM and reporting baseline requirements. The document will be updated by agreement between the PARTIES as the PROGRAM advances.

V. INTERGOVERNMENTAL AGREEMENTS

A. The TOLLWAY shall use its best efforts to enter into Intergovernmental Agreements prepared by the TOLLWAY and Tier 1 communities based upon this MOU to further determine and establish respective responsibilities toward financial partnerships, information sharing, and training.

B. These Intergovernmental Agreements shall not relieve the TOLLWAY of their responsibility to comply with the "Clean Water Act" as determined and enforced by the IEPA.

VI. FINANCIAL

A. The TOLLWAY will support financial partnerships through an Intergovernmental Agreement requiring cost sharing with a local partner as defined by the PROGRAM.

B. Project requests to the TOLLWAY will be subject to DRSCW and TOLLWAY approvals, to cost effectively promote salt usage reduction.

VII. TERMS OF THE MOU

A. The term of this MOU shall extend until such time that the PROGRAM offset has been achieved reductions have been demonstrated for a minimum of three (3) years. Either PARTY shall have the right to terminate this MOU at any time by providing at least ninety (90) days written notice to the other party in the event either PARTY breaches the terms and conditions of this MOU. At the end of the agreement period this document may be renewed by the mutual consent of the PARTIES.

(This space intentionally left blank)

Electronic Filing: Received, Clerk's Office 3/14/2019

IN WITNESS THEREOF, the PARTIES have entered into this MOU as of the date written below.

> On behalf of Prairie Rivers Network, Sierra Club and Southern Illinoisans Against Fracturing Our Environment, attached are post-hearing comments regarding the proposed NPDES Permit IL0077666 for the Pond Creek mine. As these comments will explain, the proposed permit plainly cannot be legally granted by the Illinois Environmental Protection Agency (IEPA) based on the current record. Please do not hesitate to reach out to us for further clarification.

1. INTRODUCTION AND BACKGROUND 1-1

2. PROBLEM FORMULATION 2-1
   2.1. PROBLEM IDENTIFICATION 2-1
   2.2. STRESSOR OF CONCERN—SALTS 2-2
      2.2.1. Sources of Ions 2-3
      2.2.2. Conceptual Model 2-8
      2.2.3. Environmental Transport and Fate of Ions in the Aquatic Environment 2-9
   2.3. MEASURE OF EXPOSURE 2-11
   2.4. NATURE OF THE EFFECT 2-13
   2.5. MECHANISMS AND MODES OF ACTION 2-16
      2.5.1. Physiological Mechanisms 2-17
      2.5.2. Mortality, Growth, and Reproduction 2-19
      2.5.3. Emigration 2-19
      2.5.4. Failure to Recruit 2-19
      2.5.5. Community Interactions 2-20
   2.6. ASSESSMENT ENDPOINTS AND MEASURES OF EFFECT 2-20
      2.6.1. Assessment Endpoints 2-20
      2.6.2. Measures of Effect 2-22
   2.7. SELECTION OF A FIELD-BASED METHOD 2-25

3. ANALYSIS PLAN: FIELD-BASED METHODS TO DEVELOP SPECIFIC CONDUCTIVITY CRITERIA 3-1
   3.1. DERIVING A CRITERION CONTINUOUS CONCENTRATION (CCC) 3-1
      3.1.1. Establishing the Data Set 3-4
         3.1.1.1. Information Sources 3-4
         3.1.1.2. Selection and Adequacy of Data Sets 3-5
         3.1.1.3. Quality Assurance/Quality Control (QA/QC) 3-10
      3.1.2. Calculating Genus Extirpation Concentrations (XC_{95}) 3-11
         3.1.2.1. Assigning Qualifying Designation to Extirpation Concentration (XC_{95}) Values 3-14
      3.1.3. Calculating the Community-Level Effect Estimate Hazardous Concentration (HC_{05}) 3-15
         3.1.3.1. Validating the Effect Estimate Hazardous Concentration (HC_{05}) by Bootstrapping 3-16

CONTENTS (continued)

3.1.4. Assessing Seasonality, Life History, and Sampling Methods 3-18
3.2. DERIVING A CRITERION MAXIMUM EXPOSURE CONCENTRATION (CMEC) 3-20
3.3. ESTIMATION OF CRITERIA DURATION 3-22
3.3.1. Summary of Recommended Duration for Criterion Continuous Concentration (CCC) and Criterion Maximum Exposure Concentration (CMEC) 3-25
3.4. ESTIMATION OF CRITERIA FREQUENCY 3-25
3.4.1. Recovery Rates in Literature Reviews 3-27
3.4.2. Life History Considerations 3-29
3.4.3. Summary for Field-Based Frequency for Criterion Continuous Concentration (CCC) and Criterion Maximum Exposure Concentration (CMEC) 3-30
3.5. ASSESSING CAUSATION 3-30
3.6. ASSESSING WATERBODY APPLICABILITY 3-32
3.6.1. Stream pH 3-32
3.6.2. Waterbody Type 3-32
3.7. METHODS FOR APPLICATIONS TO NEW AREAS 3-35
3.7.1. Application within an Ecoregion—Background Matching 3-36
3.7.1.1. Obtaining a Data Set 3-40
3.7.1.2. Estimating Background Specific Conductivity (SC) 3-40
3.7.1.3. Background-Matching Approach 3-41
3.7.1.4. Options When Background in New Area is Different than in Original Area 3-42
3.7.1.5. Summary of Background Matching Method 3-42
3.7.2. Developing a Criterion Using Background-to-Criterion Regression Method 3-43
3.7.2.1. Using Background to Calculate a Hazardous Concentration of the 5th centile (HC_{05}) of a Taxonomic Extirpation Concentration Distribution (XCD) 3-46
3.7.2.2. Formula for Calculating the Hazardous Concentration of the 5th centile of a Taxonomic Extirpation Concentration Distribution (HC_{05}) from the Background-to-Criterion Model 3-48
3.7.2.3. Formula for Calculating the Lower and Upper 10% Prediction Limits 3-48
3.7.2.4. Criterion Continuous Concentration (CCC) with <200 Paired Biological Data 3-50
3.7.2.5. Criterion Continuous Concentration (CCC) with 200 to 500 Paired Biological Data 3-50
3.7.2.6. Calculation of the Criterion Maximum Exposure Concentration (CMEC) 3-50
3.7.2.7. Summary 3-50

CONTENTS (continued)

4. CASE STUDY I: EXAMPLE USING EXTIRPATION CONCENTRATION DISTRIBUTION (XCD) METHOD IN A LOW BACKGROUND SPECIFIC CONDUCTIVITY ECOREGION 4-1
4.1. DATA SET CHARACTERISTICS 4-1
4.1.1. Background Specific Conductivity 4-6
4.1.2. Ionic Composition 4-9
4.1.3. Seasonal Specific Conductivity Regime 4-11
4.2. RESULTS 4-12
4.2.1. Extirpation Concentration (XC_{95}) and Hazardous Concentration (HC_{05}) Values (Example Criterion Continuous Concentration [CCC]) 4-12
4.2.2. Example Criterion Maximum Exposure Concentration 4-15
4.3. GEOGRAPHIC APPLICABILITY 4-17
4.3.1. Data Sources 4-18
4.3.2. Geographic Applicability Results 4-20
4.4. SUMMARY OF EXAMPLE CRITERIA FOR ECOREGION 69 4-22
4.5. EXAMPLE CRITERION CHARACTERIZATION 4-23
4.5.1. Factors Potentially Affecting the Extirpation Concentration Distribution (XCD) Model 4-23
4.5.1.1. Sensitivity Analyses 4-23
4.5.2. Validation of the Extirpation Concentration Distribution (XCD) Model 4-25
4.5.3. Duration and Frequency 4-26
4.6. PROTECTION OF FEDERALLY-LISTED SPECIES 4-27

5. CASE STUDY II: EXAMPLE USING THE EXTIRPATION CONCENTRATION DISTRIBUTION (XCD) METHOD IN A MODERATE BACKGROUND SPECIFIC CONDUCTIVITY ECOREGION 5-1
5.1. DATA SET CHARACTERISTICS 5-1
5.1.1. Background Specific Conductivity 5-6
5.1.2. Ionic Composition 5-9
5.1.3. Seasonal Specific Conductivity Regime 5-10
5.2. RESULTS 5-12
5.2.1. Extirpation Concentration (XC_{95}) and Hazardous Concentration (HC_{05}) Values (Example Criterion Continuous Concentration) 5-12
5.2.2. Example Criterion Maximum Exposure Concentration 5-15
5.3. GEOGRAPHIC APPLICABILITY 5-17
5.3.1. Data Sources 5-18
5.3.2. Geographic Applicability Results 5-20
5.4. SUMMARY OF EXAMPLE CRITERIA FOR ECOREGION 70 5-22
5.5. EXAMPLE CRITERION CHARACTERIZATION 5-22
5.5.1. Factors Potentially Affecting the Extirpation Concentration Distribution (XCD) Model 5-22
5.5.1.1. Sensitivity Analyses 5-22
5.5.2. Validation of the Model 5-24

CONTENTS (continued)

5.5.3. Duration and Frequency 5-25
5.6. PROTECTION OF FEDERALLY-LISTED SPECIES 5-26

6. CASE STUDY III: EXAMPLE USING THE BACKGROUND TO CRITERION (B-C) REGRESSION METHOD 6-1
6.1. DATA SET CHARACTERISTICS 6-1
6.1.1. EPA-Survey Data Set 6-3
6.1.2. U.S. Geological Survey (USGS) Data Set 6-5
6.1.3. Modeled Mean Baseflow Background Specific Conductivity (SC) 6-8
6.1.4. Characterization of Ionic Matrices 6-8
6.1.4.1. EPA-Survey Data Set Ionic Characteristics 6-8
6.1.4.2. U.S. Geological Survey (USGS) Data Set Ionic Characteristics 6-9
6.1.5. Comparison of Background Specific Conductivity (SC) Estimates 6-9
6.1.6. Calculation of Ecoregion 43 Criterion Continuous Concentration (CCC) from Background 6-11
6.1.7. Formula for Calculating the Lower 50% Prediction Limit 6-13
6.1.8. Example Criterion Maximum Exposure Concentration 6-15
6.2. EXAMPLE CRITERION CHARACTERIZATION FOR ECOREGION 43 BASED ON A BACKGROUND-TO-CRITERION MODEL 6-17
6.3. PROTECTION OF FEDERALLY-LISTED SPECIES AND OTHER HIGHLY VALUED TAXA 6-18

7. CASE STUDY IV: EXAMPLE USING THE BACKGROUND TO CRITERION (B-C) REGRESSION METHOD FOR A REGION WITH LOW CONDUCTIVITY 7-1
7.1. DATA SET CHARACTERISTICS 7-1
7.1.1. Ecoregion Description 7-1
7.1.2. General Data Set Description 7-2
7.1.3. EPA-Survey Data Set 7-4
7.1.4. State Data Set (EPA Region 10) 7-6
7.1.5. U.S. Geological Survey (USGS) Data Set 7-7
7.1.6. Modeled Mean Base Flow Background Specific Conductivity (SC) 7-9
7.1.7. Characterization of Ionic Matrices 7-11
7.1.7.1. EPA-Survey Data Set Ionic Characteristics 7-11
7.1.7.2. State Data Set Ionic Characteristics 7-11
7.1.7.3. U.S. Geological Survey (USGS) Data Set Ionic Characteristics 7-11
7.1.8. Comparison of Background Specific Conductivity (SC) Estimates 7-12
7.2. Calculation of the Criterion CONTINUOUS Concentration (CCC) 7-14
7.2.1. Calculation of the Ecoregion 4 mean Hazardous Concentration (HC_{05}) from Background 7-14
7.2.2. Calculation of the Lower 50% Prediction Limit 7-16
7.2.3. Example Criterion Maximum Exposure Concentration 7-18

LIST OF TABLES

2-1. Examples of ions associated with different anthropogenic sources 2-7

2-2. Comparison of methods to measure ionic concentration 2-12

2-3. Summary of assessment endpoints and measures of effect used in this field-based method to derive a criterion continuous concentration (CCC) and criterion maximum exposure concentration (CMEC) for specific conductivity 2-24

4-1. Summary statistics of the measured water-quality parameters used to derive the example specific conductivity criteria in Ecoregion 69 4-5

4-2. Number of samples with reported genera and specific conductivity meeting acceptance criteria for the Ecoregion 69 analysis 4-12

4-3. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 69 4-16

4-4. Description of survey data sets combined to form the EPA-survey data set used to assess applicability of the example ecoregional criteria throughout Ecoregion 69 4-19

4-5. Summary of water quality parameters for Ecoregion 69 from the EPA-survey data set excluding the sites in West Virginia 4-21

4-6. Background specific conductivity estimates for Ecoregion 69 4-22

5-1. Summary statistics of the measured water-quality parameters used to derive the example specific conductivity criteria in Ecoregion 70 5-5

5-2. Number of samples with reported genera and specific conductivity meeting data-inclusion acceptance criteria for the Ecoregion 70 analysis 5-12

5-3. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 70 5-16

5-4. Description of survey data sets combined to form the EPA-survey data set used to assess applicability of example ecoregional criteria throughout Ecoregion 70 5-19

5-5. Summary of water quality parameters for Ecoregion 70 EPA-survey data set 5-21

5-6. Background specific conductivity estimates for Ecoregion 70 5-21

6-1. EPA and U.S. Geological Survey (USGS) chemistry data sets included in this study 6-2

6-2. Summary of data for the example case for Northwestern Great Plains, Level III Ecoregion 43 from EPA-survey samples 6-5

LIST OF TABLES (continued)

6-3. Summary of data for the example case for Northwestern Great, Level III Ecoregion 43 from U.S. Geological Survey (USGS). 6-7

6-4. Summary of data for the example case for Northwestern Great Plains, Level III Ecoregion 43 from the combined EPA-survey and U.S. Geological Survey (USGS) data set..... 6-11

6-5. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 43 6-17

7-1. EPA and U.S. Geological Survey (USGS) chemistry data sets included in this study..... 7-3

7-2. Summary of data for the example case for Cascades, Level III Ecoregion 4, from EPA-survey samples. 7-4

7-3. Summary of data for the example case for Cascades, Level III Ecoregion 4 from State Data from Oregon and Washington. 7-7

7-4. Summary of data for the example case for Cascades, Level III Ecoregion 4 from the U.S. Geological Survey (USGS)..... 7-9

7-5. Summary of data for the example case for Cascades, Level III Ecoregion 4 from the combined data set..... 7-14

7-6. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 4 7-19

LIST OF FIGURES

2-1. Conceptual model showing hypothesized relationships among selected sources of ions and biotic responses to ionic stress by salt intolerant taxa (adapted from Schofield and Ziegler, 2010)..... 2-9

2-2. A species' (or genus') realized niche is defined by its lower and upper limits of occurrence..... 2-15

3-1. Example of a genus extirpation concentration distribution (XCD) depicting the proportion of genera extirpated with increasing ionic concentration measured as specific conductivity (SC)..... 3-2

3-2. Main steps in the derivation of a chronic specific conductivity (SC) criterion using the extirpation concentration distribution (XCD) method..... 3-4

3-3. Examples of weighted cumulative distribution functions (CDFs) and the associated 95th centile extirpation concentration values..... 3-13

3-4. Examples of extirpation concentration (XC_{95}s) for three genera listed as being definitive (*Neophylax*), approximate (*Amphinemura*), and greater than (*Cambarus*)..... 3-14

3-5. Diagram from *EPA Benchmark Report* depicting the process for estimating uncertainty..... 3-17

3-6. Main steps in the derivation of a criterion maximum exposure concentration (CMEC) based on field water chemistry data..... 3-21

3-7. Typical specific conductivity (SC) pattern of a stream with annual mean SC well below 310 µS/cm..... 3-24

3-8. Correlation of specific conductivity and drainage area up to 17,986 km^2, Spearman's $r = 0.25$..... 3-35

3-9. Method for selecting a criterion continuous concentration (CCC) for a new area within an ecoregion using minimally affected background..... 3-39

3-10. Empirical model of the 5th centile of a hazardous concentration (HC_{05}) and background specific conductivity (SC) estimated at the 25th centile for 23 distinct ecoregions (24 data sets)..... 3-44

3-11. A decision tree for calculating and applying a hazardous concentration of the 5th centile of a hazardous concentration (HC_{05})..... 3-47

4-1. Ecoregion 69 extends from central Pennsylvania to northern Tennessee..... 4-4

LIST OF FIGURES (continued)

4-2. Box plot showing seasonal variation of specific conductivity (µS/cm) from probability-sampled sites from Watershed Assessment Branch database (WABbase) 1997–2010. 4-7

4-3. Box plot showing seasonal variation of specific conductivity (µS/cm) in the reference streams from Watershed Assessment Branch database (WABbase) 1997–2010. 4-8

4-4. Box plot showing seasonal variation of specific conductivity (µS/cm) from all Ecoregion 69 sites from Watershed Assessment Branch database (WABbase) 1997–2010 used to develop the example criteria. 4-9

4-5. Scatter plot of relationship between $[Cl^-]$ and $([HCO_3^-] + [SO_4^{2-}])$ concentrations in streams in Ecoregion 69 data set from 1997–2010 with ionic measurements..... 4-11

4-6. Histograms of the frequencies of observed specific conductivity values in samples from Ecoregion 69 sampled between 1997 and 2010. 4-13

4-7. Example genus extirpation concentration distribution (XCD) for Ecoregion 69. 4-14

4-8. The lower end of the example genus extirpation concentration distribution for Ecoregion 69. 4-15

4-9. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station mean) in Ecoregion 69..... 4-17

4-10. Ecoregion 69 extends from central Pennsylvania to northern Tennessee..... 4-20

4-11. Relationship of the number of occurrences of a genus and the hazardous concentration (HC_{05}) based on Ecoregion 69 example Criterion-data set. 4-24

4-12. The effect of the size of the data set used to model the hazardous concentration (HC_{05}) based on the Ecoregion 69 example Criterion-data set..... 4-25

4-13. Cumulative distribution of the extirpation concentration (XC_{95}) values for the 25% most salt-intolerant genera and 95% confidence intervals based on 1,000 extirpation concentration distribution (XCD) bootstrapping results. 4-26

5-1. Ecoregion 70 extends from central Pennsylvania to northern Tennessee..... 5-4

5-2. Box plot showing seasonal variation of specific conductivity (µS/cm) from probability sites from Watershed Assessment Branch database (WABbase) 1997–2010. 5-7

5-3. Box plot showing seasonal variation of specific conductivity (µS/cm) in the reference streams of Ecoregions 70 from 1997 to 2010. 5-8

LIST OF FIGURES (continued)

5-4. Box plot showing seasonal variation of specific conductivity (µS/cm) from all Ecoregion 70 sites from Watershed Assessment Branch database (WABbase) 1997–2010 used to develop the example criteria. 5-9

5-5. Scatter plot of relationship between [Cl^-] and ([HCO_3^-] + [SO_4^{2-}]) concentrations in streams of Ecoregion 70 data set. 5-11

5-6. Histograms of the frequencies of observed specific conductivity values in samples from Ecoregion 70 sampled between 1997 and 2010. 5-13

5-7. Example genus extirpation concentration distribution (XCD) for Ecoregion 70. 5-14

5-8. The lower end of the example genus extirpation concentration distribution for Ecoregion 70. 5-15

5-9. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station mean) in Ecoregion 70. 5-17

5-10. Ecoregion 70 extends from southwestern Pennsylvania and southeastern Ohio into Kentucky. 5-19

5-11. Relationship of the number of occurrences of a genus on the hazardous concentration (HC_{05}) based on Ecoregion 70 example Criterion-data set. 5-23

5-12. Adequacy of the size of the data set used to model the hazardous concentration (HC_{05}) based on the Ecoregion 70 example Criterion-data set. 5-24

5-13. 95% confidence intervals (hatched oblique lines) for the lower portion of the Ecoregion 70 genus extirpation concentration distribution (XCD). 5-25

6-1. Sampling sites in the EPA-survey data set that were used to estimate minimally affected background in Ecoregion 43. 6-4

6-2. Sampling sites in the U.S. Geological Survey (USGS) data set in Ecoregion 43 6-6

6-3. Predicted mean natural base-flow specific conductivity in catchments of Northwestern Great Plains, Ecoregion 43, using the Olson-Hawkins model. 6-8

6-4. Box plots of specific conductivity (SC) distributions for EPA-survey, U.S. Geological Survey (USGS), combined EPA-survey and USGS data sets and predicted mean base-flow. 6-10

6-5. Process and decision path case example for Ecoregion 43. 6-13

6-6. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station mean) in Ecoregion 43. 6-16

LIST OF FIGURES (continued)

7-1. Sampling sites in the EPA survey data set that were used to estimate minimally affected background in Ecoregion 4. 7-5

7-2. Sampling sites in State data set that were used to estimate minimally affected background in Ecoregion 4. 7-6

7-3. Sampling sites in the U.S. Geological Survey (USGS) data set in Ecoregion 4..... 7-8

7-4. Predicted mean natural base-flow specific conductivity in catchments of the Cascades, Ecoregion 4, using the Olson-Hawkins model..... 7-10

7-5. Box plots of specific conductivity (SC) distributions for EPA-survey, State, U.S. Geological Survey (USGS), and combined data sets, and the predicted base flow SC for all stream segments. 7-13

7-6. Process and decision path case example for Ecoregion 4..... 7-15

7-7. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station means) in Ecoregion 4. 7-19

XCD	extirpation concentration distribution

NOTICES

This public review draft document has undergone two contractor-led external peer reviews as well as a review process within the U.S. Environmental Protection Agency (EPA). Final review by EPA's Office of Science and Technology, Health and Ecological Criteria Division, has been completed and the document has been approved for publication.

This document provides draft methods to assist states and tribes in the development of water quality criteria and other tools to protect aquatic life from effects of elevated ionic concentration as measured by specific conductivity (SC)[1] in flowing waters. States and tribes planning to develop water quality criteria for SC may consider using alternative, scientifically defensible methods. While this document reflects EPA's assessment of the best available science for identifying ambient concentrations of SC in flowing waters that protect aquatic life, it is not a regulation and does not impose legally binding requirements on EPA, states, tribes, or the regulated community, and might not apply to a particular situation based upon the circumstances. EPA may change this document in the future.

Mention of trade names or commercial products does not constitute endorsement or recommendation for use. This document can be downloaded from: https://www.epa.gov/wqc/aquatic-life-ambient-water-quality-criteria.

Cover Photo:

[1]This document uses conductivity as a measure of ionic concentration rather than as description of an electrical property of water. As ionic concentration increases, conductivity increases. The terms specific conductivity and specific conductance are often used synonymously in the open literature indicating normalization or measurement at 25°C. Conductivity is a property of water expressed in units of micro-Siemens per centimeter (µS/cm). Conductance of a sample or electrical component is measured as Siemens (S). All measurements in this document refer to specific conductivity, µS/cm at 25°C.

FOREWORD

This document, *Draft Field-based Methods for Developing Aquatic Life Criteria for Specific Conductivity,* provides states and tribes with methods that may be used to develop criteria to protect aquatic life from effects of elevated ionic concentration as measured by specific conductivity (SC) in flowing waters. The EPA tailored these methods to enable derivation of specific conductivity criteria on the scale of Level III ecoregions (Omernik, 1995, 1987) in order to account for natural differences in background ionic concentrations among ecoregions. There are 85 Level III ecoregions in the contiguous United States. Each of the states in the contiguous United States contains 1 to 12 Level III ecoregions within their political boundaries. The EPA is also providing several case studies to illustrate how these draft methods may be applied to different ecoregions with varying background ionic concentrations. The EPA may change the field-based methods and/or provide additional case studies in the future as new scientific information becomes available.

This document is nonregulatory and provides only a scientific assessment of ecological effects. It does not establish or affect legal rights or obligations. It does not establish a binding norm and cannot be finally determinative of the issues addressed. Agency decisions in any particular situation will be made by applying the Clean Water Act and EPA regulations on the basis of specific facts presented and scientific information then available.

EXECUTIVE SUMMARY

This document describes draft methods that states and tribes may use to derive field-based ecoregional ambient aquatic life criteria for specific conductivity (SC), a measurement of the concentration of ions, in flowing waters. The document also provides four case studies to illustrate how these draft field-based methods may be used to develop criteria in ecoregions with different background ionic concentrations measured as SC and to demonstrate how to assess the applicability of criteria developed for one ecoregion to a different ecoregion. The case studies use field data to demonstrate how to apply the methods described in this document to derive example criteria for SC for flowing waters dominated by calcium, magnesium, sulfate, and bicarbonate ions but not for flowing waters dominated by chloride salts. Elevated ionic concentration measured as SC has been shown to impact aquatic life in a range of freshwater resources. Different mixtures of ions that increase SC are associated with multiple anthropogenic sources, including discharges from wastewater treatment facilities, groundwater recharge affected by climate change, surface mining, oil and gas exploration, runoff from urban areas, and discharges of agricultural irrigation return waters, among others.

The EPA relied on its *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses* (1985) (EPA/822/R-85/100) and *A Field-Based Aquatic Life Benchmark for Conductivity in Central Appalachian Streams* (hereafter referred to as the "*EPA Benchmark Report*") (EPA/600/R-10/023F), among other documents, to develop the draft field-based method for SC. In the *EPA Benchmark Report*, EPA used a field data set to estimate a numeric SC benchmark for Appalachian streams. The EPA validated the method and the benchmark using an independent data set. In 2011, internal and external reviewers, including EPA's Science Advisory Board (SAB) (U.S. EPA, 2011c), favorably reviewed the analyses and method. This current document uses that same method to estimate a protective criterion continuous concentration (CCC) for chronic (long-term) exposures as well as additional methods to estimate a maximum exposure concentration protective of acute toxicity. This document also provides recommendations for SC criterion duration and frequency.

The EPA typically relies on laboratory toxicity test data for surrogate species as defined in the Agency's *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses* (U.S. EPA, 1985) for aquatic life criteria

development. The draft field-based methods used here were adapted to be consistent with the intent of the Agency's traditional approach to derive aquatic life criteria (U.S. EPA, 1985). The draft field-based methods rely on geographically referenced, paired observations of SC and the presence and absence or abundance of freshwater benthic macroinvertebrate genera from wadeable perennial streams. The case studies that are included to illustrate the method are based on more than 4,000 paired biological (macroinvertebrate) and chemical (SC) field samples from more than 3,000 stations over a 15-year period (1996–2010). An analysis of data for fish from a composite of case study ecoregions demonstrates that the example criteria based on macroinvertebrates are also protective of fish.

For this draft field-based method, the valued resource is the aquatic community. The ecological entities defining the assessment endpoints are macroinvertebrate genera and the measure of effect is extirpation, or effective absence of such genera from a site (the desired attribute is occurrence). Two relationships are derived: one for each macroinvertebrate genus and one for the overall aquatic community. First, a weighted cumulative distribution function (CDF) is developed for each genus to determine the genus extirpation concentration (XC_{95} or 95th centile of the distribution of the occurrences of a genus), the level of exposure above which a macroinvertebrate genus is effectively absent from water bodies in a region or other study area (U.S. EPA, 2011a, 2003). That is, the probability is 0.05 that an observation of a genus would occur above its XC_{95} SC value. Second, the HC_{05} (hazard concentration 5th centile) is developed using a genus-level extirpation concentration distribution (XCD) for the community from the aggregation of the XC_{95} values. This effect threshold is consistent with the intent of EPA's guidelines for aquatic life criteria development (U.S. EPA, 1985), which are designed to protect aquatic animal species (i.e., 95%) in a community.

The HC_{05} is a chronic-duration endpoint and used for derivation of a CCC because it is derived from biological field data that include exposure over whole life cycles and multiple generations of the resident biota. A criterion maximum exposure concentration (CMEC), a level of protection from acutely toxic exposures, is also derived based on stream water chemistry data. The CMEC is estimated at the 90th centile of observations at sites with water chemistry regimes meeting the CCC. The CMEC is the maximum SC level that may occur for a short duration and be protective of 95% of macroinvertebrate genera. Both of these distinct expressions of the example SC criteria would need to be met in order to adequately protect aquatic life.

The type of model used in this draft method, a genus-level XCD, describes how genera in biotic communities in general respond to a stressor (e.g., an ionic mixture dominated by sulfate and bicarbonate salts). This method is based on a distribution of extirpation concentrations and is called the XCD method to distinguish it from other field-based methods. Like the surrogate aquatic taxa that form the minimum data set for laboratory-based aquatic life criteria, the macroinvertebrate taxa included in the case studies are surrogate taxa that represent a potentially exposed aquatic community (U.S. EPA, 1985).

GLOSSARY

Assessment endpoint—An explicit expression of the actual environmental value that is to be protected, operationally defined by an ecological entity and its attribute or characteristics. An assessment endpoint may be identified at any level of organization (e.g., organism, population, community).

Assemblage, stream—A taxonomic or sampled subset of a community as may be collected from a stream.

Background specific conductivity—The specific conductivity (SC) in streams in a region that occurs naturally and not as the result of human activity. Background may also be characterized as a population of minimally affected sites or low SC sites using a weight of evidence.

Benchmark—A dose or concentration of a pollutant that, if exceeded, is expected to produce an adverse effect (called the benchmark response) in one or more assessment endpoints, signifying a decline in water quality or human health.

Bootstrapping—A statistical technique of repeated random sampling from a data set that is often used in environmental studies to estimate confidence and prediction limits of a parameter.

Box plot—A depiction of the 25th, 50th, and 75th quantiles of a distribution as a rectangle with a central line. The two standard deviation range is depicted as "whiskers" extending from the box. Data beyond two standard deviations are indicated by individual circles or dots beyond the whiskers.

Catchment area—The spatial extent of the surrounding landscape that drains into a particular river, stream, or other waterbody.

Chorionic covering—The outermost casing or membranous covering of the egg of various invertebrates.

Community—The full complement of interacting organisms within a defined area of an ecosystem.

Conductivity, specific (or specific electrical conductivity)—A measure of ionic concentration based on the electrical property of water and dissolved ions. As ionic concentration increases, conductivity increases. Standardized measurements in this document refer to specific conductivity, µS/cm (also seen as: µmho/cm) at 25°C.

Conductance, specific—Conductance is the inverse of resistance for a particular sample expressed as Seimens (S) usually at 25°C. In the literature, it is sometimes used synonymously with specific conductivity, but to avoid confusion, the term conductance is not used in this document.

Confounder—An extraneous variable that correlates with both the dependent and independent variable. The presence of confounders can interfere with the ability to characterize a causal relationship.

Criterion continuous concentration (CCC)—An estimate of the highest concentration of a material in surface water to which an aquatic community can be exposed indefinitely without resulting in an unacceptable effect.

Criterion maximum exposure concentration (CMEC)—An estimate of the maximum concentration of a material in surface water to which an aquatic community can be exposed for a short time without resulting in an unacceptable effect. In this document, the CMEC is estimated at the 90th centile of specific conductivity observations that contribute to the annual CCC.

Cumulative distribution function (CDF)—The probabilities that a random variable with a given probability distribution will be found at a value less than or equal to x. Weighted CDFs are used to estimate extirpation concentrations of individual genera or species and unweighted CDFs to estimate a SC level that is expected to extirpate 5% of aquatic invertebrate genera.

Ephemeral stream—A stream that flows briefly only in direct response to local precipitation, and whose channel is above the local groundwater table at all times.

Extirpation—The depletion of a population of a species or genus to the point that it is no longer a viable resource or is unlikely to fulfill its function in the ecosystem.

Extirpation concentration—The level above which a genus is effectively absent from its normal habitat. The threshold for extirpation is operationally defined by the level below which 95% of the observations of the genus occur.

Extrapolation—The process of extending the applicability of a model beyond the measured range of the original data set from which the model was derived.

Flowing waters—Inland waters with a unidirectional flow including permanent, intermittent and ephemeral streams.

Generalized additive model—A nonparametric, likelihood-based local regression model that replaces the linear function of a generalized linear model with a locally smoothed additive function.

Hazardous concentration—A concentration threshold that is hazardous for a proportion of taxa. In this document, it is the concentration that is hazardous to 5% of genera calculated as the 5^{th} centile of a taxonomic extirpation concentration distribution.

Intermittent stream—A stream that flows continuously for only part of the time. During low flow there may be dry reaches alternating with wetted, nonflowing reaches. The stream bed may lie below the local groundwater table for at least part of the year.

Interpolate—Process of estimating an unknown value that lies between known values.

Ionic composition—The specific ions dissolved in water. In this document, the ionic composition is used to distinguish water dominated by chloride salts from those dominated by bicarbonate and sulfate salts.

Ionic mixture—An undefined or defined blend of dissolved ions. In this document, the example case studies refer to the most common mixture of ions contaminating U.S. streams, specifically those dominated by calcium, magnesium, sulfate, and bicarbonate ions.

Ionic regulation—The passive and active physiological processes that maintain the ionic composition, pH, and water content of tissues that is necessary for life.

Least disturbed condition—the best available physical, chemical, and biological habitat conditions given today's state of the landscape or the least disturbed by human activities (Stoddard et al., 2006). Contrast with "minimally affected condition."

Major ions—The most common contributors to ionic concentration in surface waters, consisting of the following cations: Ca^{2+}, Mg^{2+}, Na^{+}, K^{+}; and anions: HCO_3^{-}, CO_3^{2-}, SO_4^{2-}, Cl^{-}.

Measure of effect—A measurable ecological characteristic that is related to the valued characteristic chosen as the assessment endpoint and is a measure of biological effects (e.g., survival, reproduction, growth). In this document it is the presence/absence of macroinvertebrate genera along a specific conductivity gradient.

Measure of exposure—A measured or estimated characteristic that is used to characterize the level of exposure to the stressor. In this document, the measure of ionic exposure is specific conductivity.

Minimally affected condition—The physical, chemical, and biological habitat found in the absence of significant human disturbance (Stoddard et al., 2006). Contrast with "least disturbed condition."

Osmoregulation—The physiological control of water content of an organism's tissues to maintain fluid and electrolyte balance within a cell or organism relative to the surrounding environment.

Perennial stream—A stream with continuous surface or shallow interstitial flow year-round, and whose stream bed intersects the local groundwater table throughout the year. Also referred to as a permanent stream.

Produced water—Waters that are produced by oil and gas development, mine dewatering, and related activities (e.g., coal bed methane mining, hydraulic fracturing).

Reference site—Sampling locations that have been identified as minimally affected or least disturbed based on land use, habitat, and water quality characteristics other than specific conductivity.

Salinity—The amount of salts dissolved in water. Traditionally expressed as parts per thousand (‰) or grams of salt per kilogram of water.

Sensitivity analysis—A process that involves changing input values of a model in various ways to see the effect on the output value. The main goal of sensitivity analysis is to gain insight into which assumptions are most critical for model building.

Total dissolved solids (TDS)—A measure of the combined content of all inorganic and organic substances dissolved in water, conventionally expressed as mg/L and operationally defined as those solids that pass through a filter, typically 0.45 μm.

Univoltine—An organism having one brood or generation per year.

Validation—Confirmation of the quality of a model and its results, typically by applying an independent data set.

Valley fill—A headwater valley filled with mining overburden. This practice usually occurs in steep terrain where there are limited disposal alternatives.

Verification—Demonstrating the accuracy of measurements or calculations.

1. INTRODUCTION AND BACKGROUND
