This document describes a set of draft methods that states and authorized tribes may use to derive field-based ecoregional ambient aquatic life criteria for ionic mixtures measured as specific conductivity (SC), a measurement of ionic concentration. Four case studies illustrate how these draft methods may be applied to develop such criteria in different ecoregions with different background SC and data sets. The case studies illustrate how these methods may be used to develop criteria applicable to flowing waters dominated by sulfate and bicarbonate salts. Chloride constitutes less than half of the total anions in the case examples. Although the methods may be appropriate for use with other ionic mixtures, the example criteria generally are not appropriate for waters with different ionic compositions (e.g., waters dominated primarily by sodium chloride).

Among the documents the U.S. Environmental Protection Agency (EPA) relied upon to develop the draft field-based method for SC are EPA's *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses* (U.S. EPA, 1985) and *A Field-Based Aquatic Life Benchmark for Conductivity in Central Appalachian Streams* (hereafter referred to as the "*EPA Benchmark Report*") (U.S. EPA, 2011a). The EPA used an extensive field data set in the *EPA Benchmark Report* to estimate a numeric SC benchmark. The EPA validated the method and benchmark using an independent data set. The *EPA Benchmark Report* provides details on the approach, as well as a causal analysis of the stressor-response relationship and a confounder analysis that explored the potential influence of habitat, water quality factors, other pollutants, and other factors. Internal and external reviewers, including EPA's Science Advisory Board (SAB), reviewed the primary method and derivation of the SC benchmark and validation exercises in 2011 (U.S. EPA, 2011c). Subsequently, the method and results of its application were published (Cormier and Suter, 2013a, b; Cormier et al., 2013a, b, c; Suter and Cormier, 2013). This current draft document uses that method as well as additional methods to estimate a protective maximum exposure concentration, duration, and frequency. It also presents a draft method for assessing applicability of field-based SC criteria developed in one geographic area to another area. In 2014 and 2015, panels of five external experts (selected independently by an EPA contractor) reviewed these additional draft methods.

These draft field-based methods may be used to develop SC criteria on the scale of Level III ecoregions (Omernik, 1995, 1987) in order to take into account natural ecoregional differences in background SC. In some areas, it may be appropriate to derive criteria at a different scale because background conductivity or ionic composition varies significantly across a Level III ecoregion (see Section 6 for an example). There are 85 Level III ecoregions in the continental United States (Omernik, 1995, 1987). SC tends to be low in most eastern and western montane ecoregions (25^{th} centiles of SC <200 µS/cm), intermediate in the midcontinent (200–600 µS/cm), and very high in arid areas (>600 µS/cm) (Griffith, 2014). States and tribes may use this method to derive ecoregional criteria for SC at a level that protects 95% of resident macroinvertebrate genera based on field sampling data from a set of sites within the ecoregion or from another ecoregion, when applicable.

The EPA typically relies on laboratory toxicity test data as defined in the Agency's *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses* (U.S. EPA, 1985). EPA designed the draft field-based methods described herein to be consistent with the intent of the Agency's traditional approach used to derive aquatic life criteria (U.S. EPA, 1985). Like the Agency's traditional approach, criteria derivation through field-based methods can capture characteristics of the stressor and the ecosystems potentially at risk (e.g., stressor occurrence and distribution, stressor-response relationships).

The structure of this draft document, *Field-based Methods for Developing Aquatic Life Criteria for Specific Conductivity*, is consistent with the EPA's *Guidelines for Ecological Risk Assessment* (U.S. EPA, 1998a; Suter and Cormier, 2008). The assessment begins with a planning phase, termed *Problem Formulation* (see Section 2), in which the stressor of concern is identified, its presence in the environment and potential impacts are described, and assessment endpoints (i.e., specific ecological entities and attributes to be protected and the level of protection to be achieved) are identified. In the case studies, the stressor is a mixture of ions in the form of dissolved bicarbonate and sulfate salts, measured as specific SC, in the field. The endpoint populations are aquatic benthic macroinvertebrates and the measure of effect is extirpation not to exceed 5% of genera. Section 2 serves as the *Problem Formulation* in general and for all four case studies.

In this draft document, the *Analysis Plan* (see Section 3), which is the last step in *Problem Formulation,* is included as a separate stand-alone section. The *Analysis Plan* describes three methods, (1) a field-based method that states may use to directly derive field-based aquatic life criteria for SC (the extirpation concentration distribution [XCD] method), (2) a regression model that can be used to derive criteria from minimally affected background (the background-to-criterion [B-C] model method), and (3) a method to assess the geographic applicability (extent) of the criteria using a weight-of-evidence approach. Section 3 serves as the *Analysis Plan* for this draft method in general and for all four of the case studies that follow in the *Case Study Analysis* sections. Each of the methods considers the causal relationship between exposure to major aqueous ions and the response of macroinvertebrates.

Next, in the *Case Study Analysis* sections (see Sections 4 and 5), the application of the draft XCD method is illustrated by deriving example SC criteria for different ecoregions with ecoregion-specific data sets. These sections describe magnitude, frequency, and duration as well as factors characterizing geographic range (see Case Studies I and II, Sections 4 and 5). Two other case studies demonstrate how to use the B-C regression method that predicts criteria from minimally affected background (see Case Studies III and IV, Sections 6 and 7). In these case studies, there are several factors relevant to determining geographic applicability (spatial extent of the criteria); among the most important are background SC and the composition of the ionic mixture present (ions of bicarbonate and sulfate salts).

Appendices A and B provide supporting materials, including assessments of potential confounding factors, and plots and effect levels for all genera represented in ecoregional XCDs used in the development of the Case Studies I and II (see Appendices A for Case Study I and B for Case Study II). Appendix C discusses the characterization of background SC and the seasonal regime of a region (a condition assessment) and includes a specific example for Case Study II. Appendix D provides the derivation of a B-C regression model that uses minimally affected background SC to calculate a SC criterion that is useful for areas lacking sufficient data to use the XCD method (see application of this model in Case Studies III and IV). Appendix E provides extirpation concentration (XC_{95}) values for the combined data sets used for Case Studies I and II. Appendix F provides results using an alternate measure of the ionic mixture, sulfate plus bicarbonate (as mg/L). Appendix G provides an analysis that shows that some fish

in streams are intolerant of high ionic concentrations and that fish are protected by criteria derived by applying the XCD method to benthic invertebrate data.

Data quality reviews of project data sets were conducted to ensure that the data used and the results of the analyses are accurate and complete. When invalid or incorrect data were identified, these data were either corrected or excluded from analyses. Methods for data extraction, data management, model development, and quality assurance/quality control (QA/QC) for this project are described in the Quality Assurance Project Plan, prepared by Tetra Tech, Inc. 2014. Validation and other QA analyses are described as each model or case study are also presented.

2. PROBLEM FORMULATION

This section serves as the *Problem Formulation* for the XCD method in general and for the case studies, which are presented in Sections 4, 5, 6, and 7. *Problem Formulation* begins with identification of the problem (see Section 2.1), the stressor of concern and its sources (see Section 2.2), and a description of how it can be measured (see Section 2.3). In the case examples, the stressor is a mixture of ions in a form dominated by bicarbonate and sulfate salts, measured using SC. The nature of effects (see Section 2.4), and mechanisms and modes of action are described (see Section 2.5). The assessment endpoints and measures of effect are described (see Section 2.6). The organisms are freshwater benthic macroinvertebrates and the measurement of effect is extirpation of 5% of genera. Extirpation is the depletion of an assessment population of a species or genus (in this case, it is the population in a stream) to the point that it is no longer a viable resource or is unlikely to fulfill its function in the ecosystem (U.S. EPA, 2003). Specifically, this effect threshold is defined in this document as the ionic concentration below which 95% of the observations of the genus occur, representing the extreme of an organism's tolerance to an ionic mixture. In the case studies, the ionic mixture as measured by SC is dominated by sulfate and bicarbonate salts, with either calcium and magnesium or sodium and potassium as the cations (U.S. EPA, 2011a). This effect threshold is consistent with the intent of EPA's guidelines for aquatic life criteria development (U.S. EPA, 1985), which are designed to protect aquatic animal species (i.e., 95%) in a community. The *Problem Formulation* section concludes with the rationale for selection of a field-based method for derivation of criteria for the ionic mixture (see Section 2.7).

2.1. PROBLEM IDENTIFICATION

Stress from elevated ionic concentration, measured as specific SC, has been shown to cause significant adverse effects on a range of freshwater ecosystems across the Nation (e.g., Cañeda-Argüelles, et al., 2013; Higgins and Wilde, 2005; Kaushal et al., 2013, 2005; Pond et al., 2008; U.S. EPA, 2011a). The sources of ions in surface waters may be natural, reflecting soils and geology, or anthropogenic. The two most common ionic mixtures in streams are those dominated by either chloride anions (Cl^-) or those dominated by bicarbonate (HCO_3^-) plus sulfate (SO_4^{2-}) anions based on mass (Hem, 1985; Griffith, 2014). The field-based methods are

illustrated using case examples with flowing waters with ionic mixtures dominated by HCO_3^- plus SO_4^{2-}. Based on mass, Cl^- constitutes less than half of the total anions in the case examples.

2.2. STRESSOR OF CONCERN—SALTS

Ionic stress has been implicated as a cause of biological impairment in aquatic systems throughout the United States (e.g., Findlay and Kelly, 2011; Farag, and Harper, 2012; Dunlop et al., 2015; Boelter, et al., 1992; Higgins and Wilde, 2005; Johnson et al., 2013; Karatayev et al., 2012; Kaushal et al., 2013, 2005; Fritz et al., 2010; Gerritsen et al., 2010; Palmer et al., 2010; Lindberg et al., 2011; Merriam et al., 2011; Pond et al., 2008, Pond, 2010; U.S. EPA, 2011a,b; Bernhardt et al., 2012; Cormier et al., 2013b; Timpano et al., 2011; Zhao et al., 2016). Nationally, sources of salts can be natural from rock formations and soils or can be associated with human activities and may be exacerbated by changes in climate. Sources include coastal salt water intrusion, irrigation, combustion wastes, resource exploration and extraction, demineralization of concrete, runoff from urban areas, inputs from deicing roads, and sewage and industrial waste (Ziegler et al., 2010; Cañeda-Argüelles, 2013) (see Table 2-1). Furthermore, salts from different sources have different ionic compositions. For example, marine evaporite deposits are dominated by NaCl whereas weathering of minerals such as limestone and dolomite produce Ca^{2+}, Mg^{2+}, and HCO_3^- salts (Hem, 1985).

Consistent with the *EPA Benchmark Report* (U.S. EPA, 2011a), these draft field-based methods may be applied for any waters with a defined ionic composition because the toxicity to aquatic organisms is dependent on the ionic composition of the solution (Mount et al., 1997; Mount et al., 2016; Erickson et al., 2016; Zalizniak et al., 2006; van Dam et al., 2010; Dunlop et al., 2005; Soucek and Kennedy, 2005; Bradley, 2009; Evans, 2008a,b; Nelson and Cox, 2005, Johnson et al., 2015). Aquatic organisms are adapted to different ionic regimes and have different tolerances to changes in ionic concentration and composition (Remane, 1971; Bradley, 2009). Although certain species, particularly of fish and Crustacea, have life histories and ionoregulatory adaptations that facilitate movement across a salinity gradient (Belli et al., 2009), most groups have distinct lineages of orders and families that are limited to either freshwater or marine environments (Remane, 1971; Berra, 2007). Outside of the physiological tolerance of a species, the toxicity of salts interferes with ionic regulation, osmoregulation, and acid-base balance (Bradley, 2009; Nelson and Cox, 2005).

Because toxicities of ions differ and because the example criteria are derived with data for streams where Ca^{2+} plus Mg^{2+}, and HCO_3^- plus SO_4^{2-} (i.e., not Na^+ and Cl^-) dominate the ionic composition on a mass basis, the case example criteria are not recommended for locations where Cl^- concentrations are greater than the combined concentrations of HCO_3^- plus SO_4^{2-}. However, the XCD method could be used to derive criteria for other ionic mixtures, including locations dominated by Cl^-.

Application of this XCD method relies on the availability of paired chemical and biological samples taken from waters with similar ionic composition (e.g., sulfate- and bicarbonate-dominated). The sites included in the data sets are screened based on ionic composition (e.g., chloride-dominated sites are removed from the data set in the case examples). However, removing them did not appreciably change the results in the case examples because there were so few sites that were chloride dominant.

2.2.1. Sources of Ions

Most fresh waters in the United States exhibit rock dominance (i.e., ion concentrations characteristic of natural weathering of minerals in the catchment) (Gibbs, 1970; Stallard and Edmond, 1987; Anning and Flynn, 2014), and the anion signature of these waters is usually dominated by HCO_3^- plus SO_4^{2-} (Wetzel, 2001; Griffith, 2014). SC tends to be low in mountainous and forested ecoregions (25^{th} centiles of SC ~50–200 µS/cm) and higher in more arid ecoregions (Griffith, 2014; Anning and Flynn, 2014). Nationally, the dominant cation combination is calcium (Ca^{2+}) plus magnesium (Mg^{2+}) and the dominant anions combination is bicarbonate (HCO_3^-) plus sulfate (SO_4^{2-}) (Griffith, 2014). Exposure of soils and geologic formations to weathering is a natural source of ions (Olson and Hawkins, 2012; Hem, 1985; Pond, 2004; U.S. EPA, 2011b). Factors such as rock texture and porosity, regional structural geology, the degree of fissuring (or fracturing), exposure time, and other factors may influence the composition of water flowing over and percolating through rocks (Hem, 1985). Igneous and metamorphic rocks do not increase the ionic concentration of water flowing over them as much as sedimentary rocks because they are generally more resistant to weathering (Anning et al., 2007). Carbonaceous sedimentary rocks, such as limestone ($CaCO_3$) and dolomite ($CaMg[CO_3]$), are sources of Ca^{2+}, HCO_3^- and Mg^{2+}, while other sedimentary rocks such as those containing gypsum ($CaSO_4 \cdot 2H_2O$) and anhydrite ($CaSO_4$) can be natural sources of SO_4^{2-},

particularly in arid regions (Hem, 1985). Sedimentary rocks and salt deposits associated with evaporation, such as ancient sea-beds, may contain high levels of Na^+ and Cl^-. Natural geologic variability among neighboring watersheds may result in differences in ionic concentration of associated streams. The ionic concentration of surface waters may increase naturally due to evapotranspiration, evaporation, or recharge from groundwater with higher ionic concentrations.

Precipitation (e.g., rain or snow melt) can also affect ionic concentration. SC increases during episodes of below-normal surface flow and decreases during periods of above-normal surface flow. Seasonal patterns can vary greatly with regional climate, with low SC associated with spring rain or during summer from snow-melt. Aerial deposition of wet and dry SO_4^{2-} strips soils of Ca^{2+} and Mg^{2+} and thus directly and indirectly increases SC (Krug and Frink, 1983; Kaushal et al., 2013). Near ocean coastlines, rain and dry deposition may contain more Cl^- from entrainment of aerosols from seawater (Griffith, 2014). Pure water has low SC, due to low concentrations of ions in solution. Surface and ground waters have a wide range of SC, from <50 microsiemens per centimeter (µS/cm), where water quality is dominated by rainfall and rocks are resistant to weathering, to over 200,000 µS/cm for brines (Hem, 1985).

Anthropogenic sources of ions can contribute to changes in both the ionic composition and concentration in freshwater resources. Human activities can increase the ionic concentration of natural waters either directly (e.g., by introducing new ions to freshwater systems) or indirectly (e.g., by changing land use to those that increase delivery of ions to freshwater systems and reduce freshwater input and recharge). For example, industrial, residential, and commercial activities may discharge ion-rich waters to surface water. Reservoirs increase evaporation, thus concentrating ions. Ionic concentration in freshwater systems can also increase as the result of discharges of brines and wastes from combustion effluents or mines, and runoff from treating pavements for icy conditions. Mining practices remove overlying vegetation and use explosives to break up underlying rock, leading to increased ionic leaching from mine overburden as well as from oxidation of exposed minerals such as pyrite (Johnson and Johnson, 2015; Bernhardt and Palmer, 2011; Fritz et al., 2010; Lindberg et al., 2011; Merriam et al., 2011; Palmer et al., 2010; Pond, 2010; Pond et al., 2008; Sams and Beer, 2000). Some mining practices deposit loosely packed spoils comprised of crushed rock overburden into valley fills, where both chemical leaching due to rainfall and direct transport of ions bound to particulate or suspended sediments (mechanical weathering) can result in an increase of major ions in receiving waters (Schlesinger,

1997) (see Figure 2-1). Most mines manage water and wastewater to minimize impacts on water quality.

Climate change can also contribute to increased salinity of freshwater from increased evaporation, intrusion through groundwater, and mobilization of geological salt deposits by changes in aquifer charge and recharge with increased rainfall. Global climate change is often linked to sea-level rises and intrusion of saltwater attributed to changes in pressure, expansion of oceans as water temperatures increase, and glacial melting (Werner and Simmons, 2009). Expansion and creation of estuarine tidal channels over time, from both anthropogenic and natural causes, and compaction of plain lands have been found to contribute to saltwater intrusion (Mulrennan and Woodroffe, 1998). Storm surges and flood tides in which water levels exceed normal high tide levels may also contribute to saltwater intrusion (Zhichang et al., 2001).

Saltwater intrusion has been well documented in coastal areas of the United States (Barlow and Reichard, 2010). Saltwater intrusion most commonly occurs as groundwater is removed and seawater infiltrates aquifers, potentially contaminating drinking water supplies and streams via groundwater discharge. Saltwater intrusion into freshwater systems can also be attributed to or exacerbated by road construction projects and culverts (Stewart et al., 2002).

Waters used for irrigation mobilize salts within the soil and may increase the ionic concentration of surface waters near agricultural fields. Agricultural irrigation return waters contain a variety of salt ions based on the water source, natural chemical composition of the soil, and ions associated with nutrient enrichment (NO_3^-, NH_4^+, and PO_4^{3-}). Ions including Na^+, Cl^-, F^-, Mg^{2+}, and SO_4^{2-} have been shown to mobilize in soils in the western United States leading to increased salinity of adjacent waterways and aquifers (El-Ashry et al., 1985; Leland et al., 2001; Scanlon et al., 2009). These processes are influenced by changes in the amount and patterns of rainfall and changes in climate. Elevated salinity is estimated to affect 10% of the world's irrigated lands (Duncan et al., 2008) and may increase as climates become more arid.

Salts are commonly used during periods of snow and freezing weather as a method for deicing roadways. The most common deicing agent is rock salt mainly in the form of sodium chloride (NaCl), though other compounds are available, such as calcium chloride ($CaCl_2$), magnesium chloride ($MgCl_2$), potassium acetate (KCH_3C0_2), or calcium magnesium acetate ($CaMg(CH_3CO_2)_4$) (Novotny et al., 2008; Forman and Alexander, 1998). The use of rock salt on snow and ice covered roads has increased salt usage in the United States from 163,000 metric

tons in 1940 to more than 23,000,000 metric tons in 2005 (Novotny et al., 2008), primarily in the northern states. As snow and ice melt, salt is transported via surface runoff to lakes and streams, or groundwater via recharge and has been found to increase concentrations of ions in surrounding waters (Blasius and Merritt, 2002; Novotny et al., 2008; Godwin et al., 2003). Water quality impacts can be important because of the greater percentages of pavement in urbanized watersheds. Salinity associated with deicing commonly occurs as seasonal pulses, as materials are applied during freezing conditions and are transported into waterways upon melting. However, in some areas, increased salinity attributed to deicing salts may persist in surface waters due to delayed transport of salts stored in soil and groundwater from previous winters (Jackson and Jobbágy, 2005, Kaushal et al., 2005).

Wastewater treatment plants and industrial discharges can contribute ions to freshwater systems and can dominate water quality in streams and rivers dominated by effluent discharge. Wastewater treatment plants have been shown to increase concentrations of Na^+, Cl^-, K^+. Total Kjehldahl nitrogen (TKN), SO_4^{2-}, and SC downstream of the treatment plant discharge (Andersen et al., 2004). Kaushal et al. (2005) found increasing concentrations of chloride in a long-term study of streams. Echols et al. (2009) measured SC below a point source brine discharge, which ranged from 5,900−18,000 µS/cm. Other industries including food processing, petroleum, and leather production also produce saline wastewaters as a byproduct of production (Lefebvre and Moletta, 2006).

Wright et al. (2011) have identified weathering of cement as a source of Ca^{2+} and HCO_3^- in streams draining urban areas. Rose (2007) also found these ions along with others to be elevated in urban subbasins.

Some specific examples of anthropogenic sources of ions illustrated in Figure 2-1 (adapted and updated from Ziegler et al., 2010) and their associated dominant ions are summarized in Table 2-1.

Table 2-1. Examples of ions associated with different anthropogenic sources

Source	Dominant ions	References
Surface coal mining and valley fills associated with mountaintop-removal coal mining	Ca^{2+}, Mg^{2+}, HCO_3^-, SO_4^{2-}	Bryant et al. (2002), Pond et al. (2008), EPA (2011a, b), Griffith et al. (2012)
Runoff and effluents from conventional coal mining and processing	Ca^{2+}, Mg^{2+}, HCO_3^-, SO_4^{2-}	Zielinski et al. (2001), Kennedy et al. (2003), Kimmel and Argent (2010)
Deep coal mining	Na^+, Ca^{2+}, Mg^{2+}, Cl^-, SO_4^{2-}	Thomas (2002), Mayhugh and Ziemkiewicz (2005)
Combustion effluents	Ca^{2+}, Mg^{2+}, HCO_3^-, SO_4^{2-}	Samarina (2007), Ruhl et al. (2012)
Historical industrial sources, such as chlor-alkali plants	Na^+, Cl^-	Echols et al. (2009)
Wastewater treatment plants	Na^+, Cl^-, K^+, TKN, SO_4^{2-}	Paul and Meyer (2001), Andersen et al. (2004)
Sewage and industrial waste discharges	Na^+, Cl^-, NH_4^+, NO_3^-, PO_4^{3-}	Carey and Migliaccio (2009)
Salt water intrusion	Na^+, Cl^-	Barlow and Reichard (2010), Mulrennan and Woodroffe (1998), Barlow (2003)
Produced water from coalbed methane production	Na^+, HCO_3^-, Cl^-	Brinck et al. (2008), Dahm et al. (2011), Jackson and Reddy (2007), National Research Council (2010), Clark et al. (2001), Veil et al. (2004)
Produced water from shale gas production (i.e., hydrofracking)	Na^+, Ca^{2+}, Mg^{2+}, Cl^-, HCO_3^-, K^+, SO_4^{2-}, Br^-	Haluszczak et al. (2013), Entrekin et al. (2011), Gregory et al. (2011), Veil et al. (2004)
Produced water from conventional production of crude oil or natural gas	Na^+, Cl^-	Meyer et al. (1985), Boelter et al. (1992), Veil et al. (2004)
Agricultural runoff, particularly associated with irrigation	Na^+, Mg^+, NH_4^+, Cl^-, F^-, SO_4^{2-}, PO_4^{3-} Ions may vary by region.	El-Ashry et al. (1985), Leland et al. (2001), Bernot et al. (2006), Lerotholi et al. (2004), Lenat (1984)

Impervious surfaces and weathering of concrete in urban drainage systems	Ca^{2+}, HCO_3^-, Cl^-	Kelting et al. (2012), Steffy et al. (2004) Wright et al. (2011), Rose (2007)
Dry and wet acid deposition	Ca^{2+}, Mg^{2+}, HCO_3^-, SO_4^{2-}	Kaushal et al. (2013)

2.2.2. Conceptual Model

A conceptual model consists of a written description and diagram that illustrates the relationships between human activities, stressors, and ecological effects on assessment endpoints (U.S. EPA, 1998a). The conceptual model links exposure characteristics with the ecological endpoints important for management goals.

The simplified conceptual model shown here (see Figure 2-1) summarizes natural and anthropogenic sources of ionic loadings in the case example study areas, transport pathways, and potential ecological responses, all of which are described in greater detail in the following sections. Sources are affected by processes or states that can result in delivery of a source to a proximate stressor to the aquatic system. Sources deliver stressors, in this case, dissolved ions to streams. The proximate stressor is the physical, chemical, or biological agent that directly causes one or more biotic responses of concern, in this case, an increase in ionic concentration and/or a change in the relative amounts of ions dissolved in the water. The physical biological exposure is the form or route of exposure or uptake, which is generally direct contact with semipermeable membranes such as gills and internal integument. The physiological mechanism is the molecular, cellular, tissue, or organ system alteration that results from exposure to the stressor. These include changes in ionic concentration, pH shifts, and possibly loss of epithelial integrity. The mode of action is the organismal effect that may reduce fitness and survivorship and increase emigration. The assessment endpoint is the adverse population level of effect, in this case, extirpation. Extirpation is the depletion of a population of a species to the point that it is no longer a viable resource or is unlikely to fulfill its function in the ecosystem (U.S. EPA, 2003). The threshold for extirpation is operationally defined by the level below which 95% of the observations of the genus occur, an XC_{95}. For a more general model showing other sources, such as marine intrusion associated with water withdrawal or fires resulting in ash, see the conceptual model for ionic concentration on the CADDIS website (http://www.epa.gov/caddis/ssr_ion4d.html).

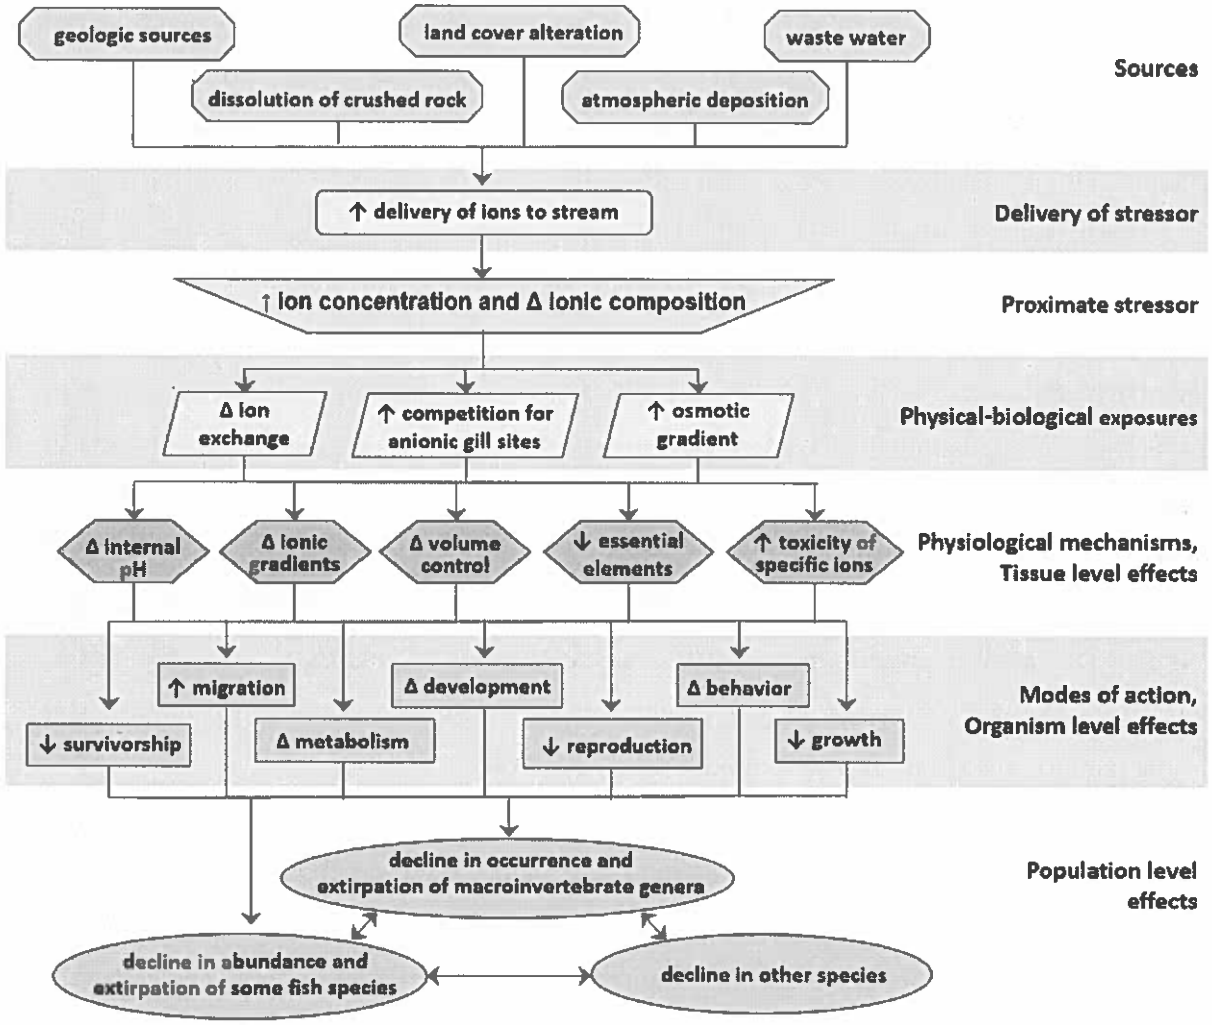

Figure 2-1. Conceptual model showing hypothesized relationships among selected sources of ions and biotic responses to ionic stress by salt intolerant taxa (adapted from Schofield and Ziegler, 2010).
Upward arrows indicate an increase, downward arrows indicate a decrease, and delta symbols indicate a change in the parameter in either direction depending on conditions. Inclusion of a linkage indicates that the linkage can occur, not that it always occurs.

2.2.3. Environmental Transport and Fate of Ions in the Aquatic Environment

The majority of calcium (Ca^{2+}) and magnesium (Mg^{2+}) found in most soils and surface water originates from chemical weathering of common minerals in rock or soils, such as limestones ($CaCO_3$) and dolomites ($CaMg(CO_3)_2$) (e.g., Goddard et al., 2007). Minerals rich in calcite, e.g., apatite ($Ca_5(PO_4)_3(F,Cl,OH)$), can be found in igneous, sedimentary, and

metamorphic rocks (e.g., Nezat et al., 2008). In many areas, these calcium and magnesium rich rocks are relatively easily weathered and soluble, with their mobility strongly affected by pH, becoming more mobile with decreasing pH (Likens et al., 1998). In forested catchments, the calcium and magnesium concentrations in surface waters can increase following disturbances, such as deforestation (Likens et al., 1970), and decrease in late successional forest stands relative to early successional forest stands (Hamburg et al., 2003). In general, anions (negatively charged ions) are more mobile than cations (positively charged ions) because they are not bound to negative binding sites on clays. Bicarbonate (HCO_3^-) ions in most soils and groundwater result from chemical weathering of calcareous minerals. Bicarbonate ions are also present in soils as a byproduct of plant and microbial respiration, as well as from the oxidation of organic matter whereby carbon dioxide released in the soil becomes hydrated to form carbonic acid (H_2CO_3) and is then dissociated into bicarbonate (HCO_3^-) and carbonate (CO_3^{2-}), depending on the local soil pH. The relative concentration of HCO_3^- compared to H_2CO_3 and CO_3^{2-} is pH dependent, with HCO_3^- being the dominant form at circumneutral pH. HCO_3^- is readily leached from soils during rainfall. Alkalinity is a measure of HCO_3^- and CO_3^{2-}.

Sulfate (SO_4^{2-}) ions found in soil and rocks can result from chemical weathering of sulfate minerals, such as gypsum (Mullins and Hansen, 2006) or from chemical weathering of coal deposits (Schlesinger, 1997). Atmospheric deposition can also be a source of sulfate found in soils and is primarily anthropogenic in origin from the burning of fossil fuels (Schlesinger, 1997). Sulfate is readily leachable in soils, and sulfate mobility was found to be positively correlated with rainfall in relatively undisturbed forested watersheds in both Central Pennsylvania (Lynch and Corbett, 1989) and the Georgia Piedmont (Huntington et al., 1994). In the Allegheny River Basin in southwestern Pennsylvania, sulfate concentrations in surface waters draining relatively undisturbed watersheds ranged from 16–20 mg/L (Sams and Beer, 2000).

In addition to runoff, ions can be transported to surface waters through groundwater discharge. Major ions can enter groundwater through dissolution of minerals in soils and rocks during recharge. Particularly during periods of low streamflow, groundwater discharge can be a major contributor of ions to surface waters (Larson and Marti, 1996).

Once mobilized, the majority of major ions that contribute to SC behave conservatively in aquatic systems and are transported in surface water and groundwater to receiving waters.

Although the ions that are the focus of these field-based methods are essential elements for living organisms (within specific ranges), biological uptake does not effectively reduce ionic concentrations in streams (U.S. EPA, 2011b). In addition, Ca^{2+}, Mg^{2+}, SO_4^{2-}, Na^+, and K^+ are not significantly degraded nor adsorbed (U.S. EPA, 2011b). As a consequence, concentrations of the transported major ions tend to increase in receiving waters unless diuted by precipitation or inflow from tributaries with lower ionic concentrations (Johnson et al., 2010; Merriam et al., 2011). An exception is bicarbonate ions, which can be taken up by photosynthetic plants. Geologically bound carbonates (HCO_3^-) are also released into the atmosphere. Vesper et al. (2016) reported a total flux of dissolved organic carbon from two sites near a coal mine that ranged from 13 to 249 kg-C/year (18–364 metric tons of CO_2/year).

2.3. MEASURE OF EXPOSURE

The concentration of a dissolved salt mixture can be measured in a number of ways: as SC, total dissolved solids (TDS), freezing point depression (also referred to as osmotic pressure or osmolarity), refractive index, density, or the sum of the concentrations of individually measured ions. A comparison of the capabilities of these different measurement methods is shown in Table 2-2. The EPA has selected SC as the parameter to represent the measure of exposure for this stressor. SC was selected as the measure of the ionic mixture for these field-based methods because (1) SC is a measure of all ions in the mixture; (2) the measurement technology is fast, inexpensive, accurate, and precise; (3) it measures only dissolved ions; (4) it can be used to provide continuous monitoring records with in situ instrumentation; (5) it is a sensitive measure in dilute waters; (6) it is less influenced by other nonfilterable material such as oils and carbohydrates that may be dissolved in water compared to some measurement methods (e.g., TDS); and (7) it is monitored by most state water monitoring programs at bioassessment sampling sites. Several approved methods for measuring SC are available, including EPA method 120.1 (U.S. EPA, 1982 revised).

SC has been commonly used as a measure of ionic concentration, and as an estimate of major solute concentrations and total dissolved solids concentrations of natural waters (McCleskey, 2011; Ziegler et al., 2010). SC is a measure of a material's ability to conduct electric current, including natural waters, and is typically expressed in units of microsiemens per centimeter (µS/cm).

Table 2-2. Comparison of methods to measure ionic concentration

Measurement method	All ions?	Speed	Approximate sample range and sample volume	Sample filtration required	Field use	Continuous measure possible	Affected by nonionic constituents
Specific conductivity	Yes	Seconds	Wide range, µL–mL, volume or in situ	No	Yes	Yes	No
Total dissolved solids (gravimetric)	Yes	Days	Requires larger volumes for freshwater	At times	No	No	Yes
Freezing point depression	Yes	Minutes	Wide range, few µL to mL volumes	At times	No	No	Yes
Refractometry	Yes	Minutes	Better suited for higher salinities, µL volumes	At times	Yes	Industrial application	Yes
Densitometry	Yes	Minutes	Better suited for higher salinities, dl volumes	No	Yes	No	Yes
Sum of ion concentrations	Typically major ions only; e.g., Ca^{2+}, Mg^{2+}, Na^{+}, K^{+}, Cl^{-}, SO_4^{2-}, and HCO_3^{-}	Hours to days	Variable depending on analytical methods	Yes	No	No	No

Because SC predictably increases with increasing ionic concentration, it is used to measure salinity (usually referring to NaCl) or ionic concentration (for any dissolved salts) (Standard Methods #2510 [APHA, 1992]; EPA method 120.1, 0950A [U.S. EPA, 1982]). SC measurements in natural waters indicate the presence of inorganic dissolved solids (e.g., chloride, nitrate, sulfate, bicarbonate, nitrite/nitrate, and phosphate anions and sodium, potassium, magnesium, calcium and iron cations). Electrical currents are carried by both positively charged cations and negatively charged anions—but to differing degrees depending on charge and mobility. Thus, the SC of a mixture depends on the type and concentration of the

ions in solution. SC is also dependent on temperature and is known to increase approximately 2% for every 1°C increase in water temperature. The term "Specific Conductivity" indicates the measurement has been standardized to 25°C, a reference temperature (Wetzel, 2001). SC is commonly reported in state monitoring programs, rather than the unstandardized conductivity measurement.

Both specific conductivity and specific conductance are often used synonymously in the open literature indicating normalization or measurement at 25°C. Conductivity is a property of water expressed as µS/cm. Conductance of a sample or electrical component is measured as Siemens (S). All measurements in this document refer to specific conductivity/specific conductance expressed as µS/cm at 25°C as it relates to water samples.

SC is an aggregate measurement of the full ionic mixture of a water sample. The total ionic concentration of natural waters is associated with biological effects. However, waters with similar SC levels may have different ionic compositions, and as a result can have different toxicities to freshwater organisms in the laboratory and in the field (Mount et al., 2016; Zalizniak et al., 2006; Dunlop et al., 2015). Therefore, when using SC as a measure of ionic concentration, it is important to characterize the specific ions and their relative concentrations.

Some states and authorized tribes may want to use an alternative measurement of ionic concentration when developing aquatic life criteria. If a different measure of the ionic mixture is selected as the measure of exposure, the reliability of the measurement should be considered. For example, TDS has greater variability than other methods. If some states and tribes prefer to measure specific ions known to be toxic to aquatic organisms, the interaction of ions within the mixture also needs to be considered. Appendix F provides an example using an alternative measure of exposure for waters dominated by Ca^{2+} and Mg^{2+}, the sum of HCO_3^- and SO_4^{2-} in mg/L.

2.4. NATURE OF THE EFFECT

All tolerances of stressors are determined by the evolutionary adaptations of organisms. The background levels of naturally occurring habitat variables such as temperature, pH, and SC are important determinants of those adaptations. Because aquatic species evolved in unpolluted waters, background levels define aspects of the niche to which the biota of a community is naturally adapted and which it potentially tolerates (MacArthur and Levins, 1967; Colwell and

Rangel, 2009; Peterson et al., 2011; Futuyma and Moreno, 1988; Wiens, 2004). Aquatic species inhabit nearly pure water, estuarine and marine conditions, hypersaline pools, and everything in between (Remane, 1971, Potapova and Charles, 2003; Potapova, 2005; Berra, 2007). In most of the United States, freshwater habitats have very low concentrations of dissolved ions relative to marine systems, so that is the condition to which most freshwater biota are adapted.

Algae, protozoans, zooplankton, and bacteria have all been shown to have SC preferences in freshwater systems (Potapova and Charles, 2003; Potapova, 2014; Bos et al., 1996). Nationally, of 230 soft-bodied algae identified to the lowest practical taxonomic level, 56% had estimated optima <500 µS/cm (Potapova, 2014). Nationally, of 683 diatoms also identified to the lowest practical taxonomic level, 84% had optima <500 µS/cm and 35% did not occur in water >500 µS/cm (Potapova, 2014).

Freshwater benthic macroinvertebrates are extirpated at different ionic concentrations (U.S. EPA, 2011a). In West Virginia, 17% of genera that occur at background SC are extirpated at 500 µS/cm and many more genera decline at that SC (Cormier et al., 2013b). Effects are not limited to Appalachia. In Nevada streams, differences between observed and expected invertebrate communities increased above natural background levels of approximately 300 µS/cm (Vander Laan et al., 2013). Freshwater fish also decline and are extirpated as ionic concentration increases (see Appendix G). Although these data are from waterbodies with a wide range of background SC values, they demonstrate that many species and genera are adapted to particular SC regimes, and many of them are quite low.

The physiological limits of species determine their tolerance ranges, in this case, their potential SC niche with respect to concentrations of a defined ionic mixture (Olson, 2012; Vander Laan et al., 2013). At the extremes of their physiological tolerance, species are less able to develop, grow, and reproduce. A species may not exploit its full tolerance range, because competitor species are better suited for a particular ionic concentration or for other ecological reasons such as predation, parasitism, and habitat requirements. The SC range that is actually inhabited by a species is called a realized niche.

The range of SC conditions varies in natural aquatic systems. Species do not occur where the SC is lower or higher than their SC tolerance. The lowest SC in a freshwater system, therefore, is the lowest possible limit of the potential SC niche (see lower tolerance limit in Figure 2-2). When mineral salts are added to an aquatic system, SC increases, part of the

potentially habitable SC niche space is lost, and the size of the realized niche for species adapted to low SC decreases. When the SC is above the physiological tolerance of a species due to natural or anthropogenic causes, it does not persist and the species is extirpated.

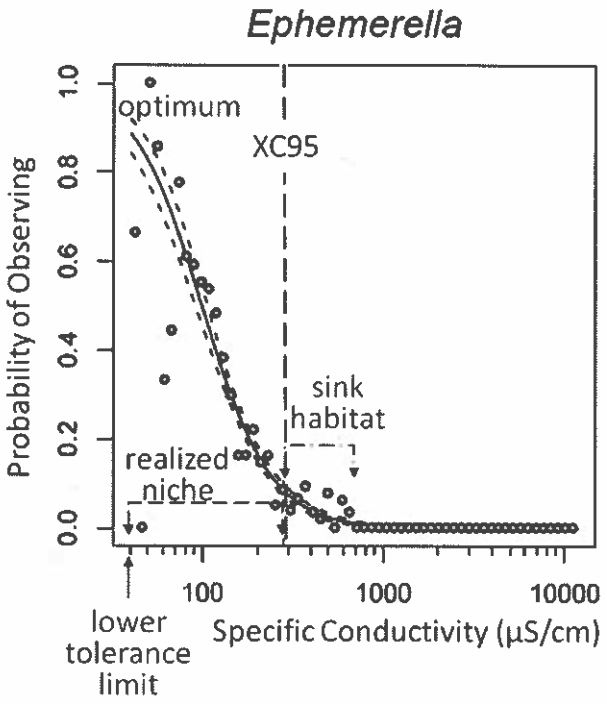

Figure 2-2. A species' (or genus') realized niche is defined by its lower and upper limits of occurrence. In this case, the lower tolerance limit is less than or equal to the lowest specific conductivity (SC), which is the lower limit of occurrence. The XC_{95} represents the upper tolerance limit. Approximately 5% of observations of a taxon are assumed to occur in sink habitats where a population cannot persist without immigration from source habitats. A species or genus optimum is the environmental condition most easily tolerated both physiologically and competitively and can be estimated by the conditions where the taxon is most often observed. The optimum SC may be estimated at the maximum probability of observing the taxon from a generalized additive model, shown here to be the minimum SC. The example involves the genus *Ephemerella* which is comprised of several species of mayflies.

The upper tolerance limit of a species is estimated by its XC_{95} (see Figure 2-2). Extirpation is the depletion of a population of a species to the point that it is no longer a viable resource or is unlikely to fulfill its function in the ecosystem (U.S. EPA, 2003). The occurrences of benthic invertebrate species at locations with a SC greater than their XC_{95} value are believed

to represent sink habitats (Pond et al., 2014). Sink habitats are those locations where occurrence of species is primarily the result of immigration from locations with low SC termed source habitats from which immigrants originate. They are "sinks" in the sense that immigrants have low success in establishing sustainable populations in those locations.

These phenomena have practical application. The proportion of species or genera extirpated as a result of increased SC in an ecoregion can be determined and is the basis for the XCD method.

Several other predictions can be made from niche theory. Species with niches that limit them to low SC water are not expected to occur where low SC water does not occur. The source of high SC could be natural or due to anthropogenic inputs (Cormier et al., 2012, Coffey et al., 2014). For example, in an ecoregion lacking streams <400 µS/cm, any species with an upper tolerance limit <400 µS/cm SC would not be expected to occur because there is no habitat for them. As a corollary, where there is a low SC habitat in an ecoregion, species tolerant to low SC will occur.

The relationship between ambient SC levels and SC tolerances of species that are present has at least two practical implications. First, it is inappropriate to set criteria below natural background for a location. Second, the lower limit for any XCD in any given ecoregion cannot be lower than the natural background of the ecoregion. In practical terms, this shifts the origins of XCDs and their 5th centiles toward higher SC (graphically to the right) as the background SC increases. Hence, when XCDs from regions of low to high natural background are simultaneously plotted on the same graph, the curves progress to the right. (For an example, see the XCDs in Appendix D, Figure D-3). Therefore, the background SC of an ecoregion is strongly associated with a predictable extirpation of 5% of species or genera. This relationship between background SC and the proportion of extirpation can be used to predict the SC that will extirpate 5% of species or genera in an ecoregion solely based on ecoregional background (see Section 3.7.2 and Appendix D, Figure D-4).

2.5. MECHANISMS AND MODES OF ACTION

The measure of effect for these field-based methods is extirpation (U.S. EPA, 2011a). The three most likely modes of action for extirpation of a genus or species are the population-level processes mortality, emigration, and failure to recruit (Rubach et al., 2011; Williams and Hynes,

1976; Clements and Kotalik 2016). The sections below discuss some physiological mechanisms of action through which SC acts on organisms and on the processes that constitute the potential modes of action.

2.5.1. Physiological Mechanisms

In exposures to elevated ionic concentrations, physiological stress could cause mortality or drift (a process in which invertebrates emigrate by releasing the substrate and allowing themselves to be carried downstream). The stress occurs because the freshwater organisms cannot maintain or need to use more energy to maintain their internal ionic concentration and pH with altered ionic composition and concentration, and water volume in waters with very high ionic concentration. The mechanism of action is believed to be due to adverse ionic gradients formed by the concentration and relative proportions of ions. For all freshwater organisms, microbes, plants and animals alike, ionic concentration is higher inside an organism than in freshwater. To concentrate and maintain the internal ion concentration, organisms have evolved many interrelated strategies. One cannot describe the specific action of toxicity of one ion or pH without considering all the others (Zhang and Wakamatsu, 2002 Griffith, 2016; Bradley, 2009; Evans, 2008a, b; Wood and Shuttleworth, 2008; Nelson and Cox, 2005; Marshall, 2002; Hille, 2001; Smith, 2001; Thorp and Covich, 2001; Komnick, 1977; Sutcliffe, 1962). For example, Na^+ and Cl^- concentrations are much higher inside organisms than in freshwater. One mechanism used by invertebrates and fish to concentrate Cl^-, an anion with a negative charge, is to exchange Cl^- for a nonmineral anion waste product (CO_2) that is produced during metabolism of sugar. An enzyme, carbonic anhydrase, rapidly and reversibly catalyzes water and CO_2 to HCO_3^- and H^+. HCO_3^- concentrations are higher inside the organism and lower in the water. This concentration gradient is favorable for the exchange of Cl^-. However, a cation also needs to be removed from the organism or else H^+ will accumulate and cause acidosis. Acidosis causes complex cellular reactions and affects function of cellular organelles that lead to many adverse effects including death (Gesser and Poupa, 1983; Vafai and Mootha, 2012). Freshwater animals exploit this increased concentration of H^+ by exchanging it for another cation, such as Na^+. Thus, Na^+ and Cl^- are concentrated inside organisms relative to freshwater. However, when the HCO_3^- concentration in freshwater is high, the concentration gradient does not favor movement of HCO_3^- out of the organism and other ions are not readily brought into the organism. Because

this anion-cation exchange mechanism uses waste CO_2, it requires less energy to maintain. Low-energy regulation of ions that depend on favorable HCO_3^- concentrations can be supplemented by adenosine triphosphate-dependent transport of ions as ion concentrations increase outside the organism and concentration gradients become less favorable for passive or low energy transport. The inability to regulate internal ionic concentrations or the greater energy demand for ion regulation may causes stress resulting in death, drift, reduced growth, or reduced reproduction, but definitive cellular studies for most aquatic organisms are lacking.

Organisms use many strategies to minimize loss of ions and the exclusion of water (see references in previous paragraph). At the interface between water and the organism's surface, epithelial tissue integrity is essential. Cell membranes are a barrier to water because they are hydrophobic bilayers of lipids. The membranes are selective for the ions and direction of movement using proteinaceous ion channels, ports, and carriers (for a review see Griffith, 2016). Between the cells making up the epithelial pavement, ultrastructural features called tight junctions hold adjacent cells together and complete the epithelial barrier restricting water and ion movement into or out of the organism. External Ca^{2+} helps maintain tight junctions (Gonzales and McDonald, 1992; Smith et al., 2005; Brown and Davis, 2002). There is some evidence from human studies of the gut that SO_4^{2-} may interfere with tight junctions causing loss of epithelial integrity but the physiological interactions of SO_4^{2-} have not been well studied in freshwater organisms. Note that ion concentrations in freshwater are always less than inside the animal and do not cause loss of water from the animal. Rather, loss of epithelial integrity can lead to excess water or loss of ions. This is a key difference between marine and freshwater organisms.

In summary, the full complement of anions and cations, including others not described here, need to be maintained by organisms. There is an extensive literature on ionoregulation of cations and anions. The higher concentration of ions inside organisms compared to freshwater provides opportunities to use ionic gradients for ionoregulation. Acid-base regulation is linked to the production of hydrogen ions involved in ionoregulation. Because useful gradients are dependent on low concentrations of ions in freshwater, relative amounts of each ion, not necessarily any individual ion, accounts for toxic effect.

2.5.2. Mortality, Growth, and Reproduction

Death of juvenile aquatic invertebrates exposed to different ionic concentrations has been demonstrated in the laboratory (Echols et al., 2010; Kennedy et al., 2003, 2004, 2005; Lasier and Hardin, 2010; Merricks et al., 2007; Mount et al., 1997; Wang et al., 2013, Kunz et al., 2013, Bringolf et al., 2007). Sublethal effects reported from laboratory studies include reduced growth, reproduction (Johnson et al., 2015), early emergence (Nietch et al., 2014), and premature release of unionid glochidia (Gillis, 2011). When death of an entire population occurs, the area remains depopulated until recolonized by aerial dispersion and egg-laying (oviposition) (Smith et al., 2009) or by organisms floating downstream (drift) from refugia at upstream reaches or tributaries to the depopulated stream reach (Williams and Hynes, 1976; Pond et al., 2014).

2.5.3. Emigration

Emigration occurs when organisms vacate a stressful environment after being challenged with a noxious stimulus or lack of food or other resources. In numerous studies, benthic invertebrate drift is induced within minutes of exposures to a range of stressors in natural and artificial streams (Svendsen et al., 2004; Wood and Dykes, 2002). Stress induced drift and avoidance behaviors have been shown to occur with salts, toxic chemical spills, floods, pesticides, drought, sediment, low dissolved oxygen (DO), heat, and organic pollution (Wood and Dykes, 2002; Svendsen et al., 2004; Crossland et al., 1991; Doeg and Millage, 1991; Wallace, 1990; Brittain and Eikeland, 1988; Sheehan and Winner, 1984; Geckler et al., 1976; Waters, 1966, 1972, 1995). In independent studies, colonized substrates were exposed to continuous flowing treatments of ionic mixtures (Clements et al., 2014, 2016; Nietch et al., 2014). The studies showed increased drift, reduced numbers of taxa, and other effects. Drift is more likely to occur when there is an abrupt change in environmental conditions rather than a slow change that allows organisms to physiologically adapt. For example, after a moderate increase in ionic concentration, some aquatic insects synthesize more ionic channels for ionic regulation (Wichard et al., 1973; Sutcliffe, 1974; Komnick, 1977).

2.5.4. Failure to Recr'uit

Development begins with gamete production. Fertilization during the terrestrial phase of the life cycle occurs internally in most aquatic insects and is unlikely to be affected by aqueous

ions. At oviposition, contact with freshwater causes the swelling and formation of an extrachorionic coating that is necessary for adherence of the eggs of some invertebrates to substrates in the stream (Percivale and Whitehead, 1928). Eggs oviposited into water with higher specific SC do not form the adhesive coating (Percivale and Whitehead, 1928) and the eggs are washed downstream and presumably perish (Gaino and Bongiovanni, 1992). Ionic gradients that initiate biological changes are also necessary to permit propagation of a fertilization potential over the surface of some eggs and to allow successful embryonic development and hatching in some species such as fish (Jaffe, 1991; Coward et al., 2002). Similarly, toxicity tests with fathead minnow larvae were more sensitive during the transitional period from embryo development to hatching (Wang et al., 2016a). Mesocosm experiments with mayflies also indicated greater vulnerability during early life stages and during emergence to winged adults (Clements and Kotalick, 2016; Nietch et al., 2014).

2.5.5. Community Interactions

Increased competition, predatation, or parasitism have been suggested as possible modes of action leading to loss of some species and an increase in salt-tolerant taxa where ions are elevated (Olson, 2012; Olson and Hawkins, 2012; Micieli et al., 2012; Wood-Eggenschwiler and Barlocher, 1983). These processes may affect the benthic invertebrate communities that form at different ionic concentrations.

2.6. ASSESSMENT ENDPOINTS AND MEASURES OF EFFECT

2.6.1. Assessment Endpoints

Assessment endpoints represent the actual environmental value to be protected. They are defined by an ecological entity (e.g., species, community, or other entity) and attributes, (e.g., survival, growth, and reproduction) (U.S. EPA, 1998a). In the development of water quality criteria for SC, the entities are aquatic biotic communities and the attribute is protection of all but a small fraction of species from extirpation.

The relevant ecological entities for these field-based methods are macroinvertebrate assemblages, which are characterized by their taxonomic composition at the genus level. Macroinvertebrates were selected because they are susceptible to ionic stress, they are important to stream function and ecosystem integrity, they provide numerous ecosystem services that

benefit humans, they can be found in all types of streams, and they are intrinsically valuable aquatic life forms (Suter and Cormier, 2015). Furthermore, because macroinvertebrates constitute the great majority of multicellular species in streams and have a wide range of sensitivities, they are excellent indicators of adverse effects on ecological processes and on the larger aquatic community. For these reasons, all states and many tribes monitor aquatic macroinvertebrates to assess the health of the aquatic community (U.S. EPA, 2002).

The most commonly recognized contribution of aquatic macroinvertebrates is that they are food for larger invertebrates and fish and other vertebrates, including recreationally important fish species (Allan, 1981; Richardson, 1993; Sweka and Harman, 2008; Hitt and Chambers, 2014), amphibians (Burton, 1976; Wallace et al., 1997), insectivorous bird species (Nakano and Murakami, 2001; Gray, 1993; Epanchin et al., 2010), bats (Clare et al., 2011), and mammals. However, the overall function of freshwater aquatic ecosystems is also dependent on macroinvertebrates (Hooper et al., 2005; Cardinale, 2011). Macroinvertebrates improve water quality through forest and stream nutrient retention (Newbold et al., 1983, 1982; Wallace and Webster, 1996; Huryn and Wallace, 2000; Evans-White et al., 2005), aid in leaf litter decomposition (Wallace and Webster, 1996), and remove pathogens and nuisance periphyton blooms by filtering and grazing (Wallace and Merrit, 1980; Yasuno et al., 1982; Hall et al., 1996). Because macroinvertebrates provide many ecosystem services, it is well understood that stream macroinvertebrate diversity and abundance are important indicators of overall stream condition (Carter et al., 2006; Resh, 1995), and many stream monitoring programs and stream condition indices rely on macroinvertebrate sampling metrics (Gerritsen et al., 2000; Pond et al., 2008; U.S. EPA, 2002).

These field-based methods can be used to develop ecoregional criteria that are fully protective of aquatic life. Many freshwater insects are among the most salt-intolerant organisms relative to other taxa, including crustaceans such as crayfish and daphnids, fish, and amphibians (compare Appendices A.4 and B.4 with Appendix G of this report). Recent studies suggest that mussels in the family Unionidae are acutely salt-intolerant (Kunz et al., 2013; Wang et al., 2016a, b), particularly during early (glochidia and juvenile) life stages (Bringolf et al., 2007; Gillis, 2011; Wang et al., 2016a, b).

Fish also are adversely affected by ionic stress (see Appendix G, Stauffer and Ferreri, 2002; Kimmel and Argent, 2010; Mount et al., 1997; Kennedy et al., 2005, 2004, 2003; Harper

et al., 2012; Farag and Harper, 2012, Hopkins and Rousch, 2013, Hitt and Chambers, 2014). EPA's assessment of fish in Appendix G indicates that they are sensitive to ionic stress but are extirpated at slightly higher SC levels than macroinvertebrates. Therefore, fish are expected to be protected by criteria based on macroinvertebrate data. More complex organisms (e.g., fish) generally have a greater ability to regulate internal ionic concentrations and water volumes than simpler organisms, such as benthic invertebrates (Dunlop et al., 2005). Fish also have greater mobility and may be able to more readily migrate from high SC sites to more habitable areas (e.g., Goldstein et al., 1999; Woodward et al., 1997, 1995).

In sum, macroinvertebrates are a critical component of ecological integrity, provide numerous ecosystem services, and appear to be a salt-intolerant ecological taxonomic group; therefore, they are used as an assessment endpoint for these field-based methods.

2.6.2. Measures of Effect

The measures of effect for these field-based methods have been selected to be consistent with the intent of the conventional laboratory-based method for developing aquatic life criteria (U.S. EPA, 1985). Two relationships are derived from the paired SC and macroinvertebrate field data: one for each macroinvertebrate genus and one for the overall macroinvertebrate community in the study area. First, a cumulative distribution function (CDF) is developed for each genus[2] to determine its genus XC_{95}, the SC level above which a genus is effectively absent from water bodies in a region (U.S. EPA, 2003). It is defined in this method as the 95th centile of the distribution of occurrences of a macroinvertebrate genus. In other words, the probability of observing a genus above its XC_{95} SC value is 0.05; i.e., if a genus is observed at 100 sites, only 5 sites would be expected to have SC above the XC_{95}. XC_{95} values that are uncertain or unmeasured within the exposure range are noted and generally do not influence the hazardous concentration (HC_{05}) because their estimated XC_{95} values are greater than those genera in the 5th centile. Second, the HC_{05} is developed using a genus-level XCD for the macroinvertebrate community from the aggregation of the XC_{95} values.

---

[2]Conventionally, species have been aggregated to the genus level. However, effect levels may be different for species within a genus due to niche partitioning afforded by naturally occurring causal agents such as dissolved ions. (Remane, 1971; Suter, 2007). Hence, an apparently salt-tolerant genus may contain both salt-intolerant species and tolerant species. Analyses with fish species indicate that the range of XC_{95} values within a genus can be quite broad and the empirical genus-level XC_{95} tends to represent the maximum XC_{95} of the species in the data set (see Appendix G).

One key difference from laboratory-based methods used to develop aquatic life criteria for chronic exposures is the measure of effect. In the XCD method, the measure of effect is genus extirpation (population-level) rather than an effect at the organism level. In the laboratory-based method, the measures of effect represent survival, growth, or reproduction (U.S. EPA, 1985). Because the example ecoregional criteria are based on field data for a large number of macroinvertebrate genera across many sites across a broad SC gradient, the EPA anticipates that a reasonable level of protection of the overall aquatic community will be provided if all except a small fraction (i.e., 5%) of sampled macroinvertebrate genera from the region are protected. In their review of the *EPA Benchmark Report*, the EPA SAB stated that this approach provides a degree of protection comparable to or more protective than a conventional water quality criteria based on conventional chronic toxicity testing (U.S. EPA, 2011c).

The genus-level XCD used in the XCD method represents the response of genera in biotic communities in general to a stressor (e.g., an ionic mixture dominated by sulfate plus bicarbonate). XCDs do not require that the species or genera be the same in all applications or at all locations (Posthuma et al., 2001; Cormier and Suter, 2013a; Cormier et al., 2013a). Similarly, the genera that form the minimum data set for laboratory-based aquatic life criteria are not intended to match any particular community; rather, they are surrogate taxa that represent any potentially exposed freshwater community (U.S. EPA, 1985). In the same way, the distribution of genera in the XCDs used in the XCD method (e.g., see Section 4.2) represent all stream communities from a similar background ionic concentration exposed to a similar ionic mixture. All of the macroinvertebrate taxa used to develop an XCD may not occur at any one site in an ecoregion.

Because this approach relies directly on paired observations of in situ measurements of SC and benthic invertebrate assemblage information, the potential adverse effects of ionic stress on all life stages is considered in the context of other complex relationships (e.g., food web dynamics) and aquatic ecosystem processes. The measures of effect (i.e., XC_{95} and HC_{05}; see Sections 3.1.2 and 3.1.3) are considered chronic-duration endpoints because the field data reflect exposures over whole life cycles and multiple generations of the resident biota (see Table 2-3). A field-based method to directly develop acute criteria for SC is not yet available due to a lack of field data with sufficiently high temporal resolution (e.g., daily measurements of SC paired with

macroinvertebrate sampling for at least 1 year). However, these field-based methods include a method that uses within-site variability of SC levels to derive a criterion maximum exposure concentration (CMEC) that will protect aquatic life from acutely toxic exposures (see Section 3.2). The CMEC differs from a criterion maximum concentration (U.S. EPA, 1985) because it is not calculated using laboratory or field data showing a direct relationship between SC and an acutely toxic biological response. However, the protectiveness of the CMEC was corroborated with field biological and SC data in Case Examples I and II (see Appendices A and B).

Table 2-3. Summary of assessment endpoints and measures of effect used in this field-based method to derive a criterion continuous concentration (CCC) and criterion maximum exposure concentration (CMEC) for specific conductivity

Stressor of concern	Measure of exposure
Mixture of ions (e.g., $([HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$	Specific conductivity
Assessment endpoints for the aquatic community	**Measures of effect**
Occurrence of macroinvertebrate populations	Chronic XC_{95} (genus-level effect) Chronic HC_{05} (assemblage-level effect)

XC_{95} = Extirpation concentration, the SC value below which 95% of the observations of a genus occur.

To summarize, for these field-based methods, the valued resource is the aquatic community, characterized by the macroinvertebrate populations that occur at a site. The ecological entities defining the assessment endpoints are populations of macroinvertebrates (aggregated to genera) and the measure of effect is extirpation (the desired attribute is occurrence). Macroinvertebrate populations are appropriate assessment entities because they occur in all but the poorest-quality streams, they are important to ecosystem structure and function, they are highly diverse, they are common forms of aquatic life, and they are affected by many different agents including ionic stress. Extirpation is the depletion of a population of a species or genus to the point that it is no longer a viable resource or is unlikely to fulfill its function in an assessed ecosystem. Extirpation of genera is an appropriate attribute for these methods that rely upon analyses of field data to determine population-level effect thresholds. Aquatic life criteria developed using these field-based methods are set at a SC level that protects

95% of resident macroinvertebrate genera that occur at reference sites in the relevant ecoregion. Aquatic communities are expected to be resilient to these effects and support the overall integrity and function of the aquatic ecosystem if the derived ecoregional criteria (magnitude, duration and frequency) are not exceeded.

2.7. SELECTION OF A FIELD-BASED METHOD

The EPA typically relies on laboratory toxicity test data for the development of aquatic life criteria (U.S. EPA, 1985). To the extent laboratory toxicity tests have been performed on similarly mixed proportions of these major ions, these tests with commonly tested laboratory species have not indicated sensitivity at the concentrations associated with loss of macroinvertebrate genera in the field (U.S. EPA, 2011a). Although it is impractical to replicate in the laboratory the range of taxa, conditions, effects, or interactions that occur in natural streams, a number of recent toxicity studies have begun to bridge the gap between physiological studies and field observations (Mount et al., 2016; Erickson et al., 2016; Wang et al., 2016a; Kunz et al. 2013). Also, mesoscosm studies have begun to identify the modes of action that likely lead to extirpation in the field and corroborate effects observed in the field (Clements and Kotalik, 2016; Nietch et al., 2014).

Analyses of field data show the reduced presence of many benthic macroinvertebrate genera at increasing SC levels. The associations between SC and benthic macroinvertebrate occurrence observed in the field have been assessed as causal (e.g., see Section 2.2 of this document; [e.g., Gerritsen et al., 2010; Palmer et al., 2010; Lindberg et al., 2011; Merriam et al., 2011; Pond et al., 2010, 2008; U.S. EPA, 2011a, b; Bernhardt et al., 2012; Cormier et al., 2013b, c; Timpano et al., 2014; Dunlop et al., 2015; Zhao et al., 2016]). Furthermore, the field data used in this analysis represent exposures to regionally representative assemblages of taxa and life stages at levels and proportions of ions under realistic physical and chemical conditions. In this case, field data can be used to directly assess ecologically-relevant measures of effects, such as extirpation of genera in aquatic communities as a result of exposure to these ionic mixtures in the field. Protection of a diverse assemblage of benthic macroinvertebrates is protective of stream communities and aquatic life.

For these reasons, the EPA concluded that a field-based approach is appropriate for developing SC criteria where there are sufficient data for analysis.

3. ANALYSIS PLAN: FIELD-BASED METHODS TO DEVELOP SPECIFIC CONDUCTIVITY CRITERIA

This section presents field-based methods that may be used to derive SC water quality criteria for the protection of aquatic life where sufficient data are available. The methods describe how to derive a criterion continuous concentration (CCC) to protect against effects from chronic exposure (see Section 3.1) and a CMEC to protect against effects from acute exposure (see Section 3.2). The methods also describe how to estimate duration (see Section 3.3) and frequency (see Section 3.4), how to assess causation (see Section 3.5), and how to determine the applicable geographic range of criteria (see Section 3.6). Because the primary method (the XCD method) requires large, paired chemical and biological data sets which are not available for all ecoregions in the United States, EPA developed another method which uses a model to calculate a CCC for SC. This method is useful for Level III ecoregions where sufficient paired biological data are lacking (see Section 3.7). Section 3 serves as the *Analysis Plan* for the case studies in Sections 4, 5, 6 and 7. Some ecoregion-specific examples are included in this section to illustrate key concepts and methods.

3.1. DERIVING A CRITERION CONTINUOUS CONCENTRATION (CCC)

The XCD method requires a field data set with paired in situ measurements of SC and benthic macroinvertebrate survey results for streams in the study area. The field SC measurements allow for the development of exposure-response relationships across a SC gradient. The inclusion of high quality and impaired sites in the data sets assures a range of SC (exposure) for characterizing changes in taxa occurrence (response). In aggregate, the in situ field measurements of SC from many sites from different times of the year represent the variability over a year.

Using this method, two relationships are derived from the field data: one for each macroinvertebrate genus and one for the overall macroinvertebrate assemblage in the study area. First, a weighted CDF is developed for each macroinvertebrate genus to determine each XC_{95}. Second, the HC_{05} is developed using a genus XCD for the macroinvertebrate community from the aggregation of the XC_{95} values (an example is provided in Figure 3-1).

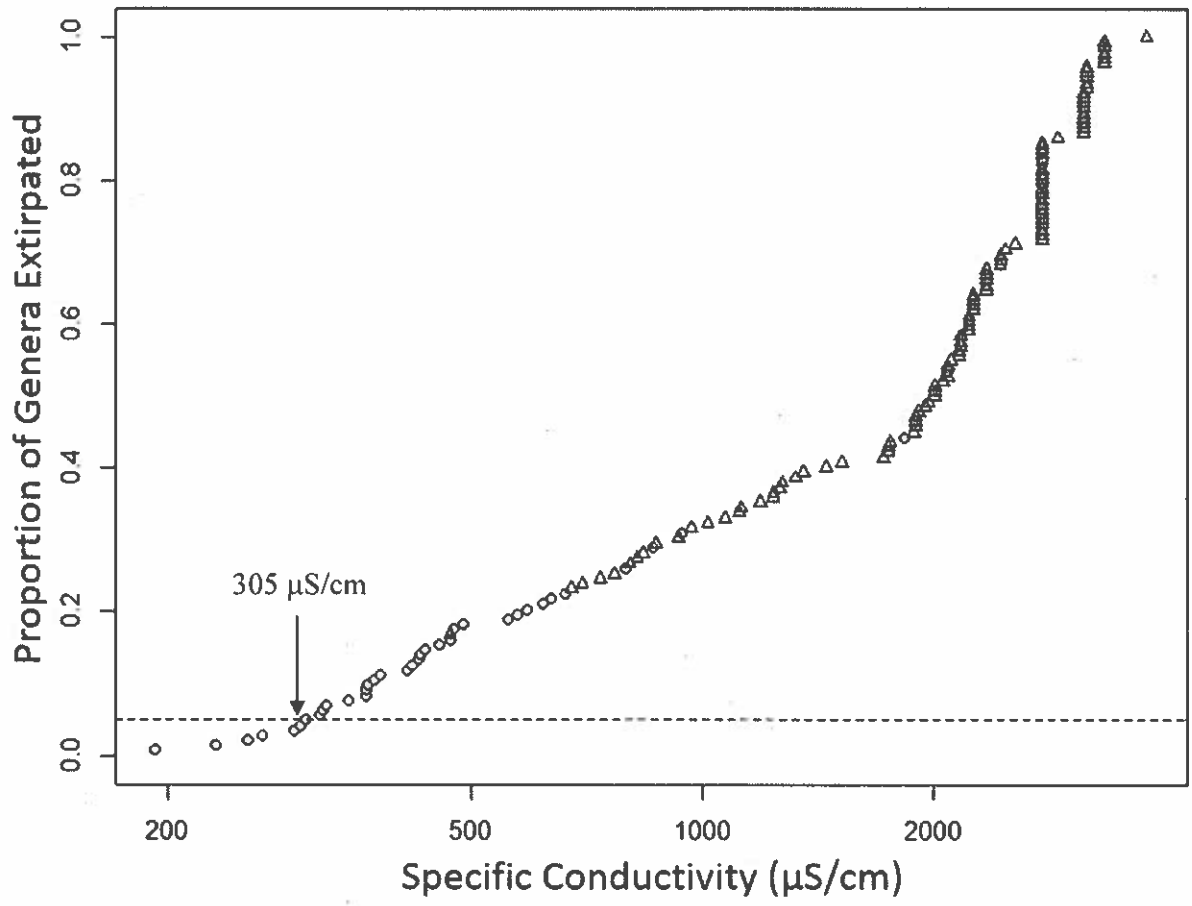

Figure 3-1. Example of a genus extirpation concentration distribution (XCD) depicting the proportion of genera extirpated with increasing ionic concentration measured as specific conductivity (SC). Each point on the XCD plot represents an extirpation concentration (XC_{95}) value of one genus arranged from the least to the most salt-tolerant. XC_{95} values that were defined as greater than values are indicated by triangles. The 5th centile of the XCD is shown as a dotted horizontal line. The 5th centile hazardous concentration (HC_{05}) is the SC at that intercept of the XCD and the 5th centile line. In this example, the HC_{05} is 305 µS/cm.

Several methods were evaluated prior to selection of a weighted CDF model to estimate an XC. They included models of XC from logistic regression, a generalized additive model (GAM), unweighted CDF, and other options. A weighted CDF model was selected because the HC_{05} value fell within the range of the other methods, and it was computationally simple. Weighting normalizes the distribution of samples taken across the SC gradient. The weighted CDF does not assume any particular shape to the distribution and does not fit a function to the

data points. Outliers were not identified or removed because little was known about the sustainability of populations in high SC water or the movement of salt-intolerant taxa from biological sources to sinks. However, at least one study indicates that apparent outliers may represent transient occurrences of genera drifting from low SC to a high SC stream reach (Pond et al., 2014). Removal of the outliers or using the area under a fitted curve such as a GAM generally yields lower XC_{95} values and a lower HC_{05}. As new information arises, the method for modeling the XC_{95} may be updated. The EPA SAB endorsed EPA's selection (U.S. EPA, 2011c) of the weighted CDF model for this field-based method (U.S. EPA, 2011a). The statistical package *R*, Version 2.12.1 (December 2010), was used for all statistical analyses in the Case Studies (*R*-Development Core Team, 2011). The program "R" is open-source and open-access computational software that runs on Microsoft Windows, Apple MacOS, and UNIX platforms. The calculations can also be performed with a hand-held calculator or with a spreadsheet such as Microsoft Excel.

Different forms of the exposure-response relationships (i.e., decreasing, unimodal, increasing, and no relationship) are expected given the nature of the ions and the physiology of a macroinvertebrate genus. For example, many ions are required for survival and are beneficial at low levels but elicit toxic effects at high levels; such a stressor-response relationship is expected to have a unimodal distribution (see Appendix A.3, *Isonychia*). In the ascending (left) limb, requirements for ions are increasingly being met; in the descending (right) limb, toxicity is increasing. However, many empirical exposure-response relationships for ions do not display both limbs of the distribution. For example, some may show: (a) only the descending portion of the curve because none of the observed SC levels are sufficiently low to show elemental deficiency for the taxon (see Appendix A, *Ephemerella and Leuctra*); (b) only the ascending portion because none of the observed SC levels are sufficiently high to show toxicity for the taxon (see Appendix A, *Cheumatopsyche*); or (c) no trend at all because the optimum is more of a plateau than a peak so it extends across the range of observed SC levels (see Appendix A.3, *Brilla*).

The steps involved in selecting, characterizing, and analyzing macroinvertebrate sampling field data to derive a CCC are depicted in Figure 3-2 and described in the following sections.

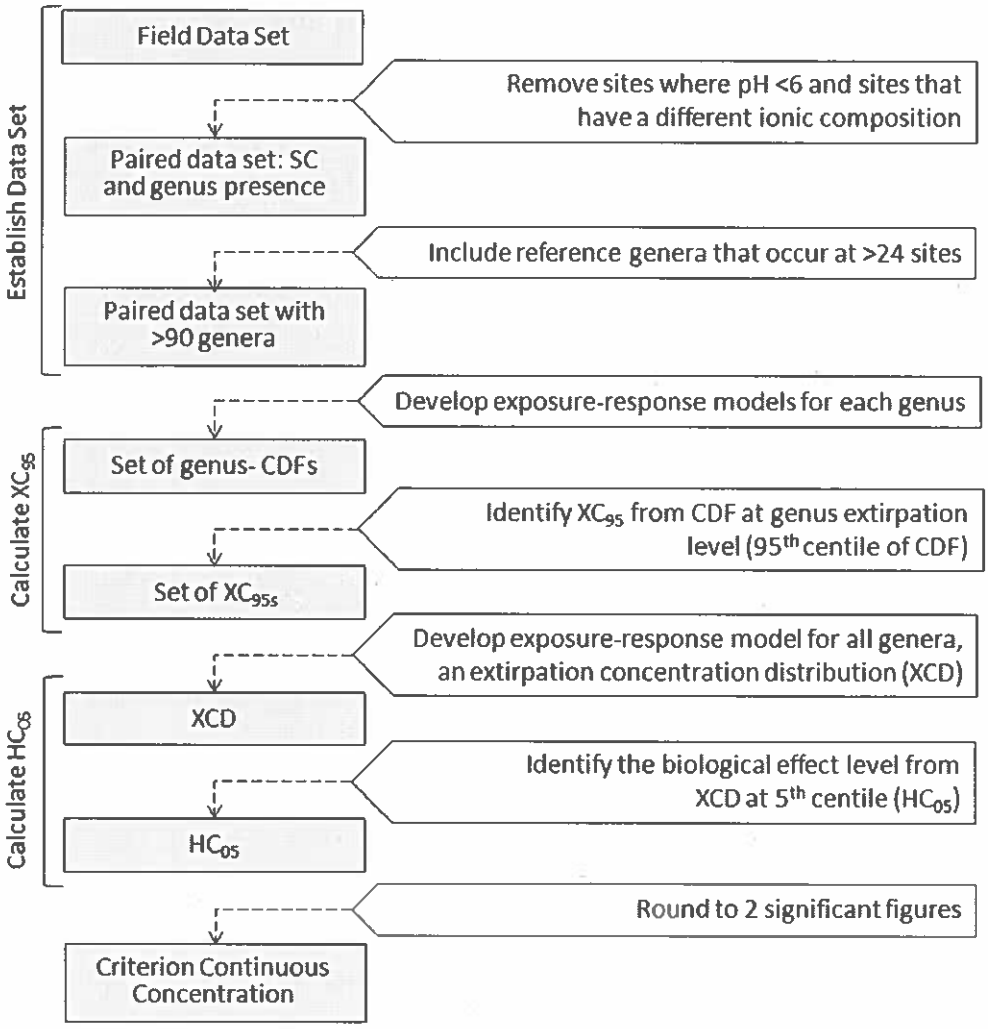

Figure 3-2. Main steps in the derivation of a chronic specific conductivity (SC) criterion using the extirpation concentration distribution (XCD) method. Rectangular boxes on left are products and pentagonal boxes on right are operations performed on those products. In the Case Studies (see Sections 4, 5, 6 and 7), example SC criteria are derived using data from sites in a defined area that have an ionic composition dominated by sulfate plus bicarbonate anions. Cumulative distribution function (CDF), 95th centile extirpation concentration (XC_{95}), 5th centile hazardous concentration (HC_{05}).

3.1.1. Establishing the Data Set

3.1.1.1. *Information Sources*

The data sets are developed at an ecoregional scale to account for natural differences in background SC levels found in different ecoregions, and QA/QC of the data sets are described.

Several data sets were used to illustrate the method in the case studies, details of which are provided in Sections 4, 5, 6, and 7. In addition to the description of field data, information available in the scientific literature is considered in the development of ecoregional SC criteria, particularly for assessing causation and confounding factors (see for example Appendices A and B in U.S. EPA, 2011a; Cormier et al., 2013b; Suter and Cormier, 2013) and to support recommendations for duration and frequency of the criteria. Relevant literature related to the characteristics of the receptor organisms, the ions of interest, and the potential confounding agents are also considered, much of which is presented in Section 2 (*Problem Formulation*) of this document and also in the precursor reports and manuscripts (U.S. EPA, 2011a; Cormier et al., 2013b; Suter and Cormier, 2013).

3.1.1.2. *Selection and Adequacy of Data Sets*

Developing aquatic life criteria for SC using the XCD method requires a large data set with certain characteristics. The adequacy of the data set can be judged by the following attributes (U.S. EPA, 2011c):

- Measurements of the agent(s) are paired in space and time with biological sampling;
- High-quality (i.e., minimally affected) sites are included in the data set;
- Background SC levels are similar throughout the region (see Section 3.7.1);
- Characteristics of the agent (i.e., ionic composition) are similar across the region for the paired data (i.e., other mixtures may occur but they are analyzed separately);
- Some biological sampling occurs when salt-intolerant genera are likely to be collected (e.g., March through June in Appalachia) and where they are likely to occur (e.g., leaf packs, riffles);
- The exposure gradient is broad enough to include no effects, weak effects, and strong effects;
- Data are available to evaluate potential confounding factors; and
- An independent data set or statistical models are available to validate the criteria.

Inclusion of many genera and a representative proportion of salt-intolerant genera help to ensure that the XCD model is representative of the aquatic community. A sensitivity analysis of data sets has determined that a reliable HC_{05} can be determined from 90–120 genera and 500–800 sites, based on the stability of the HC_{05} value as those variables increased (U.S. EPA, 2011a; see Sections 4 and 5 of this report). Samples taken throughout the year reduce biases from seasonal SC regimes and seasonal occurrence of some genera. For example, samples taken only in dry seasons when SC tends to be higher would likely bias results toward more salt-tolerant genera and to maximum SC exposures rather than an annual average.

3.1.1.2.1. Sample size

The number of observations of a genus can affect the reproducibility of the XC_{95} and the HC_{05} (Cormier et al., 2013a). Similarly, the number of genera affects the reproducibility of the HC_{05} (U.S. EPA, 2011a; Cormier et al., 2013a) and the number of genera depends on the overall number of samples in the data set and individuals in the sample that are identified to genus.

For the example case studies, EPA estimated XC_{95} values using the XCD method with genera that were observed in ≥25 samples in the ecoregion (Cormier et al., 2013a) because estimations of the 95th centile with <25 observations are less robust. The recommended number of genera in an XCD using this method is 90 (Cormier et al., 2013a). For a sampling protocol that identifies 200 individuals in a sample, the adequate number of sampling stations in an ecoregion using this method is about 500 (U.S. EPA, 2011a). However, if more individuals are identified in each sample, e.g., 300 or a full count of individuals, then fewer sampling stations may be needed to obtain XC_{95} values for 90 or more genera (see Appendix G in U.S. EPA, 2011).

The effect of selecting a minimum number of observations of a genus for calculating an XC_{95} value can be visualized in several ways. For example, for a range of genus sample sizes (e.g., N = 5–60), the HC_{05} is calculated and the number of genera in the XCD is enumerated. The resulting HC_{05} values and number of genera versus minimum number of samples are plotted. As taxa with fewer occurrences are excluded from the XCD, the number of genera decreases and the HC_{05} increases (see Figures 4-11 and 5-11). To ensure representation of salt-intolerant taxa and reasonable accuracy of the HC_{05}, the minimum number of samples is chosen that maximizes the number of taxa in the XCD while minimizing the variance in the XC_{95} and resulting XCD

near the 5th centile. The number of observations of a genus is also chosen to provide sufficient occurrences to estimate the genus XC_{95} values while minimizing bias due to eliminating salt-intolerant genera that have few occurrences. A minimum sample size of 25 maximizes the number of taxa that are included without having to extrapolate beyond the range of the data set (Cormier et al. 2013a, on-line supplemental material). Therefore, a sample size of 25 was utilized in the case studies, and in general, is a recommended minimum sample size for this method.

The effect of sample size on the HC_{05} and its confidence bounds can be estimated using a bootstrapping technique (see Section 4.5 and 5.5). Bootstrapping is a statistical technique of repeated random sampling from an empirical data set that is often used in environmental studies to estimate confidence limits of a parameter (Newman et al., 2001, 2000). This is akin to having different samples to compare results and fidelity of the model. A similar method is used to calculate confidence bounds on the HC_{05} values (described in Section 3.1.3.1). Using this technique, a data set of a selected sample size with replacement is randomly selected from the original set of samples. Next, the XC_{95} for each genus is calculated from the bootstrap data set by the same method applied to the original data, and the HC_{05} is calculated. The uncertainty in the HC_{05} value can be evaluated by repeating the random sampling and HC_{05} calculation numerous times (e.g., 1,000 times) for each selection. The distribution of 1,000 HC_{05} values is used to generate two-tailed 95% confidence bounds on these bootstrap-derived values. The whole process is repeated for a selected sample size ranging from 100 to the full data set of all samples. The mean of all bootstrapped HC_{05} values, the numbers of genera used for the HC_{05} calculation, and their 95% confidence bounds are plotted to show the effect of sample size. The number of samples at which the HC_{05} values reach an approximate asymptote (500–800) suggests the minimum sample size (500) for a data set (see Figures 4-12 and 5-12).

3.1.1.2.2. Treatment of multiple samples from a particular site

Multiple samples collected from the same site can provide valuable information especially when they are from different seasons (when SC may be different and different genera may be present), but they can be problematic if they introduce a bias (e.g., if extremely low or high SC sites are more likely to be sampled repeatedly).

In the case studies, most of the sites were sampled only once, but a portion of them were sampled more than once (see Sections 4.1 and 5.1). To assess for a potential bias, a simple inverse weighting scheme can be applied (e.g., if a site is sampled twice, each observation is weighted 0.5). In the example case studies, this weighting scheme did not substantially change the magnitude of the HC_{05} values; therefore, all data were used with no weighting. In cases where geographic distribution of sites and/or SC levels affects the HC_{05}, then some form of correction may be warranted, such as random selection of only one sample per site. In the case studies, sites were fairly evenly distributed; therefore, no weighting was performed for replicates.

3.1.1.2.3. Stressor identity

The stressor identity in this case is the proportion of constituent ions, characterized on the basis of the field data set. The stressor of concern in the example case studies is an ionic mixture dominated by sulfate (SO_4^{2-}) plus bicarbonate (HCO_3^-) (see Section 2.2). As a result, for these example criteria, sites with an ionic mixture dominated by chloride (i.e., those where the concentration of HCO_3^- plus $SO_4^{2-} \leq Cl^-$, in mg/L) are removed from the data set. The ionic mixture in the example case studies (see Section 4, 5 and 7) are dominated by the cations on a mg/L basis by ($[Mg^{2+}] + [Ca^{2+}]$) > $[Na^+]$ and one by ($[Mg^{2+}] + [Ca^{2+}]$) < ($[Na^+] + [K^+]$) (see Section 6). Alternatively, other data can be removed to focus on other mixtures or salts (e.g., NaCl).

3.1.1.2.4. Ambiguous taxa

The XCD method uses genus-level taxonomic identification. This method does not mix data of lower or higher levels of taxonomic identification. However, species-level taxonomic identification can be used when it is available and the number of species is sufficient for constructing an XCD (see Appendix G for an example). Data records with ambiguous taxonomic identification or family-level or higher identification (i.e., no genus-level identifications) are excluded from the data sets.

3.1.1.2.5. Exclusion of genera from extirpation concentration distribution (XCD)

This method is for freshwater systems, and therefore, estuarine and marine genera were not included in the XCD. One way to ensure that only freshwater organisms are represented in

the XCD is to only include genera that are present at a minimum of one freshwater reference site. The selection of reference sites is beyond the scope of this document (Stoddard et al., 2006; Herlihy et al., 2008; Whittier et al., 2007b; Hawkins, et al. 2010; U.S. EPA, 2011d; Environment Canada, 2012). For the example case studies, the reference sites used in analyses were identified by the sampling organization, but only after EPA reviewed the reference site selection criteria (see Sections 4 and 5). When reference sites were not identified by the sampling organization, all genera were used (see Appendix D).

3.1.1.2.6. Confounding factors

Field observations are uncontrolled, largely unreplicated, and may not be randomized; as a result, they are subject to confounding. Confounding is the appearance of apparently causal relationships that are due to noncausal correlations. Noncausal correlations and the inherent noisiness of environmental data can obscure true causal relationships. Reducing confounding as much as possible is recommended by identifying potential confounding variables; determining their contributions, if any, to the relationships of interest; and eliminating their influence when possible and as appropriate based on credible and objective scientific reasoning.

A method to assess the potential effect of confounders is described in the *EPA Benchmark Report* (U.S. EPA, 2011a) and in Suter and Cormier (2013). The analysis of potential effects on the model by potential confounders used a weighted scoring system to evaluate ten types of evidence that determined whether the observed relationship between benthic macroinvertebrate community composition and SC was affected by other factors. The weighted scoring system was based on work by Hill (1965) and Cormier et al. (2010) and is described in detail in Appendix B of EPA (U.S. EPA, 2011a) and in Suter and Cormier (2013). As described in the *EPA Benchmark Report*, the potential for other stressors to affect the XCD model was evaluated using a weight-of-evidence assessment that considered habitat quality, organic enrichment, nutrients, deposited sediment, pH (low and high), selenium, temperature, lack of headwaters, catchment area, settling ponds, dissolved oxygen, and metals (see Appendix B in U.S. EPA, 2011a). Overall, the analyses showed that the effects attributed to increased ionic concentration were not due to other stressors.

In these analyses (U.S. EPA, 2011a), only one of the assessed factors (pH <6) was identified as a likely confounder, so samples with pH <6 were removed from the data set to

minimize the influence of acidity and associated dissolved metals. Due to the toxicity at low pH, unless shown to the contrary, sites with pH <6 are excluded from data sets prior to analysis.

Also, when using this method, the EPA recommends that at least one sequence of analyses be used to evaluate the effect of confounding on the XCD model. For example, potential confounding can be evaluated using multiple regression analyses followed by modification of the data set to control for the strongest potential confounding factors and then calculating the HC_{05}. If the HC_{05} is not appreciably altered by this data set manipulation, the full data set can be used. If the HC_{05} is appreciably altered, the criterion data set may be modified to minimize that factor's effect on model prediction. The model is accepted if the confidence bounds of the original and new HC_{05} overlap. Examples for confounding analyses and reducing effects of confounding can be found in Case Studies I and II in Appendices A.2 and B.2, respectively.

There are two common means for reducing the influence of confounders. First, sites with a confounder can be removed from the data set, thus reducing its influence on the XC_{95} estimates and XCD model. For example, the EPA removed samples with low pH in the case study examples (see Appendices A.2.3 and B.2.3). Secondly, the effect of a confounder can be minimized by normalizing the influence of a confounder with appropriate weighting. The EPA used this approach to assess the influence of temperature and season in the case study examples and these methods could be used to adjust for confounders if necessary (see Section 3.1.4, and Appendices A.2.3 and B.2.3). Removing samples from the data set can reduce the number of species or the range of exposures of the stressor of interest, thus affecting the reliability of the estimates. Therefore, it is important to evaluate whether the manipulation of the data set improves the accuracy of the HC_{05}. Each case is different, and professional judgment is recommended.

3.1.1.3. *Quality Assurance/Quality Control (QA/QC)*

Information is reported about the specific methods used to choose sampling locations, to sample water SC and macroinvertebrates, and to assure data quality. Some considerations include whether standardized quantitative or semiquantitative techniques are used for macroinvertebrate sampling, the mesh size used in the field and lab for sampling and sorting, whether samples are subsampled, and if so, what percentage was subsampled. The data set

description and metadata include sampling dates; total number of chemical, physical, and biological samples from distinct locations (and total samples); sampled years; stream types represented by samples; and ecoregions represented by sites. Annual sampling when salt-intolerant genera are likely to be present is usually sufficient and avoids damage to the habitat and stream biota due to repeated sampling during the year. If sampling occurs more than once per year from the same location, the use or restriction of repeat samples is described. Similarly, a full description or literature references are provided for the chemical and physical parameters that are used in any analysis (see an example in Section 4.1). Additional information regarding QA/QC and other critical technical elements of a robust biological assessment program (e.g., taxonomic resolution, sample collection, sample representativeness, sample processing, data management, and professional review) can be found in EPA's technical assistance document, *Biological Assessment Program Review: Assessing Level of Technical Rigor to Support Water Quality Management* (U.S. EPA, 2013a).

3.1.2. Calculating Genus Extirpation Concentrations (XC_{95})

For each genus meeting the data-selection conditions, a CDF is constructed that is weighted to correct for any potential bias from the unequal distribution of sampling of sites across the range of logarithm10 transformed SC values. This weighted CDF represents the proportion of observations of a genus with respect to increasing exposure levels. The extirpation effect threshold for a genus is 95% of the total occurrences of the genus. The two exposure levels bracketing the 95th centile are linearly interpolated to give an XC_{95} for a genus.

In the case examples, all calculations are performed using logarithm base 10 (log10) transformed SC values. Variables are routinely log transformed when applying the field-based methods. Because environmental data are usually skewed, log transformation normalizes the data so that normality assumptions are not violated. Log transformation also tends to increase equality of variance, increase the linearity of relationships, and makes plotted relationships clearer.

First, equally-sized bins are defined to compute weights for each sample. Bin size depends on the data set and is based on balancing the requirements of sufficient observations in a single bin to define the proportion and a sufficient number of bins to define the form of the response. The effect of bin size can be analyzed by developing a series of HC_{05} values using

different bin and sample sizes. In general, 40 to 60 bins usually gives acceptable results. For example, for Case Studies I and II, the width of each bin is $1/60^{th}$ of the range of the log10 transformed SC values. Thus, each bin was assigned a width equal to 0.017 (1/60 bins) multiplied by the range of the log10 transformed SC values within the data set (for examples see Figures 4-6 and 5-6).

Next, the bins are weighted to ensure that sites in bins with many observations are not overly influential. The assigned weight for each sample within a given bin is $w_i = 1/n_i$, where n_i is the number of samples in the ith bin. The value of the weighted cumulative distribution function, $F(x)$, is computed using the following equation for each unique observed value of the agent x associated with observations of a particular genus:

$$F(x) = \frac{\sum_{i=1}^{N_b} w_i \sum_{j=1}^{M_i} I(x_{ij} < x \text{ and } G_{ij})}{\sum_{i=1}^{N_b} w_i \sum_{j=1}^{M_i} I(G_{ij})} \qquad (3\text{-}1)$$

where

x_{ij} is the stressor value in the j^{th} sample of bin i,
N_b is the total number of bins,
M_i is the number of samples in the i^{th} bin,
G_{ij} is true if the genus of interest is observed in j^{th} sample of bin i,
I is an indicator function that equals 1 if the indicated conditions are true, and 0 otherwise,
W_i is the assigned weight of a sample within the i^{th} bin, $w_i = 1/M_i$.

The XC_{95} value is defined as the stressor value corresponding to $F(x) = 0.95$. Equation 3-1 is an empirical cumulative distribution function, and the output is the proportion of observations of the genus that occur at or below a given exposure level. See Figure 3-3 for examples of weighted CDFs. Figure 3-3 shows weighted proportions of samples with *Epeorus* and *Nigronia* present at or below the indicated SC value (µS/cm). The XC_{95} is the SC at the 95^{th} centile of the weighted CDF (vertical dashed line). Within the observed ranges of SC, the weighted CDFs of some

genera demonstrate a response to SC (e.g., *Epeorus*) as shown by a steep slope and asymptote well below the maximum exposures. Conversely, genera unaffected within this SC range (e.g., *Nigronia*) have a steady increase over the entire range of measured exposure and do not reach a clear asymptote.

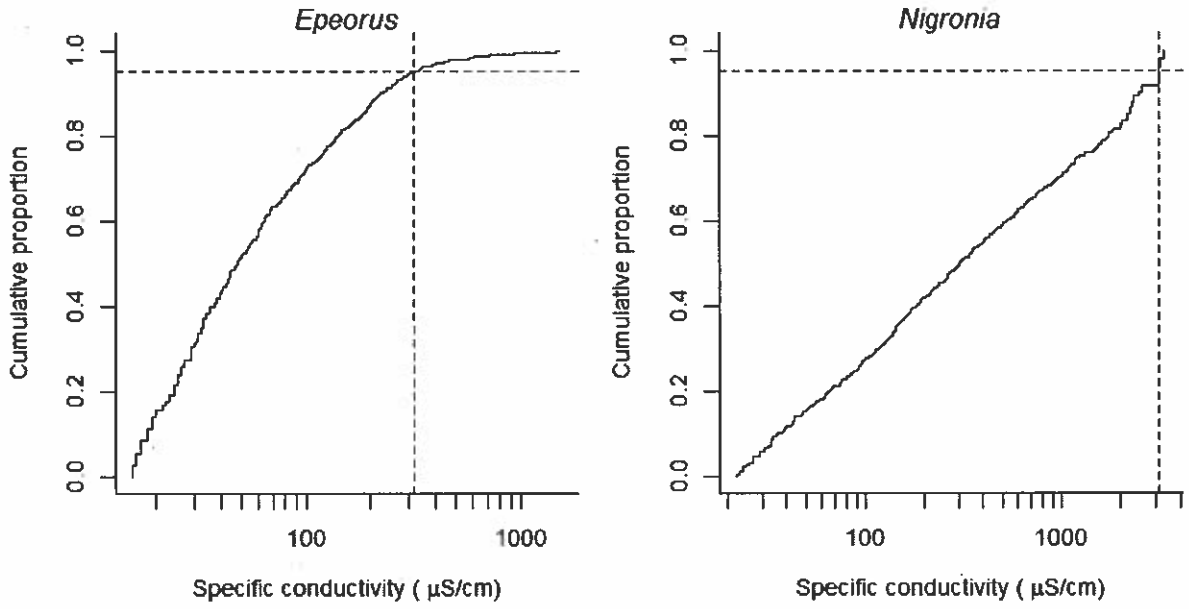

Figure 3-3. Examples of weighted cumulative distribution functions (CDFs) and the associated 95th centile extirpation concentration values.
The plot for *Epeorus* rises steeply and reaches a plateau, indicating that the genus is affected by increasing specific conductivity (SC). The plot for Nigronia increases linearly without reaching an asymptote, indicating that this genus is not as affected by changes within the tested range of SC.

This method for calculating the XC_{95} will generate a value even if the genus is not extirpated. For example, the occurrence of *Nigronia* changes little with increasing SC (i.e., the cumulative distribution is linear [see Figure 3-3]). Because of the data distributions, not all 95th centiles correspond to extirpation, and some imprecisely estimate the extirpation threshold. The weighted CDFs (see Figure 3-3, Appendices A and B) and scatter plots (see Figure 3-4, Appendices A and B) should be visually inspected for anomalies; if there is no clear trend in the response or if the response does not include extirpation, the XC_{95} can be given a qualifying assignation such as either approximately (~) or greater than (>) the calculated value. The

assignation of > or ~ does not affect the HC_{05} if the values are above the 5th centile, but it alerts users of the uncertainty of the XC_{95} values (see Section 3.1.2.1).

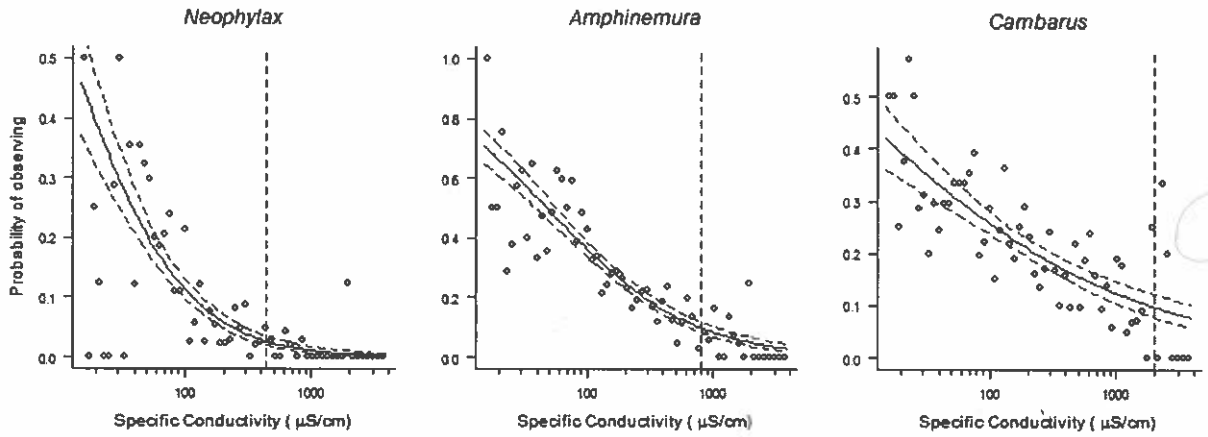

Figure 3-4. Examples of extirpation concentration (XC_{95}s) for three genera listed as being definitive (*Neophylax*), approximate (*Amphinemura*), and greater than (*Cambarus*). In this example, the probability of observing a genus is the proportion of sampled stations in a SC bin with the genus present based on taxonomic identification of 200 individuals per sample. Qualifications based on the slopes of the confidence bounds as described above. For *Neophylax*, both upper and lower 90% confidence limits intersect *x*-axis, for *Amphinemura* only the lower intersects, and for *Cambarus* neither intersect. The vertical line is the XC_{95} calculated from the weighted cumulative distribution functions.

3.1.2.1. *Assigning Qualifying Designation to Extirpation Concentration (XC_{95}) Values*

The uncertainty bounds of a GAM are used to indicate the confidence in the calculated XC_{95} and whether the value is greater than the tested range. A GAM is not used to estimate the XC_{95}. In order to examine the trend of taxa occurrence along the SC gradient, a GAM is used to model the likelihood of a taxon being observed with increasing SC (Hastie and Tibshirani, 1986). In the example, the probability of observing a genus is the percentage of sampled stations in a given SC bin with the genus present based on taxonomic identification of 200 individuals per sample (see Figure 3-4).

Three typical distributions of observational probabilities are shown in Figure 3-4. A GAM is similar to a regression model except that it iteratively fits a line to the data using a scatterplot smoother which can use any function, not only a straight line or polynomial. The form of the fit is automated and the final shape of the fitted line is useful for revealing nonlinear covariate effects. In this analysis, the GAM shows whether a genus is increasing, decreasing, or

unchanging along the SC gradient. The 90% confidence interval (CI) of the GAM is used to judge whether a decreasing model identifies the XC_{95}, approximates the XC_{95}, or is not measured within the exposure range of the data set, which is indicated as being greater than (>) the estimated value. In the figure, the solid line is the mean smoothing spline fit, and the dots are the mean observed probabilities of observing a genus within a defined SC range, estimated as the proportion of samples within each SC bin. The SC at the vertical dashed line is the estimated XC_{95} previously calculated from the weighted cumulative distributions such as depicted in Figure 3-3.

If the GAM mean fitted curve at maximum SC is approximately equal to 0 (defined as less than 1% of the maximum modeled probability), as in the *Neophylax* example in Figure 3-4, then the XC_{95} is listed without qualification (*Neophylax* XC_{95} is listed as 434 µS/cm without qualification; Appendix A.4). If the GAM mean fitted curve at maximum SC is greater than 0, but the lower 5% confidence limit is approximating to 0 (<1% of the maximum mean modeled probability), as in the *Amphinemura* example in Figure 3-4, then the value is listed as approximate (*Amphinemura* XC_{95} ~805 µS/cm). If the GAM lower 5% confidence limit is greater than 0, as in the *Cambarus* example in Figure 3-4, then the XC_{95} is listed as a greater than value (*Cambarus* XC_{95} > 1,974 µS/cm). The assignations of greater than (>) and approximately (~) does not affect the HC_{05}. They are provided to alert users of the uncertainty of the XC_{95} values for other uses such as comparison with toxicity test results or with results from other geographic regions.

3.1.3. Calculating the Community-Level Effect Estimate Hazardous Concentration (HC_{05})

The XCDs are cumulative distribution plots of XC_{95} values for each genus relative to SC level (see Figure 3-1). The XCD is useful for visualization, but not necessary to calculate the HC_{05}. The cumulative proportion for each genus P is calculated as $P = R/(N + 1)$, where R is the rank of the genus and N is the number of genera. Relatively tolerant genera coded as ~ or > are included. They are reported as ''approximate" or "greater than'' values. Their inclusion assures that N is the correct number of genera, but they do not otherwise contribute substantially to the HC_{05} because they fall in the upper portion of the XCD. The HC_{05} is derived by two-point interpolation between the XC_{95} values bracketing $P = 0.05$ (i.e., the 5th centile of modeled

genera). For an example of an XCD cumulative distribution plot of XC_{95} and HC_{05} derivation, see Figure 4-7.

3.1.3.1. *Validating the Effect Estimate Hazardous Concentration (HC_{05}) by Bootstrapping*

The EPA's Science Advisory Board (U.S. EPA, 2011c) recommended using bootstrapping as one way to validate the XCD model and estimate uncertainty around the HC_{05} values. This method generates distributions and confidence bounds for each genus in the first step and propagates the statistical uncertainty of the first step through the later steps in which the XCD is created and the HC_{05} is estimated (see Figure 3-5). A data set of the same sample size as the original data set is randomly selected with replacement from the original set of samples (Efron and Tibshirani, 1993). The XC_{95} for each genus that occurs at least once in the original data set's reference sites and in more than 24 sampled sites is calculated from the bootstrap data set by the same method applied to the original data. The XC_{95} for each genus is stored and later used to estimate the confidence bounds of each genus' XC_{95}. Then, the HC_{05} is calculated and stored. The uncertainties in the XC_{95} and HC_{05} values are estimated by repeating the sampling and calculations 1,000 times. The distribution of 1,000 HC_{05} values is used to generate two-tailed 95% confidence bounds on these bootstrap-derived values (see Figure 4-13 for an example). The particular genera and the number of genera in any bootstrapped XCD differ in each bootstrapped sample of sites; therefore, the number of bootstrapped XC_{95} values of genera may be more or less than the number of genera in the original data set. The distribution of 1,000 XC_{95} values for each genus is also used to generate two-tailed 95% confidence bounds on these bootstrap-derived XC_{95} values. See Appendices A.3 and B.3 for example 95% confidence bounds for each genus.

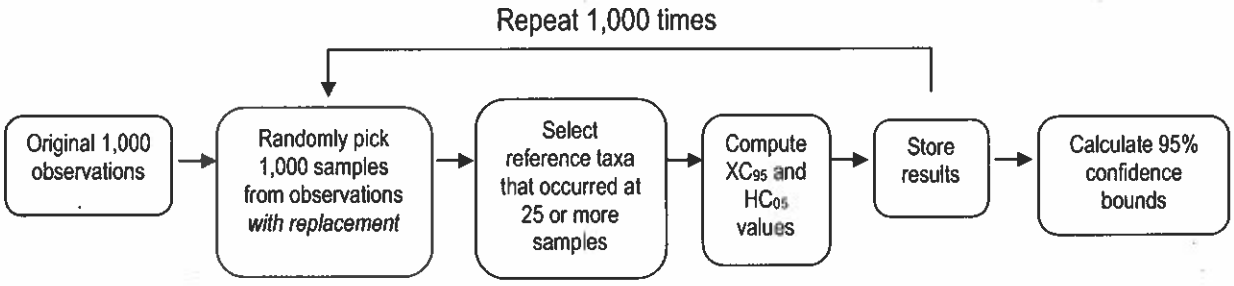

Figure 3-5. Diagram from *EPA Benchmark Report* depicting the process for estimating uncertainty. Bootstrapping is a resampling of the original data set to create 1,000 new data sets and from each of the 1,000 data sets, the extirpation concentration (XC_{95}) values are calculated. After each run, an extirpation concentration distribution (XCD) is made and a hazardous concentration (HC_{05}) estimated. This process is repeated until there are 1,000 HC_{05} values and then the confidence limits of the HC_{05} are estimated. The number of samples varies depending on the data set. The same resampling process is used to evaluate the effect of different sample sizes, exclusion of genera using different database selection criteria, or other parameter choices (see Section 3.1.1.2).

Confidence bounds represent the potential range of HC_{05} values using the XCD approach based on the data set. Conceptually, these confidence bounds may be thought to represent the potential range of HC_{05} values that one might obtain by returning to the field and resampling the same set of streams. The contributors to this uncertainty include measurement variance in determining SC and sampling variance in the locations for monitoring, collecting, and enumerating organisms. These also include variance due to differences in stream reaches, weather, and other random factors.

The confidence bounds do not address potential systematic sources of variance such as differences in sampling protocols. The contributions of those sources of uncertainty, in addition to the sampling uncertainty, can best be evaluated by comparing the results of independent studies. One estimate of that uncertainty may be provided by comparing the all-year HC_{05} values derived from the region for which criteria is being derived to another comparable region. Even if data are obtained in different areas by different agencies using different laboratory processing protocols, the HC_{05} values may be similar.

In the *EPA Benchmark Report*, the HC_{05} value was validated by an independent data set which had a similar background SC, and the values differed by less than 5% (see Appendix G in U.S. EPA, 2011a). Large data sets for ecoregions from more than one sampling organization are

rare and so EPA has provided this bootstrapping method (Newman et al., 2000) as an alternative method to validate the XCD model as suggested by the SAB in their review of the *EPA Benchmark Report* (U.S. EPA, 2011c).

3.1.4. Assessing Seasonality, Life History, and Sampling Methods

The seasonality of life-history events such as emergence of aquatic insects can affect the probability of detecting a species because eggs and early instars are not collected by most sampling methods. As an illustration, in the example cases in Sections 4 and 5, annual insects (univoltine) that emerge in the spring, although present, are less likely to be detected in the summer, when coincidently, SC levels increase in some streams (e.g., due to decreased flow). In other locations, this pattern may be different. For example, high mountain systems may be affected by melting snow pack. Seasons may shift based on latitude. Also, sampling restricted to a season can bias the estimate of natural background or effect estimates (i.e., XC_{95} values). Both high-concentration and low-concentration periods should be represented when the salt-intolerant genera are collected in order to ensure that the tolerated range is evaluated. These periods may vary by time of year among regions, and among years (based on climate variability) for any given region. Professional experience with the SC regimes and the life cycles of vulnerable species is required when assessing whether a data set is suitable for using the XCD method.

Because the hydrologic and SC regime and the natural history of salt-intolerant taxa vary by region, the potential effect of sampling date on the form of the XCD model may be assessed using several methods. As an illustration, in the example cases in Sections 4 and 5, the HC_{05} using the spring (March–June) only data set was compared with the HC_{05} based on the full-year data set for the ecoregion. If the spring HC_{05} is within the confidence bounds of the full-year data set, then the full annual data set can be used (see example in Appendix A, Figure A-8); if this is not the case, further correction for a confounding factor may be necessary as described below for the example using sampling date.

A scatter plot and regression model can be developed to evaluate the mean relationship between measurements of SC at the time of the biological sample and annual mean SC (for an example, see Appendix A, Figure A-9). The annual geometric mean SC values are calculated from at least six water samples collected before biological samples were taken. At least one

spring (when salt-intolerant taxa can be collected) and one summer macroinvertebrate sample is recommended in order to increase the likelihood that salt-intolerant taxa will be included in the data set. On the *x*-axis is the SC when biological samples are collected and on the *y*-axis is the annual geometric mean value during that rotating year for a site. A Model II regression is fitted to the data because the two SC measurements are uncertain. [A Model I regression using least squares is not used because it underestimates the slope of the linear relationship between the variables when they both contain error (Legendre, 1998)]. The mean relationship between measurements of SC at the time of the biological sample and annual mean SC is supported if the relationship approaches 1:1, and prediction for the annual mean from the regression model is within the confidence bounds of the HC_{05}.

A third approach to account for seasonal variability involves adjusting SC results collected at the time of biological sampling to estimate annual mean SC values. In situations where the SC tends to be lower in the spring than in the summer, the effect of seasonality on the HC_{05} is evaluated by converting the instantaneous biological sample SC into an annual mean value based on monthly weighting factors. Then, the XC_{95} and HC_{05} values are estimated. The average weighting factors for each month can be calculated from the previous sampling year. One way to do this is to select a subset of stations where multiple SC measurements are taken within a rotation year (e.g., from July to the following June). For each site, the annual mean SC is calculated using the monthly measurements. Then, the weights for each month are calculated as a ratio of the annual mean SC to the observed SC at each site on the day of biological sampling. Next, the average weight within each month is calculated. Finally, for the data set used to develop the XCD and the HC_{05}, the SC on the day the biological sample was collected is multiplied by the weighting factor for that month to yield the estimated annual SC for each site. The resulting products are considered the annual mean SC at each station in that rotation year, adjusted by month. The weighting factors vary slightly for different months in different data sets (see Appendix A, Table A-2 for an example). This approach may be adapted to different seasonal SC patterns, as appropriate.

If the confidence bounds of the weighted HC_{05} overlap the confidence bounds of the unweighted HC_{05}, the unweighted model is accepted. For example, the HC_{05} values in Case Studies I and II vary by less than 3%, suggesting that the impact of sampling date (seasonality) is minor for these data sets. As a result, seasonally unweighted XCDs are used for the assessment

in these case studies. In general, the use of unweighted XCDs is easier and requires fewer data points. However, all data sets may not yield similar results, and thus this method provides a way to evaluate the influence of season and also provides a method for normalizing for sampling date when necessary.

3.2. DERIVING A CRITERION MAXIMUM EXPOSURE CONCENTRATION (CMEC)

A CMEC is defined as the SC level that protects aquatic life from acutely toxic exposures. The CMEC analysis described here estimates the 90th centile of observations at sites with water chemistry regimes for sites meeting the CCC. It is not directly estimated from paired biological and water chemistry during acute exposures. However, if sufficient data are available (e.g., daily measurements of SC paired with macroinvertebrate sampling), a protective criterion maximum concentration could be estimated from the maximum concentration in a year prior to the observation of salt-intolerant genera at a site. An example of this type of analysis is provided in Appendices A.3 and B.3, but such data sets are rare. Even for the case studies using the large data sets in Ecoregions 69 and 70, there are only modest amounts of data to estimate such a criterion maximum concentration in this manner.

Using only water chemistry measurements and a previously determined CCC, a CMEC is estimated such that where the CCC is attained, 90% of observations are likely to be less than the CMEC. The steps involved in selecting, characterizing, and analyzing SC (chemistry) sampling data to derive a CMEC for flowing waters in the study area are described below (see Figure 3-6) and example derivations in Sections 4.2.2 and 5.2.2.

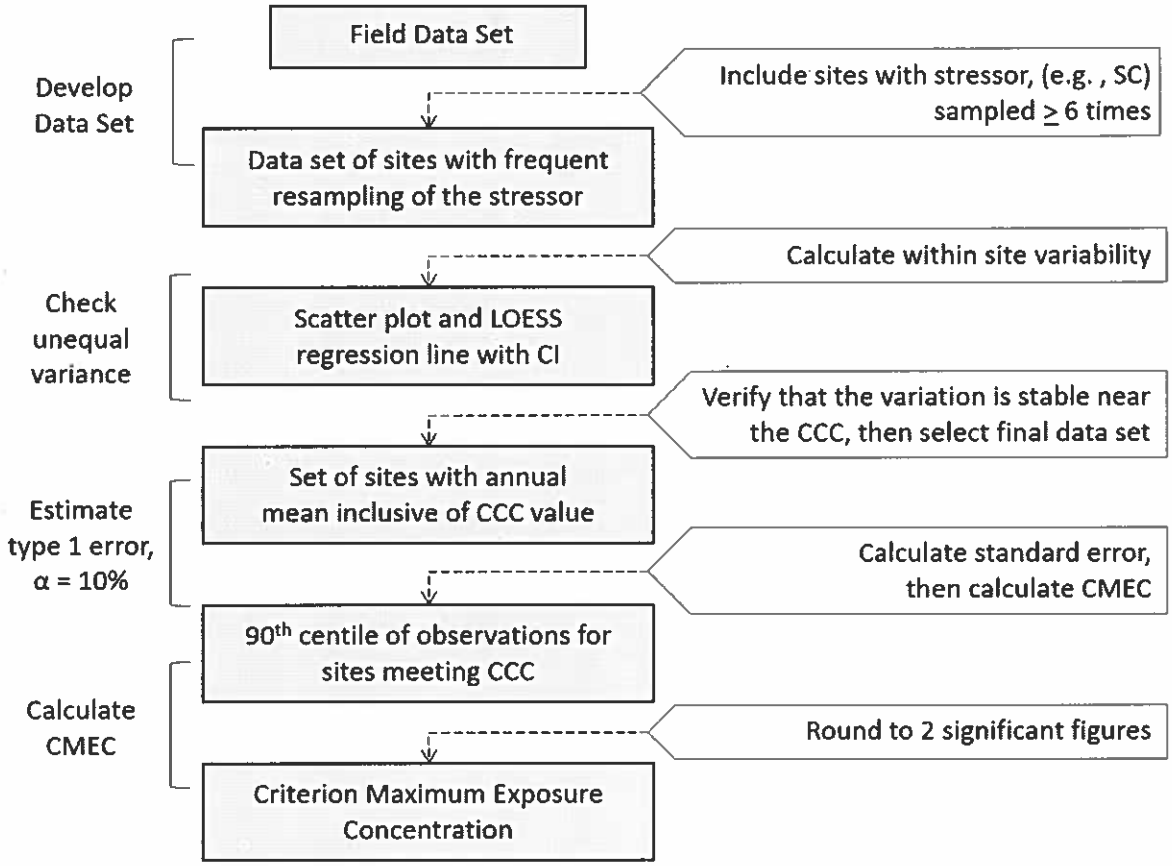

Figure 3-6. Main steps in the derivation of a criterion maximum exposure concentration (CMEC) based on field water chemistry data. Rectangular boxes on left are products and pentagonal boxes on right are operations performed on those products. A locally weighted scatterplot smoothing (LOWESS) estimates a line for a scatter plot by iteratively calculating many nonparametric regression models using local approximations (linear polynomial) from neighboring points.

The CCC is expressed as an annual geometric mean of the SC values measured from a sampling station in a particular region. Because SC values vary spatially and temporally, it is expected that the maximum SC values (or the CMEC) at any given station may be estimated by incorporating both among-station (spatial), and within-station (temporal) variability. Using the mean SC at the CCC and the variance of a SC distribution, a centile near the maximum, such as the 90th centile, for that distribution can be estimated. Thus, where the CCC is met within the region, only 10% of the observations (grab samples) would be predicted to exceed the CMEC.

To do this, a subset of frequently sampled sites is developed. For Case Studies I and II, a representative sample set was identified in which n stations (j in $1,..,$ n stations) were sampled at least six times (sample size k_i, i^{th} in $1,...,$ k_i observations) on a rotating yearly basis (in the case example from July to June). The preferred data set would have multiple SC measurements evenly distributed throughout the year. A minimum of one sample during the low SC season (e.g., March–June in Appalachia), and one sample in the high SC season (e.g., July–October in Appalachia) may be sufficient to capture temporal variability. As with the derivation of the CCC, a range of exposures that leads to adverse effects on the most salt-intolerant taxa needs to be represented in the data set and there needs to be assurance that there is no bias in the sampling within that range. The grand mean and standard deviation of this data set are calculated. The CMEC can be calculated at the 90th centile of the distribution from log values of SC in the region from this equation:

$$CMEC = 10^{(\bar{X}+z_\alpha * \sigma_r)} \quad (3\text{-}2)$$

Where $\bar{X}$ is the proposed annual geometric mean value limit for all stations ($\bar{x}_j$) (i.e., the CCC), z_α is the one-tail critical value for the 90th centile of a normal distribution (α, 10%), σ_r is the total residual standard deviation, i.e., the square root of the standard deviation. The CMEC is calculated based on eq 3-2 with $\bar{X}$ equal to log10 of the CCC for the ecoregion. For example, if the grand mean of all sites is 310 µS/cm, and the standard deviation is 0.243 µS/cm, and the z_α at 90th centile is 1.28, then the estimate of 634.1 µS/cm is rounded to two significant figures resulting in a CMEC of 630 µS/cm (see eq 3-3).

$$10^{\log10(310) + 1.28*0.243} = 630 \text{ µS/cm} \quad (3\text{-}3)$$

3.3. ESTIMATION OF CRITERIA DURATION

The water quality standards handbook (U.S. EPA, 1983) describes duration as follows:

> The quality of ambient water typically varies in response to variations of effluent quality, stream flow, and other factors. Organisms in the receiving water are not experiencing constant, steady exposure but rather are experiencing fluctuating

exposures, including periods of high concentrations, which may have adverse effects. Thus, the EPA's criteria indicate a time period over which exposure is to be averaged, as well as an upper limit on the average concentration, thereby limiting the duration of exposure to elevated concentrations.

Because this field-based approach relies directly on paired in situ measurements of SC and benthic invertebrate assemblage composition, the potential adverse effects of ionic stress on all life stages are considered in the context of other complex relationships (e.g., food web dynamics) and aquatic ecosystem processes. The measures of effect (i.e., XC_{95} and HC_{05}) are considered chronic-duration endpoints because the field data reflect exposures over whole life cycles and multiple generations of the resident biota (see Table 2-3).

The EPA typically recommends an averaging period of 4 days for a CCC, which may be appropriate for some field-derived criteria (U.S. EPA, 1985). Important considerations for estimating duration are the temporal resolution of the biological data set and the seasonal window for observing salt-intolerant genera (typically early in the year). Based on available field data, salt-intolerant macroinvertebrate genera may be exposed to a range of SC levels greater than the CCC throughout the year and often for more than 4 days (see example in Figure 3-7). For example, biological samples collected once annually (as in Case Studies I and II in Sections 4 and 5) represent the average stream chemistry and macroinvertebrate assemblage information over the course of 1 year. In cases where samples were collected on an annual basis the EPA recommends a duration of 1 year for CCCs for SC derived using the XCD method unless there are sufficient data to support an alternative duration.

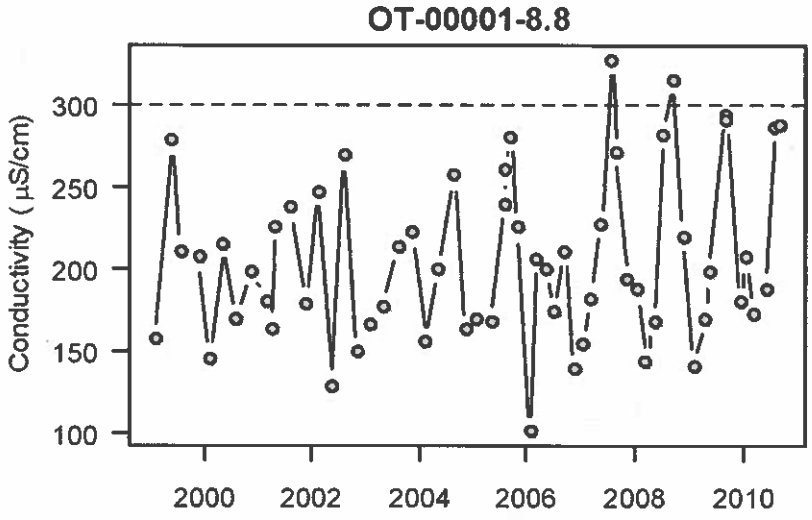

Figure 3-7. Typical specific conductivity (SC) pattern of a stream with annual mean SC well below 310 µS/cm. Aquatic life is typically exposed to a range of SC levels throughout the year.

The duration for the CMEC in Case Studies I and II is based on a literature review of the rate of onset of critical biological responses and the sampling duration used in the field data set used to establish the CMEC. Although reproductive effects (see Section 2.5) may occur rapidly following exposure, they occur only during distinct temporal windows that vary with species (life history). Increased drift (benthic invertebrates floating downstream), in contrast, can occur any time a spike in exposure occurs. In numerous studies, increased drift may be induced within minutes of stressful exposures in streams and in artificial test channels (Svendsen et al., 2004; Wood and Dykes, 2002). Most ecological studies describe drift as a part of the natural history of dispersal and colonization, but disturbance has also been identified as a cause of drift (Svendsen et al., 2004; Wood and Dykes, 2002; Crossland et al., 1991; Doeg and Millage, 1991; Wallace, 1990; Brittain and Eikeland, 1988; Sheehan and Winner, 1984; Geckler et al., 1976; Waters, 1995, 1972, 1966). In a study that induced drift from the addition of sodium chloride (NaCl), the onset of drift occurred within 15 minutes, and on average, the greatest occurrence of drifting genera took place within 4 hours (Wood and Dykes, 2002). In that study, prior to the addition of salt, SC was 110 µS/cm (River Holmes). During three trials, drift occurred at maximum total dissolved solids (~110 mg/l or SC ~157 µS/cm) and not at the lower concentration (~85 mg/L or SC ~121 µS/cm). In stream mesocosm studies with HCO_3^- and SO_4^{2-} salts, Clements and

Kotalik (2016) reported an approximate doubling of drift within 24 hrs (196 µS/cm). Avoidance and drift behaviors, in general, typically occur quickly following most noxious stimuli.

Unlike laboratory studies, maximally tolerated SC exposures were not measured. Rather, the CMEC is the 90th centile of observations measured at sites meeting the CCC. Therefore, the duration parameter is based on the rate of onset of drift described in published field experiments; the recommended duration for the CMEC is 1 day.

3.3.1. Summary of Recommended Duration for Criterion Continuous Concentration (CCC) and Criterion Maximum Exposure Concentration (CMEC)

The temporal resolution of the biological data set and the seasonal window for observing salt-intolerant genera are key considerations when estimating the duration for the CCC and CMEC for SC. In cases where sampling occurs once annually, as in Case Studies I and II provided in Sections 4 and 5, the recommended durations for the CCC and CMEC are 1 year and 1 day, respectively.

3.4. ESTIMATION OF CRITERIA FREQUENCY

The water quality standards handbook (U.S. EPA, 1983) describes frequency as follows:

> To predict or ascertain the attainment of criteria, it is necessary to specify the allowable frequency for exceeding the criteria. This is because it is statistically impossible to project that criteria will never be exceeded. As ecological communities are naturally subjected to a series of stresses, the allowable frequency of pollutant stress may be set at a value that does not significantly increase the frequency or severity of all stresses combined.

The frequency with which criteria may be exceeded depends on the rate of recovery of the biotic community. In general, if the interval between exceedances is less than the time to recovery, impairment is perpetuated. Time to recovery may be estimated mechanistically from the life histories of the organisms involved or empirically from field studies of stream community recovery.

In this case, to estimate the interval between extirpation and reestablishment of a reproducing population, the EPA adapted a list of potential factors that may affect recovery time of stream organisms (Wallace, 1990). Although these considerations were originally outlined

with respect to pesticide exposure, they are a reasonable list of factors to consider for any stressor. The revised considerations are listed below with corresponding numbers from Wallace (1990):

1a. Magnitude of the initial stressor load

1b. Adverse effect of the stressor

1c. Areal extent of continued inputs of the stressor

2. Spatial scale of the disturbance

3. Persistence of the stressor at the site

4. Vagility of the populations (ability to move and disperse) influenced by exposure

5. Timing of contamination in relation to life history stage

6. Position within the drainage network

For the purposes of estimating frequency, the concentration of the initial stressor load (see Item 1a) is greater than the magnitude of an annual average CCC or a daily CMEC. The initial adverse effects (see Item 1b) are extirpation resulting from drift and failure to recruit. Because insect colonization (the predominant invertebrate group in streams) is sometimes possible via aerial dispersal, frequency was estimated for conditions where the effect of areal extent (see Item 1c) or spatial scale of the disturbance (see Item 2) is minimal. However, on a case-by-case basis, if the disturbance by ionic concentration is spatially extensive, the frequency recommendation for these criteria might not be protective (Smith et al., 2009; Lindberg et al., 2011; Bernhardt et al., 2012). Wallace (1990) defines persistence (see Item 3) as continuation of exposure in the environment after cessation of new inputs. Because salts are highly soluble in water, they are flushed downstream (in flowing waters) when loading stops, and therefore, they are not persistent chemicals in the sense defined by Wallace (1990) although lag times can be long when contaminated groundwater flows to surface waters. Although intermittent releases of water with high specific SC result in intermittent exposures, the aquatic impacts appear to be long term owing to persistent exposures (U.S. EPA, 2011b; Pond et al., 2014; Evans et al., 2014; Williams, 1996; Feminella, 1996; Delucchi, 1988; del Rosario and Resh, 2000). Recolonization rates from upstream sources or connected tributaries that provide a source of drifting juveniles

was not used to estimate frequency so as to provide a conservative estimate and because in some situations, such as headwater streams, there may not be an upstream source of recolonizing juveniles (see Item 6). Using these conditions, the life history of salt-intolerant benthic invertebrates (see Item 5) is considered with respect to recolonization potential (vagility) (see Item 4) from aerial dispersal of adults and oviposition.

3.4.1. Recovery Rates in Literature Reviews

The frequency parameter for this method is estimated from ecosystem recovery rates following disturbance as reported in the literature. In this case, frequency is an estimate of the period of time between macroinvertebrate extirpation and recovery (reestablishment) of the population. The estimate of time to recovery is based on life cycles and natural history. The assessment is supported by a literature review of the recovery of aquatic macroinvertebrates following chemical and nonchemical-induced effects in 31 nonflowing systems (lentic) and 111 flowing (lotic) systems reviewed by Niemi et al. (1990) and more than 12 streams reviewed by Wallace (1990). Niemi et al. (1990) indicated that recovery time was less than 3 years *except* when (1) the disturbance resulted in physical alteration of the existing habitat, (2) residual pollutants remained in the system, or (3) the system was isolated and recolonization was suppressed. The frequency estimated for SC criteria applies when the three factors listed above are not operative; that is, physical alteration has not taken place, pollutants are flushed from the system, and colonization is possible.

Ionic regimes may be long lasting. In a study of 15 valley fills, Pond et al. (2014) found that SC remained elevated 11–33 years after reclamation. Despite good instream habitat, nearly 90% of these streams exhibited biological impairment. Valley fill sites with higher index scores were near unaffected tributaries, an indication that drifting colonists accounted for the presence of sensitive taxa. Based on 137 valley fills, Evans et al. (2014) estimated that it would take approximately 20 years to potentially attain SC levels <500 µS/cm after initiation of valley-fill construction. These two studies underscore the fact that although recovery can occur within 3 years when the exposure no longer exists, some streams may take decades to return to levels that salt-intolerant genera can tolerate and maintain viable populations.

Wallace (1990) also indicated that the definition of recovery was inconsistently applied in the scientific literature and in most cases true recovery was not attained within the study interval;

that is, some species had recolonized but the original assemblage was altered. Many other studies of invertebrate recovery times from single events, such as toxic chemical spills, floods, pesticides, drought, and organic pollution, indicate recovery times of a few months to several years (e.g., Kattwinkel et al., 2012; Molles, 1985; Minshall et al., 1983; Heckman, 1983; Fisher et al., 1982; Hynes, 1960; Mebane et al., 2015). However, in some situations, biological communities may have faster recovery times (Wood and Dykes, 2002) if the exposure duration is short and if there are upstream sources for recolonization. In a more recent review of 200 studies with pesticide exposures, Kattwinkel et al. (2012) reported that migration from upstream uncontaminated areas is a main driver for recovery and that recolonization varied with generation time and source of migrants; however, upstream sources of colonizers may not be present (e.g., in headwater streams). Faster recovery times were related to drift from external sources (Caquet et al., 2007; Liess and Schulz, 1999) or untreated refugia (Brock et al., 2009). Salt-intolerant univoltine species (life cycles of 1 year) do not recover within 1 year after exposure (Liess and Beketov, 2011; Liess and Schulz, 1999). Overall, most studies reported that recovery took two or more generations and as many as five generations even with upstream sources that can recolonize by drift. Furthermore, there is a trend of longer population recovery time with increasing generation time; species with long generation cycles often take longer for population recovery.

Most of the macroinvertebrate genera sensitive to ionic stress have a univoltine generation time (1-year life cycle), and therefore, their recovery time is likely to be longer compared to multivoltine genera (having less than 1-year life cycles). Where recolonization by juveniles drifting from upstream refugia is not possible, aerial dispersal from nearby streams would be necessary to reestablish populations of aquatic insects; in this case, recovery may take longer than 3 years. The frequency recommended for this method assumes there are either sources from upstream or airborn dispersal for recolonization.

In summary, if the concentration of major ions in a stream can be returned to levels that are capable of supporting aquatic life, and if the physical habitat is suitable, and if there are opportunities for recolonization from an upstream source and/or through aerial dispersal from nearby streams, then the allowable recommended frequency of exceedance for criteria derived using this method is once every 3 years. If any of these conditions are not met, then the

frequency parameter is expected to be more than 3 years, because the stream lacks the ability to recover within that span of time.

3.4.2. Life History Considerations

Often, more than 90% of benthic invertebrates in streams are insects. Several of the most salt-intolerant benthic insects (e.g., mayflies, stoneflies, caddisflies, and true flies) have a 1–2 year life cycle with emergence, mating, and early development occurring in the spring months (Merritt and Cummins, 1996; Brittain, 1982; Clifford, 1982). Hypothetically, if a univoltine genus is extirpated in the first year and in the following spring migrating insects laid eggs, offspring from the colonizers would be large enough to be observed in the collections the following year (i.e., 2 years after the initial extirpation event). Assuming that a recovered population required two reproductive seasons (Liess and Beketov, 2011; Liess and Schulz, 1999), the earliest measurable recovery would be the year after that, or 3 years after the initial extirpation event. The genetic diversity of the population founded by a few colonists may be low (i.e., the founder effect) and as a result the population may be less resilient.

Gastropods, amphipods, isopods, and crayfish tend to be more tolerant to ionic stress (see Appendix E); these taxa would likely remain provided that SC levels did not exceed their predicted extirpation concentrations. Extirpation of most noninsect benthic invertebrates is not expected to occur if the yearly average is <960 µS/cm, the XC_{95} of the most salt-intolerant crustacean based on values calculated using a combined data set from Case Studies I and II (U.S. EPA, 2011a, see Appendix D). The natural history of fish suggests that they may be able to recolonize quickly due to their greater mobility; however, immigration may be limited for some species because they are endemic to specific drainages or there may be barriers to emigration (Hitt and Chambers, 2014; see Appendix G). Unionid mussels were not evaluated by the EPA, but some field and laboratory studies suggest that Unionidae are also salt-intolerant (Price et al., 2014; Gillis, 2011; Wang et al., 2013, Kunz et al., 2013). If immigration of fish is restricted or if less mobile species such as mollusks and crayfish are extirpated, their recolonization could take much longer than 3 years, or may require reestablishing a colonizing population by stocking (Wallace, 1990).

3.4.3. Summary for Field-Based Frequency for Criterion Continuous Concentration (CCC) and Criterion Maximum Exposure Concentration (CMEC)

If SC criteria derived using this method are exceeded, it is expected that at least 5% of macroinvertebrate genera will be extirpated, and many more genera will have been exposed to levels that reduce their occurrence (U.S. EPA, 2011a). However, recovery is expected to occur in 3 years if the following conditions are met: (1) the SC regime returns to a yearly average below the CCC, (2) there are nearby streams with low SC supporting a diverse community, and (3) there is an upstream source of colonizers or the flight or recolonizing distance is within the dispersal range of genetically diverse, reproducing adult colonizers. This frequency recommendation is based on consideration of the life history of insects that are able to recolonize a site by drifting from upstream sites or aerially dispersing from a nearby stream, and published studies of recovery of stream communities. If any of these conditions are not met, the time necessary for community recovery (and thus, the allowable frequency of exceedance) would likely be longer than 3 years.

3.5. ASSESSING CAUSATION

Field studies can generate statistical relationships between environmental attributes and biological responses, but those relationships are not necessarily causal. Epidemiologists evaluate whether an apparent relationship is causal by weighing evidence of causation in terms of lists of considerations (Norton et al., 2015). General causation between SC and macroinvertebrate occurrences was previously assessed (U.S. EPA, 2011a; Cormier et al., 2013b) and therefore does not need to be repeated. Many other studies have corroborated that assessment for the particular ionic mixture, Ca^{2+}, Mg^{2+}, HCO_3^- and SO_4^{2-}, and for different salt mixtures, e.g., Na^+, K^+, HCO_3^- and SO_4^{2-}, and Na^+ and Cl^- (see Section 2.2). A new general causal assessment is recommended when it is uncertain whether an agent, for example a newly synthesized chemical or novel mixture, can or has ever harmed aquatic life. If a new causal assessment is warranted, EPA recommends using epidemiological methods to demonstrate that the agent or mixture can and does cause extirpation at concentrations using the method described in the *EPA Benchmark Report* (U.S. EPA, 2011a; Cormier and Suter, 2013b). The causal assessment methodology does not compare the relative importance of ionic-induced impairment with other known stressors such as metal toxicity, stream bed erosion and siltation, or eutrophication (U.S. EPA, 2011b; Gerritsen et al., 2010). Effects from these stressors are likely to occur and do occur in any given

ecoregion and at times concurrently with increased ionic inputs. Rather, the causal assessment is designed to determine whether the addition of ions to streams can and does cause extirpation of aquatic life.

Although causal assessments of most ionic mixtures do not need to be repeated, it is good practice to evaluate the predictive performance of the XCD model, that is, how well the model characterizes the modeled relationship, e.g., SC and extirpation. See Section 3.1.1.2.6 for analytical approaches for assessing potential confounders.

In summary, the causal relationship between elevated ionic concentration and extirpation of macroinvertebrates can be assessed using an approach modified from Hill's (1965) considerations (for complete details see Appendix A in U.S. EPA, 2011a; Cormier et al., 2013b). Hill's approach for establishing a probable causal relationship has been adapted for ecological applications (Cormier et al., 2010; Fox, 1991; Suter et al., 2001; U.S. EPA, 2000b). Based on that assessment, the body of evidence indicates that the loss of macroinvertebrate genera occurs where SC is high even when potentially confounding causes are low, but is rare when SC is low. Furthermore, there are sources of ions that increase stream SC in the region, and aquatic organisms are directly exposed to these ions. Physiological laboratory studies indicate that ionic gradients in high SC streams would not favor the exchange of ions across gill epithelia and that physiological functions of organisms are affected by elevated ionic concentration. Some genera, composite metrics, and assemblages are affected at sites with higher SC, while others are not. Laboratory studies using moderately salt-intolerant species and ionic compositions relevant to the study area support ionic stress as a cause of extirpation; and increased exposure to ionic stress affects macroinvertebrate abundance and diversity based on field observations. More recently, mesocosm studies have corroborated adverse effects at similar exposures (Clements and Kotalik, 2016).

The causal assessment confirmed that the mixture of ions in streams with elevated SC and neutral or somewhat alkaline waters can and is causing the extirpation of salt-intolerant genera of macroinvertebrates as well as in low pH systems (U.S. EPA, 2011a; Cormier et al., 2013b). The relative SC level of waters with a similar ionic composition, rather than any individual constituent of the mixture, is implicated as the cause of impairment (see Section 2.5.1). The causal relationship describes how *Ephemeroptera* and similarly salt-intolerant invertebrates, in general, respond to ionic stress and does not require that the

species or genera be the same in all applications or at all locations. Although the specific constituents of the ionic mixture were not individually assessed, the cause of impairment is attributable to one or more of the primary constituents of the mixture. Therefore, based on the causal assessment (U.S. EPA, 2011a), it is expected that SC levels sufficient to cause extirpations would occur with a similar salt mixture containing HCO_3^-, SO_4^{2-}, Ca^{2+}, and Mg^{2+} in other regions. Furthermore, based on other studies (see Section 2.2), different salt mixtures also cause extirpation, e.g., Na^+, K^+, HCO_3^- and SO_4^{2-}, and Na^+ and Cl^-.

3.6. ASSESSING WATERBODY APPLICABILITY

3.6.1. Stream pH

Due to the nature of ions and pH, it is important to consider the potential impact of pH on the XCD. Acidity (e.g., associated with acid mine drainage, atmospheric deposition and other sources) and potentially associated dissolved metals could affect the field-based XC_{95} values and the XCD model. As a result, unless shown to the contrary, it is recommended that sites with pH <6 be excluded from data sets prior to analysis.

In Case Studies I and II provided in Sections 4 and 5, sites with pH <6 were excluded from the data set prior to analysis. Therefore, the case studies were developed without the influence of pH, analogous to controlling for confounders in a laboratory test. Nevertheless, field data show that even below pH 4.5, high SC was a stronger predictor than acidity on the occurrence of *Ephemeroptera* (see Appendix B in U.S. EPA, 2011a). A contingency table showed that *Ephemeroptera* were observed at low pH unless SC was high. Also, calculating the HC_{05} using the data set from the *EPA Benchmark Report* (U.S. EPA, 2011a), with and without the inclusion of low pH sites, yielded very similar results (295 µS/cm for all sites compared to 288 µS/cm pH <6 sites removed). Therefore, although EPA recommends the removal of pH sites from the data set prior to analysis, there is evidence to suggest that the derived criteria are applicable to all streams regardless of pH.

3.6.2. Waterbody Type

Another important consideration when it comes to applicability of the field-based approach is waterbody size and type. The EPA recommends analyzing the effect of catchment size on the XCD model and documenting the decision, rationale, and supporting analyses for

applicable water body types for SC criteria derived using this method. For example, in Case Study I, the data used to derive the CCC are from perennial streams with catchments that range from 0.34 to 17,985 km^2. Literature reviews and analyses (described below) were performed in the Problem Formulation phase of this assessment to determine relevant (applicable) waterbody types. As a result, all stream types and sizes were included in the data sets for these case studies.

Although the field data used in the case studies were only collected from perennial streams, available information from the open literature indicates that many of the macroinvertebrate taxa persist in intermittent and perennial channels, albeit at different densities and for varying amounts of time. For example, Grubbs (2010) assessed the relationship between stream-flow permanence and macroinvertebrate community structure along temporary and perennial hydrologic gradients in forested headwater streams in a Cumberland Plateau watershed in the Kentucky River Basin. Grubbs found that the vast majority (91 out of 108) of macroinvertebrate taxa were observed in both the perennial and temporary channels. Macroinvertebrate taxa have many adaptations to survive temporary dry periods including egg diapause, nymph aestivation, and nymph migration into hyporheic zones (the area beneath a streambed, where shallow groundwater and surface water mix) or intermittent pools (Datry, 2012). Macroinvertebrates may use temporary stream resources for portions of their life cycle (e.g., nursery habitat) and move downstream as they get older and larger and conditions require emigration to areas of greater flow (De Jong and Canton, 2013; Feminella, 1996; Stout and Wallace, 2003). These studies suggest that temporary streams are used, at least for a portion of their life cycle, by many of the macroinvertebrate taxa considered in the XCD method.

Discharge to ephemeral streams ultimately affects downstream intermittent/perennial streams (via gravity and flow through the tributary system during precipitation events). As a result, addressing SC in upstream ephemeral streams is often critical to ensuring that downstream aquatic life is not exposed to harmful levels of SC above the criteria.

Although intermittent and perennial streams are likely to have similar SC regimes, larger catchments may not have the same background SC as smaller streams owing to hydrological contributions from different geologies or other factors. Options include limiting the use of derived criteria to the range of sampled catchments represented in the data set, developing criteria for different stream classes, or demonstrating that there is no difference due to catchment size.

In the *EPA Benchmark Report*, larger streams (catchment areas >155 km^2) were originally screened from the data set that was used because sampling methods might differ for nonwadeable streams (U.S. EPA, 2011a; Flotemersch et al., 2006). However, a subsequent analysis indicated that 25 of the 30 most salt-intolerant genera based on derived XC_{95} values for Ecoregions 69 and 70 (see Appendix E) were documented in these larger rivers (see also Appendix B in U.S. EPA, 2011a). Inclusion of the data from large streams did not significantly change the magnitude of the HC_{05} (289 µS/cm) compared to the HC_{05} without data from larger systems (295 µS/cm). Additional analyses support that result. An analysis of 3,115 sites (3,736 samples total: 1,661 in Ecoregion 69 and 2,075 in Ecoregion 70) with drainage areas up to 17,986 km^2 suggests that SC and drainage area are very weakly correlated ($r^2 = 0.044$, see Figure 3-8). These are neither random samples nor reference streams and may not represent natural background. The apparent background SC, estimated as the 25th centile of probability sites, for streams draining areas >155 km^2 in Ecoregion 69 and 70 are 148 and 188 µS/cm, respectively; both of these estimates are within the confidence bounds for estimated background SC using the example criterion-derivation data sets. Therefore, the example ecoregional criteria in the case studies are relevant for all stream sizes. However, professional judgment is warranted when applying the example criteria to streams crossing ecoregional boundaries and stream catchments draining >1,000 km^2 because they are less well represented in the data sets (see Figure 3-8). For example, great rivers such as the Ohio and Mississippi Rivers were not represented in the data set, and they cross many ecoregional boundaries.

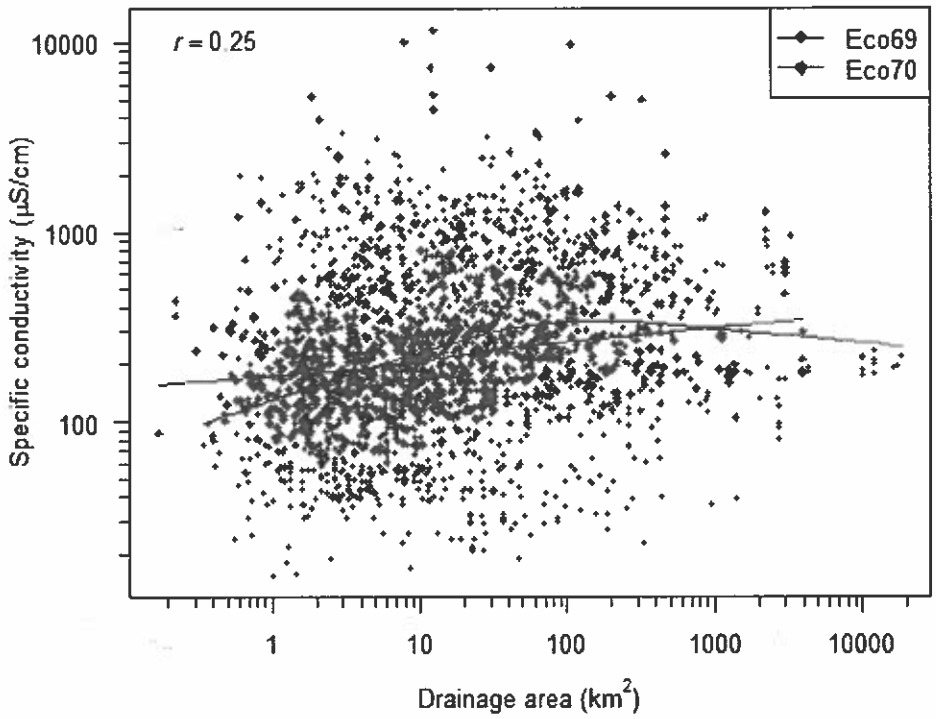

Figure 3-8. Correlation of specific conductivity and drainage area up to 17,986 km², Spearman's $r = 0.25$. This analysis shows a very weak correlation between specific conductivity and drainage area and supports inclusion of data from all stream sizes in the data set for example criteria derivation. The fitted lines are the locally weighted scatterplot smoothing (LOWESS, span = 0.75, linear polynomial) for each data set.

3.7. METHODS FOR APPLICATIONS TO NEW AREAS

Not all areas of the country have sufficient water chemistry and biology data to derive criteria for SC by the XCD method of calculating XC_{95} and HC_{05} values. For such cases, the EPA is providing alternative methods that geographically extend results of the primary XCD method (see Section 3.1). One alternative method extends criteria developed in one area to other areas within the same ecoregion. This method is termed background matching. A second alternative method estimates criteria for new areas with different background SC using a background-to-criterion regression model. Both of these methods rely on the estimated background SC.

The feasibility of applying a conductivity benchmark outside its area of derivation was considered by the EPA SAB in their review of the *EPA Benchmark Report* (see Section 3.7

Transferability of the Method to Other Regions in U.S. EPA, 2011c). In general, the SAB concluded that the numeric benchmark was applicable to the regions where the field data were collected and could be applicable to other areas where sufficient data allow for evaluation of applicability of the benchmark. Since then, the EPA has developed an understanding of the mechanistic relationship between background SC and the extirpation of salt-intolerant invertebrates. This relationship allows the EPA to relate HC_{05} values from one area to another based on background SC.

Background SC in a region and the associated HC_{05} are expected to be strongly related based on ecological and evolutionary theory and the observed responses of invertebrates to major ions (see Section 2.4). The most salt-intolerant invertebrates occur in streams with the lowest background SC (see Appendix D). As SC increases, the most salt-intolerant species are adversely affected and ultimately cannot persist. As a result, where regional background SC is higher, those taxa adapted to low SC are absent, and the SC level that is protective of 95% of taxa (HC_{05}) is higher.

The EPA developed the B-C method using 24 field XCDs from ecoregions with background SC ranging from 22 to 626 µS/cm. Relatively salt-intolerant genera, as indicated by low XC_{95} values, occupy habitats in each region with the lowest ionic concentration. When both are log-scaled, the increase in background SC is linearly related to the HC_{05}. This regular and biologically relevant relationship between background SC and the HC_{05} confirms that the lower portion of the XCDs are similar in similarly exposed communities even though the represented genera may differ among ecoregions. The relationship between background SC and the HC_{05} identified from the XCD is sufficiently strong to identify a CCC for areas with sufficient stream chemistry data but little or no paired biological data within an ecoregion or for new ecoregions (see Appendix D).

The association between background SC and the HC_{05} was used to develop the background matching approach and the approach using the B-C method described in Sections 3.7.1 and 3.7.2, respectively.

3.7.1. Application within an Ecoregion—Background Matching

If paired SC and biological data are not available for a new area within an ecoregion, the background SC may be used to assess applicability of the derived CCC to the new area using a

technique called background-matching. Regional background SC is defined here as the range of SC naturally occurring in waters that have not been affected by human activity. Background SC is important to water quality protection because it represents the ionic concentrations to which organisms in the region are naturally adapted. Minimally affected waters with low SC play a particularly important role by diluting polluted downstream waters and serving as refugia for salt-intolerant organisms. The background-matching approach is demonstrated in Case Studies I and II (see Sections 4 and 5) for the new areas within an ecoregion that were not included in the original example criterion-derivation data sets.

In this discussion, the phrase, original area, refers to the geographic area from which the data are obtained to develop SC criteria using the XCD method. The phrase, new area, refers to a geographic area within the same Level III ecoregion that was not represented in the criterion derivation data set. When applying field based SC criteria developed with data from the original area to a new area, the background SC levels and the ion composition should be similar in both areas. For instance, the example criteria are derived with data for streams where the ionic mixture is dominated on a mass basis by $([SO_4^{2-}] + [HCO_3^-]) > [Cl^-]$.

The relationship between background SC and the HC_{05} identified from the XCDs is sufficiently strong to identify a HC_{05} for areas without biological sampling within an ecoregion or for new ecoregions. This B-C regression model was developed using biological data paired with SC data from waters with ionic mixtures dominated by calcium, magnesium, sulfate and bicarbonate ions and where background SC did not exceed 626 µS/cm. Therefore, the model is most appropriate for waters with similar ionic characteristics. The model has not been thoroughly tested and professional judgment is required for places where on a mass basis the major ions are $([HCO_3^-] + [SO_4^{2-}]) < [Cl^-]$ or $([Ca^{2+}] + [Mg^{2+}]) < ([Na^+] + [K^+])$. In particular, the B-C model is not appropriate for waters dominated by NaCl (Haluszczak et al., 2013, Entrekin et al., 2011; Gregory et al., 2011; Veil et al., 2004) or road salt (Forman and Alexander, 1998; Kelly et al., 2008; Environment Canada and Health Canada, 2001; Evans and Frick, 2001; Kaushal et al., 2005). The B-C model may also be defensible for ionic mixtures dominated by sodium, sulfate and bicarbonate ions (Brinck et al., 2008; Dahm et al., 2011; Jackson and Reddy, 2007; National Research Council, 2010; Clark et al., 2001; Veil et al., 2004). This is because the toxicity of these mixtures are more similar to that of calcium, magnesium, sulfate and

bicarbonate ions than the toxicity of NaCl (Mount et al., 2016; Kunz et al., 2013; Soucek and Dickinson, 2015).

In the background-matching approach, the background for the ionic mixture of the new area is compared with the background of the original area. If the 95% CI of the background SC of the new area overlaps with the 95% CI of the background in the original area, the original criterion is considered applicable. If the CIs for the two areas do not overlap, then a dichotomous decision tree is used to guide further evaluations (see Figure 3-9). The dichotomous decision tree for assessing the applicability of criteria from the original area to a new area of an ecoregion may require a weight-of-evidence assessment described in detail in Appendix C, calculation of an HC_{05} using a regression model described in Section 3.7.2 and Appendix D, or collection of sufficient data to derive a different HC_{05} for the new area.

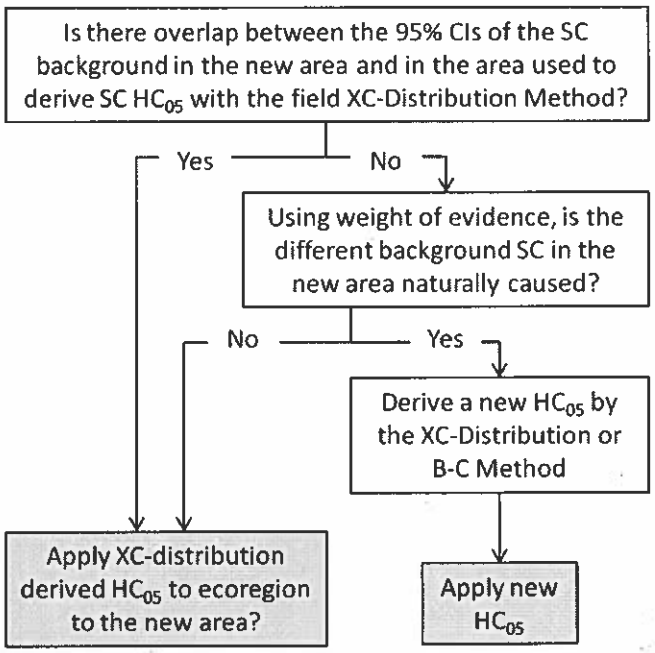

Figure 3-9. Method for selecting a criterion continuous concentration (CCC) for a new area within an ecoregion using minimally affected background. The hazardous concentration of the 5th centile of a taxonomic extirpation concentration distribution (HC_{05}) from a field derived extirpation concentration distribution (field XCD) is one that has been previously developed using a large data set. The background-to-criterion (B-C) method uses a regression model to predict a criterion and confidence interval (CI) from background specific conductivity (SC).

Portions of the same ecoregions in different political jurisdictions are expected to have similar characteristics with respect to the primary factors that control background SC (Hem, 1985, Griffith, 2014, Olson and Hawkins, 2012, see Section 2.1). These primary factors are underlying geology, physiography, and climate; secondary factors include soils and vegetative cover (Olson and Hawkins, 2012; Griffith, 2014; Hem, 1985). Because Level III ecoregions were delineated based on similar considerations (Omernik, 1987), the SC regime and ionic composition of dissolved salts in streams within an ecoregion tend to be similar throughout. However, there may be situations where it is not appropriate to apply criteria derived for the ecoregion to a particular stream reach. For example, naturally lower or higher concentrations of ions may occur due to subecoregional differences such as cross boundary influences, glacial melt, salt springs, highly soluble rock, or other natural sources.

3.7.1.1. *Obtaining a Data Set*

The first step in the background-matching approach is to assemble the data sets from sampled sites that are distributed across the full range of SC conditions in the new area. All else being equal, the larger the data set, the more reliable the estimate of background SC. Next, sites with qualitatively different ionic mixtures are removed from the data set. In the example case studies, chloride-dominated sites are removed from the data set so that background SC is estimated only for sites dominated by sulfate and bicarbonate (i.e., $([HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$ in mg/L). For three of the example case studies, Sections 4, 5, and 7, the dominant cations are Ca^{2+} and Mg^{2+}. For the example case study, Sections 6, the dominant cation is Na^+.

3.7.1.2. *Estimating Background Specific Conductivity (SC)*

If minimally affected background SC is not known, it can be estimated from field data that are representative of SC throughout the year. In particular, the data set should not be biased toward seasonal extremes by sampling only during seasons of freshets or droughts. Background SC may be estimated as a proportion of a regional sample of sites or a sample of reference sites that are judged to be among the best within a region (U.S. EPA, 2011a).

Regional samples from a random or probability-based design (Stevens and Olsen, 2004) include all waters within the sampling frame, including impaired sites. To characterize the minimally affected streams in a regional sample, the 25th centile is conventionally used (U.S. EPA, 2000a). However, when land cover modification (or other anthropogenic disturbance) is pervasive, selection of a centile lower than the 25th may be justifiable.

When estimating background concentrations using minimally affected reference sites, it is conventional to use only the lower 75% of reference values (U.S. EPA, 2000a). One indication of the need for a different centile is when reference sites have a broad range of SC values suggesting that the reference condition contains some sites with anthropogenic disturbance, or that the sites are not classified to partition natural variability (e.g., headwaters draining through limestone glacial till into an area of weathered bedrock). An expanded list of possible considerations is provided in Appendix C. When there is great confidence in the quality of reference sites, a 90th centile may be used.

When there are sufficient good quality reference sites, the regional and reference methods yield similar background estimates (NYSDEC, 2000, TDEC, 2000, U.S. EPA, 2000a). But, in

general, estimation based on a random sample of the region tends to yield a more accurate estimate of current background when there are sufficient data to characterize the full distribution of SC in the region. Unlike the selection of reference sites, a random sample does not depend on the original intent of data collection or the judgement of the data collectors (Whittier et al., 2007a, b).

After estimating background SC for both the original and new areas using the method in this section, the background-matching approach requires estimating their variability so that confidence intervals can be calculated. The confidence interval for a background SC estimate can be calculated using a bootstrapping technique. Bootstrapping is a statistical resampling technique that is often used in environmental studies to estimate confidence limits of a parameter. This bootstrapping application involves randomly resampling the original water chemistry data set 1,000 times with replacement, storing the 1,000 data sets, calculating the background for each data set, and then estimating the 95% CI for the mean of the set of 1,000 background values generated by the bootstrapping procedure. This is similar to the procedure described in Section 3.1.3.1.

3.7.1.3. *Background-Matching Approach*

Once the means and confidence limits on the background SC in the original area and new area have been estimated, they can be compared to determine whether they sufficiently match using the decision criteria depicted in Figure 3-9.

1. If the 95% CI of the background SC values from the new area overlaps with the 95% CI of the background SC values from the original area, then apply the XCD derived HC_{05} for that ecoregion throughout the new area.

2. If the 95% CIs do not overlap, then use a weight-of-evidence approach to determine whether the background in the new area represents natural or anthropogenic sources as described in Appendix C.

3. If the difference in 95% CIs is due to anthropogenic alteration, then apply the XCD derived HC_{05} from the original area to the new area.

4. If the difference in SC is naturally caused by geology, climate, or other natural factors, then derive a new HC_{05} for the new area using a sufficiently large and appropriate data set from the new area (see Section 3.1) or calculate an HC_{05} based on background SC for the new area using the B-C regression method (see Section 3.8).

For example, the decision matrix was used to determine the applicability of XCD SC criteria from an original area to a new area using this background-matching approach (see Example Case Studies in Sections 4 and 5).

3.7.1.4. *Options When Background in New Area is Different than in Original Area*

If the estimated background SC is higher or lower in the new area and the ion composition is similar compared to the original area, two possible causes should be considered. First, differences may be due to natural geological factors (e.g., higher SC due to salt springs, lower SC due to glacial melt, or other differences due to natural geological features) or to climatological factors. In these situations, criteria for the new area can be developed using either the XCD method or the B-C regression method. Second, differences may be due to widespread anthropogenic changes that have increased the apparent background (e.g., due to irrigation, agriculture, impervious surfaces, resource extraction, or acid deposition, etc.). In this second situation, the criteria developed for the original area may or may not be applicable to the new area.

To distinguish between these two possibilities, the cause of the apparent background can be evaluated in a weight of evidence. Considerations may include analysis based on geology, land use, ionic signatures and known inputs, historical and recent trend analysis, atmospheric sources, discontinuities in background across political boundaries, identification of high and low SC anomalies, stream size and connectivity, data set characteristics, sampling methods, and biological evidence of past and present observation of susceptible genera (see Appendix C).

3.7.1.5. *Summary of Background Matching Method*

The original criteria are ***applicable*** to a new area in the same region if the background SC is not different from the background of the original area (i.e., overlapping 95% CIs) and the ionic mixture is the same (e.g., in the case studies, $([HCO_3^-] + [SO_4^{2-}]) \geq [Cl^-]$ in mg/L). The original criteria are ***not applicable*** to the new area if the background for the ionic mixture is different owing to natural causes or if the ionic mixture is different. If the background SC is higher or lower than the original background, a new criterion may need to be developed for the new area. A weight-of-evidence analysis can be done to evaluate whether the difference in background SC

is due to natural causes. When possible, an independent data set should be used to corroborate the estimates of background SC.

3.7.2. Developing a Criterion Using Background-to-Criterion Regression Method

Because large sets of paired chemical and biological data are not available for all ecoregions in the United States, the EPA developed a model to calculate a CCC using the background SC of an ecoregion. The B-C regression method can be used in a new ecoregion or a new area within an ecoregion with a different SC regime (e.g., at a scale smaller than Level III ecoregions).

The relationship between minimally affected background SC and HC_{05} for 24 Level III ecoregions was characterized using least squares linear regression (see Figure 3-10). The relationship between background SC and HC_{05} was modeled and the association was strong ($r = 0.93$), as was expected given the importance of the concentrations of major ions in defining the tolerance of species (see Section 2.4). The relationship between background SC and HC_{05} is sufficiently reliable for identifying a CCC for areas without biological sampling within an ecoregion or for new ecoregions (see Appendix D).

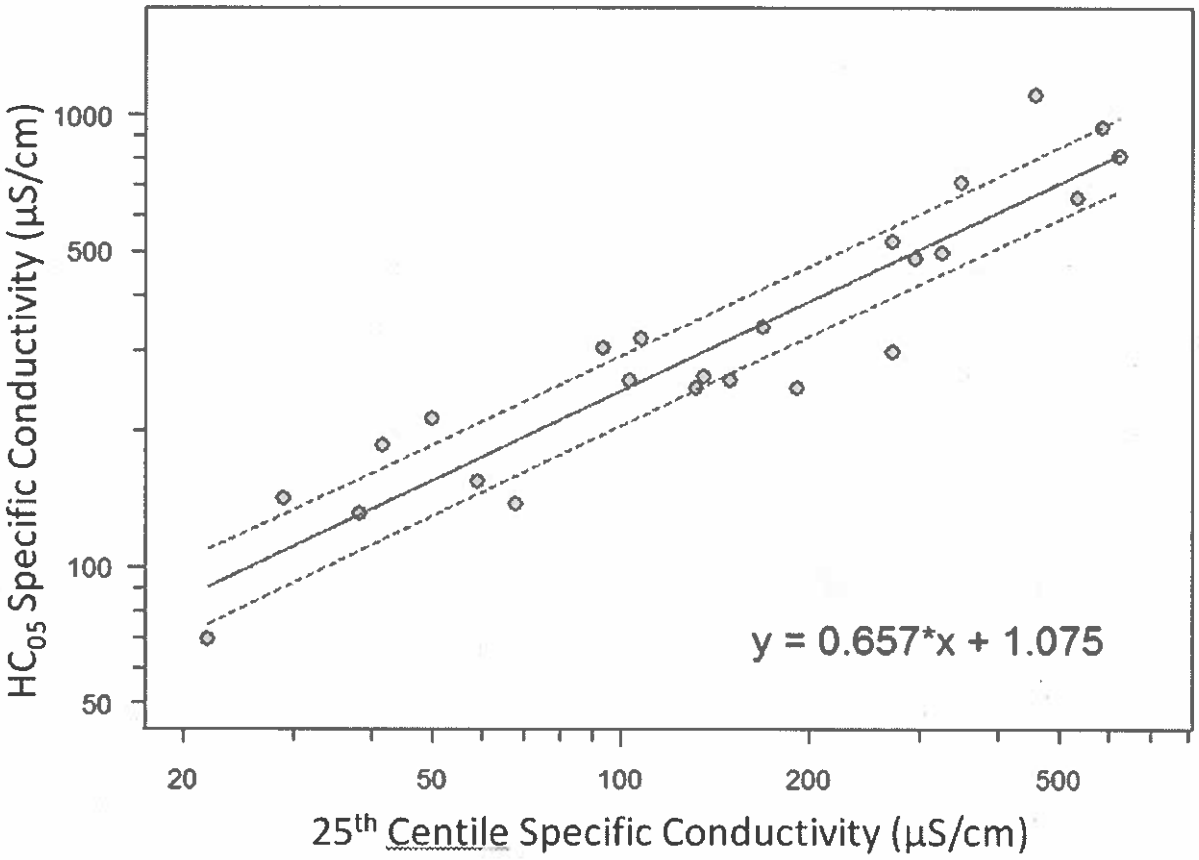

Figure 3-10. Empirical model of the 5th centile of a hazardous concentration (HC_{05}) and background specific conductivity (SC) estimated at the 25th centile for 23 distinct ecoregions (24 data sets). Solid line is the log10-log10 normal regression line; therefore, *x* and *y* are log10 expressions. Dotted lines demarcate the 50% prediction intervals, that is, the 50% probability that any new HC_{05} would plot within those bounds and only 25% below the lower prediction limit (PL). The regression coefficient $R^2 = 0.87$.

The B-C regression method shown in Figure 3-10 was derived using independent data sets from 24 ecoregions (see Appendix D). First, SC XC_{95} values were estimated. From these, 24 genus-level XCDs were constructed and HC_{05} values derived. Those HC_{05} values were regressed against the estimate of background SC for each ecoregion. In an ecoregion with low background SC, very salt-intolerant taxa are represented. In an ecoregion with a moderate background SC, taxa with an XC_{95} greater than the moderate background are likely to survive and contribute to the XCD, whereas salt-intolerant taxa with XC_{95} values less than the moderate background are not likely to contribute to the XCD. As XCDs are developed for ecoregions with

increasingly higher background SC levels, each XCD begins at a higher background SC, and thus the most salt-intolerant genera in an ecoregion occur at progressively higher SC levels. This association is evidence that where low ionic concentration waters are present in an ecoregion, organisms that are specialized for that niche are likely to inhabit them; and, where low ionic concentration waters are not present, salt-intolerant species are not likely to occur. The resulting B-C regression model provides a convenient method to predict an HC_{05} from the minimally affected or least disturbed background SC of an ecoregion. Descriptions of the derivation of the regression model, the data sets used, and the individual XCD models are presented in Appendix D.

The central tendency of a regression model is more robust than any single measurement. For the purpose of model development, data requirements were relaxed relative to those for calculating a HC_{05} using the XCD method (i.e., fewer than 90 genera across 500 sites) (see Appendix D for a description of data requirements for the B-C method). Individually, many of the 24 HC_{05} values used to develop the B-C method have not been subject to analyses needed for development of a CCC and should be considered as provisional. For example, the HC_{05} estimates used in this model were not supported by full confounding analyses, as is described in the *EPA Benchmark Report* (U.S. EPA, 2011a). However, the true HC_{05} value is expected lie between the upper and lower 50% prediction limit (PL). Values in Appendix D, Table D-3 are provisional with a good degree of confidence owing to the larger sample sizes (>60 samples) used to estimate background SC. Table D-4 lists ecoregions with background estimates based on modest survey data sets ($N = 20–60$ samples) and would benefit from additional sampling to confirm the calculated background SC and the calculated HC_{05}. Table D-5 lists ecoregions where the data set may represent fewer than 25% minimally affected streams and therefore are protective of aquatic life in least disturbed streams. Table D-6 lists ecoregions that may not be served by the B-C method because the ionic mixture is likely to be different (e.g., chloride dominated), the estimated natural background SC exceeds the range of the model, and/or there were fewer than 20 samples available. In all cases, the EPA recommends using the largest data set possible to estimate background SC, understanding and accounting for areas with different (higher or lower) background SC, and performing independent calculations to derive HC_{05} values.

3.7.2.1. *Using Background to Calculate a Hazardous Concentration of the 5th centile (HC_{05}) of a Taxonomic Extirpation Concentration Distribution (XCD)*

The HC_{05} for a defined geographic area or ecoregion without a sufficient data set or without suitable biological data may be calculated using the B-C method based on the background SC of that area or region. The decision tree for calculating a CCC from minimally affected background is shown in Figure 3-11. Equations 3-1 and 3-4 can be used to calculate the mean HC_{05} and eq 3-5 calculates the lower 50% PL for the area or region. Sections 6 and 7 provide examples that use the decision tree to develop example criteria for 2 ecoregions in the West, one with low and one moderately high background SC.

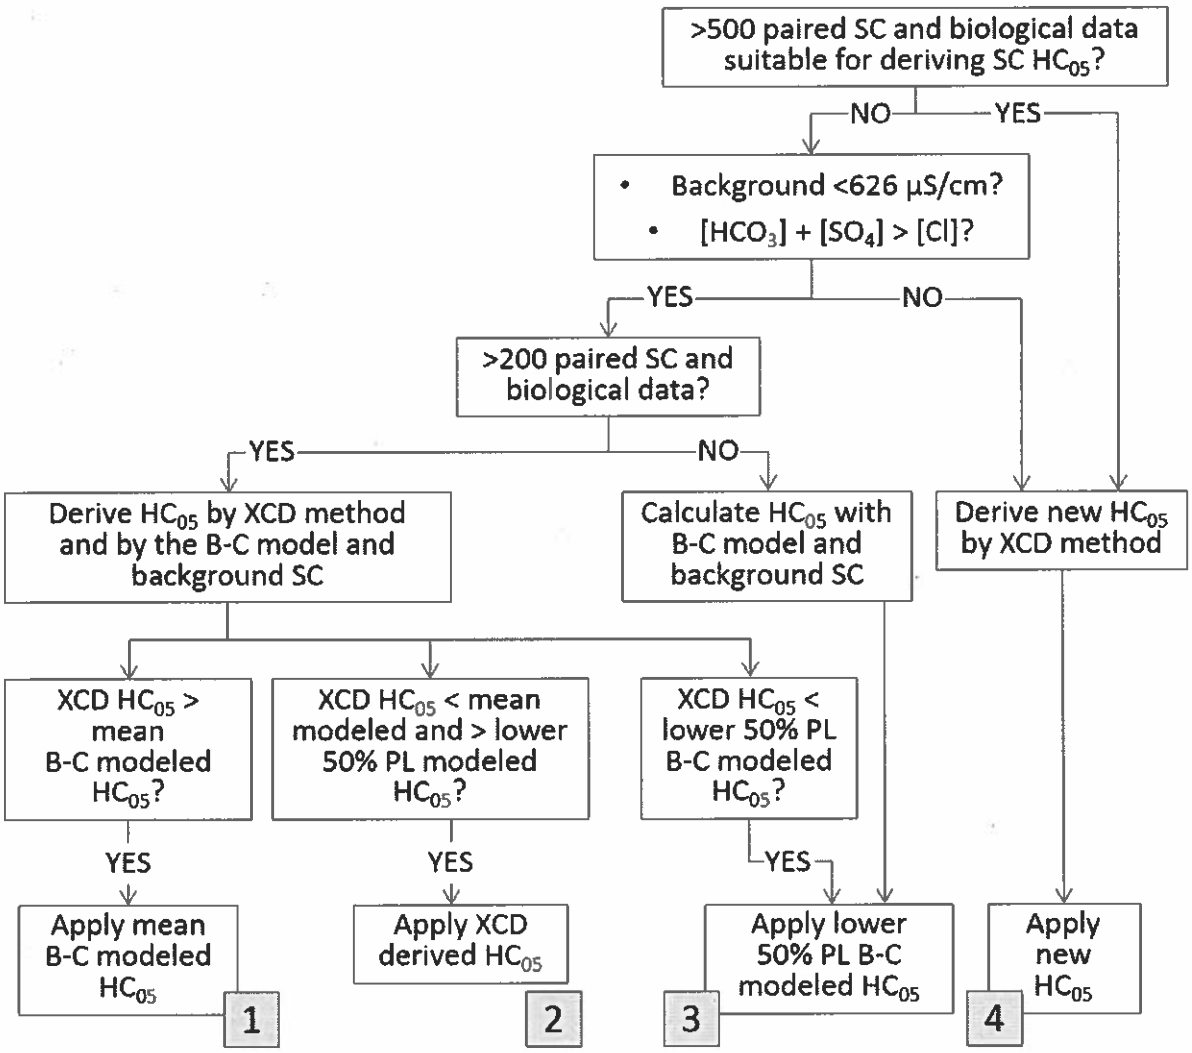

Figure 3-11. A decision tree for calculating and applying a hazardous concentration of the 5th centile of a hazardous concentration (HC_{05}). This flow chart may be used when developing a criterion continuous concentration (CCC) for new ecoregion, a new area within an ecoregion, or other defined geographic area using the field extirpation concentration distribution (XCD) method, background-to-criterion (B-C) method and minimally affected or least disturbed background specific conductivity (SC). Numbered product paths are described in the body of the text.

Where the background is less than 626 µS/cm and the waters have a similar ion composition to those used to derive the model, the B-C method can be used (see Figure 3-11). Where there are >200 but <500 sites with paired biological and SC data, HC_{05} values are derived using the XCD method and compared to the mean and lower 50% PL of the B-C model. These

values are compared to select the appropriate HC_{05} as follows. (1) If the XCD HC_{05} (see eq 3-1) is greater than the mean B-C modeled HC_{05} (see eq 3-4), then the mean B-C modeled HC_{05} is recommended (see eq 3-4) as a conservative approach to account for uncertainty associated with a smaller data set. (2) If the XCD HC_{05} is between the mean B-C modeled HC_{05} and the lower 50% PL, then the XCD HC_{05} is recommended because the XCD from measured data from the region is more likely to represent the region than the more general B-C model. (3) If the XCD estimate is below the lower 50% PL, then the lower 50% PL is recommended as the HC_{05} (see eq 3-5). This is recommended because the XCD is calculated from a smaller data set. Also, it may be overly protective because it is more uncertain than the modeled results which indicate that 75% of HC_{05} values from areas with a similar background SC are estimated to be greater than a value less than the lower PL. The lower 50% PL is also recommended when there are fewer than 200 paired biological samples because there is no XCD for comparison. For both situations, the SC data and the B-C model is used to estimate the HC_{05}. (4) Where the background SC is greater than 626 µS/cm, the range of the model is exceeded, and it is recommended that data be collected to derive the HC_{05} using the XCD method (see Section 3.1).

3.7.2.2. *Formula for Calculating the Hazardous Concentration of the 5th centile of a Taxonomic Extirpation Concentration Distribution (HC_{05}) from the Background-to-Criterion Model*

The B-C model is described by the following formula:

$$Y = 0.657X + 1.075. \quad (3\text{-}4)$$

Where:

X is the log10 of the ecoregional background SC

Y is the log10 of the predicted HC_{05}

3.7.2.3. *Formula for Calculating the Lower and Upper 10% Prediction Limits*

The upper and lower PL for a predicted log10 HC_{05} value $\hat{y}$ can be calculated from the regression line using eq 3-5 (Zaiontz, 2014) and log10 transformed SC values (x) as follows:

$$\hat{y} \pm t_{\alpha/2,n-2} S_y \sqrt{1 + \frac{1}{n} + \frac{(x^{\circ} - \bar{x})^2}{SS}} = \text{PL} \qquad (3\text{-}5)$$

Symbol	Explanation	Example from the 23 ecoregion B-C model
$\hat{y}$	Log10 of the mean predicted HC_{05}	Variable differs for each case
n	Number of samples	$n = 24$
α	Alpha error rate for prediction interval (desired confidence level)	50% prediction interval ($\alpha = 0.5$)
t_{n-2}	Student's t-value at specified confidence level (alpha, α) and n-2 degrees of freedom	For 50% prediction interval ($\alpha = 0.5$), $t_{(1-0.5)/2,24-2} = 0.686$
S_y	Residual standard error of prediction (standard deviation)	$S_y = 0.11$
SS	Sum of square of x deviation from their mean, $SS = \sum_{i=1}^{n}(x_i - \bar{x})^2$	$SS = 4.21$
$\bar{x}$	Mean x values used in the model generation	$\bar{x} = 2.15$
x°	A new log10 background *(x)* value for a new prediction interval	SC value differs for each case
PL	Upper and lower prediction limits of mean predicted $\hat{y}$	SC value differs for each case

The estimated backgrounds listed in Tables D-3, D-4, and D-5 of Appendix D for 62 of 85 Level III ecoregions were used to estimate the HC_{05} from the B-C model. HC_{05} values and the lower 50% PLs were estimated using eqs 3-4 and 3-5 and estimated background from probability survey data. Predicted base-flow SC (Olson and Hawkins, 2012) was used to assess whether the 25th centile SC used in the calculation is minimally affected (see Tables D-3 and D-4) or least disturbed background SC (see Table D-5). Although the B-C Model is strongly log-linear within the sampled SC range, the EPA recommends estimation of HC_{05} only for ecoregions with a background <626 µS/cm to avoid extrapolation beyond modeled data. Some regions may have different ionic matrices (e.g., chloride-dominant) for which the derivation of a CCC using this method has not been verified. Those ecoregions are identified in Table D-6. The decision tree depicted in Figure 3-11 was used to select example HC_{05} values that if rounded to two significant figures generates an example CCC.

3.7.2.4. *Criterion Continuous Concentration (CCC) with <200 Paired Biological Data*

When there are insufficient paired data, background SC is used to calculate the lower 50% PL of the mean HC_{05} which is rounded to two significant figures to yield the CCC (see eq 3-5). This result is shown in the Box 3 in Figure 3-11. The estimated CCC at the lower 50% PL for 62 ecoregions can be found in Tables D-3, D-4, and D-5 in Appendix D.

3.7.2.5. *Criterion Continuous Concentration (CCC) with 200 to 500 Paired Biological Data*

If a suitable paired biological and SC data set of 200 to 500 sites is available that meets the requirements outlined in Appendix D.2.1, then the HC_{05} is estimated from that data set using the XCD method (see eq 3-1) and the B-C model (see eq 3-4). The lower of the two estimates is recommended as the HC_{05} unless the XCD estimate is below the lower 50% PL from the B-C model (see Figure 3-11). This result is shown in Boxes 1 or 2 in Figure 3-11. If the XCD estimate is less than the lower 50% PL of the HC_{05} from the B-C model, then the lower PL is used (see eq 3-5). This result is shown in Box 3 in Figure 3-11. In either case, the predicted mean or the lower 50% PL HC_{05} is rounded to two significant figures to yield the CCC. The provisional or comparative values for the CCC based on the mean regression line for 62 ecoregions are shown in Tables D-3, D-4 and D-5.

3.7.2.6. *Calculation of the Criterion Maximum Exposure Concentration (CMEC)*

A CMEC based on water chemistry data can be calculated as described in Section 3.2. If there are insufficient data to calculate a CMEC, the upper 50% PL can be used to approximate a CMEC.

3.7.2.7. *Summary*

Although the B-C regression model is strong, there is scatter in the 24 HC_{05} values, so the lower 50% PL is used. In addition, when there are >200 and <500 paired biological and SC data, the XCD method is applied to check the B-C model results. The B-C model can also be used to evaluate estimates with data sets >500 when they do not meet other requirements for the SC range of exposure, unbiased sampling, seasonal bias, etc. Section 6 provides an example case for deriving an HC_{05} for the Northwestern Great Plains, Ecoregion 43 in Montana, Wyoming, North Dakota, South Dakota, and Nebraska. Section 7 provides an example case for deriving an HC_{05}

for the Level III Cascades, Ecoregion 4, in Washington, Oregon, and California. The estimation of an HC_{05} from background described here is a recommended approach for developing water quality criteria for those ecoregions lacking sufficient data to develop one by the XCD method from a regional data set.

4. CASE STUDY I: EXAMPLE USING EXTIRPATION CONCENTRATION DISTRIBUTION (XCD) METHOD IN A LOW BACKGROUND SPECIFIC CONDUCTIVITY ECOREGION

This section presents a case study for the Central Appalachians (Ecoregion 69) to illustrate how the analytical methods described in Section 3 can be used to derive example SC criteria using the XCD method in an ecoregion with low background SC. Ecoregion 69 results, including estimates of the CCC and CMEC, duration, frequency, and discussion of applicability are included as examples to demonstrate the method. The derivations of the CCC and CMEC analyses and results are based on data from Ecoregion 69 in West Virginia, and SC data from the Ecoregion 69 outside of West Virginia was used to assess applicability of the criteria throughout the ecoregion.

4.1. DATA SET CHARACTERISTICS

The Central Appalachians (Ecoregion 69) stretch from central Pennsylvania through West Virginia and Kentucky to northern Tennessee with small portions in Maryland and Virginia. The primary physiographic feature is a high, rugged plateau composed of sandstone, shale, conglomerate, limestone outcroppings, and coal. Elevation ranges from 366 to 1,402 m, with an average elevation of >790 m. Local relief between valleys and peaks can range from as low as 15 m to as high as 594 m. Rainfall is highly variable due to the topographic diversity, ranging from 96–152 cm/year, with the lowest rainfall in valleys and the highest at the peaks. The region is characterized by distinct summer and winter seasons, with growing seasons in agricultural regions (located within valleys) lasting as long as 165 days. However, pasture and agriculture are limited owing to the rugged terrain, cool climate, and infertile soils. The landcover is mostly forested with oak and northern hardwood forests. The high hills and low mountains are covered by a mixed hardwood forest. Underground and surface bituminous coal mines are common (Woods et al., 1999, 1996). Headwater streams in this ecoregion have some of the freshest (lowest SC) water in the United States. These headwater streams play an important role in diluting downstream waters that are anthropogenically impacted, and serve as refugia for fish and other salt-intolerant organisms.

The data used in this case study are from a large field data set, the West Virginia Department of Environmental Protection (WVDEP's) in-house Watershed Assessment Branch

database (WABbase). Chemical and biological samples are from 1996–2011 and 1997–2010, respectively. The WABbase contains data from Level III Ecoregions 66, 67, 69, and 70 in West Virginia (U.S. EPA. 2010; Omernik, 1987; Woods et al., 1996). The WABbase data set provides consistent sampling and analytical methods, high quality, broad spatial coverage and a large number of perennial streams (2,299 distinct locations) in Ecoregion 69.

The WABbase contains data from a mixed sampling design that collects measurements from long-term monitoring stations, targeted sites within watersheds on a rotating basin schedule, randomly selected sample sites (Smithson, 2007), and sites chosen to further define impaired stream segments in support of total maximum daily load (TMDL) development (WVDEP, 2008a). Most sites are sampled once during an annual sampling period, but some sites are sampled monthly for water quality. The data set contains water quality, habitat, watershed characteristics, macroinvertebrate data (both raw data and calculated metrics), and geographic location (WVDEP, 2008a). A wide range of SC levels were sampled, which is useful for modeling the response of organisms to different levels of ionic concentration. The WABbase includes assignation of reference status using a tiered approach. Analyses involving the use of these reference sites were drawn from the Level 1 reference status (WVDEP, 2008b) which selects reference sites that "are thought to represent the characteristics of stream reaches that are minimally affected by human activities and are used to define attainable chemical, biological and habitat conditions for a region" (WVDEP, 2013; Stoddard et al., 2006). Sites are initially selected by a map coordinator based on GIS land use data that indicate minimal human disturbance. Streamside, the appropriateness of the selected site is confirmed based on the level of anthropogenic disturbance, lack of point discharges, habitat quality, pH, dissolved oxygen, and SC (>500 µS/cm) is used to flag a site for further investigation before inclusion as a reference site (WVDEP, 2013).

Macroinvertebrate records in the data set are based on collections from a total of 1 m^2 area of a 100 m reach at each site. Using a 0.5 m wide rectangular kicknet (595 µm mesh), four 0.25 m^2 riffle areas were sampled. In narrow or shallow water, nine areas were sampled with a 0.33 m wide D-frame dipnet of the same mesh size. Composited samples were preserved in 95% denatured ethanol. A random subsample of 200 individuals (±20%) was identified in the laboratory. All contracted analyses for chemistry and macroinvertebrate identification followed WVDEP's internal quality control and quality-assurance protocols (WVDEP, 2008b, 2006).

Quality assurance of the data set was judged by the EPA to be excellent, based on the database itself and supporting documentation.

Several data filters, described in Section 3.1 (see Figure 3-2), were applied prior to finalization of the data set and analyses. A total of 9,806 records from Ecoregion 69 are included in the data set; of these, SC measurements were included in 8,989 samples. Many of these are measurements of water quality without biological sampling. There are 1,911 paired samples with SC measurements and biological samples. Of these, a total of 250 samples were removed from the data set due to low pH ≤6 (237 samples) and high proportion of chloride ions ($[HCO_3^-] + [SO_4^{2-}]) \leq [Cl^-]$ (13 samples). Additional criteria were applied to identify macroinvertebrates for inclusion in the example extirpation concentration distribution: occurrence at reference sites and occurrence in 25 or more samples. Of the 219 macroinvertebrate genera identified in this ecoregion in the WABbase, 193 genera occurred at least once at one of the 64 identified reference sites where invertebrate samples were collected. A total of 142 genera occurred at 25 or more sampling locations. The final example "Criterion-data set" has 1,661 samples belonging to 1,420 sites (stations) (depicted in Figure 4-1). Of these 1,661 samples, 186 (11.2%) were sampled more than once between 1996 and 2010. Summary statistics for the data set used to derive the example CCC is shown in Table 4-1. The statistical package R, Version 2.12.1 (December 2010), was used for all statistical analyses (R Development Core Team, 2011).

SC ranged from 15.4–3,794 µS/cm which allowed the response of organisms to be modeled for a wide range of SC levels. Scatter plots of parameters and SC are depicted in Appendix A.1.

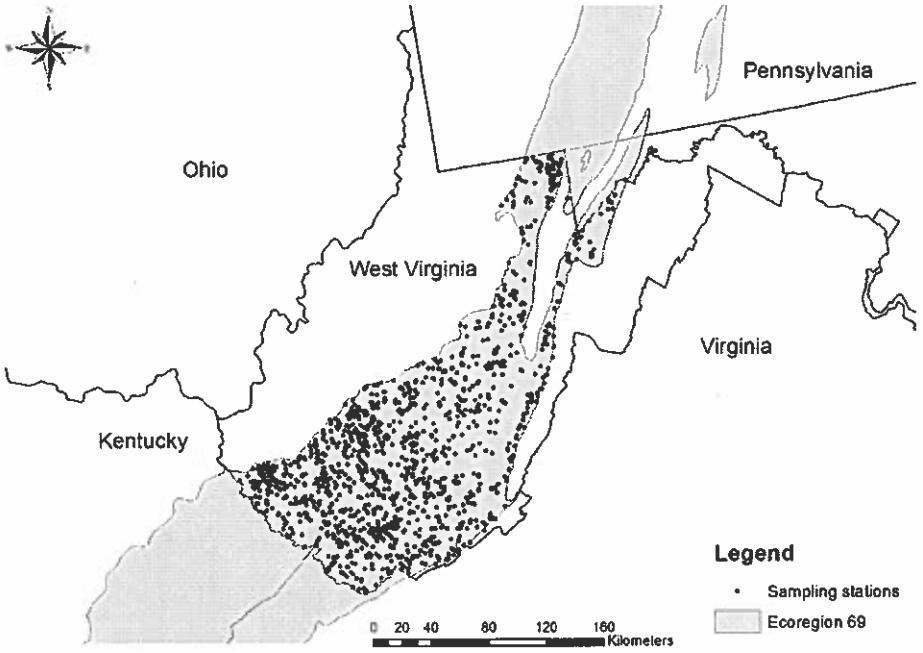

Figure 4-1. Ecoregion 69 extends from central Pennsylvania to northern Tennessee. Sampling sites (stations) (N = 1,420) in the example Criterion-data set that were used to derive the criterion continuous concentration (CCC) are indicated as points.

Table 4-1. Summary statistics of the measured water-quality parameters used to derive the example specific conductivity criteria in Ecoregion 69.
The example Criterion-data set has 1,661 samples belonging to 1,420 stations.

Parameter	Units	Min	25th	50th	75th	Max	Geomean	*N*

All means are geometric means except pH, DO, Temperature, and Habitat Scores.
RBP = rapid bioassessment protocol (Barbour et al., 1999; RBP 10Sc has 10 parameters while RBP 7 does not include 3 flow-related parameters); TSS = total suspended solids.

4.1.1. Background Specific Conductivity

Background SC was estimated at the 25th centile of the subset of probability-based samples from the example Criterion-data set because its sampling design more closely matched the ecoregional EPA-survey data set. Using this probability-based subsample of the WABbase data set, the estimated background was 80 µS/cm (25th centile, 585 samples from 544 sites; see Figure 4-2). Background was also estimated to be 63 µS/cm based on field data from reference sites from the WABbase data set (75th centile, 112 samples from 82 reference sites; see Figure 4-3). By comparison, the 25th centile was 94 µS/cm for all samples (reference and nonreference sites) from the example Criterion-data set that was used to derive the HC_{05} (1,661 samples from 1,420 sites; see Figure 4-4). The monthly 25th centiles of probability-sampled sites (see Figure 4-2) and all samples in the data set (reference and nonreference sites, see Figure 4-4) were relatively consistent and at or below 100 µS/cm except in July through October (see Figure 4-2). The effects of seasonal variability of SC on the subsequent analyses was further evaluated and are presented in Appendix A. The large size of the data set and the wide range in SC levels in the example Criterion-data set allowed for characterization of the XC_{95}.

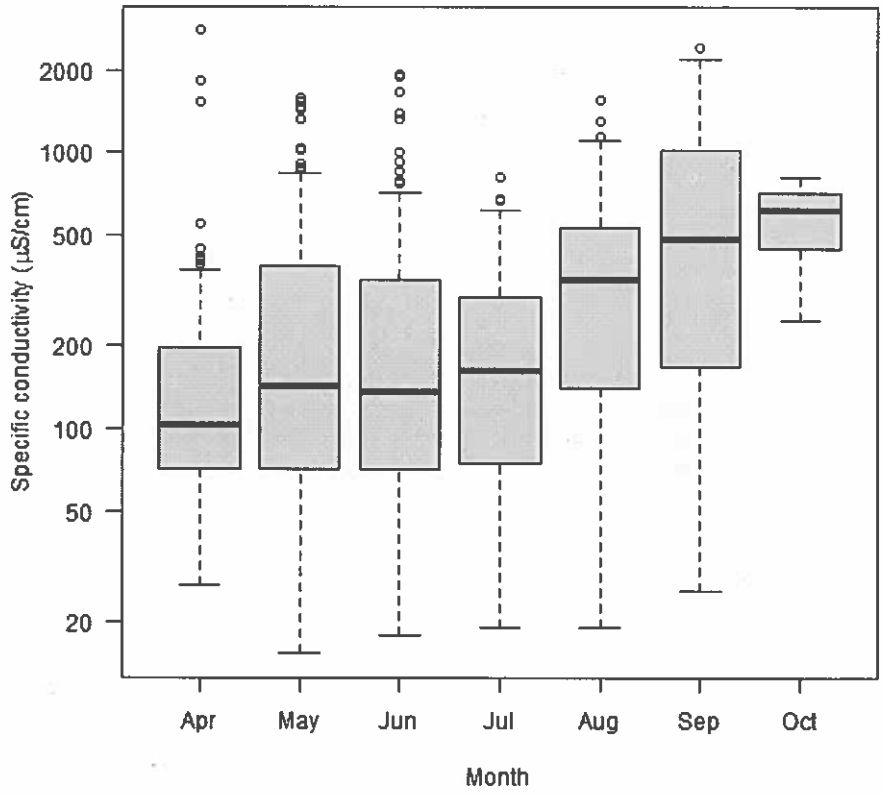

Figure 4-2. Box plot showing seasonal variation of specific conductivity (µS/cm) from probability-sampled sites from Watershed Assessment Branch database (WABbase) 1997–2010. This represents a total of 544 sites with 585 samples from 1997–2010 from Ecoregion 69 with pH >6. Note the difference in scale along the *y*-axis between Figure 4-2 (probability-sampled sites) and Figure 4-3 (reference sites). There are only eight October samples. See Table 4-2 for number of samples per month.

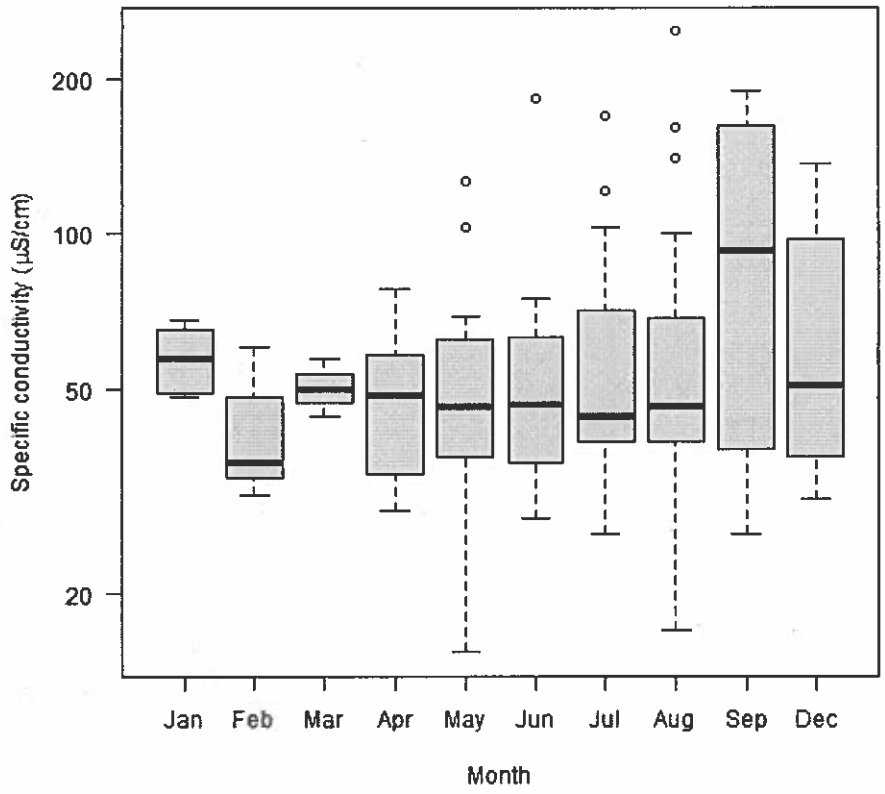

Figure 4-3. Box plot showing seasonal variation of specific conductivity (µS/cm) in the reference streams from Watershed Assessment Branch database (WABbase) 1997–2010.
A total of 112 samples from 82 reference stations were used for this analysis to estimate background specific conductivity. Please note the smaller scale on the *y*-axis compared to Figures 4-2 and 4-4. A total of 112 samples from 82 reference stations were used for this analysis to estimate background specific conductivity. Please note the smaller scale on the *y*-axis compared to Figures 4-2 and 4-4. See Table 4-2 for number of samples per month.

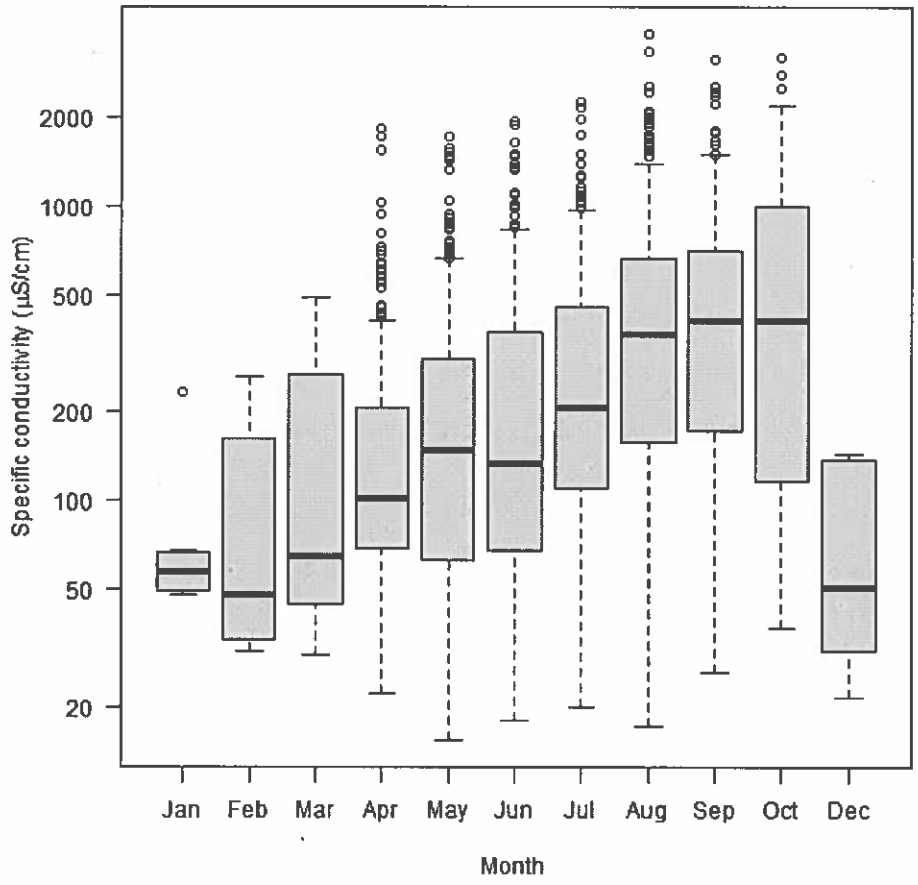

Figure 4-4. Box plot showing seasonal variation of specific conductivity (µS/cm) from all Ecoregion 69 sites from Watershed Assessment Branch database (WABbase) 1997–2010 used to develop the example criteria. This represents a total of 1,661 samples from 1,420 sites from 1997–2010. Note the difference in scale along the *y*-axis between Figure 4-4 (all sites, reference and nonreference) and Figure 4-3 (reference sites). See Table 4-2 for number of samples per month.

4.1.2. Ionic Composition

The ionic composition of the samples in the Ecoregion 69 data set was assessed to ensure that the example criteria were derived for waters dominated by sulfate and bicarbonate anions (see Figure 4-5). Of the 1,674 samples after low pH samples were removed, 56% of samples (938 in total) included measures of calcium, magnesium, sulfate, bicarbonate, and chloride. All but 13 sites (>98%) were dominated by bicarbonate and sulfate anions ($[HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$. The 13 chloride-dominated sites were excluded from the derivation

analysis but are shown in Figure 3. Sodium and potassium were less frequently measured, but did not exceed calcium and magnesium where measured for samples in the data set. Sites with no ion measurements were retained in the data set because the data had shown that >98% of samples were dominated by bicarbonate and sulfate anions; thus, it is expected that less than 2% of samples in the Ecoregion 69 Criterion-data set are chloride-dominated.

The analysis may also be defensible for mixtures dominated by sodium, sulfate and bicarbonate ions, e.g., produced water from deep coal mines (Thomas, 2002; Mayhugh and Ziemkiewicz, 2005). This is because the toxicity of these mixtures are more similar to that of calcium, magnesium, sulfate and bicarbonate ions than the toxicity of NaCl (Mount et al., 2016; Kunz et al., 2013; Soucek and Dickinson, 2015).

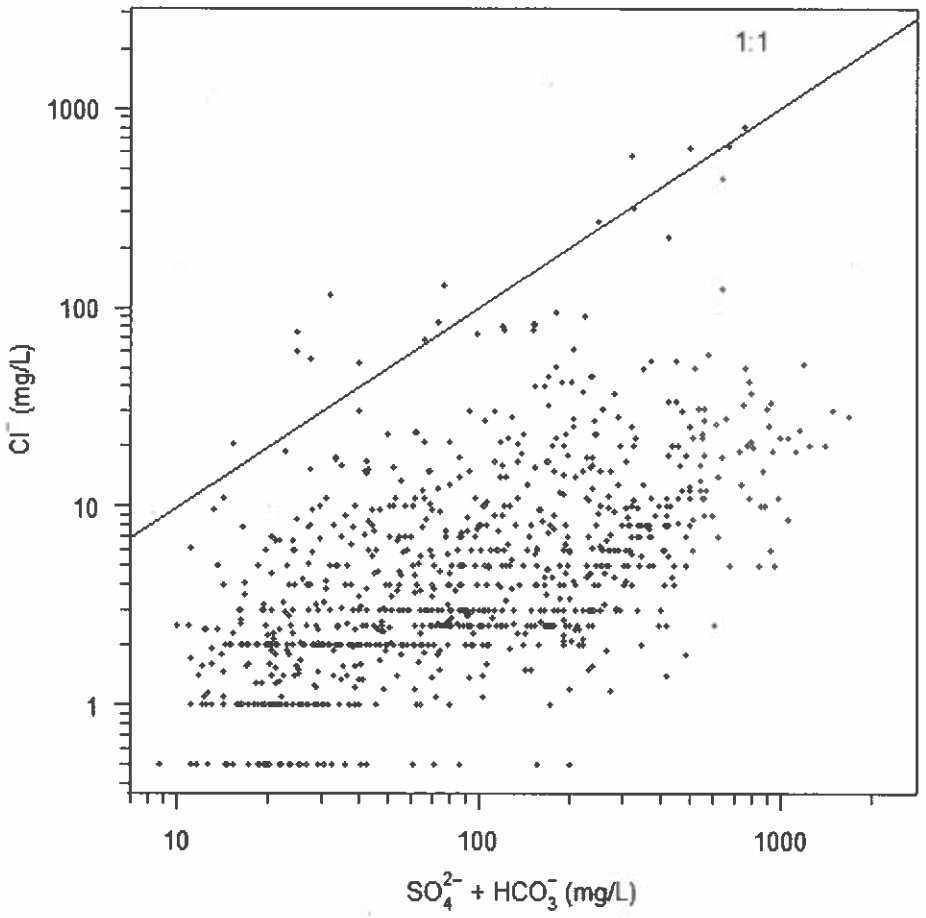

Figure 4-5. Scatter plot of relationship between [Cl^-] and ([HCO_3^-] + [SO_4^{2-}]) concentrations in streams in Ecoregion 69 data set from 1997–2010 with ionic measurements. Most (98.6%) of the samples (n = 938) are below the diagonal line representing the separation between ([HCO_3^-] + [SO_4^{2-}])-dominated and Cl^--dominated mixtures. Sites above the 1:1 line were excluded from the example Criterion derivation data set. Samples depicted here include all sites regardless of pH.

4.1.3. Seasonal Specific Conductivity Regime

For this case study, chemical, physical, and/or biological samples were collected during the sampling years 1997–2010 (January–December). Most (>85%) sites were sampled once during an annual sampling period, but some (e.g., sites being studied to improve stream condition within the TMDL Program) were sampled monthly for water quality parameters (see Table 4-2).

Table 4-2. Number of samples with reported genera and specific conductivity meeting acceptance criteria for the Ecoregion 69 analysis

Number of samples[a]	Month												Total
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	
Full data set	8	4	36	159	269	163	197	388	342	89	0	6	1,661

Reference sites	6	3	3	10	19	12	27	24	4	0	0	4	82
Percentage of total	0.5	0.2	2.2	9.6	16.2	9.8	11.9	23.4	20.6	5.4	0	0.4	(100)

[a]Number of samples is presented for each month.

Samples collected from the WVDEP-identified reference sites indicate that SC levels are generally low and similar throughout the year, although slightly higher in September (see Figure 4-3). These data show that SC concentrations in flowing waters in the study area can vary somewhat by season, likely depending on stream discharge, rainfall, snowmelt, and other hydrological factors. As described in Section 3.1.4 (and in greater detail in the *EPA Benchmark Report*), the effects of seasonal differences in SC levels and aquatic insect life history were evaluated by comparing HC_{05} values partitioned for season. After careful consideration of the similarity between the spring HC_{05} and the HC_{05} based on the full data set at the low end of the XCD, the example ecoregional criteria were derived using all available data, regardless of the time of year they were collected (see Sections 3.1.4 and Appendix A.2 in this assessment, and U.S. EPA, 2011a).

4.2. RESULTS

4.2.1. Extirpation Concentration (XC_{95}) and Hazardous Concentration (HC_{05}) Values (Example Criterion Continuous Concentration [CCC])

The Ecoregion 69 example Criterion-data set (see Table 4-1) was used to develop XC_{95} values from weighted CDFs. The histogram used to develop weights is depicted in Figure 4-6. The XC_{95} values that were used in the XCDs are listed in the order of least to most salt-tolerant in Appendix A.3. The generalized additive model plots used to designate ~ and > values for those XC_{95} values are depicted in Appendix A.4. The weighted CDFs used to derive the XC_{95}

values are shown in Appendix A.5. The HC_{05} for Ecoregion 69 was calculated at 305.4 µS/cm (see Figures 4-7 and 4-8); the two-tailed 95% confidence bounds were 233–329 µS/cm. Those bounds, derived by bootstrap resampling, indicate that different data sets could yield HC_{05} values within that interval. Rounding to two significant figures, the example CCC for Ecoregion 69 is 310 µS/cm.

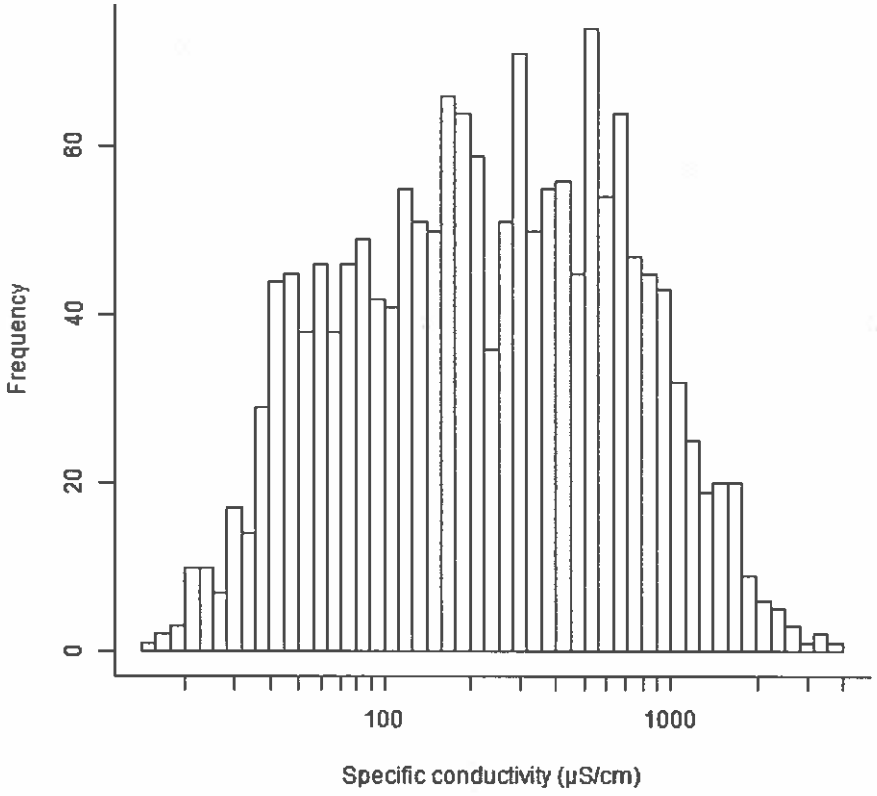

Figure 4-6. Histograms of the frequencies of observed specific conductivity values in samples from Ecoregion 69 sampled between 1997 and 2010. Bins are each 0.017 (1/60) of the range of log10 specific conductivity units wide.

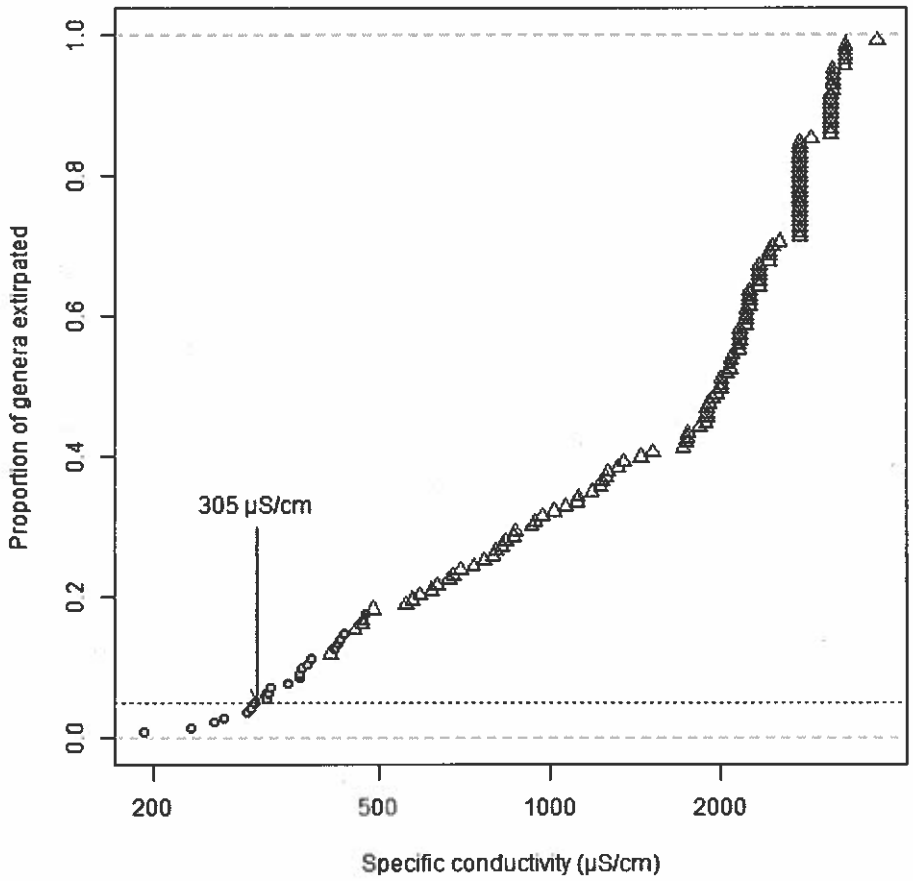

Figure 4-7. Example genus extirpation concentration distribution (XCD) for Ecoregion 69. Each point is an extirpation concentration (XC_{95}) value for a genus. There are 142 genera. The hazardous concentration (HC_{05}) is 305 µS/cm (95% confidence interval is 233−329 µS/cm) and is the specific conductivity at the intersection of the XCD with the horizontal line at the 5th centile. XC_{95} with an approximate or greater than designation are shown as triangles.

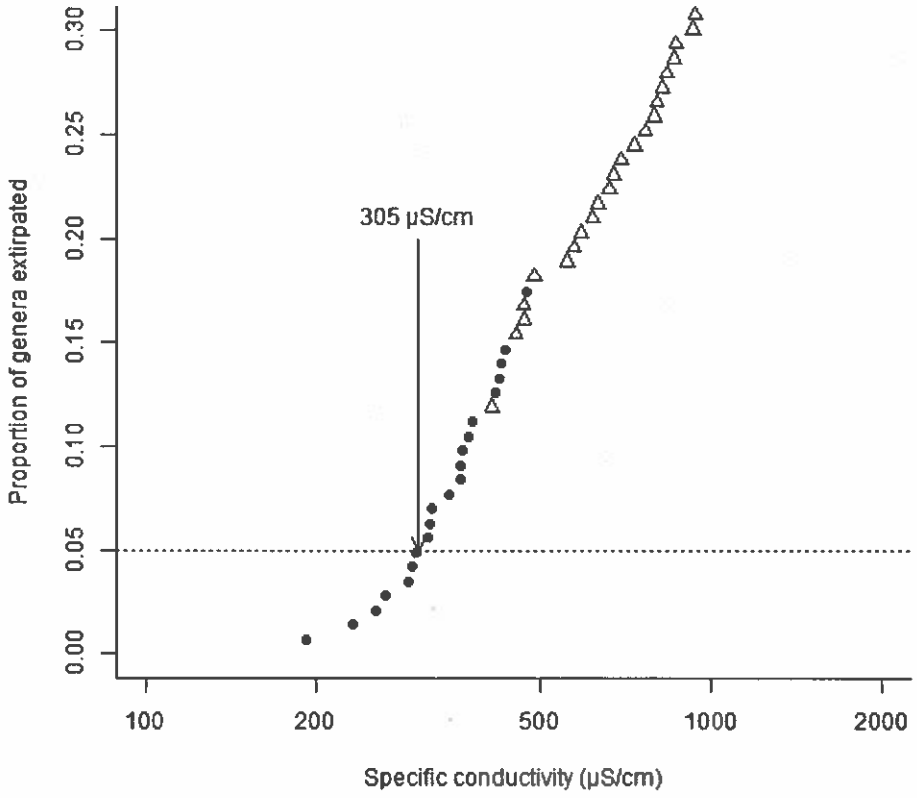

Figure 4-8. The lower end of the example genus extirpation concentration distribution for Ecoregion 69. The dotted horizontal line is the 5th centile. The vertical arrow indicates the hazardous concentration (HC_{05}) of 305 µS/cm (95% confidence intervals 233–329 µS/cm). Only the 50 most salt-intolerant genera are shown to better discriminate the points on the left side of the distribution. The six most salt-intolerant genera (i.e., extirpation concentration [XC_{95}] ≤ 305 µS/cm) are *Leptophlebia, Remenus, Pycnopsyche, Paraleptophlebia, Bezzia,* and *Alloperla*). XC_{95} values with an approximate or greater than designation are shown as triangles.

4.2.2. Example Criterion Maximum Exposure Concentration

At sites meeting the CCC of 310 µS/cm, 90% of the SC observations are estimated to occur below the CMEC (see Section 3.2). The CMEC was derived using the full Ecoregion 69 data set (9,806 samples collected between 1996–2011). Of the 9,806 samples in this ecoregion, there are 5,823 samples in a July to June rotating year representing 564 rotation years, 536 unique stations, with at least 1 sample from July to October and 1 sample from March to

June, and at least 6 samples within a rotation year (see Table 4-3). Note that inclusion of samples is not contingent on biological data. Reference and nonreference sites were included to ensure a range of SC (see Table 4-1).

Table 4-3. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 69

Number of samples July to June prior to biological sampling	5,811
Number of unique stations/rotation years	536/564
Number of WVDEP reference sites	15
CCC	310 µS/cm
CMEC	630 µS/cm

Of the 564 rotation years (536 unique stations) with multiple SC measurements, the variability of within station SC was found to differ for streams with different mean SC (see Figure 4-9). The locally weighted scatterplot smoothing (LOWESS) lines indicated that the average variability (residual standard deviation for a station) in the middle of the SC gradient is slightly higher than both the lower and higher ends of the gradient. The stations with annual mean SC values between the 25th and 75th centile (which is approximately between 120−520 µS/cm) have relatively similar variances, and therefore, could be used to estimate the standard deviation components of annual mean SC (310 µS/cm). There are 2,855 samples from 278 station years (265 stations) in the selected data sets for Ecoregion 69 with streams having mean SC values between 120 and 520 µS/cm. The grand mean and standard deviation of this data set were determined and the CMEC was calculated. The example CMEC calculation is shown below:

$$\text{CMEC for Ecoregion 69: } 10^{\log10(310) + 1.28*0.243} = 634.1 \text{ µS/cm} \qquad (4\text{-}1)$$

The example CMEC (see Table 4-3) rounded to two significant figures yields a CMEC of 630 µS/cm for Ecoregion 69. At this level, where the annual average SC is <310 µS/cm, 90% of the observations are expected to be less than the CMEC.

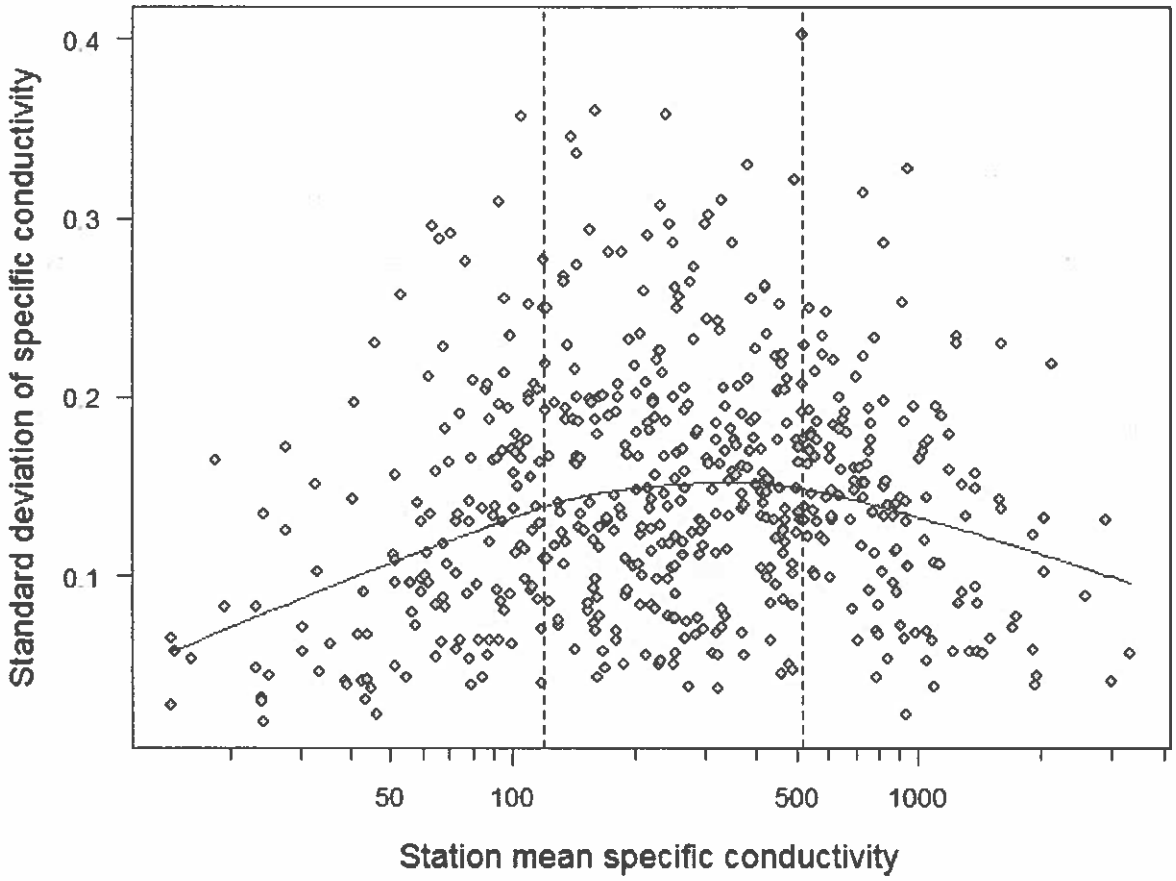

Figure 4-9. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station mean) in Ecoregion 69. The *x*-axis is log annual mean specific conductivity. Each dot represents a station. The fitted line is a locally weighted linear scatterplot smoothing (LOWESS, span = 0.75, linear polynomial model), while the two vertical dashed lines represent logarithm mean specific conductivity of 120 and 520 µS/cm, respectively. Within those bounds the standard deviation is fairly constant.

4.3. GEOGRAPHIC APPLICABILITY

The geographical applicability of the criteria throughout Ecoregion 69 was assessed using the background-matching approach (see Section 3.7.1). The background SC of the new area (i.e., the portion of Ecoregion 69 beyond the original data set) was estimated at the 25th centile

(see Section 3.7.1.2; and Cormier and Suter, 2013a) and compared with the background SC estimates for the original data set.

Because the example SC criteria presented here have been developed for a dissolved mixture dominated by sulfate and bicarbonate anions, ($[HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$ in mg/L, all chloride-dominated samples, ($[HCO_3^-] + [SO_4^{2-}]) \leq [Cl^-]$ in mg/L, were removed from the data set before estimating background SC. Thereby, the background for the new area is estimated for the same ionic mixture as the example criteria.

4.3.1. Data Sources

Two data sets were used for this example applicability assessment: the original data set used to derive the HC_{05} described in Section 4.1 and an EPA-survey data set (see Table 4-4).

The EPA-survey data set was used to evaluate and characterize ion concentrations and water chemistry in the ecoregion (see Table 4-5). The primary sources of the combined data are from EPA survey programs including the National Rivers and Streams Assessment (NRSA) 2008–2009 surveys (U.S. EPA, 2013b, 2009), Wadeable Streams Assessment (WSA) 2004 survey (U.S. EPA, 2006), Environmental Monitoring and Assessment Program (EMAP) 1993–1998 and Regional-EMAP (R-EMAP) 1999 surveys (U.S. EPA, 2013c), and National Acid Precipitation Assessment Program (NAPAP) 1986 survey (NADP, 2013). Data sets are based on random samples from June through September. Most report SC, alkalinity, hardness, sulfate, chloride, bicarbonate, pH, and other water quality parameters. Ecoregions and sampling sites are shown in Figure 4-10. All samples were collected from first-through fourth-order streams as part of a probability-based design intended to estimate proportions of parameters for various stream classes. The probability-design weights were not used in this characterization. Analysis of water chemistry samples followed EPA procedural and QA/QC protocols from EMAP (U.S. EPA. 2001, 1998b, 1994, 1987), Wadeable Streams Assessment (U.S. EPA, 2004a, b), the NRSA (U.S. EPA, 2009), and NAPAP (Drousé et al., 1986; U.S. EPA, 1987). These data sets were also selected so that methods would be comparable across the data set, and because these studies used probability-based designs (i.e., randomly assigned sampling locations).

Table 4-4. Description of survey data sets combined to form the EPA-survey data set used to assess applicability of the example ecoregional criteria throughout Ecoregion 69

Data set	Sampling period	Total *N*	KY	MD	PA	TN	VA
MAHA EMAP	1993–1995	42	0	3	35	0	4
MAIA EMAP	1997–1998	12	0	0	8	0	4
WSA	2004	9	3	1	0	3	2
NRSA	2008–2009	8	4	0	1	2	1
NAPAP	1986	41	2	6	29	4	0
Region 4 Wadeable Streams R-EMAP	1999–2002	9	7	0	0	2	0
Total		121	16	10	73	11	11

MAHA = Mid-Atlantic Highland Assessment; MAIA = Mid-Atlantic Integrated Assessment.

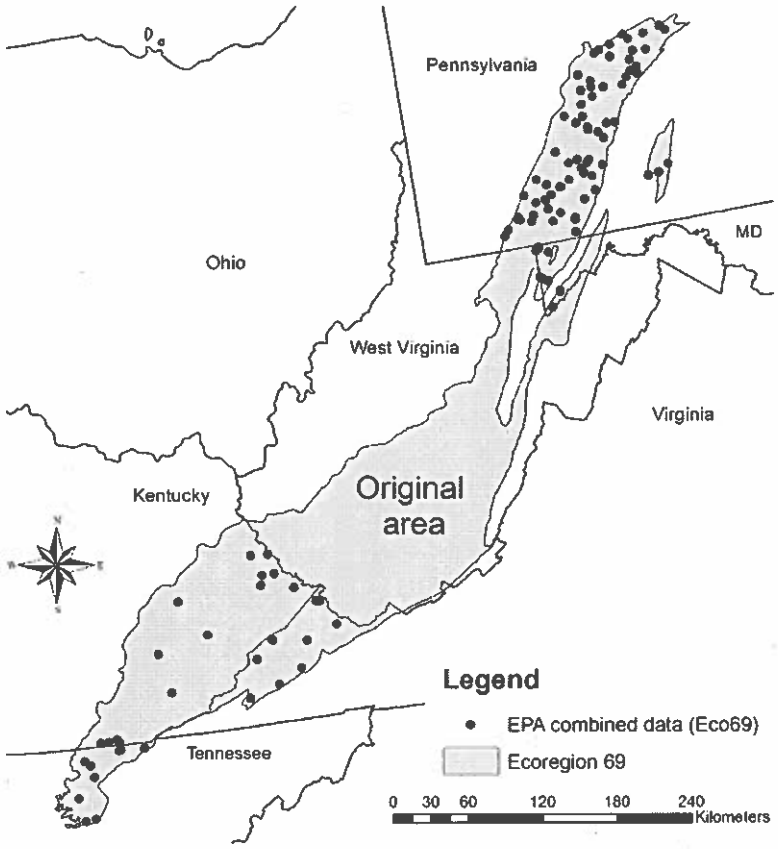

Figure 4-10. Ecoregion 69 extends from central Pennsylvania to northern Tennessee. Sampling sites in the EPA-survey data set that were used to estimate background in the "new" area for Ecoregion 69 are indicated as points. The figure depicts 121 samples from 121 stations.

4.3.2. Geographic Applicability Results

A summary of water quality for the EPA-survey data set (see Section 4.3.1) for Ecoregion 69, including major ionic constituents, is provided in Table 4-5. Background SC in the new area was estimated from the full EPA-survey data set because no sample was dominated by chloride ions.

Background SC for bicarbonate and sulfate dominated waters estimated as the 25th centile of the EPA-survey data set for the new area in Ecoregion 69 (outside the area used to develop the example criteria) was 63.5 µS/cm (95% CI 46–89 µS/cm) (see Table 4-6). The 25th centile from the probability sample from the example Criterion-data set was 66 µS/cm (95% CI 60–75) (see Table 4-6). The confidence bounds for background estimated from the example Criterion-data

set overlap with the confidence bounds for background estimated for the rest of Ecoregion 69. Therefore, the background SC regime throughout Ecoregion 69 appears to be similar, and thus, the example criteria (CCC = 310 µS/cm, CMEC = 630 µS/cm) are considered geographically applicable throughout the ecoregion. Other estimates of background from the reference sites in the example Criterion-data set (63 µS/cm; 95% CI 60–65 µS/cm) and the example Criterion data set (94 µS/cm; 95% CI 86–101 µS/cm) also overlap with the CI of the background for the rest of Ecoregion 69 (see Table 4-6).

Table 4-5. Summary of water quality parameters for Ecoregion 69 from the EPA-survey data set excluding the sites in West Virginia

Ecoregion	Ion	Min	Centile				Max	Relevant *N*
			10th	25th	50th	75th		
Ecoregion 69	HCO_3^- (mg/L)	0.0	0.1	1.3	12.5	37.3	241.8	102
	SO_4^{2-} (mg/L)	3.2	7.6	10.0	21.4	136.3	1,622.8	112
	Cl^- (mg/L)	0.5	1.1	1.7	3.0	8.6	59.0	112
	Ca^{2+} (mg/L)	1.2	2.2	5.6	13.7	39.1	186.0	112
	Mg^{2+} (mg/L)	0.6	1.0	1.5	4.5	17.3	152.1	112
	Na^+ (mg/L)	0.2	0.6	1.1	2.9	9.3	93.4	112
	K^+ (mg/L)	0.4	0.6	0.8	1.3	2.2	8.0	112
	pH (SU)	3.0	4.7	6.2	7.1	7.7	8.6	121
	[a]$(HCO_3^- + SO_4^{2-})/Cl^-$	1.4	3.0	5.4	13.6	41.4	497.5	102
	SC (µS/cm)	23.7	34.5	63.5	183.5	426.8	2,515	121

[a]Value within category calculated from individual sample ion concentrations. $HCO_3^- + SO_4^{2-}/Cl^-$ in mg/L greater than 1 indicates the mixture is dominated by $HCO_3^- + SO_4^{2-}$.

Table 4-6. Background specific conductivity estimates for Ecoregion 69

Data set	Centile used to estimate background	Background µS/cm	Confidence interval µS/cm	Relevant *N* (sites/samples)
EPA-survey data set from geographic area not represented in the example criterion derivation data set	25th	64	46–89	121/121
WABbase data set, probability sample subset	25th	66	60–75	544/583
WABbase data set, reference sample subset	75th	63	60–65	82/112
Example criterion derivation data set, full data set	25th	94	86–101	1,420/1,661

4.4. SUMMARY OF EXAMPLE CRITERIA FOR ECOREGION 69

The case example for Ecoregion 69 includes an annual geometric mean (i.e., CCC) and a 1-day mean (i.e., CMEC), not to be exceeded more than once in 3 years on average. Both of these distinct expressions of the example SC criteria would need to be met in order to adequately protect aquatic life. These values indicate that freshwater animals in Ecoregion 69 would be protected if the annual geometric mean SC concentration in flowing waters does not exceed 310 µS/cm and the 1-day mean does not exceed 630 µS/cm, more than once every 3 years on average. These example criteria would apply to all flowing freshwaters (ephemeral, intermittent, and perennial streams) in Ecoregion 69 inclusive of portions of Kentucky, West Virginia, Maryland, Virginia, Tennessee, and Pennsylvania. On a site-by-site basis, these example ecoregional criteria apply if the ionic mixture is dominated by anions of bicarbonate and sulfate. For streams crossing into Ecoregion 69, professional judgment may be needed to assess the potential effect of different ionic composition or concentration. Professional judgment is recommended when applying to sites with a catchment area greater than 1,000 km^2 (386 mi^2) owing to lesser representation in the example data set by this class of stream. On a site-by-site basis, alternative specific conductivity criteria may be more appropriate if the natural background of a site is shown to be lower or higher than its regional background specific conductivity.

4.5. EXAMPLE CRITERION CHARACTERIZATION

4.5.1. Factors Potentially Affecting the Extirpation Concentration Distribution (XCD) Model

An assessment of potential confounders and an analysis of the influence of habitat quality and sampling date for Ecoregion 69 can be found in Appendix A.2.

4.5.1.1. *Sensitivity Analyses*

As the minimum number of occurrences of a genus for inclusion in the data set increases, fewer genera are included in the XCD. The HC_{05} increases greatly when a taxon in the lower 5th centile is removed because it does not meet the minimum number of samples and then more slowly alternates between increasing and decreasing as genera either above or below the 5th centile are removed because they do not meet the minimum number of samples (see Figure 4-11). The pattern repeats until all genera above and below the lower 5th centile have the same XC_{95} value (not shown). To maximize the number of genera included in the XCD, a minimum of 25 occurrences was utilized.

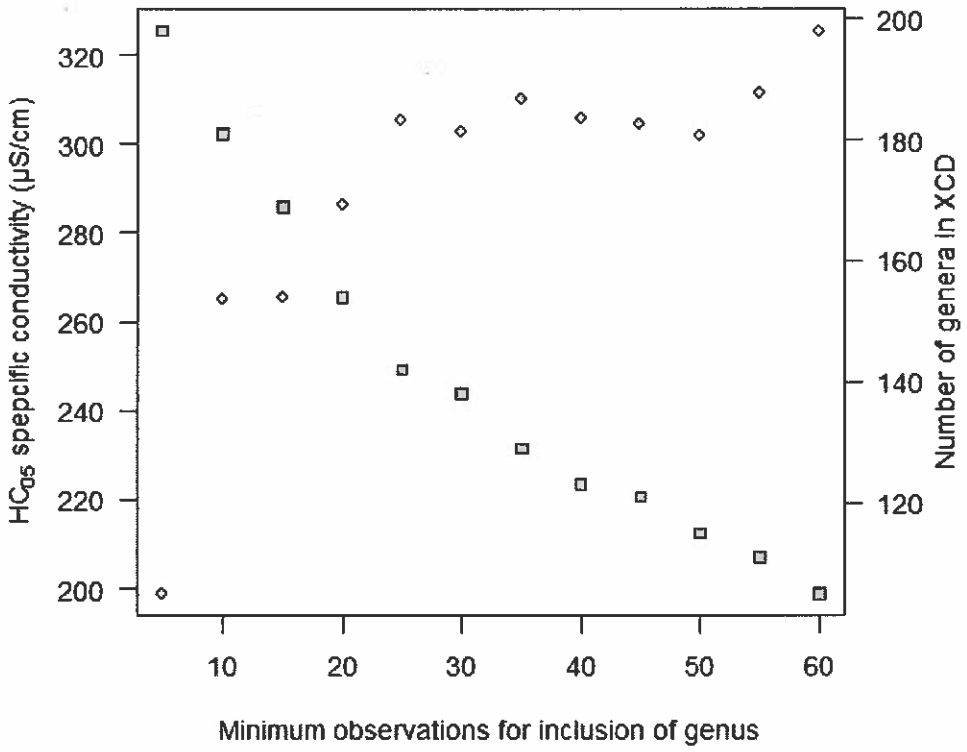

Figure 4-11. Relationship of the number of occurrences of a genus and the hazardous concentration (HC_{05}) based on Ecoregion 69 example Criterion-data set. Estimates of HC_{05} values (blue diamonds, left axis) and the number of taxa in the extirpation concentration distribution (XCD) (red squares, right *y*-axis) based on minimum number of samples (5–60, *x*-axis). As the minimum number of observations of a genus increases, fewer are included in the XCD.

The number of samples in the data set affected the number of genera included in the XCD and the resulting example HC_{05}. The effects of data set size on the HC_{05} estimates and on their confidence bounds were estimated using a bootstrapping technique. The mean of all bootstrapped HC_{05} values, the numbers of genera used for the HC_{05} calculation, and their 95% CI were plotted to show the effect of sample sizes. As shown in Figure 4-12, the HC_{05} for this data set stabilizes, reaching an asymptote at approximately 500–800 sites sampled and 90–120 genera evaluated. Therefore, the original data set was considered adequate for estimating the example.

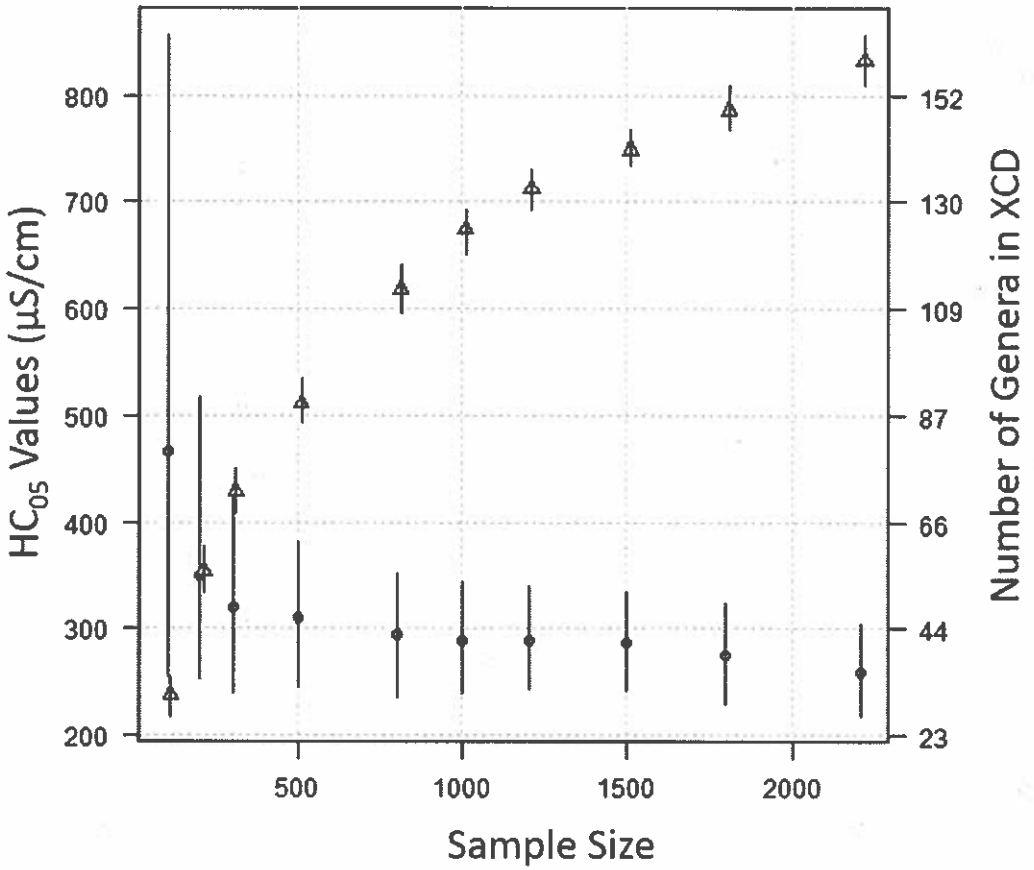

Figure 4-12. The effect of the size of the data set used to model the hazardous concentration (HC_{05}) based on the Ecoregion 69 example Criterion-data set. As size of the data set increases, the number of genera included in the extirpation concentration distribution (XCD) increases (triangles). The HC_{05} stabilizes reaching an asymptote at approximately 500−800 sites sampled (circles) and 90−120 evaluated genera.

4.5.2. Validation of the Extirpation Concentration Distribution (XCD) Model

The XCD model was validated and uncertainty around the HC_{05} values was estimated using bootstrapping, as recommended by the EPA SAB in their review of the *EPA Benchmark Report* (U.S. EPA, 2011c). The median HC_{05} estimated from bootstrapping was 281 µS/cm (95% CI 233−329 µS/cm) which is similar to the HC_{05} of 305 µS/cm measured using a 2-point interpolation of the original XCD. The similarity between the two HC_{05} values indicates a similar model would be generated using an independent data set (see Figure 4-13).

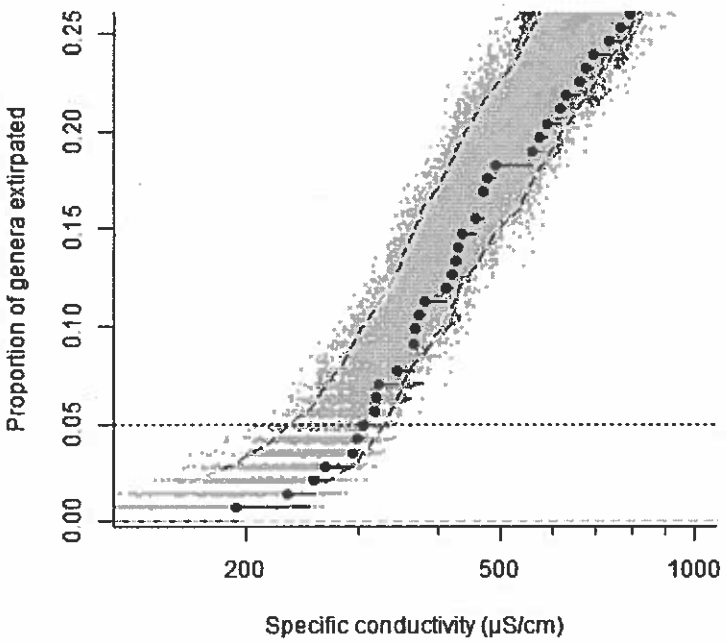

Figure 4-13. Cumulative distribution of the extirpation concentration (XC_{95}) values for the 25% most salt-intolerant genera (blue circles) and 95% confidence intervals (dotted lines) based on 1,000 extirpation concentration distribution (XCD) bootstrapping results. Each tiny gray dot represents an XC_{95} value for a bootstrapping iteration (note that the genera in each percentage varies with each XCD iteration). Each larger blue filled dot represents the calculated XC_{95} of the XCD for the criterion continuous concentration (CCC). The median bootstrapped hazardous concentration (HC_{05}) is 281 µS/cm.

4.5.3. Duration and Frequency

Numeric criteria include magnitude (i.e., how much), duration (i.e., how long), and frequency (i.e., how often) components. Appropriate duration and frequency components of criteria are determined based on consideration of available data and understanding the exposure-response relationship in the context of protecting the aquatic life of a water body. The significant consideration used in setting the duration component of aquatic life criteria is how long the exposure concentration can be above the criteria without affecting the endpoint on which the criteria are based (U.S. EPA, 1991, 1985). Based on the temporal resolution of the available field data set and an analysis of within-site variability of SC levels, EPA developed two

different expressions for the example SC criteria in order to provide adequate protection for aquatic life.

In this case, the majority (>85%) of sites used to derive the example CCC for Ecoregion 69 were sampled once during an annual sampling period and thus represent the average stream SC and macroinvertebrate assemblage information over the course of 1 year. As a result, the appropriate duration for the CCC is 1 year. The duration for the CMEC, a level of protection from acutely toxic exposures, is 1 day based on a review of the literature regarding the onset of macroinvertebrate drift in response to elevated SC (see Section 3.3). At sites meeting the CCC, 90% of the SC observations are estimated to occur below the CMEC.

EPA anticipates that an appropriate allowable frequency of exceedance for these example criteria is no more than once in 3 years, based on recovery rates from literature reviews and consideration of the life history of insects able to recolonize a site via drift or aerial dispersal (see Section 3.4). Recovery is expected to occur in 3 years if the following conditions are met: (1) the SC regime returns to a yearly average below the CCC, (2) there are nearby streams with low SC supporting a diverse community, and (3) there is an upstream source of colonizers or the flight or recolonizing distance is within the dispersal range of genetically diverse, reproducing adult colonizers. If any of these conditions are not met, the time necessary for ecosystem recovery (and thus, the allowable frequency of exceedance) would likely be longer than 3 years.

4.6. PROTECTION OF FEDERALLY-LISTED SPECIES

Although the derivation of the example criteria was limited to the macroinvertebrate taxa represented in the data sets, the available evidence indicates that other taxa in the streams would likely be protected as well (see Section 2.6 and Appendix G). Hence, no adjustment was made for unanalyzed taxa. However, on a site-specific basis, the example criterion could be adjusted or recalculated to protect important species, highly valued aquatic communities, or specially protected waters.

5. CASE STUDY II: EXAMPLE USING THE EXTIRPATION CONCENTRATION DISTRIBUTION (XCD) METHOD IN A MODERATE BACKGROUND SPECIFIC CONDUCTIVITY ECOREGION

This section presents a case study for the Western Allegheny Plateau (Ecoregion 70) to illustrate how the analytical methods described in Section 3 can be used to derive example SC criteria using the XCD method in an area with slightly higher background SC than Ecoregion 69 (see Section 4). Ecoregion 70 results, including estimates of the CCC and CMEC, duration, frequency, and discussion of applicability are included as examples to demonstrate the method. The derivations of the CCC and CMEC analyses and results are based on data from Ecoregion 70 in West Virginia, and SC data from the Ecoregion 70 outside of WV was used to assess applicability of the criteria throughout the ecoregion.

5.1. DATA SET CHARACTERISTICS

The Western Allegheny Plateau (Ecoregion 70) extends from the corner of southwestern Pennsylvania and southeastern Ohio into Kentucky and West Virginia. The hilly and wooded terrain of the Western Allegheny Plateau is mostly unglaciated and well dissected, with local relief of 61 to 229 m, and peak elevations of around 610 m. Many of the rivers in this ecoregion are entrenched, as a result of the rugged, hilly terrain, particularly within the Permain Hills (70a) and Monongahela Transition Zones (70b). The ecoregion is predominantly forested, but also consists of a mosaic of urbanized areas, pastures, farms, and coal mines (Woods et al., 1999). Extensive mixed mesophytic forests and mixed oak forests originally grew in the Western Allegheny Plateau and, today, most of its rounded hills remain in forest; dairy, livestock, and general farms, with residential developments concentrated in the valleys. The Western Allegheny Plateau is composed of horizontally bedded sandstone, shale, siltstone, limestone, and coal. The horizontally-bedded sedimentary rock underlying the region has been mined for bituminous coal (Woods et al., 1996).

The data used in this case study are from a large field data set, the WVDEP's in-house WABbase. Chemical and biological samples are from 1996–2011 and 1997–2010, respectively. The WABbase contains data from Level III Ecoregions 66, 67, 69, and 70 in West Virginia (U.S. EPA, 2000a; Omernik, 1987; Woods et al., 1996). The WABbase data set provides

consistent sampling and analytical methods, high quality, broad spatial coverage of a large number of perennial streams (2,011 distinct locations) in Ecoregion 70.

The WABbase contains data from a mixed sampling design that collects measurements from long-term monitoring stations, targeted sites within watersheds on a rotating basin schedule, randomly selected sample sites (Smithson, 2007), and sites chosen to further define impaired stream segments in support of TMDL development (WVDEP, 2008a). Most sites are sampled once during an annual sampling period, but most TMDL sites are sampled monthly for water quality. The data set contains water quality, habitat, watershed characteristics, macroinvertebrate data (both raw data and calculated metrics), and geographic location (WVDEP, 2008a). A wide range of SC levels were sampled, which is useful for modeling the response of organisms to different ionic concentrations. Level 1 reference status (WVDEP, 2008b) which selects reference sites that "are thought to represent the characteristics of stream reaches that are minimally affected by human activities and are used to define attainable chemical, biological and habitat conditions for a region" (WVDEP, 2013). Sites are initially selected by a map coordinator based on GIS land use data that indicate minimal human disturbance. Streamside, the appropriateness of the selected site is confirmed based on the level of anthropogenic disturbance, lack of point discharges, habitat quality, pH, dissolved oxygen, and SC (>500 µS/cm) is used to flag a site for further investigation before inclusion as a reference site (WVDEP, 2013).

Macroinvertebrate records in the data set are based on collections from a total of 1 m^2 area from a 100 m reach at each site. Using a 0.5 m wide rectangular kicknet (595 µm mesh), four 0.25 m^2 riffle areas were sampled. In streams narrower than 1 m, nine areas were sampled with a 0.33 m wide D-frame dipnet of the same mesh size. Composited samples were preserved in 95% denatured ethanol. A random subsample of 200 individuals (±20%) was identified in the laboratory. All contracted analyses for chemistry and macroinvertebrate identification followed WVDEP's internal quality control and quality-assurance protocols (WVDEP 2008b, 2006). Quality assurance of the data set was judged by EPA to be excellent, based on the database itself and supporting documentation.

Several data filters, described in Section 3.1 (see Figure 3.2), were applied prior to finalization of the data set and analyses. A total of 12,909 records from Ecoregion 70 are included in the data set; of those, SC measurements were included in 11,600 of these samples.

Many of these are measurements of water quality without biological sampling. Of the 11,600, there are 2,126 paired samples with SC measurements and biological samples identified to genus. Of these, a total of 51 samples were removed from the data set due to low pH ≤6 (48 samples) and high proportion of chloride ions, ($[HCO_3^-] + [SO_4^{2-}]) \leq [Cl^-]$ (3 samples). Additional criteria were used to identify macroinvertebrates for inclusion in the extirpation concentration distribution: occurrence at reference sites and occurrence in 25 or more samples. Of the 217 macroinvertebrate genera identified in this ecoregion of the WABbase, 179 genera occurred at least once at one of the 29 identified reference sites where invertebrate samples were collected and identified to genus. A total of 139 genera occurred at 25 or more sampling locations. The final example Criterion-data set has 2,075 samples belonging to 1,695 stations (as depicted in Figure 5-1). Multiple samples were obtained from 19% of stations. Summary statistics for the data set used to derive the criterion is shown in Table 5-1. The statistical package R, Version 2.12.1 (December 2010), was used for all statistical analyses (R Development Core Team, 2011).

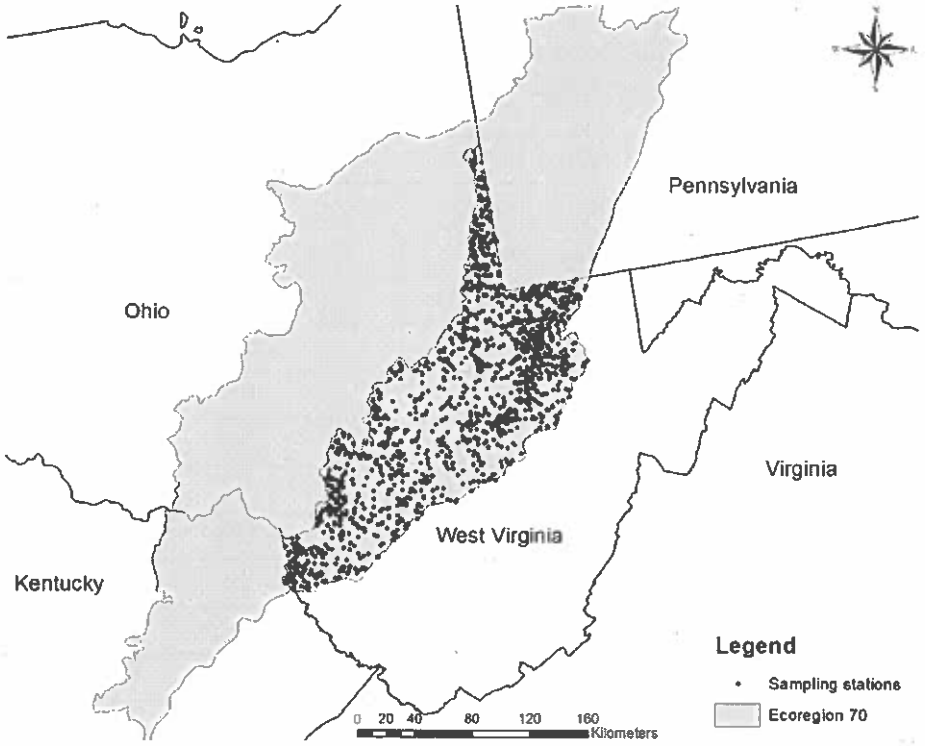

Figure 5-1. Ecoregion 70 extends from central Pennsylvania to northern Tennessee. Sampling sites (stations) (N = 1,695) in the example Criterion data set that were used to derive the example criterion continuous concentration (CCC) are indicated as points.

Table 5-1. Summary statistics of the measured water-quality parameters used to derive the example specific conductivity criteria in Ecoregion 70.
The example Criterion data set has 2,075 samples belonging to 1,695 stations.

Parameter	Units	Min	25th	50th	75th	Max	Mean [a]	*N*

[a]All means are geometric means except pH, DO, Temperature, and Habitat variables.
RBP = rapid bioassessment protocol (Barbour et al., 1999; RBP 10Sc has 10 parameters while RBP 7 does not include three flow-related parameters).

SC ranged from 40–11,646 µS/cm, which allowed the response of organisms to be modeled for a wide range of SC levels. This maximum is SC is three times higher than the background SC estimated for the data set analyzed in Case Study I (15–3,794 µS/cm). Scatter plots of parameters and SC are depicted in Appendix B.1.

5.1.1. Background Specific Conductivity

Background SC was estimated at the 25th centile from the probability-based samples from the example Criterion-data set because its sampling design more closely matched the ecoregional EPA-survey data set. Using this probability-based subsample of the WABbase data set, the estimated background for Ecoregion 70 was 147 µS/cm (681 samples from 617 sites; see Figure 5-2). Background was also estimated to be 201 µS/cm based on field data from 30 reference sites from the WABbase data set (75th centile; see Figure 5-3). By comparison, the 25th centile for all samples used to derive the example HC_{05} was estimated (166 µS/cm) (see Figure 5-4). The higher estimated background SC based on state-selected reference sites (n = 30)[3] reflects the importance of habitat in site selection and the smaller data set. Seasonal patterns of SC are evident in the probability-based samples and example Criterion-data set (see Figures 5-2 and 5-4). The apparent Background SC is <200 µS/cm December through June and >200 µS/cm July through October (no samples were available for November; see Figure 5-4). The effect of seasonal variability of SC on the subsequent analyses was further evaluated and presented in Appendix B. The large size of the data set and the wide range in SC levels in the example Criterion-data set allowed for genus XC_{95} to be calculated.

[3]29 of these sites have biological sampling available as described in Section 5.1.

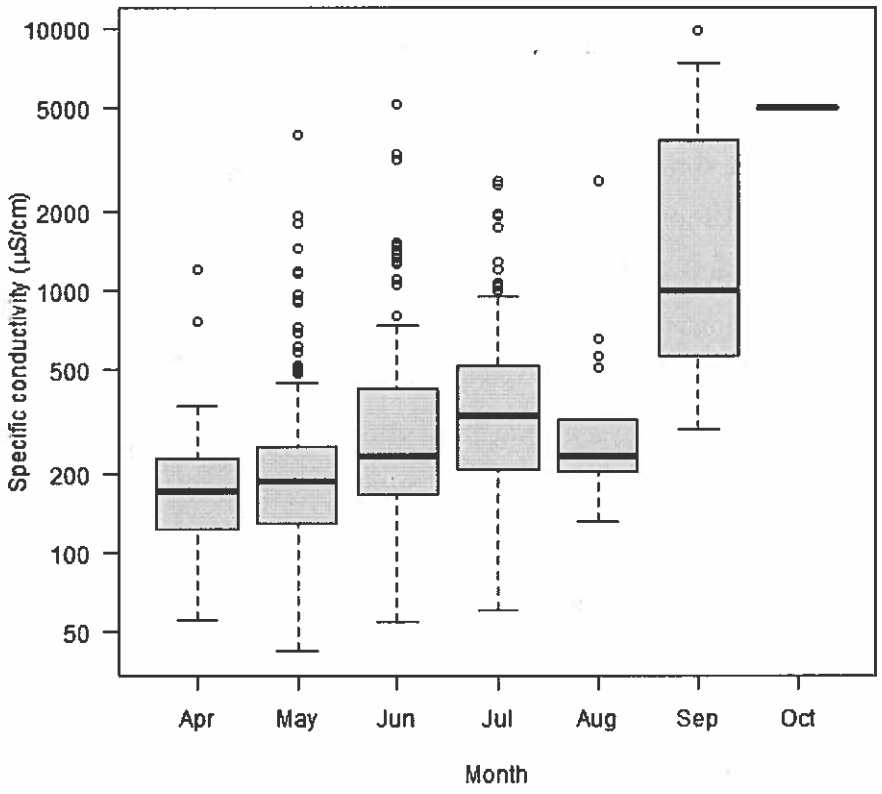

Figure 5-2. Box plot showing seasonal variation of specific conductivity (µS/cm) from probability sites from Watershed Assessment Branch database (WABbase) 1997–2010. This represents a total of 617 sites with 681 samples from 1997–2010 from Ecoregion 70 with pH >6. Note the difference in scale along the *y*-axis between Figure 5-2 (probability sites) compared to Figure 5-3 (reference sites). See Table 5-2 for sample sizes.

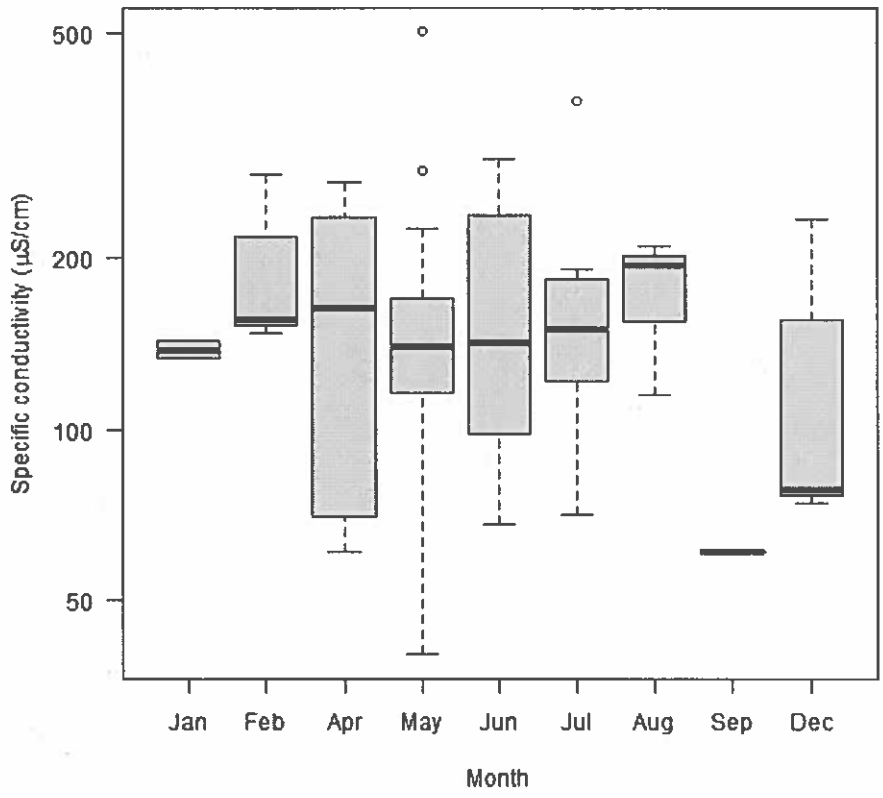

Figure 5-3. Box plot showing seasonal variation of specific conductivity (µS/cm) in the reference streams of Ecoregions 70 from 1997 to 2010. A total of 55 samples from 30 reference stations were used for this analysis. Please note the smaller scale on the *y*-axis compared to Figures 5-2 and 5-4. See Table 5-2 for sample sizes.

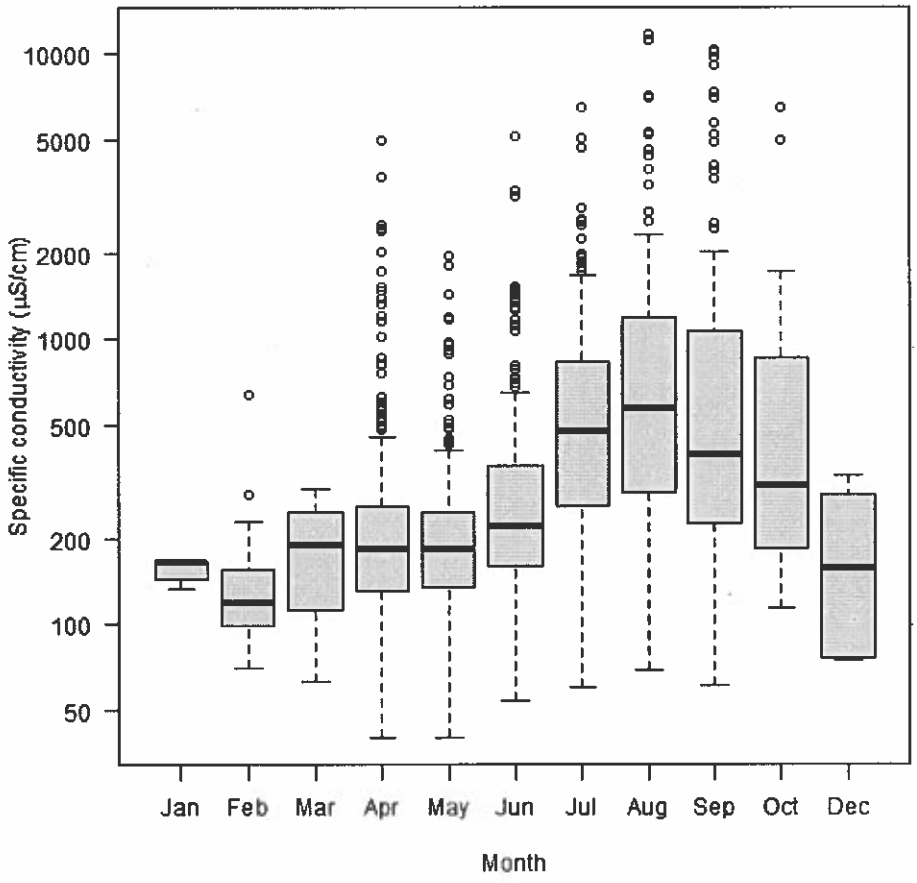

Figure 5-4. Box plot showing seasonal variation of specific conductivity (µS/cm) from all Ecoregion 70 sites from Watershed Assessment Branch database (WABbase) 1997–2010 used to develop the example criteria. The example Criterion-data set has 2,075 samples from 1,695 sites. Note the difference in scale along the *y*-axis between Figure 5-2 (all sites, reference and nonreference) and Figure 5-3 (reference sites). See Table 5-2 for sample sizes.

5.1.2. Ionic Composition

The ionic composition of the samples in the data set for Ecoregion 70 waters was assessed to ensure that the example criteria were derived for waters dominated by sulfate and bicarbonate anions (see Figure 5-5). Of the 2,082 samples after low pH samples were removed, 50.3% of samples (1,048 in total) included measures of calcium, magnesium, sulfate, bicarbonate, and chloride. All but three sites (>99.7%) were dominated by bicarbonate and sulfate anions, ($[HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$. The three chloride-dominated sites were excluded from the derivation analysis but are shown in Figure 3. Sodium and potassium were less

frequently measured, but did not exceed calcium and magnesium where measured. Sites with no ion measurements were retained in the data set because the data had shown that >99.7% of samples were dominated by bicarbonate and sulfate anions; thus, it is expected that less than 1% of samples in the Ecoregion 70 Criterion-data set are chloride-dominated. However, the analysis may also be defensible for ionic mixtures dominated by sodium, sulfate and bicarbonate ions, e.g., produced water from deep coal mines (Thomas, 2002; Mayhugh and Ziemkiewicz, 2005). This is because the toxicity of these mixtures are more similar to that of calcium, magnesium, sulfate and bicarbonate ions than the toxicity of NaCl (Mount et al., 2016; Kunz et al., 2013; Soucek and Dickinson, 2015).

5.1.3. Seasonal Specific Conductivity Regime

Chemical, physical, and/or biological samples were collected during the sampling years 1997–2010 (January–December). Most sites were sampled once during an annual sampling period, but some (e.g., sites being studied to improve stream condition within the TMDL Program) were sampled monthly for water quality parameters (see Table 5-2).

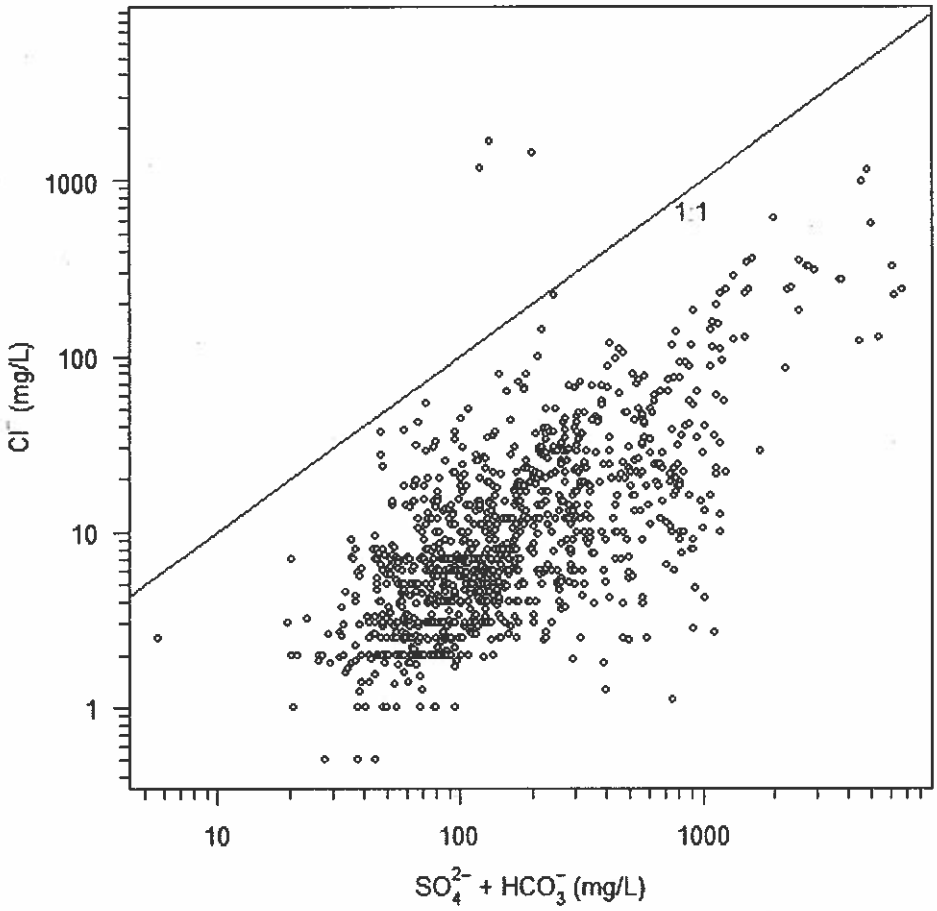

Figure 5-5. Scatter plot of relationship between [Cl^-] and ([HCO_3^-] + [SO_4^{2-}]) concentrations in streams of Ecoregion 70 data set. Most (99.7%) samples (n = 1,045) are below the diagonal line representing the separation between (HCO_3^- + SO_4^{2-})-dominated and Cl^--dominated mixtures. Sites above the 1:1 line were excluded from the example criterion derivation data set. The Ecoregion 70 data set includes all samples with (HCO_3^- + SO_4^{2-}), and Cl^- measurements. Samples depicted here include all sites regardless of pH.

Table 5-2. Number of samples with reported genera and specific conductivity meeting data-inclusion acceptance criteria for the Ecoregion 70 analysis

Number of samples[a]	Month												Total
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	
Full data set	5	33	11	362	381	290	333	439	193	24	0	4	2,075
Probability sites	0	0	0	151	262	157	70	17	18	1	0	0	676
Reference sites	2	3	0	6	15	8	7	3	1	0	0	3	48
Percentage of total	0.2	1.6	0.5	17.4	18.4	14	16	21.1	9.3	1.2	0	0.2	100

[a]Number of samples is presented for each month.

Samples collected from the WABbase-identified reference sites indicate that SC levels are generally low and similar throughout the year, although slightly higher in summer/fall (see Figures 5-2 and 5-3). These data show that SC concentrations in flowing waters in the study area can vary somewhat by season, likely depending on stream discharge, rainfall, snowmelt, and other hydrological factors. As described in Section 3.1.4 (and in greater detail in U.S. EPA, 2011a), the effects of seasonal differences in SC levels and aquatic insect life history were evaluated by comparing HC_{05} values partitioned for season. After consideration of the similarity between the spring HC_{05} and the HC_{05} based on the full data set at the low end of the genus XCD, the example ecoregional criteria were derived using all available data, regardless of the time of year they were collected (see Section 3.1.4 and Appendix B.2 in this assessment and U.S. EPA, 2011a).

5.2. RESULTS

5.2.1. Extirpation Concentration (XC_{95}) and Hazardous Concentration (HC_{05}) Values (Example Criterion Continuous Concentration)

The Ecoregion 70 example Criterion-data set (see Table 5-1) was used to develop XC_{95} values from weighted CDFs. The histogram used to develop weights is depicted in Figure 5-6. The XC_{95} values that were used in the XCDs are listed in the order of least to most salt-tolerant

in Appendix B.3. The GAM plots used to designate ~ and > values for those XC_{95} values are depicted in Appendix B.4, and the weighted CDFs used to derive the XC_{95} values used to assign the XC_{95} values are shown in Appendix B.5. The example HC_{05} was calculated at 338 µS/cm (see Figures 5-7 and 5-8); the two-tailed 95% confidence bounds were 272−365 µS/cm. Those bounds, derived by bootstrap resampling, indicate that different data sets could yield HC_{05} values within that interval. Rounding to two significant figures, the example CCC is 340 µS/cm.

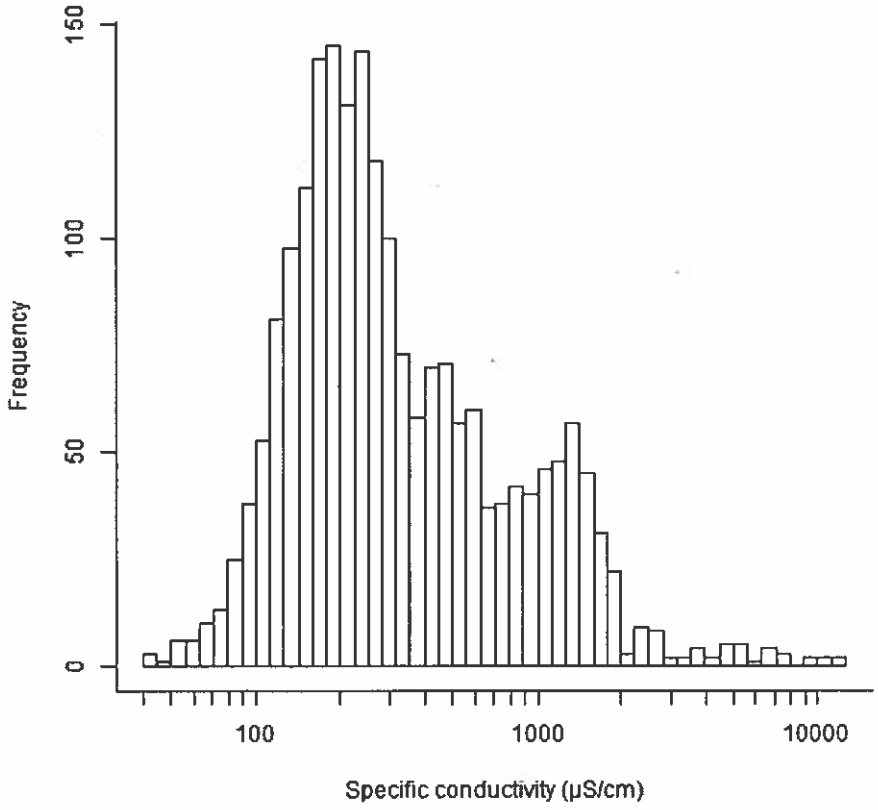

Figure 5-6. Histograms of the frequencies of observed specific conductivity values in samples from Ecoregion 70 sampled between 1997 and 2010.
Bins are each 0.017 (1/60) of the range of log10 specific conductivity units wide.

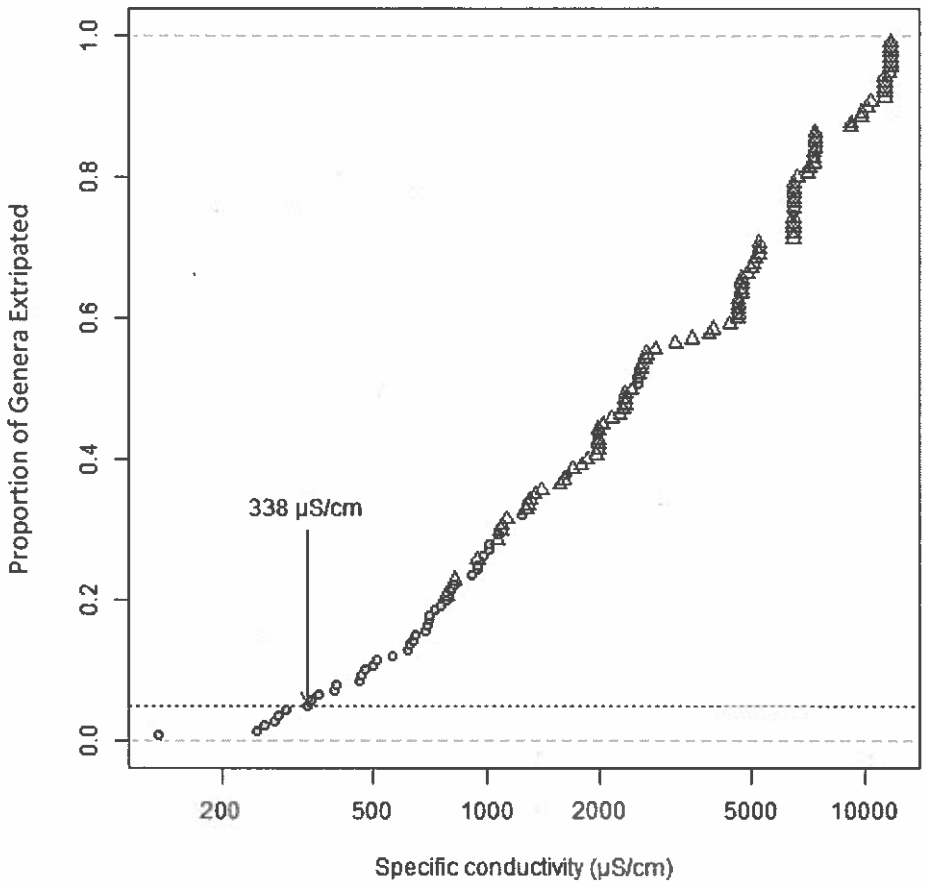

Figure 5-7. Example genus extirpation concentration distribution (XCD) for Ecoregion 70. Each point is an extirpation concentration (XC_{95}) value for a genus (n = 139 genera). The hazardous concentration (HC_{05}) is 338 µS/cm (95% confidence interval 272−365 µS/cm) and is the specific conductivity at the intersection of the genus XCD with the horizontal line at the 5th centile. XC_{95} values with an approximate or greater than designation are shown as triangles.

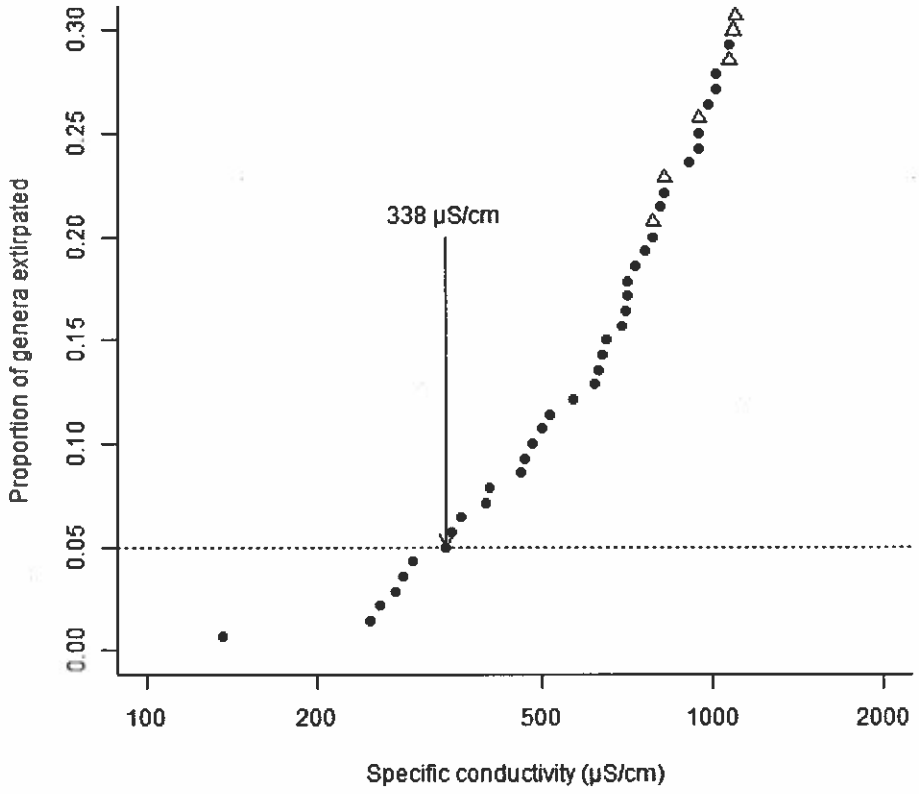

Figure 5-8. The lower end of the example genus extirpation concentration distribution for Ecoregion 70. The dotted horizontal line is the 5th centile. The vertical arrow indicates the hazardous concentration (HC_{05}) of 338 µS/cm (95% confidence interval 272–365 µS/cm). Only the 50 most salt-intolerant genera are shown to better discriminate the points on the left side of the distribution. The six most salt-intolerant genera (i.e., extirpation concentration [XC_{95}] ≤ 338 µS/cm) are *Drunella, Utaperla, Cinygmula, Alloperla, Ephemerella* and *Heptagenia.* XC_{95} values with an approximate or greater than designations are shown as triangles.

5.2.2. Example Criterion Maximum Exposure Concentration

At sites meeting the CCC of 340 µS/cm, 90% of the SC observations are estimated to occur below the CMEC (see Section 3.2). The CMEC was derived using the Ecoregion 70 data set. Out of the 12,909 samples collected between 1996–2011, 8,302 samples had a July-to-June rotating year representing 819 rotation years and 805 unique stations, with at least 1 sample from July to October and one from March to June, and at least 6 samples within a rotation year with

SC measurements (see Table 5-3). Note that inclusion of samples is not contingent on biological data. Reference and nonreference sites were included to ensure a range of SC (see Table 5-1).

Table 5-3. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 70

Number of samples June to July prior to biological sampling	8,302
Number of rotation years (# unique stations)	819 (805)
Number of WVDEP reference sites	12
CCC	340 µS/cm
CMEC	680 µS/cm

Of the 819 rotation years (805 unique stations) with multiple SC measurements, the variability of within station SC was found to differ among streams (see Figure 5-9); however, the LOWESS line indicated that the average variability (residual standard deviation for a station) is not very different across the entire gradient in Ecoregion 70. The stations with annual mean SC between the 25th and 75th centile (120 and 520 µS/cm) were used to estimate the variance components of annual mean SC (at 340 µS/cm). The selected data sets with mean SC values between 120 and 520 µS/cm in respective data sets have a sample size of 518 rotation years (513 stations) and 5,272 observations. The grand mean and standard deviation of this data set were determined and the CMEC was calculated. The CMEC calculation is shown below:

$$\text{CMEC for Ecoregion 70: } 10^{\log10(340)+\ 1.28*0.237} = 684\ \mu S/cm \qquad (5\text{-}1)$$

The example field-based calculated CMEC rounded to two significant figures yields a CMEC of 680 µS/cm for Ecoregion 70. At this level, where the annual average SC <340 µS/cm, 90% of the observations are expected to be less than the CMEC.

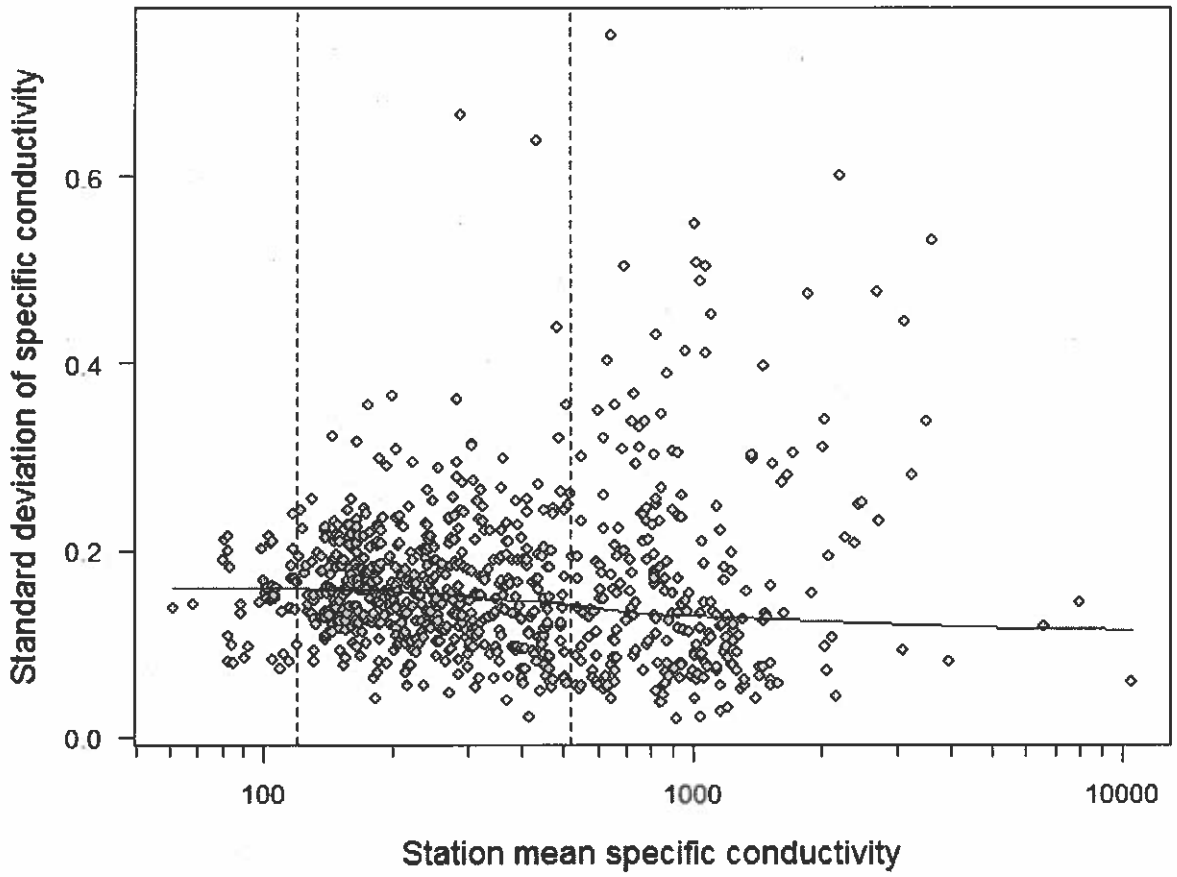

Figure 5-9. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station mean) in Ecoregion 70. The *x*-axis is log annual mean specific conductivity. Each dot represents a station. The fitted line is the locally weighted scatterplot smoothing (LOWESS, span = 0.75, linear polynomial model), while the two vertical dashed lines represent logarithm mean specific conductivity of 120 and 520 µS/cm respectively. Within those bounds, the standard deviation is fairly constant.

5.3. GEOGRAPHIC APPLICABILITY

The geographical applicability of the example criteria throughout Ecoregion 70 was assessed using the background-matching approach (see Section 3.7.1). The background SC of the new area (i.e., Ecoregion 70 beyond West Virginia) was estimated at the 25th centile (see Section 3.7.1.2; and Cormier and Suter, 2013a) and compared with the background estimates for Ecoregion 70 within West Virginia.

Because the example SC criteria presented here have been developed for a dissolved mixture dominated by sulfate and bicarbonate anions ($[HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$ in mg/L), all chloride-dominated samples ($([HCO_3^-] + [SO_4^{2-}]) \leq [Cl^-]$ in mg/L) were removed from the data set before estimating background SC. Thereby, the background for the new area is estimated for the same ionic mixture as the example criteria.

5.3.1. Data Sources

Two data sets were used for this example applicability assessment: the original data set used to derive the HC_{05} described in Section 5.1 and an EPA-survey data set.

An EPA-survey data set was used to evaluate and characterize ion concentrations and water chemistry in the ecoregion. The primary sources of the combined data are from EPA survey programs: the NRSA 2008–2009 data set (U.S. EPA, 2013b), WSA 2004 data set (U.S. EPA, 2006), EMAP 1993–1998 data sets and R-EMAP 1999 data set (U.S. EPA, 2013c), and NAPAP data set collected in 1986 (NADP, 2013) (see Table 5-4). Data sets are based on single random samples from June through September. Most report SC, alkalinity, hardness, sulfate, chloride, bicarbonate, pH and other water quality parameters. Ecoregions and sampling sites are shown in Figure 5-10. All samples were collected from first-through fourth-order streams as part of a probability-based design intended to estimate proportions of parameters for various stream classes. The probability-design weights were not used in this characterization. Analysis of water chemistry samples followed EPA procedural and quality assurance/quality control protocols from EMAP (U.S. EPA, 2001, 1998b, 1994, 1987), Wadeable Streams Assessment (U.S. EPA, 2004a, b), NRSA (U.S. EPA, 2009), and NAPAP (Drousé et al., 1986; U.S. EPA, 1987). These data sets were also selected so that methods would be comparable across the data set and because these studies used probability-based designs (i.e., randomly assigned sampling locations).

Table 5-4. Description of survey data sets combined to form the EPA-survey data set used to assess applicability of example ecoregional criteria throughout Ecoregion 70

Data set	Sampling period	Total *N*	KY	OH	PA
MAHA EMAP	1993–1995	14	0	0	14
MAIA EMAP	1997–1998	10	0	0	10
WSA	2004	16	5	6	5
NRSA	2008–2009	14	4	6	4
NAPAP	1986	5	0	0	5
Region 4 Wadeable Streams R-EMAP	1999–2002	2	2	0	0
Total		**61**	**11**	**12**	**38**

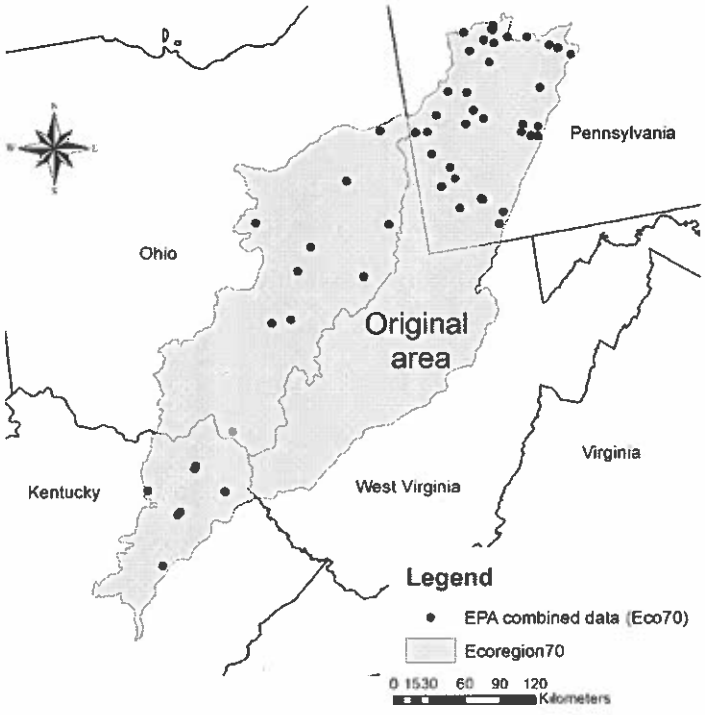

Figure 5-10. Ecoregion 70 extends from southwestern Pennsylvania and southeastern Ohio into Kentucky. Sampling sites in the EPA-survey data set that were used to estimate background in the "new" area for Ecoregion 70 are indicated as points. There are 61 samples from 61 stations.

5.3.2. Geographic Applicability Results

A summary of water quality for the ecoregion, including major ionic constituents, for the EPA-survey data set is listed in Table 5-5. Sites with HCO_3^- + SO_4^{2-} concentrations on a mass basis greater than or equal to Cl^- were used to estimate background SC. This mixture is common in the ecoregion, and only one site was dominated by chloride anions in the EPA-survey data set and none in the example Criterion-data set. Therefore, this one site was excluded so the natural background was estimated from the altered EPA-survey data set.

Background SC for bicarbonate and sulfate dominated waters estimated as the 25th centile of the EPA-survey data set for the area in Ecoregion 70 outside the area used to develop the example criteria was 197 µS/cm (95% CI 145–272 µS/cm) (see Table 5-6). The 25th centile from the probability sample from the example Criterion-data set was 147 µS/cm (95% CI 136–159) (see Table 5-6). The confidence bounds for background estimated from the example Criterion-data set overlap with the confidence bounds for background estimated for the rest of the ecoregion. Therefore, the background SC regime throughout Ecoregion 70 appears to be similar, and the example criteria (CCC = 340 µS/cm, CMEC = 680 µS/cm) are considered geographically applicable throughout the ecoregion. Other estimates of background from the reference sites in the example Criterion-data set (201 µS/cm; 95% CI 164–210 µS/cm) and the example Criterion data set (169 µS/cm; 95% CI 161–171 µS/cm) also overlap with the CI of the background for the rest of the ecoregion. As a validation of background specifically for the portion of Ecoregion 70 in Ohio, a weight of evidence was performed (see Appendix C).

Table 5-5. Summary of water quality parameters for Ecoregion 70 EPA-survey data set

Ion or specific conductivity	Min	Centile				Max	[a]*N*
		10th	25th	50th	75th		
HCO_3^- (mg/L)	0.0	1.8	18.1	52.2	121.0	241.8	42
SO_4^{2-} (mg/L)	11.5	17.2	24.1	52.6	144.7	955.8	58
Cl^- (mg/L)	1.0	3.8	6.0	9.6	26.3	204.5	58
Ca^{2+} (mg/L)	4.9	10.5	19.0	47.8	69.3	240.8	58
Mg^{2+} (mg/L)	1.8	3.5	6.2	12.5	22.7	87.7	58
Na^+ (mg/L)	1.0	3.1	4.3	9.1	22.8	161.2	58
K^+ (mg/L)	1.0	1.6	1.9	2.4	3.0	9.6	58
pH (SU)	4.0	6.3	7.3	7.7	8.1	8.6	60
[b]$(HCO_3^- + SO_4^{2-})/Cl^-$	1.7	3.7	8.0	10.6	22.8	103.8	42
SC (µS/cm)	66.7	108	197	398	631	1,860	60

[a]Relevant *N* indicates the number of samples from the large data set relevant to each water quality parameter.
[b]Value within category calculated from individual sample ion concentrations. $HCO_3^- + SO_4^{2-}/Cl^-$ in mg/L greater than 1 indicates the mixture is dominated by $HCO_3^- + SO_4^{2-}$. One site dominated by Cl^- was removed from the data set.

Table 5-6. Background specific conductivity estimates for Ecoregion 70

Data set	Centile used to estimate background	Estimated background µS/cm	Confidence interval µS/cm	Relevant *N* (stations/ samples)
EPA-survey data set from geographic area in Ecoregion 70 not represented in the example criterion derivation data set	25th	197	135–240	60/61
WABbase data set, probability sample subset	25th	147	136–159	617/681
WABbase data set, reference sample subset	75th	201	164–210	30/55
Ecoregion 70 example criterion derivation data set, full data set	25th	169	161–171	1,695/2,075

5.4. SUMMARY OF EXAMPLE CRITERIA FOR ECOREGION 70

The case example for Ecoregion 70 includes an annual geometric mean (i.e., CCC) and a 1-day mean (i.e., CMEC), not to be exceeded more than once in 3 years on average. Both of these distinct expressions of the example SC criteria would need to be met in order to adequately protect aquatic life. These values indicate that freshwater animals would be protected if the annual geometric mean SC concentration does not exceed 340 µS/cm and the 1-day mean does not exceed 680 µS/cm, more than once every 3 years on average. These example criteria would apply to all flowing freshwaters (ephemeral, intermittent, and perennial streams) in Ecoregion 70 inclusive of portions of Kentucky, West Virginia, Pennsylvania, and Ohio. On a site-by-site basis, these example ecoregional criteria apply if the ionic mixture is dominated by anions of bicarbonate and sulfate. For streams crossing into Ecoregion 70, professional judgment may be needed to assess the potential effect of different ionic composition or concentration. Professional judgment is recommended when applying to sites with a catchment area greater than 1,000 km^2 (386 mi^2) owing to lesser representation in the example data set by this class of stream. On a site-by-site basis, alternative SC criteria may be more appropriate if the natural background of a site is shown to be lower or higher than its regional background specific conductivity.

5.5. EXAMPLE CRITERION CHARACTERIZATION

5.5.1. Factors Potentially Affecting the Extirpation Concentration Distribution (XCD) Model

An assessment of potential confounders and an analysis of the influence of habitat quality and sampling date for Ecoregion 70 can be found in Appendix B.2.

5.5.1.1. *Sensitivity Analyses*

As the minimum number of occurrences of a genus for inclusion in the data set increases, fewer genera are included in the XCD. The HC_{05} increases greatly when a taxon in the lower 5th centile is removed because it does not meet the minimum number of samples and then more slowly alternates between increasing and decreasing as genera either above or below the 5th centile are removed because they do not meet the minimum number of samples (see Figure 5-11). The pattern repeats until all genera above and below the lower 5th centile have the same XC_{95} value (not shown). To maximize the number of genera included in the XCD, a minimum of 25 occurrences was utilized.

The number of samples in the data set affected the number of genera included in the XCD and the resulting example HC_{05}. The effects of data set size on the HC_{05} estimates and on their confidence bounds were estimated using a bootstrapping technique. The mean of all bootstrapped HC_{05} values, the numbers of genera used for the HC_{05} calculation, and their 95% CI were plotted to show the effect of sample sizes. As shown in Figure 5-12, the HC_{05} for this data set stabilizes, reaching an asymptote at approximately 500–800 sites sampled and 90–100 genera evaluated. Therefore, the original data set was considered adequate for estimating the example CCC.

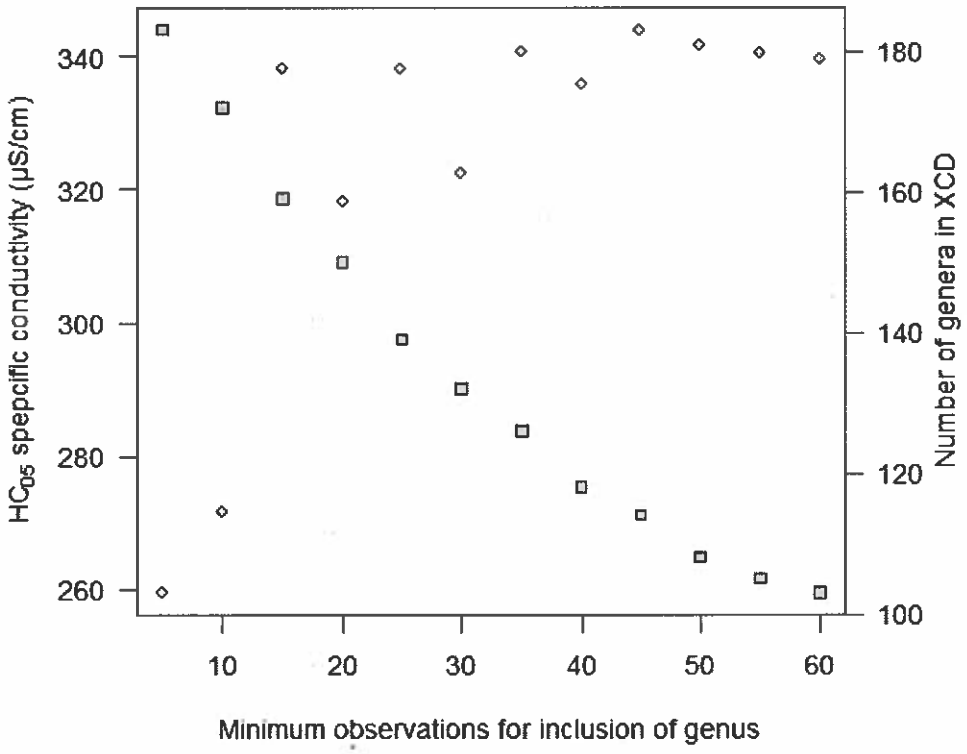

Figure 5-11. Relationship of the number of occurrences of a genus on the hazardous concentration (HC_{05}) based on Ecoregion 70 example Criterion-data set. Estimates of HC_{05} values (blue diamonds, left axis) and the number of taxa in the extirpation concentration distribution (XCD) (red squares, right *y*-axis) based on minimum number of samples (5–60, *x*-axis). As the minimum number of occurrences of a genus increases, fewer are included in the XCD.

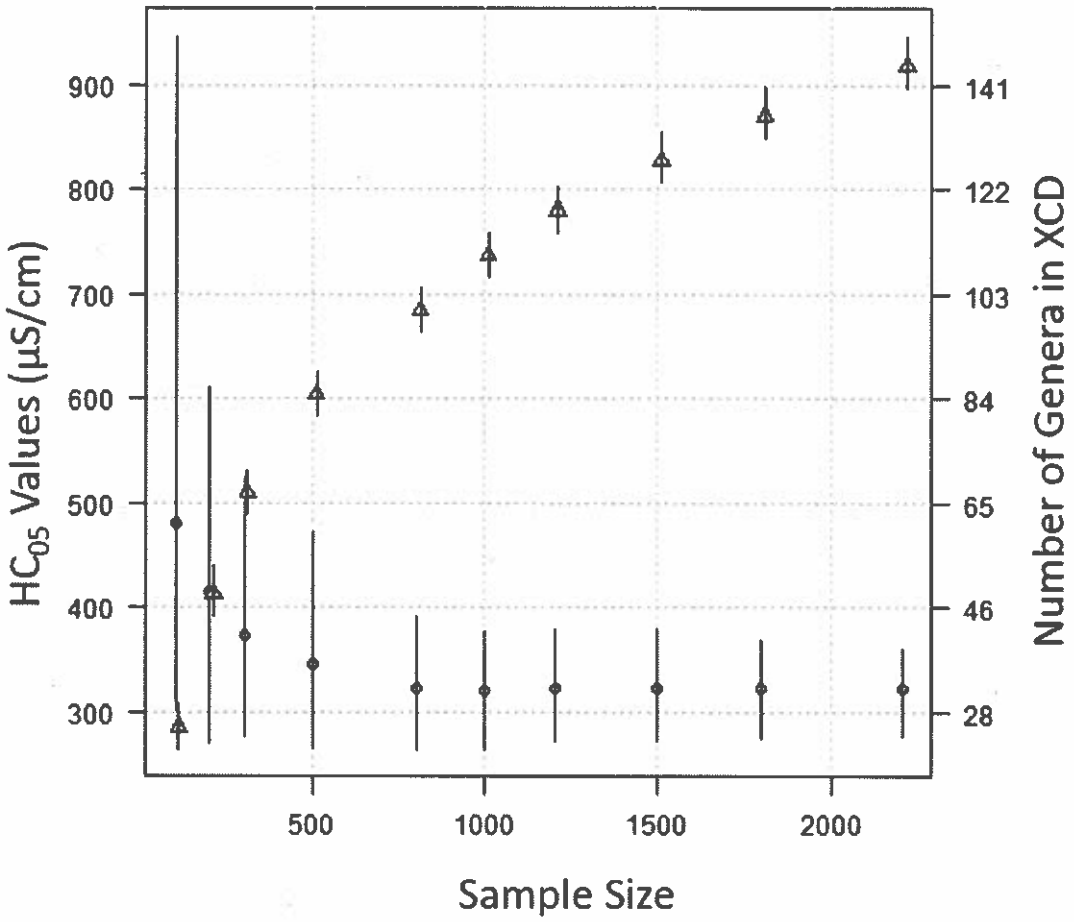

Figure 5-12. Adequacy of the size of the data set used to model the hazardous concentration (HC_{05}) based on the Ecoregion 70 example Criterion-data set. As size of the data set increases, the number of genera included in the genus extirpation concentration distribution (XCD) increases (triangles). The HC_{05} stabilizes, reaching an asymptote at approximately 500−800 sites sampled (circles) and 90−100 evaluated genera.

5.5.2. Validation of the Model

As recommended by the SAB (U.S. EPA, 2011c), the XCD model was validated and uncertainty around the HC_{05} values was estimated using bootstrapping. The median HC_{05} estimated from bootstrapping was 323 µS/cm (95% CI 272−365 µS/cm) which is similar to the HC_{05} of 338 µS/cm measured using a two-point interpolation from the original XCD. The similarity between the two HC_{05} values indicates a similar model would be generated using an independent data set (see Figure 5-13).

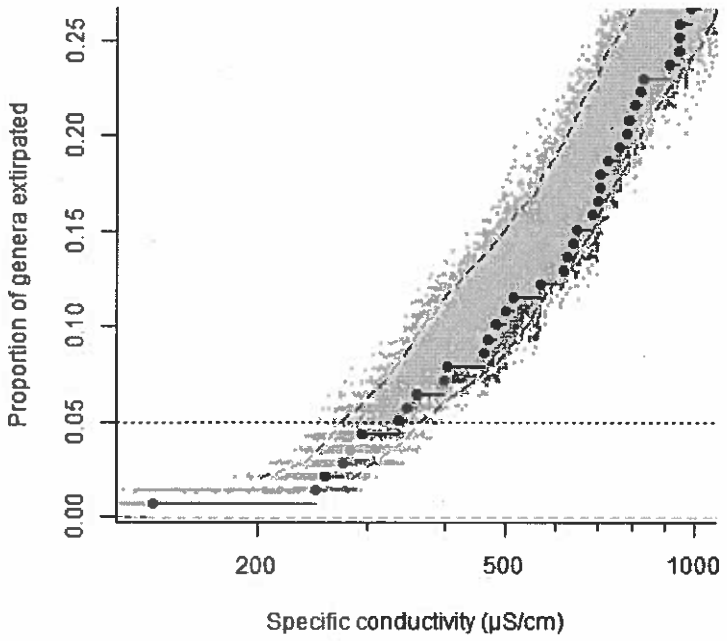

Figure 5-13. 95% confidence intervals (hatched oblique lines) for the lower portion of the Ecoregion 70 genus extirpation concentration distribution (XCD). Each tiny gray dot represents an extirpation concentration (XC_{95}) value from one of 1,000 XCD bootstrapping iterations (note that the genera and their order varies with each XCD-iteration). Each of the 36 blue filled dots represents the calculated XC_{95} of the XCD for the example criterion continuous concentration (CCC). Hazardous concentration (HC_{05}) based on the bootstrap medians is 323 µS/cm.

5.5.3. Duration and Frequency

Numeric criteria include magnitude (i.e., how much), duration (i.e., how long), and frequency (i.e., how often) components. Appropriate duration and frequency components of criteria are determined based on consideration of available data and understanding the exposure-response relationship in the context of protecting the aquatic life of a water body. The significant consideration used in setting the duration component of aquatic life criteria is how long the exposure concentration can be above the criteria without affecting the endpoint on which the criteria are based (U.S. EPA, 1985, 1991). Based on the temporal resolution of the available field data set and an analysis of within-site variability of SC levels, EPA developed two

different expressions for the example SC criteria in order to provide adequate protection for aquatic life.

In this case, the majority (>81%) of sites used to derive the example CCC for Ecoregion 70 were sampled once during an annual sampling period and thus represent the average stream chemistry (SC) and macroinvertebrate assemblage information over the course of 1 year. As a result, the appropriate duration for the CCC is 1 year. The duration for the CMEC, a level of protection from acutely toxic exposures, is 1 day based on a review of the literature on the onset of macroinvertebrate drift in response to elevated SC (see Section 3.3). At sites meeting the CCC, 90% of the SC observations are estimated to occur below the CMEC.

EPA anticipates that an appropriate allowable frequency of exceedance for these example criteria is no more than once in 3 years, based on recovery rates from literature reviews and consideration of the life history of insects able to recolonize a site via drift or aerial dispersal (see Section 3.4). Recovery is expected to occur in 3 years if the following conditions are met: (1) the SC regime returns to a yearly average below the CCC, (2) there are nearby streams with low SC supporting a diverse community, and (3) there is an upstream source of colonizers or the flight or recolonizing distance is within the dispersal range of genetically diverse, reproducing adult colonizers. If any of these conditions are not met, the time necessary for ecosystem recovery (and thus, the allowable frequency of exceedance) would likely be longer than 3 years.

5.6. PROTECTION OF FEDERALLY-LISTED SPECIES

Although the derivation of the example criteria was limited to the macroinvertebrate taxa represented in the data sets, the available evidence indicates that other taxa in the streams would likely be protected as well (see Section 2.6 and Appendix G). Hence, no adjustment was made for unanalyzed taxa. However, on a site-specific basis, the example criterion could be adjusted or recalculated to protect important species, highly valued aquatic communities, or specially protected waters.

6. CASE STUDY III: EXAMPLE USING THE BACKGROUND TO CRITERION (B-C) REGRESSION METHOD

This section presents an example calculation of an ecoregional CCC using the B-C method (see Section 3.7.2 and Appendix D). In this example, a CCC for the Northwestern Great Plains, Level III Ecoregion 43, was calculated using SC data from the ecoregion and the B-C method because there were insufficient paired SC and biological data to use the XCD method in this ecoregion.

First, the water chemistry data set was screened for ionic composition to ensure samples were dominated by sulfate and bicarbonate anions, and sampled sites were mapped to determine whether the geographic distribution of sites was representative of (dispersed throughout) the ecoregion. Minimally affected background SC of the new ecoregion was estimated at the 25th centile of probability samples (see Section 3.7.1.2; Cormier and Suter, 2013a). Least disturbed background SC was estimated at the 25th centile of a combined data set of targeted and probability samples. The CCC was calculated using the least disturbed 25th centile background SC as the independent variable (x) in the B-C regression model to yield an HC_{05} (y). Depending on available data and analytical results (see Figure 3-11), an HC_{05} may take the form of (1) the y-value at the mean of the regression line from the B-C mode, (2) the y-value at the lower 50% PL of the regression line, or (3) an HC_{05} derived from a data set based on ≥200 paired SC and biological samples. In this example case for Ecoregion 43, there were <200 paired SC and biological samples, so the lower 50% PL was used to develop the example CCC.

6.1. DATA SET CHARACTERISTICS

The Northwest Great Plains is mostly an unglaciated, semiarid, rolling plain with rolling hills and occasional buttes and badlands (Woods et al., 2002). Elevation ranges from 458 to 1,200 meters (McNab and Avers, 1994). The area covers approximately 347,000 km^2 and extends from southeastern Montana and northeastern Wyoming into western parts of North Dakota and South Dakota. Ecoregion 43 is bordered by the Northwestern Glaciated Plains to the north and east, the Middle Rockies and Wyoming Basin to the west, the Eastern High Plains and Nebraska Sand Hills to the south. An outcropping of the Middle Rockies occurs in the south of the ecoregion. The shallow soil is underlain with shale, siltstone, and sandstone. Where there is

sandstone, aquifers can produce groundwater. Otherwise, there are few perennial rivers, and the rainfall is erratic with approximately 250–510 ml/year. The low precipitation and high evapotranspiration lead to less groundwater recharge and baseflow contributing to streams; therefore, many small streams are intermittent or ephemeral. Grazing and ranching is a common land use with some dryland and irrigated agriculture. Surface coal mining and oil and gas production also occur. The often alkali-rich soils in the steppes are dominated by sagebrush; whereas, the buttes are more moist and can support forests.

Only existing data were used for this example assessment (see Table 6-1). An EPA-survey data set and a U.S. Geological Survey (USGS) data set were combined to characterize ion concentrations and water chemistry and then used to calculate a provisional CCC. The USGS data set was also used to calculate the CMEC. The statistical package R, Version 2.12.1 (December 2010), was used for all statistical analyses (R Development Core Team, 2011).

Table 6-1. EPA and U.S. Geological Survey (USGS) chemistry data sets included in this study.
Years indicate the period during which the samples were collected. Western Environmental Monitoring and Assessment Program (EMAP) survey sites are included in the count of sites from the National Wadeable Streams Assessment (NWSA).

Survey	Years	# of sites	# of samples
EPA probability samples

USGS mixed sampling			
USGS: full data set	1946–2008	281	45,489
USGS: subset ≥ six samples per rotation year, July–June	1946–2008	148	41,648

This B-C regression model was developed using biological data paired with SC data from 24 data sets with waters having ionic mixtures dominated by calcium, magnesium, sulfate and bicarbonate ions and where background SC did not exceed 626 µS/cm. Therefore, the model is

most appropriate for waters with similar ionic characteristics. The model has not been thoroughly tested with waters dominated by other mixtures, i.e., ($[SO_4^{2-}] + [HCO_3^-]$) < $[Cl^-]$, and ($[Ca^{2+}] + [Mg^{2+}]$) < ($[Na^+] + [K^+]$) in mg/L. In particular, the B-C model is not appropriate for waters dominated by NaCl (Haluszczak et al., 2013, Entrekin et al., 2011; Gregory et al., 2011; Veil et al., 2004) or road salt (Forman and Alexander, 1998; Kelly et al., 2008; Environment Canada and Health Canada, 2001; Evans and Frick, 2001; Kaushal et al., 2005). However, the model and this analysis may be defensible for ionic mixtures dominated by sodium, sulfate and bicarbonate ions (Brinck et al., 2008; Dahm et al., 2011; Jackson and Reddy, 2007; National Research Council, 2010; Clark et al., 2001; Veil et al., 2004). This is because the toxicity of these mixtures are more similar to that of calcium, magnesium, sulfate and bicarbonate ions than the toxicity of NaCl (Mount et al., 2016; Kunz et al., 2013; Soucek and Dickinson, 2015).

In this example case study, more than half of the sampled sites were dominated by sulfate, bicarbonate, sodium, and potassium ions, ($[SO_4^{2-}] + [HCO_3^-]$) > $[Cl^-]$, and ($[Ca^{2+}] + [Mg^{2+}]$) < ($[Na^+] + [K^+]$) in mg/L. No samples were excluded based on cations. All samples in the EPA-survey data set were used because no samples were dominated by chloride ions. A USGS data set of 281 sites was used to verify ionic composition. Of 7,461 samples, 7,456 (>99.9%) were dominated by sulfate plus bicarbonate. The five samples not dominated by sulfate and bicarbonate occurred at sites sampled multiple times that more often than not were dominated by sulfate and bicarbonate, so these sites were retained. All sites in the combined EPA-USGS data set had pH data, but none were <6 nor >9.8, so no sites were removed from the data set.

6.1.1. EPA-Survey Data Set

Data sources, sampling period, and number of samples used to estimate background SC in the new area (Ecoregion 43) are provided in Table 6-1. The NRSA 2008–2009 data set (U.S. EPA, 2013b), WSA 2004 data set (U.S. EPA, 2006), EMAP 1993–1998 data sets and R-EMAP 1999 data sets (U.S. EPA, 2013c), are based on single random (i.e., probability-based design) samples from June through September.

EPA-survey data sampling sites within the ecoregion are shown in Figure 6-1. Water quality parameters collected in Ecoregion 43 are included in Table 6-2. Most of the samples

have reported SC, alkalinity, hardness, sulfate, chloride, bicarbonate, and pH, as well as other water quality parameters. When necessary, ionic concentrations in milliequivalents (meq/L) were converted to mg/L [(meq/L) × (ion MW)/(ionic charge)] (Hem, 1985).

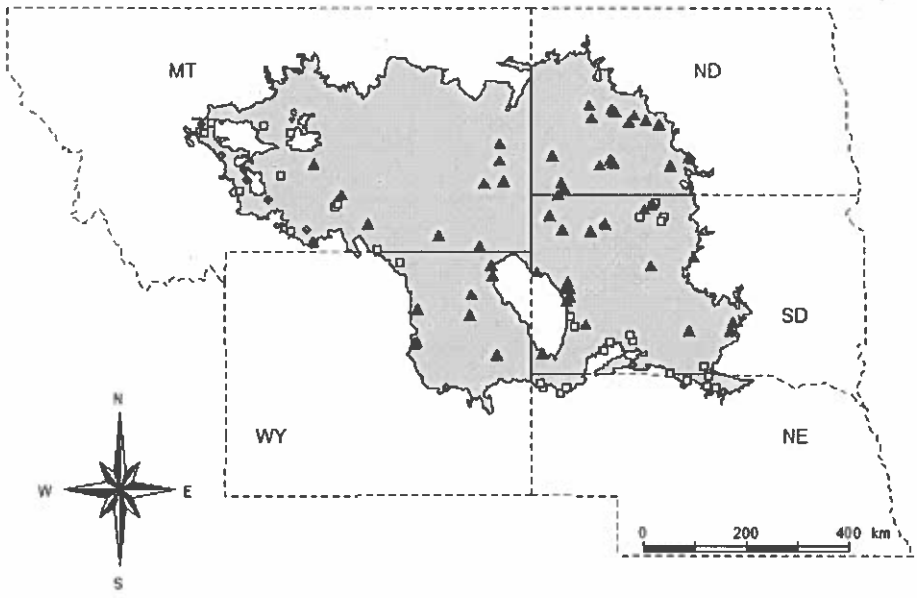

Figure 6-1. Sampling sites in the EPA-survey data set that were used to estimate minimally affected background in Ecoregion 43. For the purpose of demonstrating the background-to-criterion approach, Level III Ecoregion 43 which encompasses portions of Montana, North and South Dakota, Wyoming, and Nebraska is shaded gray. A total of 115 sampling sites is depicted. Sampling locations are color-coded by site-specific conductivity range: green diamonds <300 µS/cm, yellow squares 300−1,000 µS/cm, and red triangles ≥1,000 µS/cm. Geodetic reference system = North American Datum (NAD83).

Table 6-2. Summary of data for the example case for Northwestern Great Plains, Level III Ecoregion 43 from EPA-survey samples.
Geometric means were calculated except for pH and ion ratio.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	118	57	483	1,257	1,041	2,406	5,769
pH (SU)	118	6.70	8.06	8.27	8.30	8.47	9.88
Ca^{2+} (mg/L)	111	3.62	37.6	53.5	62.6	139	511
Mg^{2+}(mg/L)	111	0.65	9.34	33.0	26.8	82.1	240
Na^{+} (mg/L)	106	1.23	23.7	162.97	99.2	390	1,059
K^{+} (mg/L)	106	0.44	4.16	7.95	6.73	12.6	80.1
HCO_3^{-} (mg/L)	53	45.8	205	277	286	429	987
SO_4^{2-} (mg/L)	106	3.33	52.4	367	214	1,074	2,750
Cl^{-} (mg/L)	106	0.20	3.80	8.50	8.63	18.9	520
[a] $HCO_3^{-} + SO_4^{2-}/Cl^{-}$	53	3.26	35.2	73.3	99.4	129	464

[a]Ratio of mg/L $HCO_3^{-} + SO_4^{2-}/Cl^{-}$ greater than 1 indicates the mixture is dominated by $HCO_3^{-} + SO_4^{2-}$.

All samples were collected from first-through fourth-order streams as part of a probability-based design intended to estimate proportions of parameters for various stream classes. The probability-design sampling weights for stream order were not used in the characterization. Analysis of water chemistry samples followed procedural and QA/QC protocols of EPA and EMAP (U.S. EPA, 2001, 1998b, 1994, 1987), Wadeable Streams Assessment (U.S. EPA 2006, 2004a, b), NRSA (U.S. EPA, 2009), and NAPAP (Drousé et al., 1986; U.S. EPA, 1987).

6.1.2. U.S. Geological Survey (USGS) Data Set

The USGS survey data set used in this example is composed of 45,489 water quality samples, from 281 stations within Ecoregion 43 (see Table 6-1; Figure 6-2). Some stations were sampled only once while others were sampled as many as 5,445 times. The data were collected between 1946 and 2015 during all seasons. Water quality parameters collected in Ecoregion 43 are included in Table 6-3. Most of the samples have reported SC, alkalinity, hardness, sulfate, chloride, bicarbonate, and pH, as well as other water quality parameters. Analysis of water

chemistry samples followed procedural and QA/QC protocols for USGS data sets (Mueller et al. 1997).

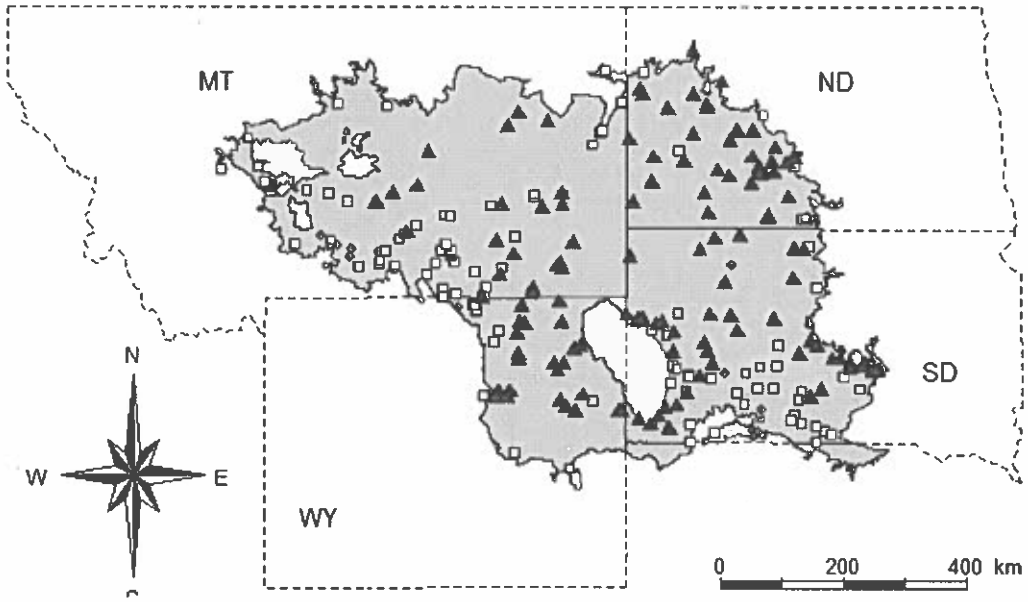

Figure 6-2. Sampling sites in the U.S. Geological Survey (USGS) data set in Ecoregion 43. Ecoregion 43 is shaded gray. Geometric mean specific conductivity at sampling locations is color-coded: green diamonds <300 µS/cm, yellow squares 300−1,000 µS/cm, and red triangles ≥1,000 µS/cm. Geodetic reference system = North American Datum (NAD83).

Table 6-3. Summary of data for the example case for Northwestern Great, Level III Ecoregion 43 from U.S. Geological Survey (USGS).
Geometric means were calculated for all variables except for pH and ion ratio.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	281	85	564	1,045	986	1,816	7,330
pH (SU)	170	7.30	8.1	8.2	8.2	8.3	9.0
Ca^{2+} (mg/L)	118	21.87	50.9	69.0	76.4	114.9	464
Mg^{2+} (mg/L)	118	5.81	28.4	46.6	45.0	75.5	654
Hardness (mg/L)	52	121.1	290	479.7	432.4	608.1	1,040
Na^{+} (mg/L)	118	1.55	59.4	180.3	132.5	325	1,186
K^{+} (mg/L)	110	0.74	5.1	9.2	8.1	13.3	25.1
HCO_3^{-} (mg/L)	92	2.00	224.4	278.5	204.2	405	765
SO_4^{2-}(mg/L)	120	4.56	189.5	464.2	362.4	808.3	2,283
Cl^{-} (mg/L)	117	0.97	6.9	10.7	14.7	27.6	938
[a]$HCO_3^{-} + SO_4^{2-}/Cl^{-}$	86	2.35	22.9	77.6	82.6	116	363

[a]ratio of mg/L $HCO_3^{-} + SO_4^{2-}/Cl^{-}$ greater than 1 indicates the mixture is dominated by $HCO_3^{-} + SO_4^{2-}$.

All samples were collected from first-through fourth-order streams for various research purposes and thus the targeted sampling design may emphasize areas with increased anthropogenic disturbance or some geologic formations. In this respect, the data may skew the background SC estimates. Background SC was not estimated from this data set because sampling stations were not randomly assigned. However, after weighing the potential bias that could be introduced with the benefits of having greater coverage across the ecoregion, the EPA-survey and USGS data sets were combined and used to estimate background SC.

Because the USGS data set contained multiple measurements in an annual rotation from sampling locations, the data set was used to estimate a CMEC and to explore the variability of SC patterns within the region. Therefore, a second data set was selected by excluding stations with fewer than six SC measurements throughout the year. A minimum of one sample during the first 6 months and one in the last 6 months of the previous year were also required so that at least one low and high SC sample was included in the data set. The second USGS data set that included 41,648 samples from 168 stations was used to calculate the variance near the CCC for the CMEC calculation.

6.1.3. Modeled Mean Baseflow Background Specific Conductivity (SC)

Predicted mean natural base-flow SC in catchments of Northwestern Great Plains, Ecoregion 43, was also considered for comparison purposes (Olson and Hawkins, 2012). The stream length weighted, mean natural SC (each SC was multiplied by the proportion of stream segment length) at base flow for each ecoregion (see Appendix D). Figure 6-3 shows the predicted SC at 300m resolution in order to emphasize the general trends across Ecoregion 43.

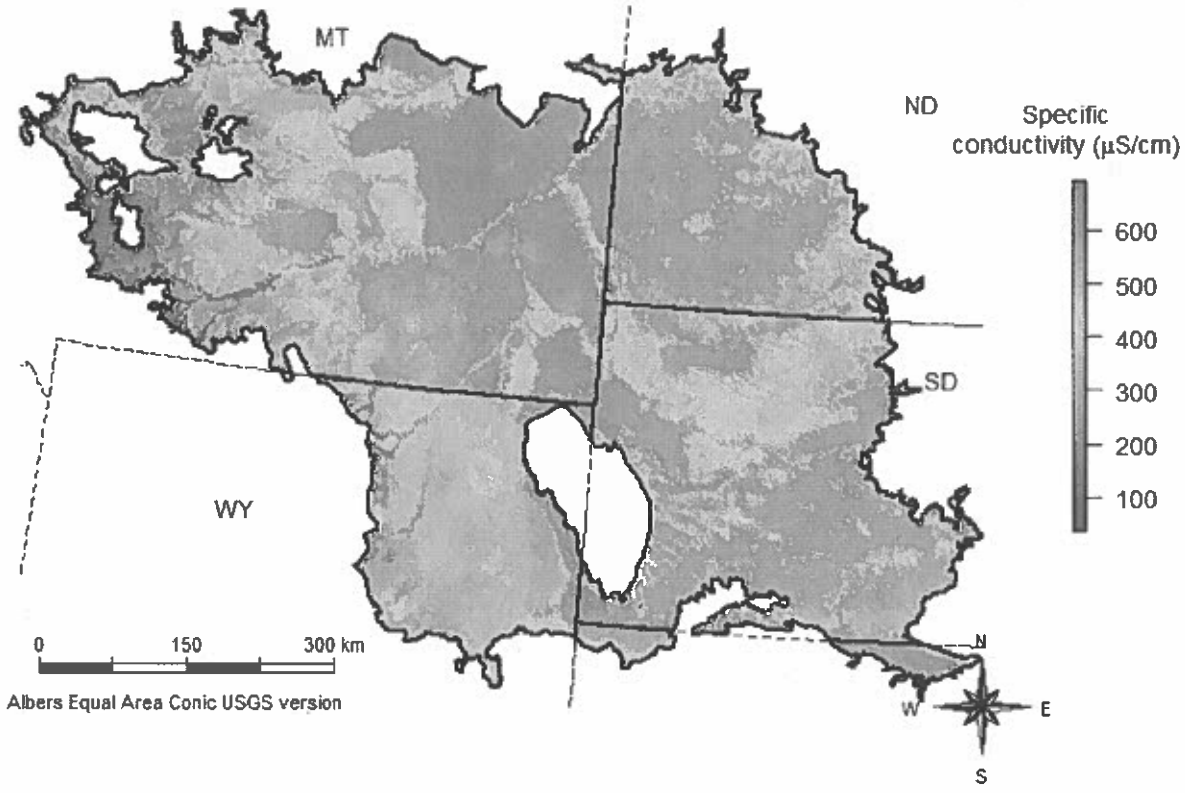

Figure 6-3. Predicted mean natural base-flow specific conductivity in catchments of Northwestern Great Plains, Ecoregion 43, using the Olson-Hawkins model. Albers projection used for mapping.

6.1.4. Characterization of Ionic Matrices

6.1.4.1. *EPA-Survey Data Set Ionic Characteristics*

A summary of water quality ionic constituents including major ionic constituents for Ecoregion 43 is provided in Table 6-2. Centiles were calculated using each sample observation

because most measurements were single grab samples. There were no chloride-dominated sites where ($[Cl^-] \geq [HCO_3^-]) + [SO_4^{2-}]$ in the EPA-survey data ($N = 118$); therefore, no sites were excluded from the data sets. Sodium was the dominant cation at more than half the sampled sites. This mixture was judged as acceptable for use with the B-C model, but with less confidence than a calcium and magnesium dominated mixture. Ionic characteristics for Ecoregion 43 are shown for the EPA-survey in Table 6-2 and the USGS data set in Table 6-3.

6.1.4.2. *U.S. Geological Survey (USGS) Data Set Ionic Characteristics*

Table 6-3 summarizes the water quality parameters including major ionic constituents for Ecoregion 43 in the USGS data set. Unlike the EPA-survey data set, the USGS data set contains targeted sites of interest rather than probability samples. Also, in some cases, there are multiple measurements from the same site, and other sites are autocorrelated with downstream sampling locations. Therefore, the distribution of sites in this data set is not necessarily representative of Ecoregion 43 in its entirety; however, the data set can be used to define the overall pattern of SC for the ecoregion because it contains samples in areas not represented in the EPA-survey data set. Centiles were calculated using the geometric mean of site measurements (except pH and the ionic ratio) and were qualitatively compared to the probability-based EPA-survey data set.

Two samples with pH <6 and a few observations (less than 10) with some ion concentrations recorded as 0 were removed from the USGS data set. Only 5 out of 45,489 samples collected in this data set were dominated on some days by chloride, $[Cl^-] \geq ([HCO_3^-] + [SO_4^{2-}])$ in mg/L; however, on average, these 5 sites were not dominated by chloride ions, so those samples were not removed. Sodium was the dominant cation in more than half of the samples. This mixture was judged as acceptable for use with the B-C model, but with less confidence than a calcium and magnesium dominated mixture.

6.1.5. Comparison of Background Specific Conductivity (SC) Estimates

In this case example, the stream length weighted average predicted mean base flow SC from the Olson-Hawkin's model in Ecoregion 43 is 489 µS/cm. Raw values for predicted mean flow for stream segments are shown as box plot in Figure 6-4. The 25th centile of the EPA-survey data set is 483 µS/cm. The USGS SC data set has a slightly narrower overall range and mid-range of values resulting in a slightly higher quartile SC than the EPA survey data set

(564 µS/cm) (see Figure 6-4 and Table 6-3). When the USGS data set is combined with the EPA-survey data set, the 25th centile (542 µS/cm) is also greater than the predicted mean baseflow of 489 µS/cm (see Table 6-4, Figure 6-4). Therefore, this background SC estimated from the combined EPA-USGS data set is least disturbed.

The 25th centile of the combined EPA-survey and USGS data set was used to calculate the HC_{05} following the decision tree described Section 3.7.2 and Figure 3-11. Because the lower quartile ranges from 85 to 564 µS/cm, additional analysis is recommended for streams known to have low SC regimes.

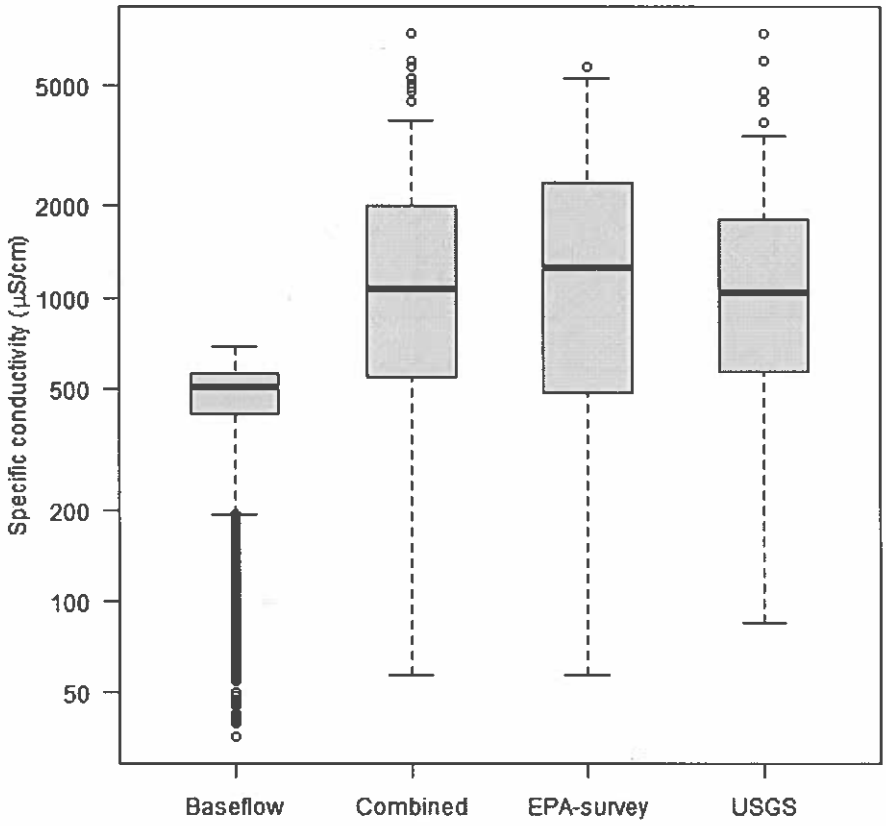

Figure 6-4. Box plots of specific conductivity (SC) distributions for EPA-survey, U.S. Geological Survey (USGS), combined EPA-survey and USGS data sets and predicted mean base-flow. The USGS data set captures a slightly narrower midrange of values possibly owing to the targeted sampling and the mean values rather than the single measurements in the EPA sample. The 25th centile of the combined and USGS data set is greater than the mean predicted base-flow. The mean baseflow model predicts many outliers for the region <200 µS/cm.

Table 6-4. Summary of data for the example case for Northwestern Great Plains, Level III Ecoregion 43 from the combined EPA-survey and U.S. Geological Survey (USGS) data set.
Geometric means for sampled sites were calculated for all variables except for pH and ion ratio.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	399	57	542	1,074	1,002	2,006	7,330
pH (SU)	288	6.7	8.1	8.2	8.3	8.4	9.9
Ca^{2+} (mg/L)	229	3.6	46.2	63.0	69.4	122.5	511.2
Mg^{2+} (mg/L)	229	0.65	20.0	43.7	35.0	77.6	654.4
Hardness (mg/L)	163	11.7	184.5	377.8	325.0	642.5	1,828.1
Na^{+} (mg/L)	224	1.2	49.1	173.7	115.5	337.7	1,185.6
K^{+} (mg/L)	216	0.44	4.5	8.7	7.4	12.9	80.1
HCO_3^{-} (mg/L)	145	2.0	212.9	277.8	231.0	410.8	986.7
SO_4^{2-}(mg/L)	226	3.33	129.5	452.9	283.0	940.8	2,750.7
Cl^{-} (mg/L)	223	0.20	5.3	9.9	11.4	20.6	937.8
[a]$HCO_3^{-} + SO_4^{2-}/Cl^{-}$	139	2.35[b]	33.6[b]	76.25[b]	89[b]	123.0[b]	464[b]

[a]Ratio of mg/L $HCO_3^{-} + SO_4^{2-}/Cl^{-}$ greater than 1 indicates the mixture is dominated by $HCO_3^{-} + SO_4^{2-}$.

6.1.6. Calculation of Ecoregion 43 Criterion Continuous Concentration (CCC) from Background

Because available paired SC and biological data represented <200 sites, the HC_{05} was estimated at the lower 50% PL using the B-C model (see Figure 6-5). The 25th centile of SC from the EPA-survey data set of Ecoregion 43 was used to identify the lower 50% PL using eqs 3-4 and 3-5. The B-C model development is described in Appendix D. The *x*-variable is the background SC in Ecoregion 43 which was log10 transformed. The calculated *y*-value is the predicted mean log10 HC_{05}. In this example case, the least disturbed background is 542 µS/cm (see Table 6-4). It was estimated at the 25th centile from the combined EPA-survey and USGS data set to improve representation of samples from the entire ecoregion. The calculation of the predicted mean log10 of HC_{05} (*y*) is shown in eqs 6-1 and 6-2 and that value is used to estimate the lower 50% PL using eq 6-3.

The B-C model is described by the following formula:

$$Y = 0.657X + 1.075 \quad (6\text{-}1)$$

Where:

X is the log10 of the ecoregional background SC

Y is the log10 of the predicted HC_{05}

The background for Ecoregion 43 (542 µS/cm) is converted to log10, replacing X in the formula with that value and Y is computed (see eq 6.2). The predicted value Y is converted from log10 to a number that is the modeled HC_{05} for that region. In Ecoregion 43 the mean modeled HC_{05} is 740 µS/cm after rounding to two significant figures.

$$\text{Log Predicted } HC_{05} = (0.657 \times 2.73) + 1.075 = 2.87 \text{ µS/cm} \quad (6\text{-}2)$$

Then

$$\text{Predicted } HC_{05} = 10^{2.87} \text{ µS/cm} = 743 \text{ µS/cm}$$

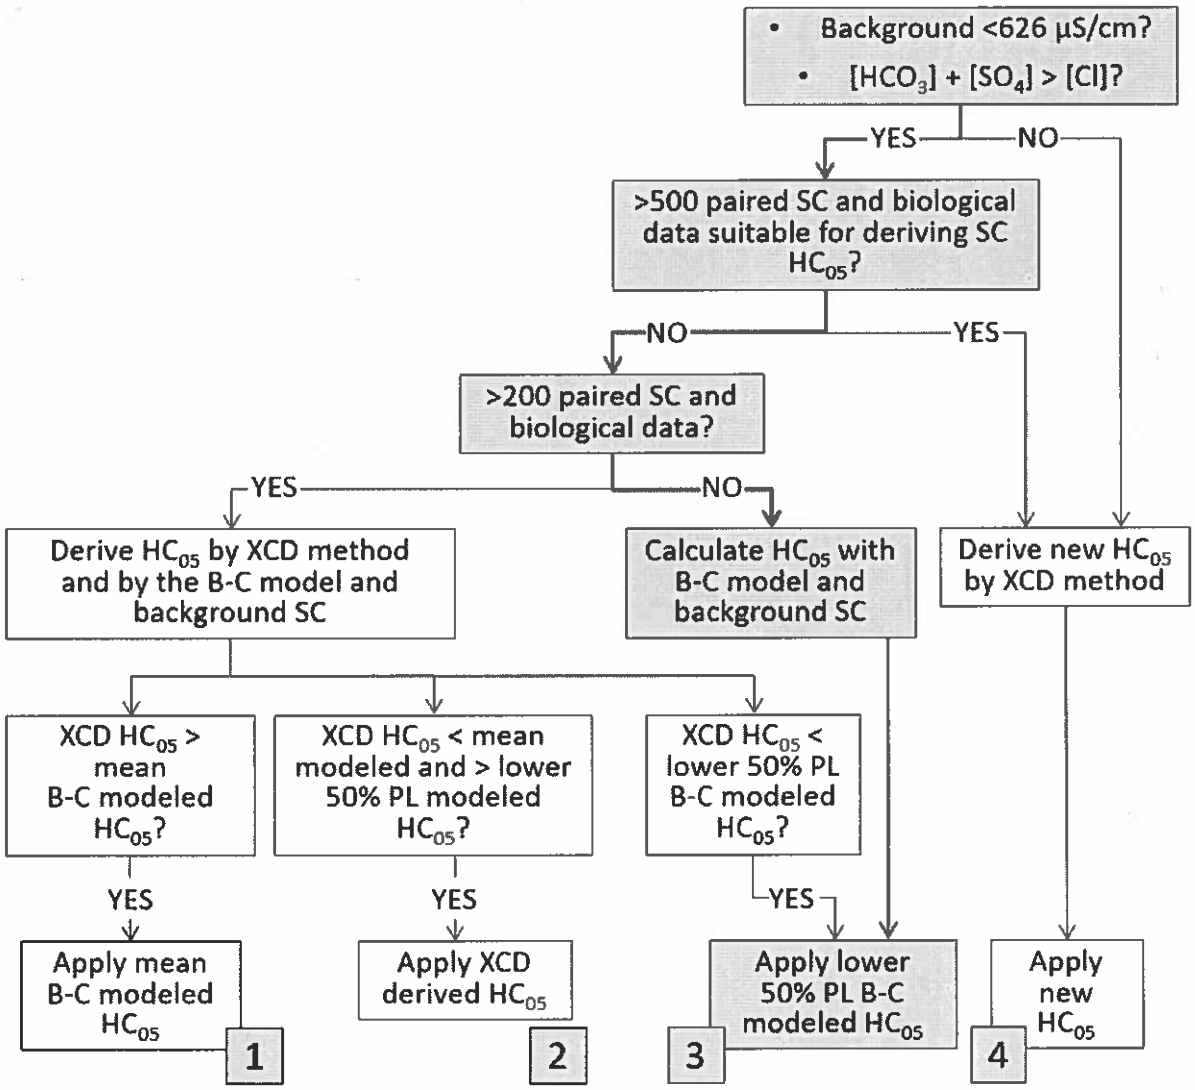

Figure 6-5. Process and decision path case example for Ecoregion 43. Decision path is highlighted in gray and connected by bold lines. Because there was no previously derived hazardous concentration at the 5th centile (HC_{05}) of a taxonomic extirpation concentration distribution (XCD) for Ecoregion 43, and the background was <626 µS/cm, and there were <200 paired specific conductivity (SC) measurements, the HC_{05} was calculated with the background-to-criterion (B-C) model at the lower 50% prediction limit (PL).

6.1.7. Formula for Calculating the Lower 50% Prediction Limit

Because the available paired SC and biological data constitute <200 sites, the HC_{05} was estimated at the lower 50% PL (see Figure 6-5). The 25th centile of background SC and the predicted mean HC_{05} of a region and variance of the B-C model is used to calculate the lower

50% PL (see eq 6-3). In this case example for Ecoregion 43, the background is 542 µS/cm and the mean modeled HC_{05} is 743 µS/cm. Both values are converted to log10 (x, y) as shown in eq 6-4. The prediction interval from the regression line for a mean predicted value $\hat{y}$ can be calculated as follows or more conveniently using statistical software thus avoiding rounding errors:

$$\hat{y} \pm t_{\alpha/2,n-2} S_y \sqrt{1 + \frac{1}{n} + \frac{(x^* - \bar{x})^2}{SS}} = \log 10 \text{ PL} \qquad (6\text{-}3)$$

Symbol	Explanation	Example from the B-C model
$\hat{y}$	Log10 of mean predicted HC_{05}	2.87 µS/cm, log10 of 743 µS/cm
n	Number of samples in the model	$n = 24$
α	Alpha error rate for prediction interval (desired confidence level)	50% prediction interval (α = 0.5)
t_{n-2}	t-value at specific level (alpha, α) and degrees of freedom $(n - 2)$ of interval	For 50% prediction interval (α = 0.5), $t_{(1-0.5)/2,24-2} = 0.686$
S_y	Residual standard error of prediction (standard deviation)	$S_y = 0.11$
SS	Sum of square of x deviation from their mean, $SS = \sum_{i=1}^{n}(x_i - \bar{x})^2$	$SS = 4.21$
$\bar{x}$	Mean x values used in the model generation	$\bar{x} = 2.15$
x^*	x value for a new prediction interval	Log10 542 µS/cm = 2.73
PL	Upper and lower prediction limits of mean predicted $\hat{y}$	calculated in eq 6-4

Using x^* = log10 (542) µS/cm and the mean predicted HC_{05} for Ecoregion 43 value, ($\hat{y}$ = 2.87, the log10 of 743 µS/cm) the lower 50% PL is calculated as follows in eq 6-4. Note, the upper 50% PL is not calculated but is included in the formula because it may be used to estimate a CMEC where there are insufficient data to calculate a CMEC using the method described in Section 3.2.

$$log10\ (743)\ \pm 0.686 \times\ 0.11\sqrt{1+\frac{1}{24}+\frac{(log_{10}(542)-2.15)^2}{4.21}} \quad (6\text{-}4)$$

So:

$$2.87-0.686\ \times 0.11\sqrt{\frac{25}{24}+\frac{(2.73-2.15)^2}{4.21}}$$

$$2.87-0.686\ \times 0.11\times 1.06$$

$$10^{2.79} = 617\ \mu S/cm$$

The log of the lower calculated 50% PL is 2.79 which equals 617 µS/cm after back transformation. The lower 50% PL rounded to two significant figures yields a CCC of 620 µS/cm.

6.1.8. Example Criterion Maximum Exposure Concentration

At sites meeting the CCC of 620 µS/cm, 90% of the SC observations are estimated to occur below the CMEC (see Section 3.2). The CMEC was derived using the USGS data set (45,489 samples collected between 1946–2015). This data set was used because it contained multiple measures of SC within a year whereas the EPA survey data set consisted of single measurements at each site. Of the 45,489 samples in this ecoregion, there are 41,648 samples in a July-to-June rotating year representing 1,241 rotation years, 148 unique stations, with at least 1 sample from July to October and one from March to June and at least 6 samples within a rotation year. Note that inclusion of samples is not contingent on biological data.

Of the 1,241 rotation years (148 unique stations) with multiple SC measurements, the variability of within station SC slightly differed for streams with different mean SC (see Figure 6-6). However, the LOWESS indicated that the average variability (residual standard deviation for a station) was relatively stable (see Figure 6-6); therefore, the entire data set was used to estimate the standard deviation components of annual mean SC (620 µS/cm). The grand mean and standard deviation of this data set was determined, and the CMEC was calculated. The example calculation of the CMEC for Ecoregion 43 is shown below using eq 3-2 from Section 3.2:

$$10^{\log10(620) + 1.28*0.333} = 1{,}656\ \mu S/cm \qquad (6\text{-}5)$$

The example CMEC (see Table 6-5) rounded to two significant figures yields a CMEC of 1,700 µS/cm for Ecoregion 43. If this level is not exceeded, where the annual geometric mean SC <620 µS/cm, 90% of the observations are expected to be less than the CMEC.

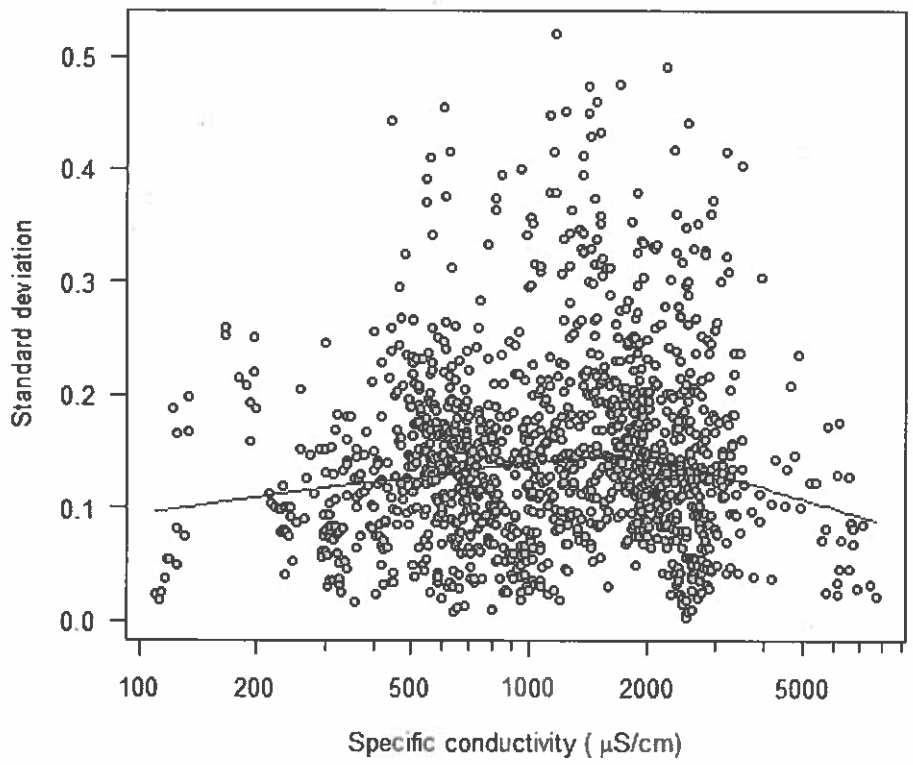

Figure 6-6. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station mean) in Ecoregion 43. The *x*-axis is annual mean specific conductivity. Each dot represents a station. The fitted line is a locally weighted scatterplot smoothing (LOWESS, span = 0.75, linear polynomial model).

Table 6-5. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 43

Number of samples July to June prior to biological sampling	41,648
Number of unique stations/rotation years	148/1,241
CCC	620 µS/cm
CMEC	1,700 µS/cm

6.2. EXAMPLE CRITERION CHARACTERIZATION FOR ECOREGION 43 BASED ON A BACKGROUND-TO-CRITERION MODEL

The case example for Ecoregion 43 includes an annual geometric mean (i.e., CCC) and a 1-day mean (i.e., CMEC), not to be exceeded more than once in 3 years on average. Both of these distinct expressions of the example SC criteria would need to be met in order to adequately protect aquatic life. These values indicate that freshwater animals are protected if the annual geometric mean SC concentration in flowing waters does not exceed 620 µS/cm and the 1-day mean does not exceed 1,700 µS/cm more than once every 3 years on average. These example criteria would apply to all flowing freshwaters (ephemeral, intermittent, and perennial streams) in Ecoregion 43 inclusive of portions of Montana, Wyoming, South Dakota, North Dakota, and Nebraska. On a site-by-site basis, these example ecoregional criteria apply if the ionic mixture is dominated by anions of bicarbonate and sulfate and either sodium or calcium cations. For streams crossing into Ecoregion 43 from ecoregions with either lower or higher background SC, professional judgment may be needed to assess the potential effect of different ionic composition or concentration. Professional judgment is recommended when applying to sites with a catchment area greater than 1,000 km^2 (386 mi^2) owing to lesser representation in the data set by this class of stream in the development of the B-C model. On a site by site basis, alternative SC criteria may be more appropriate if the natural background of a site is shown to be lower or higher than its regional background SC.

In particular, some streams in Ecoregion 43 may have consistently low SC throughout the year (Keya Paha Tablelands [43i], Niobara River Breaks [43r], Noncalcareous Foothill Grasslands [43s], Shield-Smith Valleys [43t], Limy Foothill Grassland [43u], and Pryor-Big Horn Foothills [43v]). Because all or most of the sampled sites in these Level IV ecoregions were measured at less than 500 µS/cm, a finer resolution (subecoregional) analysis is

recommended to adequately protect these areas of Ecoregion 43. Specifically, because the more western parts of the ecoregion provide sources of freshwater and dilution to the rest of the ecoregion and ecoregions to the east, subdividing the ecoregion according to background SC and developing different SC criteria may help to protect regional water quality where geophysical and climatic conditions lead to higher natural SC regimes.

The weight-of-evidence method described in Appendix C could be used to evaluate subregions or stream classes that may have different background SC in this large ecoregion where natural background SC may range from <100 µS/cm to >1,000 µS/cm. For example, higher criteria may be appropriate for areas such as the Little Missouri Badlands (43b).

6.3. PROTECTION OF FEDERALLY-LISTED SPECIES AND OTHER HIGHLY VALUED TAXA

Although the example criteria were derived using the macroinvertebrate taxa represented in the data sets, the available evidence indicates that other taxa in the streams would likely be protected as well (see Section 2.6 and Appendix G). Hence, no adjustment was made for unanalyzed taxa. However, on a site-specific basis, the example criterion could be adjusted or recalculated to protect important species, highly valued aquatic communities, or specially protected waters.

7. CASE STUDY IV: EXAMPLE USING THE BACKGROUND TO CRITERION (B-C) REGRESSION METHOD FOR A REGION WITH LOW CONDUCTIVITY

This section presents an example calculation of an ecoregional CCC using the B-C method (see Section 3.7.2 and Appendix D). In this example, a CCC for the Cascades Level III Ecoregion 4 was calculated using SC data from the ecoregion and the B-C method because there were insufficient paired SC and biological data to accurately estimate the XC_{95} values for the XCD method in this ecoregion.

First, the water chemistry data set was screened for ionic composition to ensure samples were dominated by sulfate and bicarbonate anions and calcium and magnesium cations. Sampled sites were mapped to determine whether the geographic distribution of sites was representative of (dispersed throughout) the ecoregion. Minimally affected background SC of the new ecoregion was estimated at the 25th centile of probability samples (see Section 3.7.1.2; Cormier and Suter, 2013a). Least disturbed background SC was estimated at the 25th centile of a combined data set of targeted and probability samples. The CCC was calculated using the 25th centile least disturbed background SC as the independent variable (x) in the B-C regression model to yield an HC_{05} (y). Depending on available data and analytical results (see Figure 3-11), an HC_{05} may take the form of (1) the y-value at the mean of the regression line from the B-C model, (2) the y-value at the lower 50% PL of the regression line from the B-C model, or (3) an HC_{05} derived from a data set based on ≥200 paired SC and biological samples. In this example case for Ecoregion 4, the range of SC conditions was narrow with few sites exceeding 200 µS/cm and only two SC measurements exceeding 1,000 µS/cm, so any HC_{05} would be uncertain using paired SC and biological measurements. Therefore, an HC_{05} was not calculated using paired SC and biological measurements and the lower 50% PL was used to develop the example CCC.

7.1. DATA SET CHARACTERISTICS

7.1.1. Ecoregion Description

The Cascades (Ecoregion 4) is a mountainous ecoregion extending from the central portion of western Washington into Oregon and, after a separation by the Klamath River, another separate mountainous area in northern California (U.S. EPA, 2013d). The mountain ranges of

the Cascades continue northerly into the North Cascades (Ecoregion 77), and south into the Sierra Nevada (Ecoregion 5). To the east lies the Eastern Cascades Slopes and Foothills (Ecoregion 9). To the west in Washington state is the Puget Lowlands (Ecoregion 2) and in Oregon the fertile Willamette Valley (Ecoregion 3). To the west in southern Oregon and northern California, the Cascades are bounded by the Klamath Mountains/California High North Coast Range (Ecoregion 78).

Some peaks in Ecoregion 4 are snow-capped or glaciated year round. Both active and dormant volcanoes are located on the high plateau in the eastern part of the ecoregion. The highest strato-volcano is Mount Ranier with an elevation of 4,392 m (USGS, 2016). The western Cascades in Oregon and Washington are dissected by numerous, steep-sided stream valleys (U.S. EPA, 2013d).

This geologic area is underlain by Cenozoic volcanics that have been affected by alpine glaciation (U.S. EPA, 2013d). Soils are characterized by frigid temperature regimes and at lower elevations in the south. Some soils are mesic. Common soils include andisols, formed in volcanic ash containing high proportions of glass and amorphous colloidal materials, and inceptisols, nearly like the parent material and having little or no clay, iron, aluminum or organic matter. The mean annual precipitation ranges from 180 cm and ranges from 115 in the Southern Cascades to 360 cm on some of the highest peaks of the Cascades Subalpine/Alpine subecoregion (OWEB 2001, Wilkins et al. 2011). Two of the larger rivers include the Columbia and Klamath Rivers.

The Cascades have a moist, temperate climate that supports an extensive and highly productive coniferous forest that is intensively managed for logging. Conifers dominate except at the highest elevations where there are alpine meadows and rocky alpine zones.

7.1.2. General Data Set Description

Only preexisting water chemistry data were used for this example assessment (see Table 7-1). EPA-survey, State, and USGS data sets were combined to characterize ion concentrations and water chemistry and then calculate a provisional CCC. The USGS data set was also used to calculate the CMEC because this data set had many within-year samples at each site. The statistical package R, Version 2.12.1 (December 2010), was used for all statistical analyses (R Development Core Team, 2011).

Table 7-1. EPA and U.S. Geological Survey (USGS) chemistry data sets included in this study.
Years indicate the period during which the samples were collected. Western Environmental Monitoring and Assessment Program (EMAP) survey sites are included in the count of sites from the National Wadeable Streams Assessment (NWSA). Specific conductivity was not measured at all sites.

Survey	Years	# of sites	# of samples
EPA probability samples (sample size in parenthesis)			
NWSA, NRSA, Region 10 R-EMAP	1995–2009	152	152
Total		152	152
State data from EPA Region 10			
Oregon	1990–2014	418	2,511
Washington	1990–2015	121	562
Total (only 90 with SC)		539	3,073
State: subset ≥ six samples per year, January–December	1990–2015	19	1,111
USGS mixed sampling			
USGS: full data set	1958–2016	290	6,258
USGS: subset ≥ six samples per year, January–December	1959–2014	50	5,019

The B-C regression model was developed using biological data paired with SC data from 24 data sets with waters having ionic mixtures dominated by calcium, magnesium, sulfate and bicarbonate ions and where background SC did not exceed 626 µS/cm. Therefore, the model is most appropriate for waters with similar ionic characteristics.

Because the B-C regression model was developed with an ionic mixture dominated by bicarbonate and sulfate (i.e., $([HCO_3^-] + [SO_4^{2-}]) > [Cl^-]$ in mg/L), samples dominated by chloride (i.e., $([HCO_3^-] + [SO_4^{2-}]) \leq [Cl^-]$ in mg/L) should be removed from the data set prior to estimating background SC. In this case, no samples were dominated by chloride ions and so all samples in the EPA-survey data set were used. The State data set of 539 sites was used to verify ionic composition. Of 359 samples of the State data set with ionic measurements, all samples were dominated by sulfate plus bicarbonate. Therefore, none was removed from the final analysis. All sites in the combined EPA-USGS data set had pH data. Because none were <6 or >8.7, no sites were removed from the data set.

7.1.3. EPA-Survey Data Set

Data sources, sampling period, and number of samples used to estimate background SC in the new area (Ecoregion 4) are provided in Table 7-1. The NRSA 2008–2009 data set (U.S. EPA, 2013b), NWSA 2004 data set (U.S. EPA, 2006), R-EMAP 1999 data sets (U.S. EPA, 2013c), are based on single random (i.e., probability-based design) samples from June through September.

EPA-survey data sampling sites within the ecoregion are shown in Figure 7-1. Water quality parameters collected in Ecoregion 4 are included in Table 7-2. Most of the samples have reported SC, alkalinity, hardness, sulfate, chloride, bicarbonate, and pH, as well as other water quality parameters. When necessary, ionic concentrations in milliequivalents (meq/L) were converted to mg/L [(meq/L) × (ion MW)/(ionic charge)] (Hem, 1985).

Table 7-2. Summary of data for the example case for Cascades, Level III Ecoregion 4, from EPA-survey samples.
Calculated means are geometric except for pH values and ion ratios.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	152	1.56	33.9	44.9	44.8	61.8	205.0
pH (SU)	144	6.17	7.3	7.5	7.5	7.7	9.0
Ca^{2+} (mg/L)	70	0.04	3.1	4.8	4.7	8.1	22.7
Mg^{2+}(mg/L)	70	0.03	0.7	1.3	1.2	1.9	8.8
Na^{+} (mg/L)	70	0.08	2.1	2.8	2.7	4.0	10.4
K^{+} (mg/L)	70	0.01	0.2	0.5	0.5	0.8	3.2
HCO_3^{-} (mg/L)	46	0.46	18.3	26.4	25.4	40.0	132.2
SO_4^{2-} (mg/L)	121	0.07	0.4	1.0	1.0	2.3	34.3
Cl^{-} (mg/L)	136	0.14	0.6	0.9	0.8	1.1	12.2
[a] $HCO_3^{-} + SO_4^{2-}/Cl^{-}$	46	3.88	24.5	32.3	50.4	58.4	211.1

[a]Ratio of mg/L $HCO_3^{-} + SO_4^{2-}/Cl^{-}$ greater than 1 indicates the mixture is dominated by $HCO_3^{-} + SO_4^{2-}$.

All samples were collected from first-through fourth-order streams as part of a probability-based design intended to estimate proportions of parameters for various stream classes. The probability-design sampling weights for stream order were not used in the

characterization. Analysis of water chemistry samples followed procedural and QA/QC protocols of EPA and EMAP (U.S. EPA, 2001, 1998b, 1994, 1987), Wadeable Streams Assessment (U.S. EPA 2006, 2004a, b), NRSA (U.S. EPA, 2009), and NAPAP (Drousé et al., 1986; U.S. EPA, 1987).

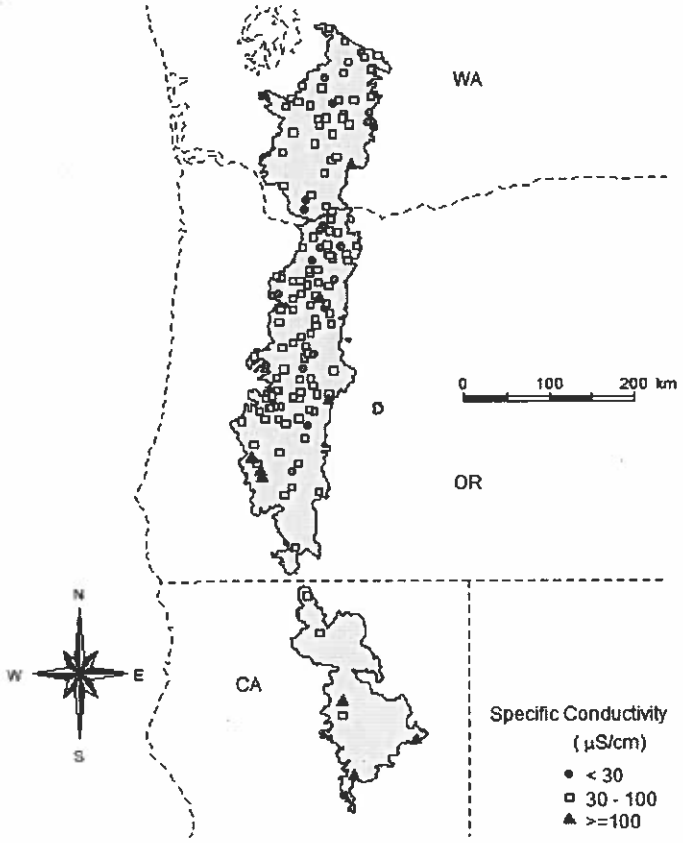

Figure 7-1. Sampling sites in the EPA survey data set that were used to estimate minimally affected background in Ecoregion 4.
For the purpose of demonstrating the background-to-criterion approach, Level III Ecoregion 4, is shaded gray. A total of 152 sites with specific conductivity measurements are depicted. Sampling locations are color coded by site-specific conductivity range: green diamonds <30 µS/cm, yellow squares 30−100 µS/cm, and red triangles ≥100 µS/cm. Geodetic reference system = North American Datum (NAD83).

7.1.4. State Data Set (EPA Region 10)

The State data set includes data from the Oregon DEQ 1990–2014 data set (Oregon DEQ, 2009) and the Washington Department of Ecology (WDE) 1990–2015 data set (WDE, 2014). Monthly sampling was performed throughout the year in many sites.

State sampling sites within the ecoregion are shown in Figure 7-2. Water quality parameters collected in Ecoregion 4 are included in Table 7-3. Most of the samples have reported SC, sulfate, chloride, and pH.

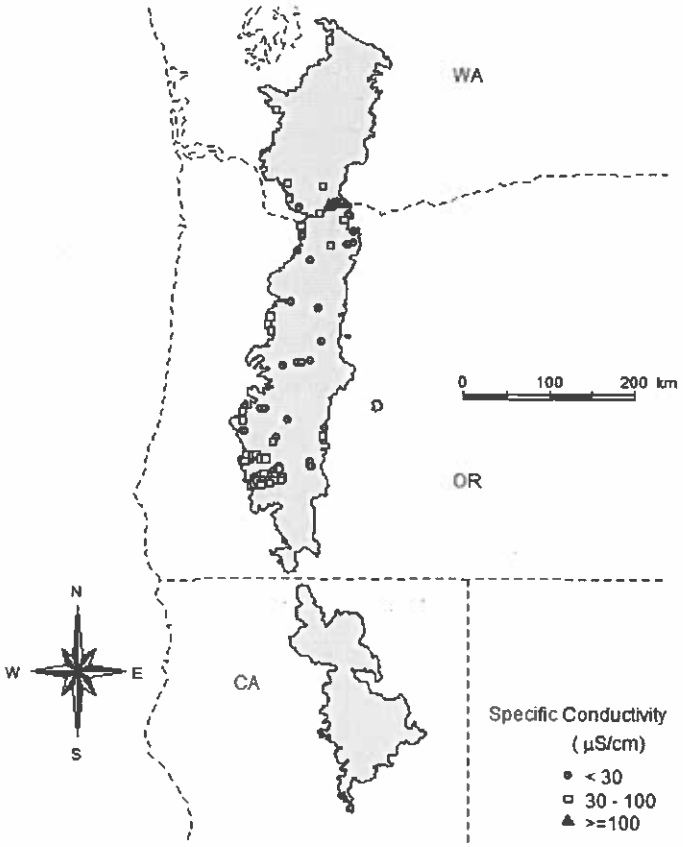

Figure 7-2. Sampling sites in State data set that were used to estimate minimally affected background in Ecoregion 4.
For the purpose of demonstrating the background-to-criterion approach, Level III Ecoregion 4 is shaded gray. A total of 539 sampling sites are in the state data set, but only 95 sites with conductivity measurements are shown here. Sampling locations are color coded by site-specific conductivity range: green diamonds <30 µS/cm, yellow squares 30–100 µS/cm, and red triangles ≥100 µS/cm. Geodetic reference system = North American Datum (NAD83).

Table 7-3. Summary of data for the example case for Cascades, Level III Ecoregion 4 from State Data from Oregon and Washington.
Calculated means are geometric except for pHs and ion ratios.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	95	6.8	24.0	32.4	31.9	39.4	126
Ca^{2+} (mg/L)	78	1.0	2.3	3.0	3.7	4.3	1,100
HCO_3^- (mg/L)	300	7.7	19.9	25.8	27.5	38.0	3,966
SO_4^{2-} (mg/L)	252	0.1	0.3	0.6	0.8	1.7	36.2
Cl^- (mg/L)	315	0.3	0.7	1.0	1.1	1.5	250.0
[a]$HCO_3^- + SO_4^{2-}/Cl^-$	203	3.3	18.0	28.2	37.6	46.0	225.7

[a]ratio of mg/L $HCO_3^- + SO_4^{2-}/Cl^-$ greater than 1 indicates the mixture is dominated by $HCO_3^- + SO_4^{2-}$.

7.1.5. U.S. Geological Survey (USGS) Data Set

The USGS survey data set used in this example is composed of 6,258 water quality samples, from 290 stations within Ecoregion 4 (see Table 7-1; Figure 7-3). Some stations were sampled only once while others were sampled as many as 641 times. The data were collected between 1958 and 2016 during all seasons. Water quality parameters collected in Ecoregion 4 are included in Table 7-4. Most of the samples have reported SC, alkalinity, hardness, chloride, bicarbonate, and pH, as well as other water quality parameters. Analysis of water chemistry samples followed procedural and QA/QC protocols for USGS data sets (Mueller et al. 1997).

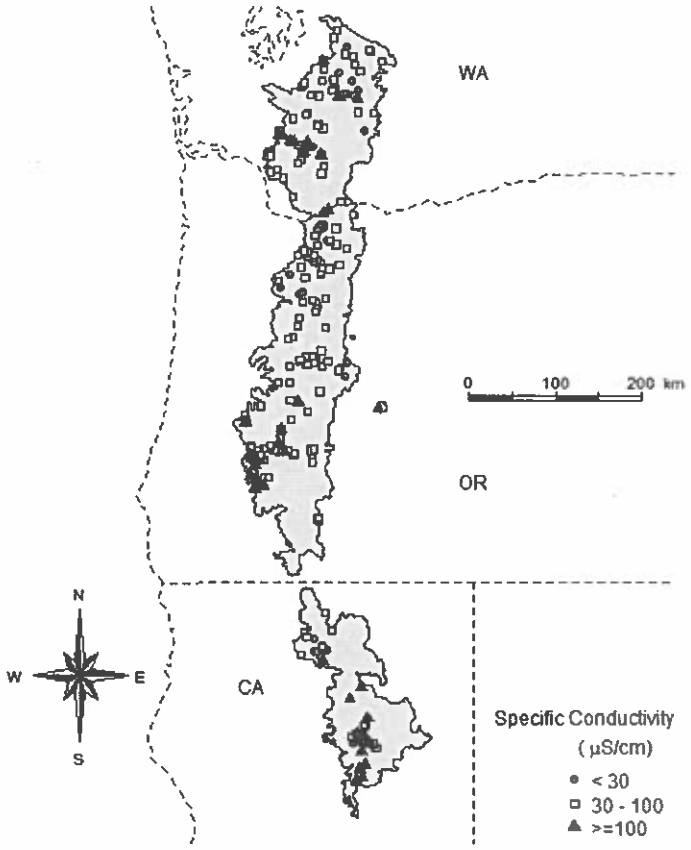

Figure 7-3. Sampling sites in the U.S. Geological Survey (USGS) data set in Ecoregion 4.

Ecoregion 4 is shaded gray. Geometric mean specific conductivity at 290 sampling locations is color-coded: green diamonds <30 µS/cm, yellow squares 30–100 µS/cm, and red triangles ≥100 µS/cm. Geodetic reference system = North American Datum (NAD83).

Table 7-4. Summary of data for the example case for Cascades, Level III Ecoregion 4 from the U.S. Geological Survey (USGS).
Calculated means are geometric except for pH.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	282	3.50	38	53.9	53.6	78.3	370
pH (SU)	274	6.2	7.2	7.5	7.4	7.7	8.7
Ca^{2+} (mg/L)	5	1.6	1.7	2.1	2.9	5.6	15.7
Mg^{2+} (mg/L)	158	0.10	0.78	1.39	1.31	2.43	9.08
Na^{+} (mg/L)	5	1.2	1.2	1.3	1.7	2.5	5.6
K^{+} (mg/L)	5	0.1	0.2	0.2	0.3	0.5	1.3
HCO_3^{-} (mg/L)	57	3.0	29.8	35.0	37.0	51.3	122.0

All samples were collected from first-through fourth-order streams for various research purposes, and those targeted sampling designs may emphasize areas with increased anthropogenic disturbance. In this respect, the data may skew the background estimates. Background SC was not estimated from this data set alone because sampling stations were not randomly assigned.

Because the USGS and State data sets contained multiple measurements in a year from sampling locations, the data sets were used to estimate a CMEC and explore the variability of SC patterns within the region. Therefore, a second data set was selected by excluding stations with fewer than 6 SC measurements throughout the year. A minimum of one sample during the spring (March to June) and one in the summer (July to October) were also required so that at least one lower and one higher SC sample were included in the data set. The second USGS data set included 5,019 samples from 50 stations, while the second State data set include 1,111 samples from 19 stations. The USGS and State data sets were combined was used to calculate the variance near the CCC for the CMEC calculation.

7.1.6. Modeled Mean Base Flow Background Specific Conductivity (SC)

Predicted mean natural base-flow specific conductivity in catchments of Cascades, was also considered for comparison purposes (Olson and Hawkins, 2012). The stream length weighted, mean natural SC from the modeled base flow were calculated for the SC at base flow

for each ecoregion (see Appendix D). Figure 7-4 shows the predicted SC with 300 m resolution in order to emphasize the general trends across Ecoregion 4.

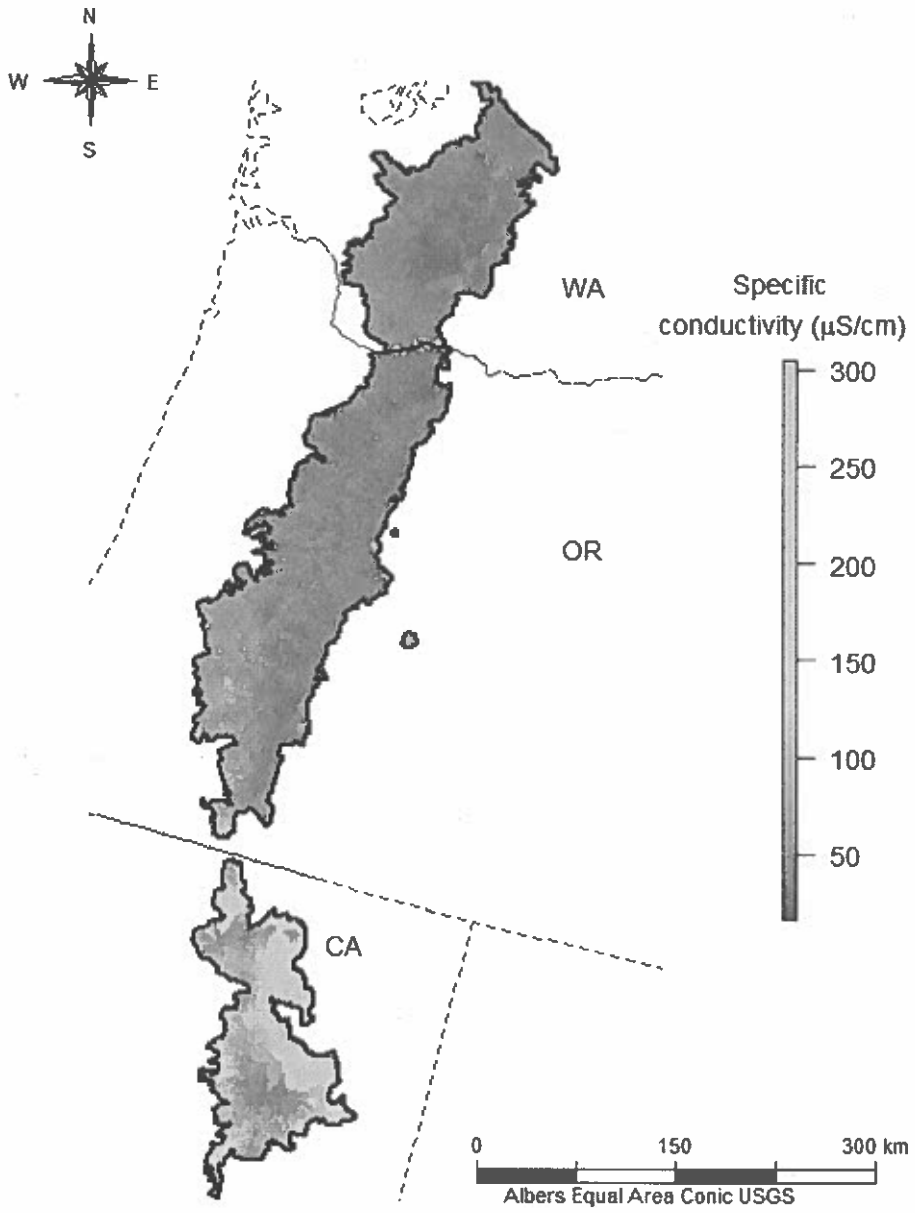

Figure 7-4. Predicted mean natural base-flow specific conductivity in catchments of the Cascades, Ecoregion 4, using the Olson-Hawkins model. Albers projection used for mapping.

7.1.7. Characterization of Ionic Matrices

7.1.7.1. *EPA-Survey Data Set Ionic Characteristics*

A summary of water quality ionic constituents including major ionic constituents from EPA-survey data for Ecoregion 4 is provided in Table 7-2. Centiles were calculated using each sample observation because most measurements were single grab samples. There were no chloride-dominated sites where $[Cl^-] \geq ([HCO_3^-] + [SO_4^{2-}])$ in mg/L in the EPA-survey data ($N = 152$); therefore, no sites were excluded from the data sets. Calcium plus magnesium were the dominant cations $([Ca^{2+}] + [Mg^{2+}]) > ([Na^+] + [K^+])$.

7.1.7.2. *State Data Set Ionic Characteristics*

A summary of water quality ionic constituents including major ionic constituents from State data for Ecoregion 4 is provided in Table 7-3. Centiles were calculated using each sample observation because most measurements were single grab samples. There were no chloride-dominated sites (where $[Cl^-] \geq ([HCO_3^-] + [SO_4^{2-}])$ in the state data ($N = 539$); therefore, no sites were excluded from the data sets. Likewise, calcium plus magnesium were the dominant cations, $([Ca^{2+}] + [Mg^{2+}]) > ([Na^+] + [K^+])$.

7.1.7.3. *U.S. Geological Survey (USGS) Data Set Ionic Characteristics*

Table 7-4 summarizes the water quality parameters including major ionic constituents for Ecoregion 4 in the USGS data set. Unlike the EPA-survey data set, the USGS data set are targeted sites of interest rather than probability samples. Also, in some cases, there are multiple measurements from the same site, and other sites are auto-correlated with downstream sampling locations. Therefore, the distribution of sites in this data set is not necessarily representative of Ecoregion 4 in its entirety; however, the data set can be used to define the overall pattern of SC for the ecoregion because it contains samples in areas not represented in the EPA-survey data set. Centiles were calculated using the geometric mean of site measurements (except pH and the ionic ratio) and were qualitatively compared to the probability-based EPA-survey data set. No sulfate measurements were found so $([HCO_3^-] + [SO_4^{2-}])/[Cl^-]$ ratios were not determined for this data set. Calcium plus magnesium were the dominant cations $([Ca^{2+}] + [Mg^{2+}]) > ([Na^+] + [K^+])$.

Two samples from the USGS data set were in the 1,000 µS/cm range and were associated with salt springs at Lake Paulina and Longmire Meadow mineral springs and were removed from the data set (Ingebritsen et al., 2014). Six sites (421−1,030 µS/cm) were sampled on the flanks of Mount St. Helen after the 1980 eruption; and, these were removed. These eight sites represent a small proportion of the data set, and the example criterion would not apply to these or similar areas with naturally higher background SC. The background SC was 39.5 µS/cm with these eight sites included and 38.2 µS/cm with them removed.

7.1.8. Comparison of Background Specific Conductivity (SC) Estimates

SC data from the three data sets, the combined data, and the Olson-Hawkins base flow model are summarized in Figure 7-5. The stream length weighted average predicted mean base flow SC from the Olson-Hawkins model in Ecoregion 4 is 65.7 µS/cm. The 25th centile of the EPA-survey data set is 33.9 µS/cm, of the State data set is 24 µS/cm, and of the USGS SC data set is 39.5 µS/cm. All three are less than the mean base flow SC (65.7 µS/cm), so these background SC are characterized as minimally affected (see Figure 7-5 and Tables 7-2, 7-3, and 7-4). When data are combined, the 25th centile (≈33 µS/cm) is still lower than the predicted mean base flow of 65.7 µS/cm (see Table 7-5, Figure 7-5). Therefore, this background SC estimated from the combined State-EPA-USGS data set also represents minimally affected background SC.

The 25th centile of the combined data set was used to calculate the HC_{05} following the decision tree described Section 3.7.2 and Figure 3-11.

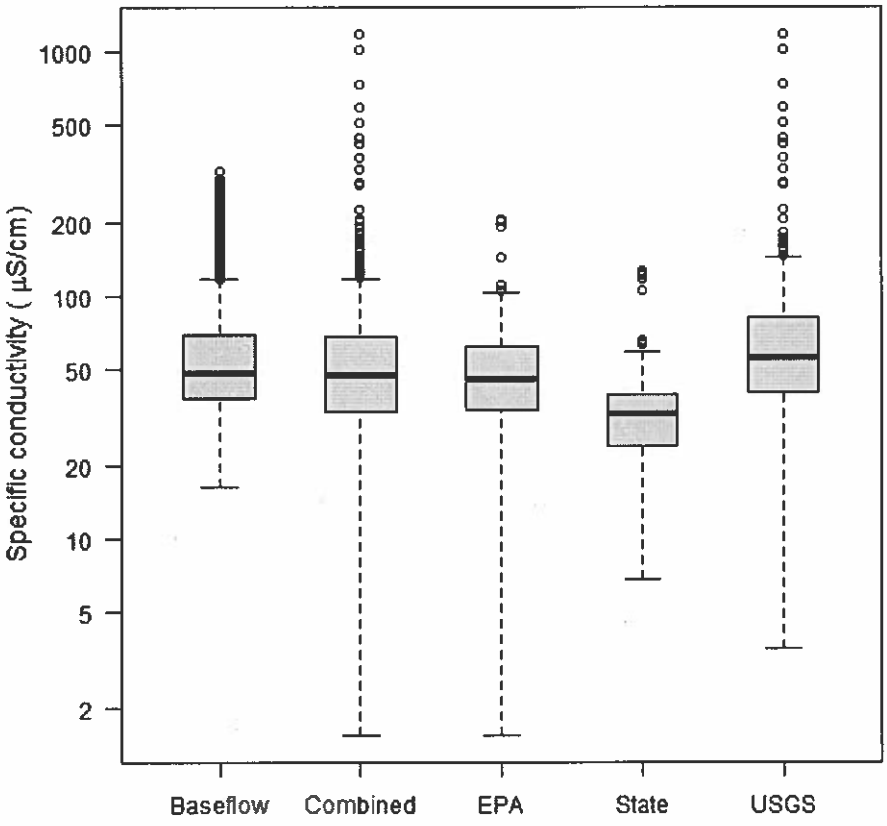

Figure 7-5. Box plots of specific conductivity (SC) distributions for EPA-survey, State, U.S. Geological Survey (USGS), and combined data sets, and the predicted base flow SC for all stream segments.
The State data set captures a slightly narrower range of values possibly owing to the targeted sampling. The USGS samples greater than 400 µS/cm include some samples from mineral springs and Mt. St. Helen ash flows which have been removed from the combined data set. The 25th centiles of the observed data sets are fairly similar to the 25th centile of predicted base-flow.

Table 7-5. Summary of data for the example case for Cascades, Level III Ecoregion 4 from the combined data set.
Calculated means for sampled sites are geometric for all variables except for pH and ion ratio.

Parameter	*N*	Minimum	25th	50th	Mean	75th	Maximum
SC (µS/cm)	529	1.56	32.7	46.4	46.4	66	370
pH (SU)	418	6.2	7.2	7.5	7.4	7.7	9.0
Ca^{2+} (mg/L)	153	0.04	2.51	3.59	4.06	6.36	1,100
Mg^{2+} (mg/L)	228	0.03	0.77	1.34	1.29	2.20	9.08
Na^{+} (mg/L)	75	0.08	2.03	2.76	2.59	3.96	10.45
K^{+} (mg/L)	75	0.01	0.22	0.49	0.44	0.77	3.17
HCO_3^{-} (mg/L)	403	0.46	20.4	28.0	28.4	40.2	3,966
SO_4^{2-} (mg/L)	373	0.07	0.34	0.78	0.85	2.17	36.2
Cl^{-} (mg/L)	451	0.14	0.63	1.00	1.00	1.40	250
$HCO_3^{-} + SO_4^{2-}/Cl^{-}$	249	3.29	18.3	28.6	40	48.5	226

[a]ratio in mg/L $HCO_3^{-} + SO_4^{2-}/Cl^{-}$ greater than 1 indicates the mixture is dominated by $HCO_3^{-} + SO_4^{2-}$.

7.2. CALCULATION OF THE CRITERION CONTINUOUS CONCENTRATION (CCC)

7.2.1. Calculation of the Ecoregion 4 mean Hazardous Concentration (HC_{05}) from Background

Because paired SC and biological data are available for <200 sites, the HC_{05} was estimated at the lower 50% PL of the B-C model (see Figure 7-6). The 25th centile of SC from the combined data set of Ecoregion 4 was used to identify the lower 50% PL using eqs 3-4 and 3-5. The B-C model development is described in Appendix D. The *x*-variable is the background SC in Ecoregion 4 which was log10 transformed. The calculated *y*-value is the predicted mean log10 HC_{05}. In this example case, the minimally affected background is 33 µS/cm (see Table 7-5). It was estimated at the 25th centile from the combined data set. The calculation of the predicted mean log10 of HC_{05} (*y*) is shown in eqs 7-1 and 7-2 and that value is used to estimate the lower 50% PL using eq 7-3.

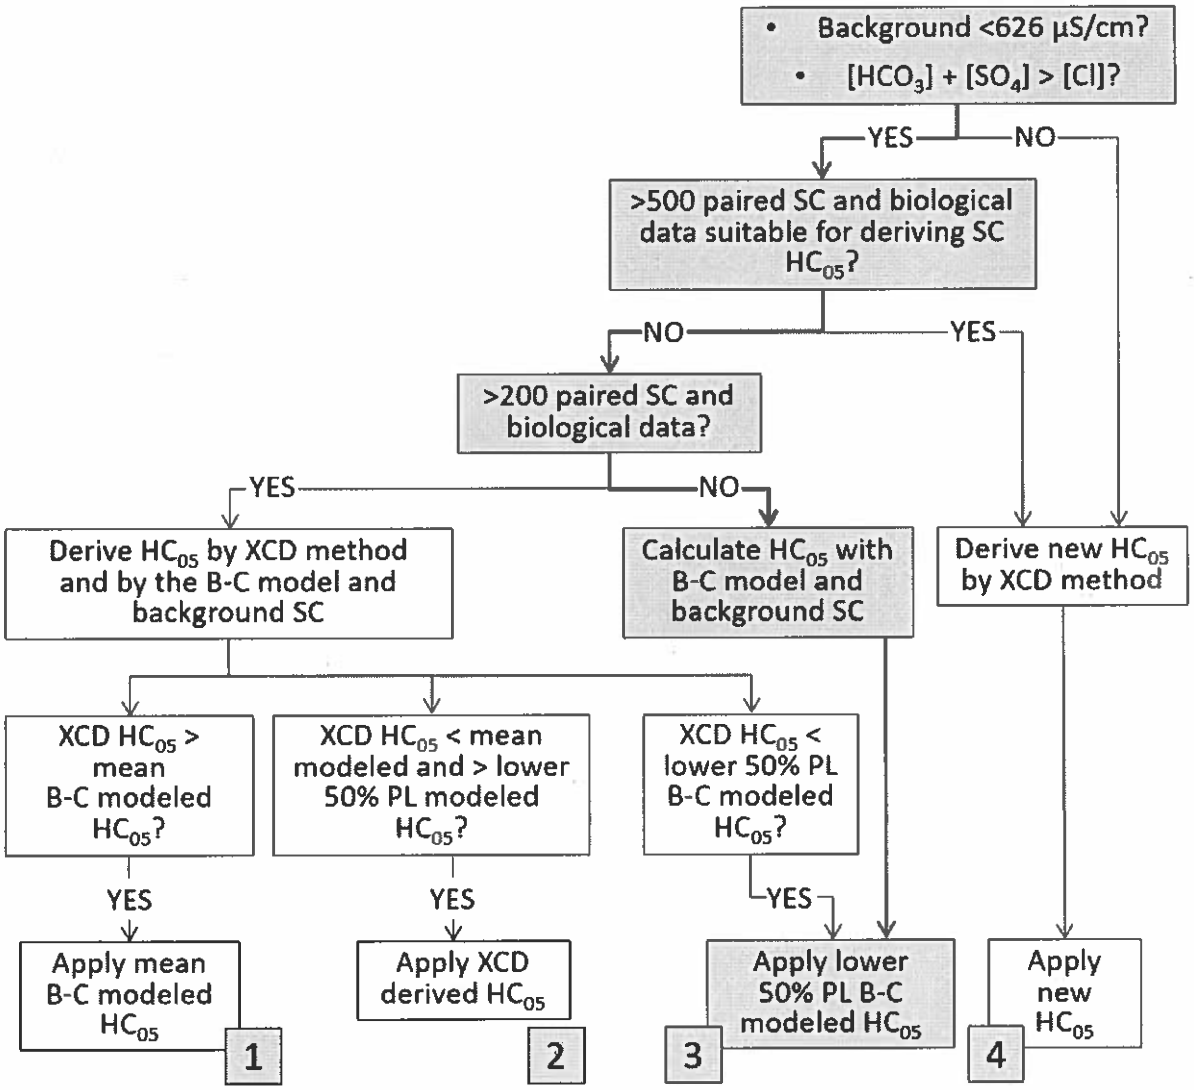

Figure 7-6. Process and decision path case example for Ecoregion 4. Decision path is highlighted in gray and connected by bold lines. Because there was no previously derived hazardous concentration at the 5th centile (HC_{05}) of a taxonomic extirpation concentration distribution (XCD) for Ecoregion 4, and the background was <33 µS/cm, and there were <200 paired specific conductivity (SC) measurements, the HC_{05} was calculated with the background-to-criterion (B-C) model at the lower 50% prediction limit (PL).

The B-C model is described by the following formula:

$$Y = 0.657X + 1.075 \quad (7\text{-}1)$$

Where:

X is the log10 of the ecoregional background SC
Y is the log10 of the predicted HC_{05}

The background for Ecoregion 4 (33 µS/cm) is converted to log10, replacing X in the formula with that value and Y is computed (see eq 7-2). The predicted value Y is converted from log10 to a number that is the mean modeled HC_{05} for that region. In Ecoregion 4 the mean modeled HC_{05} is 118 µS/cm after rounding to two significant figures.

$$\text{Log Predicted } HC_{05} = (0.657 \times 1.518\ \mu S/cm) + 1.075 = 2.072\ \mu S/cm \quad (7\text{-}2)$$

Then

$$\text{Predicted } HC_{05} = 10^{2.072}\ \mu S/cm = 118\ \mu S/cm$$

7.2.2. Calculation of the Lower 50% Prediction Limit

Because the available paired SC and biological data constitute <200 sites, the CCC was estimated at the lower 50% PL of the HC_{05} (see Figure 7-6). The 25th centile of background SC and the predicted mean HC_{05} of a region and variance of the B-C model is used to calculate the lower 50% PL (see eq 7-3). In this case example for Ecoregion 4, the background is 33 µS/cm and the mean modeled HC_{05} is 118 µS/cm. Both values are converted to log10 (x, y) as shown in eq 7-4. The prediction interval from the regression line for a mean predicted value $\hat{y}$ can be calculated as follows or more conveniently using statistical software thus avoiding rounding errors:

$$\hat{y} \pm t_{\alpha/2,n-2} S_y \sqrt{1 + \frac{1}{n} + \frac{(x^* - \bar{x})^2}{SS}} = \text{PL} \quad (7\text{-}3)$$

Symbol	Explanation	Example from the B-C model
$\hat{y}$	Log10 of mean predicted HC_{05}	2.072 µS/cm, log10 of 118 µS/cm
n	Number of samples in the model	$n = 24$
α	Alpha error rate for prediction interval (desired confidence level)	50% prediction interval ($\alpha = 0.5$)
t_{n-2}	t-value at specific level (alpha, α) and degrees of freedom ($n - 2$) of interval	For 50% prediction interval ($\alpha = 0.5$), $t_{(1-0.5)/2,24-2} = 0.686$
S_y	Residual standard error of prediction (standard deviation)	$S_y = 0.11$
SS	Sum of square of x deviation from their mean, $SS = \sum_{i=1}^{n}(x_i - \bar{x})^2$	$SS = 4.21$
$\bar{x}$	Mean x values used in the model generation	$\bar{x} = 2.15$
x°	x value for a new prediction interval	Log10 118 µS/cm = 2.072
PL	Upper and lower prediction limits of mean predicted $\hat{y}$	calculated in eq 6-4

Using x° = log10 (118) µS/cm and the mean predicted HC_{05} for Ecoregion 4 value, ($\hat{y} = 2.072$, the log10 of 118 µS/cm) the lower 50% PL is calculated as follows in eq 7-4. Note, the upper 50% PL is not calculated but is included in the formula because it may be used to estimate a CMEC where there are insufficient data to calculate a CMEC using the method described in Section 3.2.

$$log10\,(118)\ \pm 0.686 \times\ 0.11\sqrt{1 + \frac{1}{24} + \frac{(log_{10}(118) - 2.15)^2}{4.21}} \qquad (7\text{-}4)$$

So:

$$2.072 - 0.686\ \times 0.11\sqrt{\frac{25}{24} + \frac{(2.072 - 2.15)^2}{4.21}}$$

$$2.072 - 0.686\ \times 0.11 \times 1.02$$

$$\text{Log10}^{1.997} = 98\ \mu\text{S/cm}$$

The log of the lower calculated 50% PL is log10 1.997 which equals 98 µS/cm after back transformation and rounding to two significant figures yields a CCC of 98 µS/cm.

7.2.3. Example Criterion Maximum Exposure Concentration

At sites meeting the CCC of 98 µS/cm, 90% of the SC observations are estimated to occur below the CMEC (see Section 3.2). The CMEC was derived using a combined USGS (6,258 samples collected between 1959–2016) and State data sets (3,073 samples collected between 1990–2015). These data sets were used because they contained multiple measures of SC within a year whereas the EPA survey data set consisted of single measurements at each site. Of the 9,331 samples in this ecoregion, there are 6,130 samples in a year representing 312 station years, 69 unique stations, with at least 1 sample from March to June and one from July to October and at least 6 samples within a year. Note that inclusion of samples is not contingent on biological data.

Of the 312 station years (69 unique stations) with multiple SC measurements, the variability of within station SC was slightly differed for streams with different mean SC (see Figure 7-7). However, the LOWESS and confidence bounds for any detectable change points indicated that the average variability (residual standard deviation for a station) was relatively stable generally between 0.05 and 0.1 (see Figure 7-7); therefore, the entire data set was used to estimate the standard deviation components of the annual mean SC (98 µS/cm). The proposed CCC and standard deviation of this data set was determined, and the CMEC was calculated. The example calculation of the CMEC for Ecoregion 4 is shown below (see eq 7-5) using eq 3-2 from Section 3.2:

$$10^{\log10(98) + 1.28*0.234} = 196\ \mu S/cm \qquad (7\text{-}5)$$

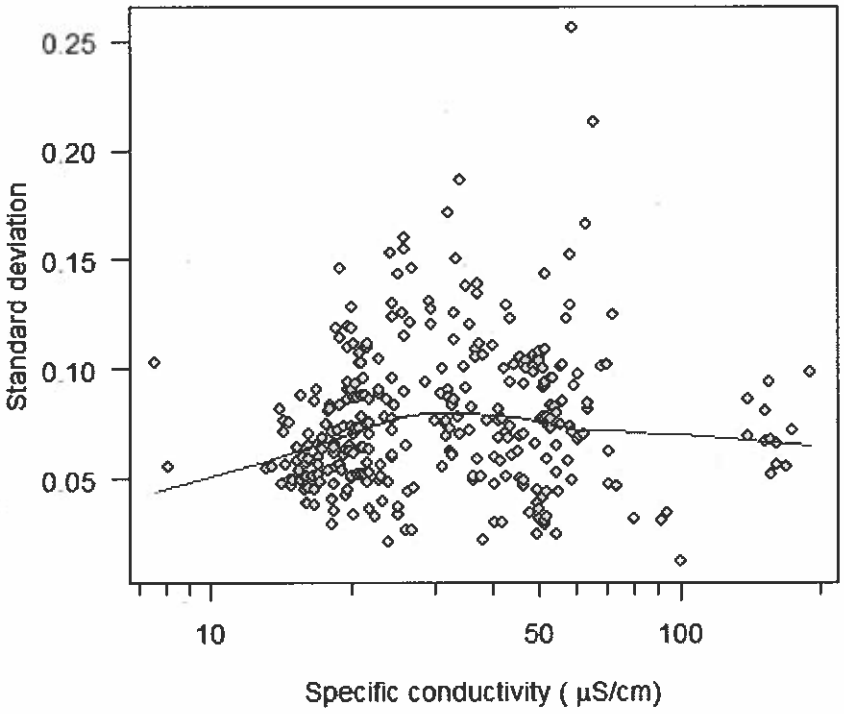

Figure 7-7. Illustration of within site variability (residual standard deviation for each station) along the specific conductivity gradient (station means) in Ecoregion 4.
The *x*-axis is log annual mean specific conductivity. Each dot represents a station. The fitted line is a locally weighted scatterplot smoothing spline (LOWESS, span = 0.75, linear polynomial model).

The example CMEC (see Table 7-6) rounded to two significant figures yields a CMEC of 200 µS/cm for Ecoregion 4. At this level, where the annual geometric mean SC <98 µS/cm, 90% of the observations are expected to be less than the CMEC.

Table 7-6. Summary data related to the calculation of the example criterion maximum exposure concentration (CMEC) for Ecoregion 4

Number of samples July to June prior to biological sampling	6,130
Number of unique stations/rotation year	69/312
CCC	98 µS/cm
CMEC	200 µS/cm

7.3. EXAMPLE CRITERION CHARACTERIZATION FOR ECOREGION 4 BASED ON A BACKGROUND-TO-CRITERION MODEL

The case example for Ecoregion 4 includes an annual geometric mean (i.e., CCC) and a 1-day mean (i.e., CMEC), not to be exceeded more than once in 3 years on average. Both of these distinct expressions of the example SC criteria would need to be met in order to adequately protect aquatic life. These values indicate that freshwater animals are protected if the annual geometric mean SC concentration in flowing waters does not exceed 98 µS/cm and the 1-day mean does not exceed 200 µS/cm more than once every 3 years on average. These example criteria would apply to all flowing freshwaters (ephemeral, intermittent, and perennial streams) in Ecoregion 4 inclusive of portions of Washington, Oregon, and California. On a site-by-site basis, these example ecoregional criteria apply if the ionic mixture is dominated by anions of bicarbonate and sulfate and cations calcium and magnesium. For streams crossing into Ecoregion 4 from ecoregions with either lower or higher background SC, professional judgment may be needed to assess the potential effect of different ionic composition or concentration. Professional judgment is recommended when applying to sites with a catchment area greater than 1,000 km^2 (386 mi^2) owing to lesser representation in the data set by this class of stream in the development of the B-C model. On a site by site basis, alternative SC criteria may be more appropriate if the natural background of a site is shown to be lower or higher than its regional background SC.

The Cascades ecoregion has less sources of ionic inputs and the igneous geology leads to very low stream SC (background SC of 33 µS/cm), which represents minimally affected conditions with respect to SC. Reference sites were not identified in the data sets so a comparison with the 75th centile SC in any data set was not possible. About 88% of the sampled sites (537) meet the CCC and more than 99% of all samples (7,855) meet the CMEC calculated for this example. Owing to the very low conductivity, there is very little difference between the lower 50% prediction interval or the mean modeled HC_{05}, 98 versus 118 µS/cm, respectively. Two samples from the USGS data set were in the 1,000 µS/cm range and were associated with salt springs at Lake Paulina and Longmire Meadow mineral springs and were removed from the data set (Ingebritsen et al., 2014). Six sites (421−1,030 µS/cm) were sampled on the flanks of Mount St. Helen after the 1980 eruption, and they were also removed before the analysis. The example criterion would not apply to these areas with naturally higher background SC. The

weight-of-evidence method described in Appendix C could be used to evaluate subregions or stream classes that may have different background SC in this large ecoregion. In particular, the isolated area in Northern California may have a naturally higher background SC based on the USGS measurements (see Figure 7-3) and the mean predicted baseflow (see Figure 7-4). Also, potential unique sources of salt such as fumaroles and salt springs may naturally raise SC.

7.4. PROTECTION OF FEDERALLY-LISTED SPECIES AND OTHER HIGHLY VALUED TAXA

Although the example criteria were derived using XC_{95} values for the macroinvertebrate taxa represented in the data sets used to develop the B-C model, the available evidence indicates that other taxa in the streams would likely be protected as well (see Section 2.6 and Appendix G). Hence, no adjustment was made for unanalyzed taxa. However, on a site-specific basis, the example criterion could be adjusted or recalculated to protect important species, highly valued aquatic communities, or specially protected waters.

REVIEWER: SAB

DATE: 13 December 2016

TO: Iwona Ward

FROM: Scott Twait ST

SUBJECT: WQBELs
Williamson Energy, LLC – Pond Creek Mine
NPDES Permit No. IL007766 (Williamson County)

The subject facility discharges to the unnamed tributaries of Pond Creek through Outfalls 001 – 008 at a point where 0 cfs of flow exists upstream of the outfalls during critical 7Q10 low-flow conditions. The unnamed tributaries of Pond Creek are classified as a General Use Water. The unnamed tributaries of Pond Creek are not listed as a biologically significant streams in the 2008 Illinois Department of Natural Resources Publication *Integrating Multiple Taxa in a Biological Stream Rating System*, nor are they given an integrity rating in that document. The unnamed tributaries of Pond Creek, tributary to Waterbody Segment, NG-02, is not listed on the draft 2016 Illinois Integrated Water Quality Report and Section 303(d) List since they have not been assessed. The unnamed tributaries of Pond Creek are not subject to enhanced dissolved oxygen standards.

The subject facility proposes to discharge to Pond Creek through Outfall 009 at a point where 0 cfs of flow exists upstream of the outfalls during critical 7Q10 low-flow conditions. Pond Creek is classified as a General Use Water. Pond Creek is not listed as a biologically significant streams in the 2008 Illinois Department of Natural Resources Publication *Integrating Multiple Taxa in a Biological Stream Rating System*, nor is it given an integrity rating in that document. Pond Creek, Waterbody Segment, NG-02, is listed on the draft 2016 Illinois Integrated Water Quality Report and Section 303(d) List as impaired for aquatic life use with potential causes given as alteration in stream-side or littoral vegetative cover (non-pollutant), changes in stream depth and velocity patterns (non-pollutant), chlorides, loss of instream cover (non-pollutant), dissolved oxygen (non-pollutant), and sedimentation/siltation. Primary contact recreation and secondary contact uses are fully supported. Pond Creek is not subject to enhanced dissolved oxygen standards.

Outfalls 001 through 005 are alkaline mine drainage and outfalls 006 - 009 are acid mine drainage. The NPDES application did not indicate any watershed sizes or flow expected for mixing, however, Outfall 009 has mixing based on the stream flow and the stream chloride concentration.

Chloride should be regulated as a daily maximum at the water quality standard of 500 mg/L for all of the outfalls, except Outfall 009 which will be based on stream flow and chloride concentration as mentioned below.

Where appropriate, Manganese should be regulated as a daily maximum at the water quality standard of 1.0 mg/L.

The Sulfate limit is determined according to the water quality standards at 302.208(h)(2). The chloride and hardness data is from AWQMN station NG-02, Pond Creek, South edge of West Frankfort, downstream of the Williamson Energy, LLC – Pond Creek Mine No. 1 property, so this limit should be used for all outfalls. Flow data was not provided, so calculation of mixing was not completed. No mixing for sulfate in Outfall 009 is necessary. No mixing was used in the derivation of the effluent limit. The following table shows the results of downstream chloride and hardness.

Outfalls	Average Receiving Stream Chloride (mg/L)	Receiving Stream Critical Hardness (mg/L)	Sulfate Water Quality Standard (mg/L)
001-009	21.5	141	1250

The sulfate values in the far right column are applied as daily maximum permit limits.

Monitoring for chloride, sulfate and hardness should be periodically required at a downstream location from each outfall, or downstream of the mine property, during the course of the permit. This data will be used to recalculate sulfate limits for the next renewed or modified permit.

Cadmium, Chromium (Trivalent), Copper, Fluoride, Lead, Manganese, Nickel, and Zinc standards are based on hardness data collected at AWQMN station NG-02, Pond Creek, S edge of West Frankfort, with a critical hardness value of 141 mg/L as $CaCO_3$. Water quality standards identified in the table are expressed in units of mg/L except where noted. Dissolved metals standards have been converted to total metal except where noted. All data was provided by the discharger.

Outfall 001

Substance	Max. Eff. Conc.	No. of Samples	Multiply by	95% Potential	Acute Standard	302.208(g) standard	Further Analysis?
Arsenic	< 0.002	1	6.2	0.0124	0.3600	-	No RP*
Cadmium	0.018	1	6.2	0.1116	0.0144	-	Yes
Chromium (Total)	< 0.006	1	6.2	0.0372	2.3009	-	No RP*
Copper	< 0.003	1	6.2	0.0186	0.0245	-	No RP*
Lead	< 0.0075	1	6.2	0.0465	0.1482	-	No RP*
Nickel	0.067	1	6.2	0.4154	0.1104	-	Yes
Phenols	< 0.01	1	6.2	0.062	-	0.1	No RP*
Silver	< 0.002	1	6.2	0.0124	-	0.005	Yes
Zinc	0.025	1	6.2	0.155	0.1635	-	No RP*
Selenium	< 0.002	1	6.2	0.0124	-	1.0	No RP*
Mercury	< 0.002	1	6.2	0.0124	0.0026	-	Yes

* No RP = no reasonable potential to exceed water quality standards.

Further Analysis:

Under Agency policy, substances designated in the first table as being in need of further analysis, and for which five or fewer effluent results are available, will not be evaluated for reasonable potential to exceed standards per the USEPA *Technical Support Document for Water Quality Based Toxics Control.* Rather, these substances will be directly evaluated against the water quality standards applicable to the receiving stream. We do not believe that the USEPA procedure is valid when only a very small sample population exists due to the high multipliers applied. We believe that our approach is appropriate for facilities that have been previously identified through the pre-treatment program as having a low risk for high levels of metals and other industrial pollutants in their treated domestic waste effluents. For the Williamson Energy – Pond Creek Mine #1 Outfall 001, the parameters relevant to this policy are Cadmium, Nickel, Silver, and Mercury and have been evaluated as follows:

There is a reasonable potential to exceed the acute water quality standard for Cadmium. Cadmium should be regulated as a daily maximum in the NPDES permit at the acute water quality standard using the default metals translator.

The Nickel sample was reported less than the acute water quality standard. My conclusion is that no regulation of Nickel is necessary and that no monitoring beyond the routine requirements is needed.

The Williamson Energy – Pond Creek Mine #1 facility STP had no detections reported for Silver and Mercury. My conclusion is that no regulation of Silver and Mercury is necessary and that no monitoring beyond the routine requirements is needed.

Outfall 002

Substance	Max. Eff. Conc.	No. of Samples	Multiply by	95% Potential	Acute Standard	302.208(g) standard	Further Analysis?

Selenium	0.011	9	1.8	0.0198	-	1.0	No RP*

* No RP = no reasonable potential to exceed water quality standards.

Further Analysis:

There is a reasonable potential to exceed the acute water quality standard for Copper. Copper should be regulated as a daily maximum in the NPDES permit at the acute water quality standard using the default metals translator.

Chloride should be limited in the NPDES permit at the limits described below. All other parameters will meet water quality standards at the end of the pipe. According to the effluent data received, Chloride needs mixing to allow water quality standards to be achieved at the edge of allowed mixing.

A mixing analysis was performed and detailed in a document by AquAeTer, Inc. titled "Williamson Energy Mine – Proposed Pond Creek Discharge Mixing Zone Analysis".

The permit only allows a discharge when the receiving stream is flowing. The permittee should use the following equation to demonstrate that water quality standards will be met downstream of the discharge.

$C_{DS} = [C_E Q_E + 0.25 C_{US} Q_{US}] / (0.25 Q_{US} + Q_E)$

Where:

C_E = Effluent concentration (mg/L)
Q_E = Effluent flow rate (cfs) for Outfall 017
Q_{US} = Upstream flow rate (cfs)
C_{US} = Upstream concentration (mg/L)
C_{DS} = Downstream concentration (mg/L)

The permittee has committed to install a gauging station and TDS monitor upstream of the discharge to determine an upstream flow (Q_{US}) and a chloride concentration (C_{US}) correlated to the TDS value. In addition, the permittee has agreed to install a continuous TDS monitor downstream to ensure that the chloride concentration (correlated to the TDS value) stays within the chloride water quality standard.

The "calculated" downstream concentration shall be less than 500 mg/L for chloride and reported on the discharge monitoring reports (DMRs).

If there is no upstream mixing available for Outfall 009, the NPDES permit should be regulated at 500 mg/L for chlorides and 1250 mg/L for sulfates.

Recommendations:

My evaluation of the metals and other substances given in the first table finds that water quality based permit limits are necessary for Cadmium in Outfalls 001, 002, 003, 004, 005, 006, and 007 at the limit below. Permit limits identified in the table are expressed in units of mg/L.

Substance	Daily Maximum
Cadmium	0.0144

My evaluation of the metals and other substances given in the first table finds that water quality based permit limits are necessary for Copper in Outfall 009 at the limit below. Permit limits identified in the table are expressed in units of mg/L.

Substance	Daily Maximum
Copper	0.0245

These recommendations reflect a water quality standards perspective only and should not be construed as being inclusive of all factors that must be taken into consideration by the permit writer.

Freshwater Mussels of the Big Muddy River

2012

Illinois Natural History Survey, Prairie Research Institute, University of Illinois
Illinois Department of Natural Resources

Diane Shasteen, Alison Price, Sarah Bales

Preface

While broad geographic information is available on the distribution and abundance of mussels in Illinois, systematically collected mussel-community data sets required to integrate mussels into aquatic community assessments do not exist. In 2009, a project funded by a US Fish and Wildlife Service State Wildlife Grant was undertaken to survey and assess the freshwater mussel populations at wadeable sites from 33 stream basins in conjunction with the Illinois Department of Natural Resources (IDNR)/Illinois Environmental Protection Agency (IEPA) basin surveys. Inclusion of mussels into these basin surveys contributes to the comprehensive basin monitoring programs that include water and sediment chemistry, instream habitat, macroinvertebrate, and fish, which reflect a broad spectrum of abiotic and biotic stream resources. These mussel surveys will provide reliable and repeatable techniques for assessing the freshwater mussel community in sampled streams. These surveys also provide data for future monitoring of freshwater mussel populations on a local, regional, and watershed basis.

Acknowledgements
This study was supported by funding from the US Fish and Wildlife Service, State Wildlife Grant (T-53-D-1, Investigating Mussel Communities in Illinois Streams), the IDNR, and the Illinois Natural History Survey (INHS). Our extreme gratitude goes to the primary investigators for the project: Ann Holtrop, Kevin Cummings, Robert Szafoni, and Dr. Yong Cao, who served as our mentors and made this project possible. We would like to thank all people involved in our surveys, especially our field assistants (A.J. Berger, Otis Foster, Colleen McLean, Hunter Ray, Jen Schwab, and Rachel Vinsel), IDNR fisheries biologists, IEPA water monitoring biologists, and volunteers from other agencies. We would like to extend gratitude to all the land owners, both public and private, who allowed us access to their properties. We would like to thank Andrew Hulin for the creation of maps for this report and Christine Mayer for INHS Collection database support.

Introduction

Freshwater mussel populations have been declining for decades and are among the most seriously impacted aquatic animals worldwide (Bogan 1993, Williams et al. 1993). It is estimated that nearly 70% of the approximately 300 North American mussel taxa are extinct, federally-listed as endangered or threatened, or in need of conservation status (Williams et al. 1993, Strayer et al. 2004). In Illinois, 25 of the 62 extant species (44%) are listed as threatened or endangered (Illinois Endangered Species Protection Board 2011). While broad geographic information is available on the distribution and abundance of mussels in Illinois, systematically collected mussel-community data sets required to integrate mussels into aquatic community assessments do not exist. Sampling of mussels has been very sporadic and limited in the Big Muddy River basin and no known reports pertaining to mussel communities of the basin have been published. This report summarizes the mussel survey conducted in the Big Muddy River basin in 2009-2010 in conjunction with IDNR and IEPA basin surveys.

The Big Muddy River basin drains 3798 km^2 (2360 mi^2) in the southern part of Illinois and contains principal tributaries of Casey Fork, Middle Fork Big Muddy, Beaucoup Creek, Little Muddy River, and Crab Orchard Creek (Page et al. 1992). Originating near Cravat in Jefferson County, the Big Muddy River basin drains through the counties of Jefferson, Washington, Perry, Franklin, Williamson, and Jackson. The river mainstem forms the Jackson /Union county line and joins the Mississippi River south of Grand Tower (Figure 1). The Big Muddy River basin flows through four natural divisions, including the Lower Mississippi River Bottomlands, Ozark, Shawnee Hills, and Southern Till Plain (Schwegman 1973). The Southern Till Plain comprises the majority of the basin which is characterized by hilly upland topography and a broad flood plain (Forbes and Richardson 1908).

Land-use and Instream Habitat

In the Big Muddy River basin, land use varies slightly by county with approximately 50 to 75% of the area in agriculture. Forested lands account for 8 to nearly 25% of the landscape with the larger forested areas being located in Jackson and Williamson counties (IDA 2000). Three of the largest cities in southern Illinois with populations between 15,000 and 28,000 (Marion, Mt. Vernon, and Carbondale) are also located in this basin (IEPA 1996, US Census Bureau 2010). In 1965, the Big Muddy River was dammed near Benton and thus Rend Lake, the second largest inland impoundment in the state, was created (Page et al. 1992, USACE 2005). This reservoir provides over 15 million gallons of water per day to approximately 300,000 people in over 60 communities throughout the basin. It is also used extensively for recreational activities including boating, fishing, waterfowl hunting and camping (USACE 2005). These recreational activities are also popular in the Shawnee National Forest, Giant City State Park, Lake Kinkaid and Murphysboro, Crab Orchard National Wildlife Refuge, and LaRue Pine Hills Ecological Area,

which are all located within the Big Muddy River basin. In the southwestern part of this basin, especially near the Murphysboro area, strip mining for coal was prevalent during the early 20th century and pollution from the remaining spoil banks continues to be a problem in the basin (Page et al. 1992).

During glacial activity in the region, the Mississippi River exceeded its sediment transporting capacity thus closing off the mouths of its tributary streams, including the Big Muddy River. The Big Muddy River temporarily formed a lake; once the natural process of removing sediment returned to the Mississippi River a deeper channel emerged. As the Big Muddy River drained, soils typical of a lake bed were left behind (LeTellier 1971). Today, the soils of the Big Muddy basin consist of impervious clays, silt and fine sand. The substrates in all of the streams of this basin were dominated by some combination of sand, silt, and clay. Excessive siltation along with large woody debris was common at many sites within the basin (Figure 2 and 3). Most of the sites in the basin had wadeable water depths; however sampling sites were limited on the mainstem of the Big Muddy and on Beaucoup Creek due to non-wadeable water depths (e.g., depth>1m).

Methods

During the 2009/2010 surveys, freshwater mussel data were collected at 30 sites: 3 mainstem and 27 tributary sites in the Big Muddy River basin (Figure 1, Table 1). Locations of sampling sites are listed in Table 1 along with information regarding IDNR/IEPA sampling at the site. In most cases, mussel survey locations were the same as IDNR/IEPA sites.

Live mussels and shells were collected at each sample site to assess past and current freshwater mussel occurrences. Live mussels were surveyed by hand grabbing and visual detection (e.g. trails, siphons, exposed shell) when water conditions permitted. Efforts were made to cover all available habitat types present at a site including riffles, pools, slack water, and areas of differing substrates. A four-hour timed search method was implemented at each site. Live mussels were held in the stream until processing.

Following the timed search, all live mussels and shells were identified to species and recorded (Table 2). For each live individual, shell length (mm), gender, and an estimate of the number of growth rings were recorded. Shell material was classified as recent dead (periostracum present, nacre pearly, and soft tissue may be present) or relict (periostracum eroded, nacre faded, shell chalky) based on condition of the best shell found. A species was considered extant at a site if it was represented by live or recently dead shell material (Szafoni 2001). The nomenclature employed in this report (Appendix 1) follows Turgeon et al. (1998) except for recent taxonomic changes to the gender ending of lilliput (*Toxolasma parvum*), which follows Williams et al. (2008). Voucher specimens were retained and deposited in the Illinois Natural History Survey

Mollusk Collection. All non-vouchered live mussels were returned to the stream reach where they were collected.

Parameters recorded included extant and total species richness, presence of rare or listed species, and individuals collected, expressed as catch-per-unit-effort (CPUE; Table 2). A population was considered to indicate recent recruitment if individuals less than 30 mm in length or with 3 or fewer growth rings were recorded. Finally, mussel resources were classified as Unique, Highly Valued, Moderate, Limited, or Restricted (Table 2) based on the above parameters (Table 3) and following criteria outlined in Table 4 (Szafoni 2001).

Results

Species Richness

A total of 19 species of freshwater mussels were observed in the Big Muddy River basin, all of which were collected live (Table 2). Across all sites, the number of live species collected, the number of extant species collected (live + dead), and the total number of species collected (live + dead + relict) ranged from 0 to 13. The giant floater (*Pyganodon grandis*) had the most occurrences across sites sampled with live mussels present (11 of 30 sites; 37%; Figure 4). The lilliput (*Toxolasma parvum*), paper pondshell (*Utterbackia imbecillis*), pondhorn (*Uniomerus tetralasmus*) and white heelsplitter (*Lasmigona complanata*) were other commonly occurring species (Figure 4), occupying 17% of these sites. Site 6, the Big Muddy River near Benton, had the greatest species richness with 12 live species.

Abundance and Recruitment

A total of 358 individuals were collected across 30 sites. The number of live specimens collected at a given site ranged from 0 to 133, with an average of 16 mussels per site where live mussels were collected (22 of 30 sites; Table 2). A total of 120 collector-hours were spent sampling with an average of three mussels collected per hour. Nine sites yielded more than 10 live individuals and 2 of the 9 sites (sites 6 and 15) yielded more than 45 live individuals. The most common species collected in the Big Muddy basin were giant floater (*n*=131), mapleleaf (*Quadrula quadrula*; n=37), white heelsplitter (n=34), lilliput (n=24), and pink papershell (*Potamilus ohiensis;* n=20), which together comprised approximately 70% of the individuals collected.

Recruitment for each species was determined by the presence of individuals less than 30mm or with 3 or fewer growth rings. Smaller (i.e., younger) mussels are harder to locate by hand grab methods and large sample sizes can be needed to accurately assess population reproduction. However, a small sample size can provide evidence of recruitment if it includes individuals that are small or possess few growth rings. Alternatively, a sample consisting of very large (for the species) individuals with numerous growth rings suggests a senescent population.

Recruitment at individual sites ranged from none observed to high across the basin. Recruitment levels, referred to in Table 3 as Reproduction Factor, varied from one to five, and three of the sites in the Big Muddy River basin exhibited high to very high recruitment. Recruitment was over 50% at site 7, Andy Creek, and 30 to 50% at sites 1 and 9, Snow Creek and Middle Fork Big Muddy (Figure 5). Sites 2 and 29, Big Muddy River and Cedar Creek, exhibited recruitment from 1 to 30% of species collected. Recruitment may be occurring at site 30, Big Muddy mainstem, where dead shells of nearly all species collected were less than 3 years of age. All other sites in the Big Muddy River basin (24 of 30) exhibited no observed recruitment during this survey.

Mussel Community Classification

Based on the data collected in the 2009/2010 basin surveys, nearly 75% of the sites in the Big Muddy River basin have Restricted or Limited mussel communities using the current MCI classification system (Table 4, Figure 5). No sites are ranked as Unique or Highly Valued in the basin. Eight sites (sites 1, 2, 6, 7, 9, 15, 23, and 29) in the Big Muddy River basin were ranked as Moderate mussel resources.

Noteworthy Finds

According to historical records, 25 species are known from the Big Muddy River basin (Tiemann et al. 2007). All 19 species found during this survey had been recorded in the basin historically. However, three of these species had not been recorded live since 1969; these species included Wabash pigtoe (*Fusconaia flava*), pondmussel (*Ligumia subrostrata*), and deertoe (*Truncilla truncata*). Historic species not detected during this survey include creeper (*Strophitus undulatus*), spike (*Elliptio dilatata*), pimpleback (*Quadrula pustulosa*), plain pocketbook (*Lampsilis cardium*), pink heelsplitter (*Potamilus alatus*), and fawnsfoot (*Truncilla donaciformis*).

A possible range expansion may be occurring with the Louisiana fatmucket (*Lampsilis hydiana)* which occurs in the upper Arkansas, White and St. Francis rivers and in Louisiana and East Texas (NatureServe 2011). Specimens collected during this survey were classified as *Lampsilis siliquoidea* (*hydiana*) due to morphological features that resemble the Louisiana fatmucket (pers. comm. Kevin Cummings). Additional genetic testing would need to be conducted to correctly determine which species, *Lampsilis siliquoidea* or *Lampsilis hydiana*, exists in the Big Muddy basin.

Discussion

Our survey documented 19 species from the Big Muddy River basin, all were recorded live. No new species were found that had previously been undetected and six species previously detected were not found during our survey. Of these six species, only the plain pocketbook has

been documented as live in the basin. This species was found at three tributaries in the late 1990's to early 2000's; however these streams were not sampled during our survey. These sites would need to be surveyed to determine if this species is still present in the basin. Of the remaining five species not collected, deertoe and creeper have been documented only by relict shell, and the pink heelsplitter, pimpleback, and spike have not been documented since the late 1800's, early 1900's. All of these species were collected from the Big Muddy mainstem. These particular species, except for spike, are widespread and common throughout most of Illinois (Cummings and Mayer 1992) and all of these species are known from other major Mississippi River tributaries including the Rock, Illinois, and Kaskaskia Rivers (INHS Mollusk Collection Database). Sampling the mainstem of the Big Muddy was hindered by non-wadeable water depths; therefore additional sampling by alternative means would need to be conducted to determine if these species have indeed been extirpated from the basin.

Recruitment

Data collected during this survey indicate that very recent recruitment may not be occurring at most (25 of 30) sites in the Big Muddy basin. Only 3 of the 30 sites exhibited high to very high recruitment and 2 other sites had moderate recruitment noted. This finding suggests that most mussel communities of the Big Muddy may not be viable and self-maintaining. Although very few mussels collected during this basin survey fell into the category of 3 age rings or younger, many of them ranged from 4 to 10 years of age. This would indicate that the populations observed in most streams are within the age range thought to be reproductively active (Haag and Staton 2003). Therefore, we cannot conclusively state that the mussel communities of this system are void of recruitment. Recruitment may also be occurring on the Big Muddy mainstem near the Mississippi as nearly all of the dead shells found at site 30 were less than 3 years of age. Sampling methods to target juvenile mussels would be necessary to better assess the reproductive status of these populations.

Mussel community of the Big Muddy River basin

There is limited mussel community information relating to this basin from past surveys and reports. Nearly 90% of the sites sampled had no historical data available (Table 2), and there is no known intensive survey for mussels in this basin. Our surveys documented the existence of 19 species in the Big Muddy River basin from which 25 species were known historically. Additionally, our surveys found that all 19 species were represented by live individuals. Five of the six species not collected during this survey are represented by either relict shell or pre-1930 collections.

Other major Mississippi tributaries such as the Kaskaskia, Rock, and Illinois Rivers have a larger mussel fauna base according to historical records and recent surveys. Historically, these basins

contained 43, 47, and 49 species, respectively, while the Big Muddy has only 25 recorded species (Tiemann et al. 2007). Several theories could be offered on the disparity of species in this basin including the inability to conduct wadeable surveys, challenging diving conditions, lack of river access by vehicle, or the lack of suitable substrate composition for varying species. Substrates such as gravel, cobble, and boulder are practically nonexistent in the Big Muddy basin. As mentioned in the introduction, the substrate of the Big Muddy is predominately impervious clay, silt, and sand. The Big Muddy basin provides suitable substrates for many mussel species such as the giant floater, white heelsplitter, and other Anodontines. However, many species that occur in the other major Mississippi tributaries such as mucket (*Actinonaias ligamentina*), black sandshell (*Ligumia recta*), and threehorn wartyback (*Obliquaria reflexa*) prefer a mixture of substrate types including gravel, sand, and cobble (Cummings and Mayer 1992). Sedimentation and siltation of the streams in this basin may be another factor influencing the lack of these species. These factors are listed as impairments for aquatic life for many mainstem sites on the Big Muddy and several tributaries within the basin (IEPA 2010). With the lack of coarser substrates from the basin both today and historically, it may be safe to assume that many of these species have never existed in the basin. However, this statement cannot be made conclusively, due to a lack in historical information.

Living up to its name, sampling in the Big Muddy basin is challenging at best due to water depths (Big) and high turbidity (Muddy). The Big Muddy mainstem and many of its larger tributaries, such as Beaucoup and Drury Creeks, are not easily surveyed for freshwater mussels, thus it is difficult to accurately determine species richness of the basin. It is possible that the Big Muddy River provides a haven for the recruitment of many mussel species, based on the dead shells less than 3 years of age found at site 30, the nature of its substrates, and the river's connection with the Mississippi River. We are unable to conclusively state that the Big Muddy is serving as a source population for mussel species because of the lack of historical data and difficulty in sampling the basin. Additional sampling, either diving or boating to shallow areas on the lower portion of the mainstem and larger tributaries, would be needed to adequately determine the mussel fauna of this basin.

Table 2. Mussel data for sites sampled during 2009/2010 surveys (Table 1). Numbers in columns are live individuals collected; "D" and "R" indicates dead or relict shells collected. Shaded boxes are historic collections at the specific site location obtained from the INHS Mollusk Collection records. Species in bold are federally or state-listed species or species in Greatest Need of Conservation by IL DNR. Proportion of total is number of individuals of a species divided by total number of individuals at all sites. Extant species is live + dead shell and total species is live + dead + relict shell. NDA represents no historical data available. MCI scores and Resource Classification are based on values in Tables 3 and 4 (R= Restricted, L= Limited, M= Moderate, HV= Highly Valued, and U= Unique).
*Includes *Strophitus undulatus*, *Elliptio dilatata*, *Quadrula pustulosa*, *Lampsilis cardium*, *Potamilus alatus*, and *Truncilla donaciformis*, historical species not collected during this survey.

1-30	3		1	3
>30-50	4		2+	5
>50	5			

Table 4. Freshwater mussel resource categories based on species richness, abundance, and population structure. MCI = Mussel Community Index Score

Unique Resource MCI ≥ 16	Very high species richness (10 + species) &/or abundance (CPUE > 80); intolerant species typically present; recruitment noted for most species
Highly Valued Resource MCI = 12- 15	High species richness (7-9 species) &/or abundance (CPUE 51-80); intolerant species likely present; recruitment noted for several species
Moderate Resource MCI = 8 - 11	Moderate species richness (4-6 species) &/or abundance (CPUE 11-50) typical for stream of given location and order; intolerant species likely not present; recruitment noted for a few species
Limited Resource MCI = 5 - 7	Low species richness (1-3 species) &/or abundance (CPUE 1-10); lack of intolerant species; no evidence of recent recruitment (all individuals old or large for the species)
Restricted Resource MCI = 0 - 4	No live mussels present; only weathered dead, sub-fossil, or no shell material found

IEEFA report: Dim future for Illinois Basin coal

Customer base eroding for domestic and export markets; Regional industry will be gone in 20 years

(https://ieefa.org/wp-content/uploads/2019/12/2019-12-10-IB-mine-map-sample-360x216.jpg)December 10, 2019 (IEEFA U.S.) – The Illinois Coal Basin, one of the most important coal-producing regions in the U.S., will likely see declining production and mine closures as the industry continues to contract in the wake of coal-fired power plant retirements and falling exports, concludes a report published today (https://ieefa.org/wp-content/uploads/2019/12/Dim-Future-for-Illinois-Basin-Coal_December-2019.pdf) by the Institute for Energy Economics and Financial Analysis.

The report, Dim Future for Illinois Basin Coal (https://ieefa.org/wp-content/uploads/2019/12/Dim-Future-for-Illinois-Basin-Coal_December-2019.pdf), details how coal companies in Illinois, Indiana, and Kentucky, which are already facing challenging prospects, will most likely fade away over the next two decades. A significant number of the coal-fired power plants supplied by the three-state Basin are already scheduled to be shut down by utilities while others are being run less and less often, trends that will likely continue.

By 2024, at least 15 U.S. plants that buy Illinois Basin coal will be fully or partially retired

"From the beginning of 2019 through 2024, at least 15 American plants that buy Illinois Basin coal—in Alabama, Florida, Georgia, Indiana, Kentucky, North Carolina and Tennessee—will be fully or partially retired," said Seth Feaster, an IEEFA data analyst and lead author of the report. "That number, which reflects formal announcements by utilities, is likely to grow as the economics of coal-fired generation continue to deteriorate relative to renewables and gas."

"Meanwhile, demand for Illinois Basin coal is shrinking in key overseas markets too, a trend driven by market forces similar to those at work in the U.S.: foreign competition, and increasingly attractive forms of alternative power generation," Feaster said.

THE REPORT OFFERS A COMPANY-BY-COMPANY OVERVIEW OF THE ILLINOIS BASIN COAL INDUSTRY, noting the coal-mining companies that stand to be affected include (in order of production level): Alliance Resource Partners, Murray Energy and its partner Foresight Energy, Peabody Energy, Hallador, Arch Coal and White Stallion.

IEEFA also notes that the rising number of mine idlings or closures in the past year or so by Alliance, Foresight/Murray, and Peabody may be insufficient to match falling demand from power plants or declines in exports in the wake of recent diminishing international market prices.

Report conclusions:

- The Illinois Basin's customer base in the U.S. continues to shrink as utilities move toward other forms of generation.
- Export-market demand is trending downwards and will continue to do so because the same policy and market forces at work in the U.S. are also transforming power-generation business models in other countries and regions.
- More Illinois Basin mines will close in the months and years ahead as the coal industry continues its structural and permanent decline.
- Communities and areas that prepare for and are proactive in embracing the energy transition will fare best.

THE REPORT URGES POLICYMAKERS IN ILLINOIS, INDIANA AND KENTUCKY TO PREPARE FOR IMPACTS on industry workers and local households, community tax bases, businesses and the regional economy as a whole, as well as provide leadership and sound policy initiatives to take advantage of the changes that are taking place in the energy industry.

Full report: Dim Future for Illinois Basin Coal: Market Forces and Shifting Preferences Are Eroding Customer Base Domestically and Abroad (https://ieefa.org/wp-content/uploads/2019/12/Dim-Future-for-Illinois-Basin-Coal_December-2019.pdf)

Commercial Fishing in the Big Muddy River Memo
Prepared by PRN and SC
Information from the IDNR Division of Fisheries Annual Commercial Catch Reports (obtained via FOIA) for 2013 through 2018 (2017 most recent compilation provided)

Reported number of full-time and part-time commercial fishermen actively engaged in commercial fishing in the following years:

YEAR	Full-Time	Part-Time	Big Muddy River Reported Catch in Pounds
2013		3	11,179
2014	1	3	9,737
2015		2	7,210
2016		1	10,382
		*13	*4,983
2017		6	14,720
		*18	*8,884

*New Category of Recreational commercial fishermen actively engaged in commercial fishing

A BLUEPRINT FOR CHANGE

SHARING THE CHALLENGE:
FLOODPLAIN MANAGEMENT INTO THE 21ST CENTURY

Report of the Interagency Floodplain Management Review Committee
To the Administration Floodplain Management Task Force

THE FLOOD

Then God, our Lord, hindered the work with a mighty flood of the great river, which at that time -- about the eighth or tenth of March [of 1543] -- began to come down with an enormous increase of water: Which in the beginning overflowed the wide level ground between the river and cliffs; then little by little it rose to the top of the cliffs. Soon it began to flow over the fields in an immense flood, and as the land was level without any hills there was nothing to stop the inundation.

...The flood was 40 days in reaching its greatest height, which was the 20th of April, and it was a beautiful thing to look upon the sea where there had been fields, for on each side of the river the water extended over twenty leagues of land, and all this area was navigated by canoes, and nothing was seen but the top of the tallest trees...

...By the end of May the river had returned within its banks.

Garciliaso de la Vega describing the DeSoto Expedition
On the banks of the Mississippi River near Tunica, Mississippi
History of Hernando DeSoto, Lisbon, 1605

EXECUTIVE OFFICE OF THE PRESIDENT
INTERAGENCY FLOODPLAIN MANAGEMENT REVIEW COMMITTEE
WASHINGTON, D.C. 20503

June 30, 1994

TO: The Administration Floodplain Management Task Force
T. J. Glauthier, Associate Director, Office of Management and Budget
Kathleen McGinty, Director, White House Office of Environmental Policy
James R. Lyons, Assistant Secretary of Agriculture for Natural Resources

SUBJECT: Final Report

Forwarded herewith for your consideration is, *Sharing the Challenge: Floodplain Management into the 21st Century,* the final report of the Interagency floodplain Management Review Committee.

In January 1994 you assigned the Review Committee the mission to delineate the major causes and consequences of the 1993 Midwest flooding; to evaluate the performance of existing floodplain management and related watershed management programs. The Review Committee also was to make recommendations to the Task Force on changes in current policies, programs, and activities of the federal government that most effectively would achieve risk reduction, economic efficiency, and environmental enhancement in the floodplain and related watersheds.

The report provides the Review Committee's findings and recommendations for action. The thesis of the report is straightforward. Floods will continue to occur. The goals for floodplain management are clear. The means to carry out effective floodplain management exist today but need improvement and refocusing. It is now time to organize a national effort to conduct effective and efficient floodplain management. It is time to share responsibility and accountability for accomplishing floodplain management among all levels of government and with the citizens of the nation.

I would emphasize that the report represents the views of the Review Committee and is based on its research and interactions with federal, state and local officials, businesses, interest groups, and individuals in and outside the upper Mississippi River Basin. It does not necessarily represent the views of the agencies represented on the Review Committee or the views of the Administration. It is now up to the Administration to determine which of the recommendations and actions should be implemented on what schedule.

The Review Committee appreciates the support and guidance that you provided over the past six months as well as the opportunity to participate in such an interesting and important endeavor.

Gerald E. Galloway
Brigadier General, U.S. Army
Executive Director

Thanks

The Review Committee acknowledges with deep appreciation the assistance and thoughtful advice received from many federal, state, and local agencies, organizations, and individuals contacted during the course of this review. The collective wisdom, insights and experiences of these many people provided the Review Committee with an understanding of the problems and challenges of both living in and managing the floodplain. The Review Committee owes a debt of gratitude to those who set up and facilitated the public outreach sessions and the visits to flood affected areas. There will never be a substitute for seeing the problem area or talking to someone who has been through a flood.

Far too many people contributed to the effort to name them all individually. Because of their special contributions, however, the Review Committee would like to give special thanks to several groups and individuals. The leadership of the Administration Floodplain Management Task Force -- T. J. Glauthier, Associate Director, Office of Management and Budget; Kathleen McGinty Director, White House Office for Environmental Policy; James R. Lyons, Assistant Secretary of Agriculture for Natural Resources -- gave the Committee its charge and guided it along its path. Kathryn Way, White House Domestic Policy Council assisted in coordinating efforts with the states. Bruce Long, OMB, and Will Stelle, White House Office for Environmental Policy provided both expertise and day-to-day shepherding of committee activities, Mark Schaefer, White House Office of Science and Technology Policy, assisted with SAST. Ray Clark, Patti Leppert-Slack and Kathleen Gallagher, Council on Environmental Quality, provided substantive insights and moral and administrative support. The White House Council of Economic Advisors sponsored Economics Advisory Group with Erik Lichtenberg, Chair; Jon Goldstein, USFWS; Jim Schaub, USDA; Peter Kuch, EPA; Robert Stearns, Department of the Army; and Norm Starler, OMB, served as an invaluable sounding board. Margaret Siegel, the National Governors Association, facilitated contacts with the flood-affected and other interested states. Connie Hunt, the World Wildlife Fund, sponsored three in-basin workshops on use of the floodplain. Chris Brescia, MARC 2000, facilitated access to the agriculture and river communities. W. H. Klingner and John Rob, Upper Mississippi Flood Control Association, provided entry to the many levee and drainage districts of the basin. Tom Waters, the Missouri Levee and Drainage District Association, offered a steady stream of information about the Missouri River levee situation. The Universities Council on Water Resources, Duane Baumann, gathered a team of distinguished academicians -- Ray Burby, Shirley Laska, Luna Leopold, Mary Fran Myers, Leonard Shabman, and Gilbert White -- to provide their views on floodplain management. Doug Plasencia and Larry Larson, Association of State Floodplain Managers, and Jon Kusler, Association of State Wetland Managers, shared their experiences and opened their files and their membership to the Review Committee. The nine flood state governors and their representatives facilitated and guided the Committee's extensive contacts within the states: Al Grosoboll, Don Vonnahme and Marueen Cracker, Illinois; General Harold (Tommy) Thompson and LTC Tom Tucker, Iowa; Cindy Luxem, Kansas; Todd Johnson and Jim Franklin, Minnesota; Jerry Uhlman and Jill Friedman, Missoui; Dayle Williamson and Brian Dunnigan, Nebraska; Dave Sprynczynatyk and Jeff Klein, North Dakota; Gary Whitney, South Dakota; Lee Conner and Diane Kleiboer, Wisconsin. Holly Stoerker, Upper Mississippi River Basin

Association, and Richard Oppek, Missouri River Basin Association invited the Review Committee to participate in the meetings of the Associations and shared their years of experience.

Throughout the study process, the Review Committee benefited from the advice and information provided by many members of Congress, by their staff members, and by the key committee staffs.

The Review Committee would also like to thank the many Washington and basin based organizations that provided assistance and advice, especially the American Farm Bureau Federation, the American Society of Civil Engineers, the Association of State Flood and Stormwater Managers, the Association of American State Geologists, the Environmental Defense Fund, the Illinois Farm Bureau Federation, the McKnight Foundation, the National Association of Conservation Districts, the National Corn Growers Association, the National Waterways Conference, the National Wildlife Federation, the Natural Disaster Coalition, the Nature Conservancy, and the Sierra Club.

The individuals within federal agencies who served as advisors on agency activities and as focal points to facilitate information exchange with the Review Committee deserve special note: Army, John Zirschky; DOI, Michelle Altemus and Russ Earnest; USDA, Tom Hebert, Oleta Fitzgerald, and Eric Olsen; EPA, Dick Sanderson and David Davis; FEMA, Dick Moore, Dick Krimm, Jane Bullock, Morrie Goodman, and Martha Braddock; HHS, RADM Frank Young; HUD, Truman Goins; DOT, Susan Gaskins; DOL, Ed Flynn; NWS, Eugene Stallings; and USACE, MG Stan Genega, Hugh Wright, and Jerry Peterson.

During the preparation of any report, invaluable assistance is provided by the individuals who go beyond 'the call of duty.' The Review Committee would like to extend its thanks to Paul Alberti, Don Barnes, Whalen Blair, Patti Cogdell, Gary Dyhouse, Mary Lou East, Brian Hyde, George Johnson, Jim Kazel, Stuart Kasden, John Kerr, David Lawson, Andy Manale, Kermit Mann, David May, John McShane, Jeanne Melanson, Mark Merritt, Matt Miller, Marty Reuss, Kyle Schilling, Josephine Scott, Eugene Stakhiv, Kevin Tonat, Nancy Yeager, Chet Worm, Larry Zensinger, and Don Zochi.

Thanks are due to the National Park Service, the USACE, the USDA and the Missouri Department of Conservation for the photographs used in the report.

Wile the above groups and individuals have provided much valuable advice, the Review Committee bears sole responsibility for all views expressed in this report.

SHARING THE CHALLENGE: FLOODPLAIN MANAGEMENT INTO THE 21ST CENTURY

The Report of the Interagency Floodplain Management Review Committee

ABSTRACT

June 1994

The Midwest Flood of 1993 was a significant hydrometeorological event. In some areas it represented an unusual event; in most others, however, it was just another of the many that have been seen before and will be seen again. Flood flows similar to those experienced by most of the Midwest can occur at any time. During the decade ending in 1993, average annual flood damages in the United States exceed $3 billion. Flood damages are not a national problem.

Excessive rainfall, which produced standing water, saturated soils, and overland flow, caused major damages to upland agriculture and some communities. In turn, runoff from this rainfall created, throughout the basin, flood events that became a part of the nation's 1993 TV experience. Damages overall were extensive: between $12 billion and $16 billion that can be counted, and a large amount in unquantifiable impacts on the health and well-being of the population of the Midwest.

Human activities in the floodplains of the Midwest over the last three centuries have placed people and property at risk. Local and federal flood damage reduction projects were constructed to minimize the annual risk, and, during the 1993 flood, prevented nearly $20 billion in damages. Some of these programs, however, attracted people to high risk areas and created greater exposure to future damages. In addition, flood control, navigation, and agricultural activities severely reduced available floodplain habitat and compromised natural functions upon which fish and wildlife rely.

Over the last 30 years the nation has learned that effective floodplain management can reduce vulnerability to damages and create a balance among natural and human uses of floodplains and their related watersheds to meet both social and environmental goals. The nation, however, has not taken full advantage of this knowledge. The United States simply has lacked the focus and incentive to engage itself seriously in floodplain management. The 1993 flood has managed to focus attention on the floodplain and has provided the incentive for action.

The Interagency Floodplain Management Review Committee proposes a better way to manage the floodplains. It begins by establishing that all levels of government, all businesses and all citizens have a stake in properly managing the floodplain. All of those who support risky behavior, either directly or indirectly, must share in floodplain management and in the costs of reducing that risk. The federal government can lead by example; but state and local governments must manage their own floodplains. Individual citizens must adjust their actions to the risk they face and bear a greater share of the economic costs.

The Review Committee supports a floodplain management strategy of, sequentially, avoiding inappropriate use of the floodplain, minimizing vulnerability to damage through both structural and nonstructural means, and mitigating flood damages when they do occur.

By controlling runoff, managing ecosystems for all their benefits, planning the use of the land and identifying those areas at risk; many hazards can be avoided. Where the risk cannot be avoided, damage minimization approaches, such as elevation and relocation of buildings or construction of reservoirs or flood protection structures, are used only when they can be integrated into a systems approach to flood damage reduction in the basin. When floods occur, impacts on individuals and communities can be mitigated with a flood insurance program that is funded by those who are protected. Full disaster support for those in the floodplain is contingent on their participation in these self-help mitigation programs. Measures that internalize risks reduce the moral hazard associated with full government support.

To ensure a long-term, nationwide approach to floodplain management, the Review Committee proposes legislation

to develop and fund a national Floodplain Management Program with principal responsibility and accountability at the state level. It also proposes revitalization of the federal Water Resources Council to better coordinate federal activities, limited restoration of some basin commissions for basin-wide planning, and issuance of a Presidential Executive Order requiring federal agencies to follow floodplain management principles in the execution of their programs.

The upper Mississippi River Basin includes both individually authorized federal flood damage reduction projects and levees built by local groups and individuals. This pattern of development is unique and requires a unique approach. The Review Committee proposes a plan to identify and evaluate the needs of the basin, to ensure the integrity of a flood damage reduction system that meets the needs of the basin, and to restore natural floodplain functions on appropriate lands.

The nation knows where to go with floodplain management and how to get there. This report provides a map showing the shortest route to success. The nation now must take the actions required to do so.

REPORT OF THE INTERAGENCY FLOODPLAIN MANAGEMENT REVIEW COMMITTEE
to the
ADMINISTRATION FLOODPLAIN MANAGEMENT TASK FORCE

EXECUTIVE SUMMARY

The time has come to fact the fact that this Nation can no longer afford the high costs of natural disasters. We can no longer afford the economic costs to the American taxpayer, nor can we afford the social costs to our communities and individuals.

James L. Witt
Director, Federal Emergency Management Agency
Testimony before Congress, October 27, 1993

FLOODPLAINS AND THE NATION

The upper Mississippi and Missouri rivers and their tributaries have played a major role in the nation's history. Their existence was critical to the growth of the upper Midwest region of the United States and fostered the development of major cities and a transportation network linking the region to the rest of the world. The floodplains of these rivers provide some of the most productive farmland in the country. They offer diverse recreational opportunities and contain important ecological systems. While development of the region has produced significant benefits, it has not always been conducted in a wise manner. As a result, today the nation faces three major problems:

First, as the Midwest Flood of 1993 has shown, people and property remain at risk, not only in the floodplains of the upper Mississippi River Basin, but also throughout the nation. Many of those at risk do not fully understand the nature and the potential consequences of that risk; nor do they share fully in the fiscal implications of bearing that risk.

Second, only in recent years has the nation come to appreciate fully the significance of the fragile ecosystems of the upper Mississippi River Basin. Given the tremendous loss of habitat over the last two centuries, many suggest that the nation now face severe ecological consequences.

Third, the division of responsibilities for floodplain management among federal, state, tribal and local governments needs clear definition. Currently, attention to floodplain management varies widely among and within federal, state, tribal and local governments.

The Interagency Floodplain Management Review Committee proposes a better way to manage the nation's floodplains. This report not only describes the nature and extent of the 1993 flooding and government efforts to cope with the event but also presents a blueprint for change.

This blueprint is directed at both the upper Mississippi River Basin and the nation as a whole. Its foundation is a sharing of responsibilities and accountability among all levels of the government, business, and private citizens. It provides for a balance among the many competing uses of the rivers and their floodplains; it recognizes, however, that all existing activities in the floodplain simply cannot be discarded as inappropriate. Implementing this approach, the Review Committee believes, will bring about changes necessary to reduce flood vulnerability to both the infrequent major flood events and the more frequent smaller ones. Implementation also will reduce the environmental, social, and economic burdens imposed by current conditions on both public and private sectors.

SHARING THE CHALLENGE - FEDERAL, STATE, TRIBAL AND LOCAL GOVERNMENTS, BUSINESSES, CITIZENS

Since passage of the Flood Control Act of 1936, the federal government has dominated the nation's flood damage reduction efforts and as a result, the nation's floodplain management activity. Structural programs were deemed important and were also the principal sources of funds for any efforts to stem the rising tide of flood losses. In recent years, the federal government has begun to support nonstructural approaches. Many states, tribes, and local governments have developed and carried out floodplain management efforts that both reduced flood damages and enhanced the natural functions of floodplains. In carrying out these programs, however, they have been hampered by uncoordinated and conflicting federal programs, policies, regulations and guidelines that have hindered efficient floodplain management. Some state and local governments have not been as active in floodplain management. With the federal government assuming the dominant role and funding most ecosystem restoration, flood damage reduction, and flood recovery activities, the incentive has been limited for many state, tribal and local governments, businesses, and private citizens to share responsibility for making wise decisions concerning floodplain activity. Now is the time to:

- Share responsibility and accountability for accomplishing floodplain management among all levels government and with all citizens of the nation. The federal government cannot go it alone nor should it take a dominant role in the process.

- Establish, as goals for the future, the reduction of the vulnerability of the nation to the dangers and damages that result from floods and the concurrent and integrated preservation and enhancement of the natural resources and functions of floodplains. Such an approach seeks to avoid unwise use of the floodplain, to minimize vulnerability when floodplains must be used, and to mitigate damages when they do occur.

- Organize federal programs to provide the support and the tools necessary for all levels of government to carry out and participate in effective floodplain management.

COMMITTEE FINDINGS:

In conducting the review, the Committee divided its findings into two areas; the Midwest Flood of 1993, and Federal, State, Tribal, and Local Floodplain Management.

The Midwest Flood of 1993

In reviewing the Midwest Flood of 1993, the Committee found that:

- The Midwest Flood of 1993 was a hydrometeorological event unprecedented in recent times. It was caused by excessive rainfall that occurred throughout a significant section of the upper Mississippi River Basin. The damaging impacts of this rainfall and

related runoff were felt both in upland areas and in the floodplains. Pre-flood rainfall saturated the ground and swelled tributary rivers. Subsequent rains quickly filled surface areas, forcing runoff into the lower lands and creating flood conditions. The recurrence interval of the flood ranged from less than 100 years at many locations to near 500 years on segments of the Mississippi River from Keithsburg, Illinois, to above St. Louis, Missouri, and on segments of the Missouri River from Rulo, Nebraska, to above Hermann, Missouri. At 45 U.S. Geological Survey (USGS) gaging stations, the flow levels exceeded the 100-year mark. The duration of the flood added to its significance. Many areas were under water for months.

- Rainfall and floods like the 1993 event will continue to occur. Floods are natural repetitive phenomena. Considering the nation's short history of hydrologic record-keeping as well as the limited knowledge of long-term weather patterns, flood recurrence intervals are difficult to predict. Activities in the floodplain, even with levee protection, continue to remain at risk.

- The loss of the wetlands and upland cover and the modification of the landscape throughout the basin over the last century and a half significantly increased runoff. Most losses occurred prior to 1930, but some are related to more recent drainage, flood damage reduction, and navigation development. Although upland watershed treatment and restoration of upland and bottomland wetlands can reduce flood stages in more frequent floods (25 years and less) it is questionable whether they would have significantly altered the 1993 conditions.

- Human activity throughout the basin has caused significant loss of habitat and ecosystem diversity. Flood damage reduction and navigation works and land uses practices have altered bottomland habitat adversely.

- The costs to the nation from the flood were extensive. Thirty-eight deaths can be attributed directly to the flood and estimates of fiscal damages range from $12 billion to 16 billion. Agriculture accounted for over half of the damages. More than 70 percent of the crop disaster assistance payments were made to counties in upland areas where ground saturation prevented planting or killed the crop. Nearly 50 percent of the approximately 100,000 homes damaged, suffered losses due to groundwater or sewer backup as opposed to riverine flooding. Flood response and recovery operations cost the nation more than $6 billion. In addition many costs can not yet be quantified. Impacts on businesses in out of the basin have not been calculated. Tax losses to governments are unknown. The impacts of the flood on the population's physical and mental well-being are just being identified and are of concern.

- Flood damage reduction projects and floodplain management programs, where implemented, worked essentially as designed and significantly reduced the damages to population centers, agriculture, and industry. It is estimated that reservoirs and levees built by the U.S. Army Corps of Engineers (USACE), prevented more than $19 billion in potential damages. Large areas of Kansas City and St. Louis were spared the ravages of flood, although several suburbs suffered heavy damages. Watershed projects built by the Soil Conservation Service saved an estimated additional $400 million. Land use controls required by the National Flood Insurance Program (NFIP) and state floodplain management programs reduced the number of structures at risk throughout the basin.

- Many locally constructed levees breached and/or overtopped. Frequently, these events resulted in considerable damage to the land behind the levees through scour and deposition.

- Flooding during the 1993 event would have covered much of the floodplains of the main stem lower Missouri and upper Mississippi rivers whether or not levees were there. Levees can cause problems in some critical reaches by backing water up on other levees or lowlands. Locks and dams and other navigation related structures did not raise flood heights. For more frequent floods -- less flow -- navigation dikes may cause some minor increase in flood heights.

Federal, State, Tribal and Local Floodplain Management

The Review Committee examined the structure of current federal programs, relationships among federal, state, tribal and local governments, the performance of various programs during and after the flood, and the after action reports stemming from these activities. The Review Committee reached the following conclusions:

- The division of responsibilities floodplain management activities among and between federal, state, tribal, and local governments needs to be clearly defined. Within the federal system, water resources activities in general flood and floodplain management in particular need better coordination. State and local governments must have a fiscal stake in floodplain management; without this stake, few incentives exist for them to be fully involved in floodplain management. State governments must assist local governments in dealing with federal programs. The federal government must set the example in floodplain management activities.

- The National Flood Insurance Program (NFIP) needs improvement. Penetration of flood insurance into the target market -- floodplain occupants -- is very low, 20-30 percent. Communities choosing not to participate in the NFIP continue to receive substantial disaster assistance. Provision of major federal disaster assistance to those without insurance creates a perception with many floodplain residents that purchase of flood insurance is not a worthwhile investment. The mapping program is underfunded and needs greater accuracy and coverage. Some requirements within the program that vary from disaster to disaster need stabilization.

- The principal federal water resources planning document, *Principles and Guidelines,* is outdated and does not reflect a balance among the economic, social, and environmental goals of the nation. This lack of balance is exacerbated by a present inability to quantify, in monetary terms, some environmental and social impacts. As result, these impacts are frequently understated or omitted. Many critics of *Principles and Guidelines* see it as biased against nonstructural approaches.

- Existing federal programs designed to protect and enhance the floodplain and watershed environment are not as effective as they should be. They lack support, flexibility and funding, and are not well coordinated. As a result, progress in habitat improvement is slow.

- Federal pre-disaster, response, recovery and mitigation programs need streamlining but are making marked progress. The nation clearly recognized the aggressive and caring response of the government to the needs of flood victims, but coordination problems that developed need to be addressed. Buyouts of floodprone homes and damaged lands make considerable inroads in reducing future flood losses.

- The nation needs a coordinated strategy for effective management of the water resources of the upper Mississippi River Basin. Responsibility for integrated navigation, flood damage reduction and ecosystem management is divided among several federal programs.

- The current flood damage reduction system in the upper Mississippi River Basin represents a loose aggregation of federal, local, and individual levees and reservoirs. This aggregation does not ensure the desired reduction in the vulnerability of floodplain activities to damages. Many levees are poorly sited and will fail again in the future. Without change in current federal programs, source of these levees will remain eligible for post-disaster support. Levee restoration programs need greater flexibility to provide for concurrent environmental restoration.

- The nation is not using science and technology to full advantage in gathering and disseminating critical water resources management information. Opportunities exist to provide information needed to better plan the use of the floodplain and to operate during crisis conditions.

COMMITTEE RECOMMENDATIONS

The Review Committee developed recommendations in consonance with the proposed goals:

- To ensure that the floodplain management effort is organized for success, the President should:

  Propose enactment of a Floodplain Management Act which establishes a national model for floodplain management, clearly delineates federal, state, tribal, and local responsibilities, provides fiscal support for state and local floodplain management activities, and recognizes states as the nation's principal floodplain managers;

  Issue a revised Executive Order clearly defining the responsibility of federal agencies to exercise sound judgement in floodplain activities; and

  Activate the Water Resources Council to coordinate federal and federal-state-tribal activities in water resources; as appropriate, reestablish basin commissions to provide a forum for federal-state-tribal coordination on regional issues.

- To focus attention on comprehensive evaluation of all federal water project and program effects, the President should immediately establish environmental quality and national economic development as co-equal objectives of planning conducted under the *Principles and Guidelines*. *Principles and Guidelines* should be revised to accommodate the new objectives and to ensure full consideration of nonstructural alternatives.

- To enhance coordination of project development, to address multiple objective planning, and to increase customer service, the Administration should support collaborative efforts among federal agencies and across state, tribal, and local governments.

- To ensure continuing state, tribal and local interest in floodplain management success, the Administration should provide for federal, state, tribal, and/or local cost-sharing in pre-disaster, recovery, response, and mitigation activities.

- To provide for coordination of the multiple federal programs dealing with watershed management, the Administration should establish an Interagency Task Force to develop a coordination strategy to guide these actions.

- To take full advantage of existing federal programs which enhance the floodplain environment and provide for natural storage in bottomlands and uplands, the Administration should:

  Seek legislative authority to increase post-disaster flexibility in the execution of the land acquisition programs;

  Increase environmental attention in federal operation and maintenance and disaster recovery activities;

  Better coordinate the environmentally-related land interest acquisition activities of the federal government; and

  Fund, through existing authorities, programmatic acquisition of needed lands from willing sellers.

- To enhance the efficiency and effectiveness of the National Flood Insurance Program, the Administration should:

  Take vigorous steps to improve the marketing of flood insurance, enforce lender compliance rules, and seek state support of insurance marketing;

  Reduce the amount of post-disaster support to those who were eligible to buy insurance but did not to that level needed to provide for immediate health, safety, and welfare; provide a safety net for low income flood victims who were unable to afford flood insurance;

  Reduce repetitive loss outlays by adding a surcharge to flood insurance policies following each claim under a policy, providing for mitigation insurance riders, and supporting other mitigation activities;

Require those who are behind levees that provide protection against less than the standard project flood discharge to purchase actuarially based insurance;

Increase the waiting period for activation of flood insurance policies from 5 to 15 days to avoid purchases when flooding is imminent;

Leverage technology to improve the timeliness, coverage, and accuracy of flood insurance maps; support map development by levies on the policy base and from appropriated funds because the general taxpayer benefits from this program; and

Provide for the purchase of mitigation insurance to cover the cost of elevating, demolishing, or relocating substantially damaged buildings.

- To reduce the vulnerability to flood damages of those in the floodplain, the Administration should:

Give full consideration to all possible alternatives for vulnerability reduction, including permanent evacuation of floodprone areas, flood warning, floodproofing of structures remaining in the floodplain, creation of additional natural and artificial storage, and adequately sized and maintained levees and other structures;

Adopt flood damage reduction guidelines based on a revised *Principles and Guidelines* which would give full weight to social, economic, and environmental values and assure that all vulnerability reduction alternatives are given equal consideration; and

Where appropriate, reduce the vulnerability of population centers and critical infrastructure to the standard project flood discharge through use of floodplain management activities and programs.

- To ensure that existing federally constructed water resources projects continue to meet their intended purposes and are reflective of current national social and environmental goals, the Administration should require periodic review of completed projects.

- To provide for efficiency in operations and for consistency of standards, the Administration should assign principal responsibility for repair, rehabilitation, and construction of levees under federal programs to the U.S. Army Corps of Engineers.

- To ensure the integrity of levee and the environmental and hydraulic efficiencies of the floodplain, states and tribes should ensure proper siting, construction, and maintenance of non-federal levees.

- To capitalize on the successes in federal, state, tribal, and local pre-disaster, response, recovery, and mitigation efforts during and following the 1993 flood and to Streamline future efforts, the Administration should:

Through the NFIP Community Rating System encourage states and communities to develop and implement floodplain management and hazard mitigation plans;

Provide funding for programmatic buyouts of Structures at risk in the floodplain;

Provide states the option of receiving Section 404 Hazard Mitigation Grants as block grants;

Assign the Director of the Federal Emergency Management Agency responsibility for integrating federal disaster response and recovery operations; and

Encourage federal agencies to use non-disaster funding to support hazard mitigation activities on a routine basis.

- To provide integrated, hydrologic, hydraulic, and ecosystems management of the upper Mississippi River basin, the Administration should:

Establish upper Mississippi River Basin and Missouri River Basin commissions to deal with basin-level program coordination;

Assign responsibility, in consultation with the Congress, to the Mississippi River Commission (MRC), for integrated management of flood damage reduction, ecosystem management, and navigation on the upper Mississippi River and

tributaries; expand MRC membership to include representation from the Department of the Interior; assign MRC responsibility for development of a plan to provide long-term control an maintenance of sound federally built and federally supported levees along the main stems of Mississippi and Missouri rivers; this support would be contingent on meeting appropriate engineering, environmental, and social standards.

Seek authorization from the Congress to establish an Upper Mississippi River and Tributaries project for management of the federal flood damage reduction and navigation activities in the upper Mississippi River Basin;

Establish the upper Mississippi River Basin as an additional national cross-agency Ecosystem Management Demonstration Project; and Charge the Department of the Interior with conducting an ecosystem needs analysis of the upper Mississippi River Basin.

- To provide timely gathering and dissemination of the critical water resources information needed for floodplain management and disaster operations, the Administration should:

Establish an information clearing house at USGS to provide federal agencies and state and local activities the information already gathered by the federal government during and following the 1993 flood and to build on the pioneering nature of this effort; and

Exploit science and technology to support monitoring, analysis, modeling, and the development of decision support systems and geographic information systems for floodplain activities.

STRUCTURE OF THE REVIEW

Throughout the spring, summer, and fall of 1993, the people of the United States were faced each night with pictures of the devastation brought on the midwestern United States by the Great Flood of 1993. For nearly six decades, the nation had labored to reduce the impacts of floods, yet the toll in lives lost, homes damaged, and property destroyed was enormous. Why had this happened? What caused the flood? Had human intervention over time exacerbated the situation? What should the nation be doing to prevent a repetition? To answer these questions, the Administration Floodplain Management Task Force, part of the Administration Flood Recovery Task Force headed by Secretary of Agriculture Mike Espy, established the Interagency Floodplain Management Review Committee, a group of 31 professionals assigned to federal agencies with responsibilities in the water resources arena.

The Review Committee conducted its activity from January through June 1994 in Washington and throughout the Midwest. Working through the offices of the governors of the nine flood-affected states, the Review Committee met with state and local officials and visited over 60 locations. The Review Committee also made extensive contacts with federal agencies, interest groups, members of Congress and their staffs and numerous private citizens who expressed an interest in the flood. A part of the Review Committee, the Scientific Assessment and Strategy Team, chartered in November 1993 by the White House, conducted its activities at the EROS Data Center in Sioux Falls, South Dakota, where it developed a major database of flood and basin information.

The report of the Review Committee includes an action plan delineating proposed responsibilities and timelines for execution of the recommendations, a fiscal impact statement, and the preliminary report of the Scientific Assessment and Strategy Team.

INTRODUCTION

The time has come to face the fact that this Nation can no longer afford the high costs of natural disaster. We can no longer afford the economic costs to the American taxpayer, nor can we afford the social costs to our communities and individuals.

James L. Witt
Director, Federal Emergency Management Agency
Testimony before Congress, October 27, 1993

Throughout the spring, summer, and fall of 1993, the people of the United State were faced with pictures of the devastation wrought on the Midwest by what became know as "The Great Flood of 1993." For nearly six decades, the nation had labored to reduce the impacts of floods, yet within a few months tens of thousands of homes were damaged, and the lives of hundreds of thousands of Americans disrupted. Acre upon acre of some of the nation's richest farmland lay fallow. Why did this happen? What caused the flood? Did human intervention over the years exacerbate the situation? What should the nation be doing to prevent a repetition of the 1993 event? The Administration Floodplain Management Task Force, a part of the Clinton Administration's flood Recovery Task Force, headed by Secretary of Agriculture Mike Espy, established the Interagency Floodplain Management Review Committee to seek answers to these questions and to make recommendations.

The charter of the Review Committee (see Appendix A) assigns it the mission to:

- Delineate the major causes and consequences of the 1993 flooding;

- Evaluate the performance of existing floodplain management and related watershed management programs; and

- Make recommendations to the Task force on changes in current policies, programs, and activities of the federal government that would most effectively achieve risk reduction, economic efficiency, and environmental enhancement in the floodplain and related watersheds.

The Review Committee consisted of federal engineers and physical, social, and biological scientists who contributed technical and institutional knowledge in the fields of flood damage-reduction and river basin ecosystem management. Of the 31 -member Review Committee, 15 members were located in Washington, D.C., and 16 formed the Scientific Assessment and Strategy Team (SAST), which operated from the Earth Resource Observation System (EROS) center at Sioux Falls, South Dakota. The SAST was chartered by the White House in November 1993 "to provide scientific advice and assistance to officials responsible for making decisions with respect to flood recovery in the upper Mississippi River Basin." It was incorporated into the Review Committee in January 1994 to serve as its research arm for scientific analysis. For a full listing of Review Committee members and their parent agencies, see Appendix B.

The Review Committee began its work in January 1994, focusing on federal agency briefings and consultations with other levels of government to gain a better understanding of the complex intergovernmental system of

WHAT IS A FLOODPLAIN?

Floodplains are the relatively low and periodically inundated areas adjacent to rivers, lakes, and oceans. Floodplain lands and adjacent waters combine to form a complex, dynamic physical and biological system that supports a multitude of water resources, living resources, water filtering processes, a wide variety of habitats for flora and fauna, places for recreation and scientific study, and historic and archeological sites. They are also the locus of a variety of human activities, including commerce, agriculture, residence, and infrastructure.

Estimates of the extent of the nation's floodplains vary according to the areas measured. In 1977 the U.S. Water Resources Council estimated that floodplains comprise about 7 percent, or 178.8 million acres of the total area of the United States and its territories.

During the 1993 flood, floodplains along the upper Mississippi and Missouri Rivers became part of the rivers when they were inundated by river stages exceeding channel capacity or the design elevations of flood-control levees or when the levees failed or overtopped.

Adapted, in part, from the draft 1994 Unified National Program for Floodplain Management

responsibilities and decision making in floodplain management. This initial effort was followed by discussions in the nine Midwest states most affected by the flood. Review Committee members met with the governors and their representatives, state flood recovery and mitigation task forces, staffs or relevant congressional committees, staffs of congressional members from the flood states, and interest groups at the national, regional, and local level. In March the Review Committee shifted its focus to outreach visits in the Midwest communities and areas affected by the flood. During this phase of review, the Review Committee visited over 60 communities where county, city, and other local officials and citizens assembled to provide information and insights. The Review committee asked those contacted to share their candid opinions about the best use of flood hazard areas, their visions of the future, and how that vision was changed by the 1993 flood. They were asked about hazard mitigation, floodplain management, and the emergency response plans of the flood-affected communities, with particular regard to whether such plans were useful during or after the flood. All were asked to critique the strengths and weaknesses of federal programs and policies as presently structured, and to discuss what federal and state roles should be in long-term management of floodplains.

Throughout the review process, a steady stream of letters arrived from organizations, interest groups, state and local officials, and from individuals offering information, personal viewpoints, and advice, all of which the Review Committee greatly appreciated.

Following visits to the Midwest, the Review Committee formulated an array of floodplain management options, briefs of which were presented to the Administration Floodplain Management Task force, congressional interests, federal agencies, state officials, and interest groups. Meetings to review the options were held in Washington, D.C.; Kansas City, Missouri; Springfield, Illinois; and Minneapolis, Minneapolis, Minnesota. The Review Committee then developed its recommendations.

FLOODPLAIN MANAGEMENT

Floodplain management is a decision making process whose goal is to achieve appropriate use of the nation's floodplains. Appropriate use is any activity or set of activities compatible with the risk to natural resources (natural and beneficial functions of floodplains) and human resources (life and property).

The history of the nation's floodplain activity is as old as the nation itself and is well chronicled in *An Assessment Report: Floodplain Management in the United States,* prepared in 1992 for the Federal Interagency Floodplain Management Task Force

GOOD NEWS

Although the flood of 1993 ultimately caused major damages throughout the upper Mississippi river basin, many elements of structural and nonstructural flood damage reduction systems put in place by federal, state, and local governments over the years did work and prevented billions of dollars in damages.

During the flood the outreach from all over the country and the world to those suffering the effects of the flooding was most impressive. Thousands filled and stacked sandbags to hold weakening levees; others worked day after day to help clean the homes and businesses of people they had never met. Dry communities adopted those in need. Contributions to assist flood victims poured in from people in many nations. Federal, state, and local disaster teams worked around the clock, month after month, to Mitigate damages and suffering. Those who were recipients of this assistance will never forget this demonstration of true caring. While the Review Committee report will not address all of these successes, they should not be forgotten.

SHARING THE CHALLENGE

Today the nation faces three major problems in floodplain management:

- As the Midwest Flood of 1993 has shown, people and property remain at risk, not only in the floodplains of the upper Mississippi River Basin but also throughout the nation. Many of those at risk neither fully understand the nature and the potential consequences of that risk nor share fully in the fiscal implications of bearing that risk. Over the last thirty years, average annual riverine flood damages have exceeded $2 billion. Over the last ten, they have been over $3 billion. Between 1988 and 1992, the Federal Emergency Management Agency has expended nearly $200 million each year in flood recovery activities.

- Only in recent years has the nation come to appreciate fully the significance of the fragile ecosystems of the upper Mississippi River Basin. Given the tremendous loss of habitat over the last two centuries, many suggest that we now face severe ecological consequences.

A lot of great things have been done that prevented damages and mitigated the damages that did occur... we can't lose sight of this.

Terry Brandstad
Governor Of Iowa
February 16, 1994

∑ The division of responsibilities for floodplain management among federal, state, tribal, and local governments is not clearly defined. As a result, attention to floodplain management varies widely among and within federal, state, tribal, and local governments.

This report provides the Review Committee's findings and recommendations for action. Part I (Chapters 1-3) discusses the flood event and its impacts as well as the effects of human intervention, over time, on the nature of this flood. It also provides insights into the potential for recurrence of the event. Part II (Chapters 4-9) provides a blueprint for the future -- a consensus view of floodplain management for the 21st century. Part III addresses the residual problems with floodplain management in the upper Mississippi River Basin. Part IV (Chapters 11-15) highlights needs in the fields of research, science, and technology; discusses the economic impacts of the report's findings and recommendations; converts the general actions proposed in Chapters 5 to 11 into specific tasks for accomplishment and summarizes the report.

The report contains conclusions, actions, and recommendations. Conclusions represent the Committee's evaluation of its research or analysis related to the Flood of 1993 and its consequences. The Review Committee identified specific approaches required to move forward in floodplain management as actions. Actions may involve resource commitments beyond an agency's baseline posture. Recommendations address problems that the Review Committee believes merit attention; however, the solutions to these problems can be accomplished within agency resources, existing programs, or cooperative efforts.

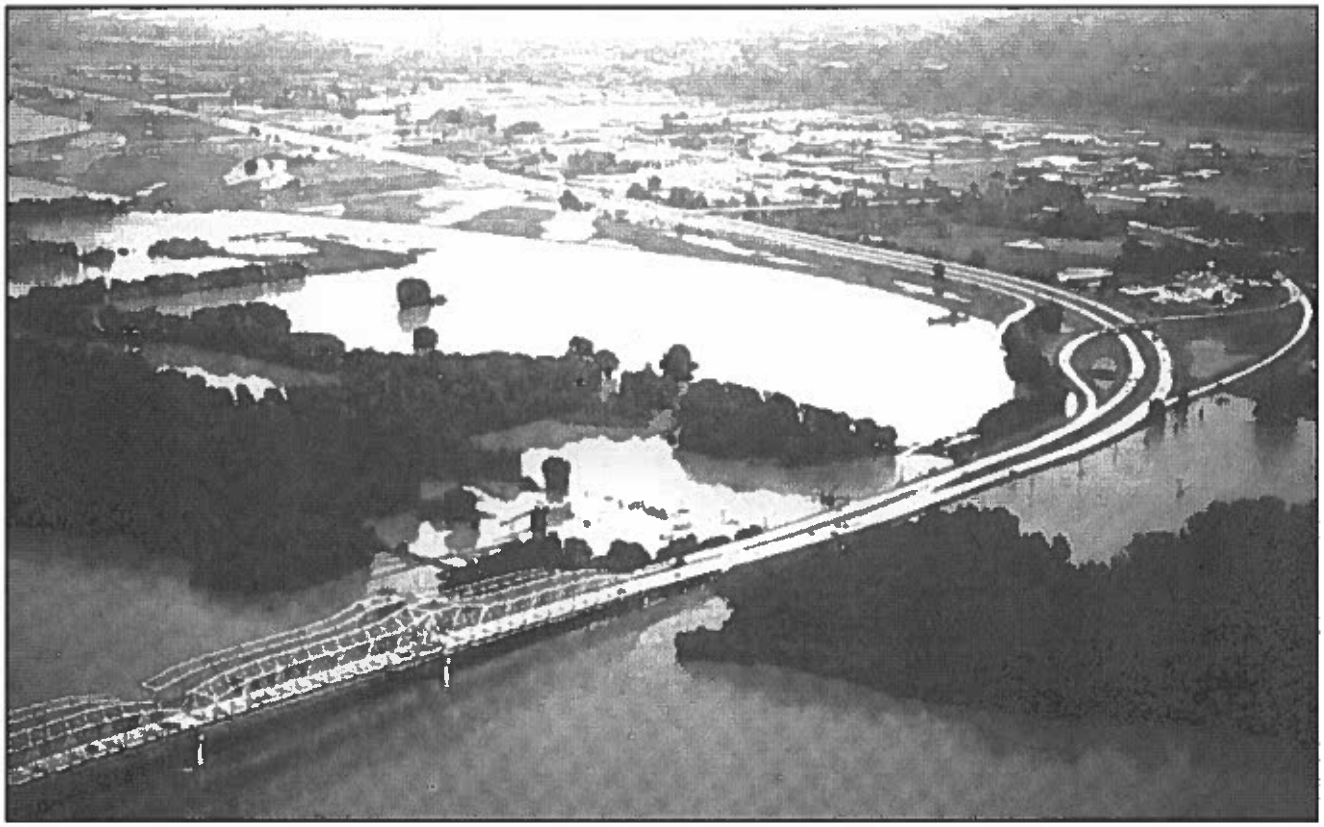
The thesis of this report is straightforward. The tools to carry out effective floodplain management exist today but need improvement. The goals are clear. It is now time to organize a national effort to conduct effective and efficient floodplain management. It is time to share responsibility and accountability for accomplishing floodplain management among all levels of government and with the citizens of the nation. Working together, the nation's public and private sectors can accomplish the mission.

A MESSAGE FROM ELIZABETH

Dear General Galloway:

My name is Elizabeth Darabcsek. I am eleven years old and in the 5th grade at Christ Prince of Peace School.

I read your article in the newspaper and was interested. I thought I could help.



I did a science fair project on floods. I tested levees, back to nature and something I made up, it was a small levee by the river and a larger one a little farther back. The little one held most of the water but not all. The water that was not held back from the small levee would then stay in the space between the big and little levee. The land between the two levees could be used as farm land or other things that could not be badly damaged by a big flood. The damaged levee could be used as the levee in the front (the smaller levee). Therefore, we would only have to build one new levee. This information may not help you, but I wanted you to know that I am trying to help protect our cities too.

Sincerely,
Elizabeth Darabcsek

P.S. Just to tell you, I won first place for my project out of the whole 5th grade.

ENDNOTE

Part I

THE FLOOD

Chapter 1

THE FLOOD OF 1993

I have visited the Midwest states affected by the '93 Flood many times. Each time I have come away saddened by the enormous loss. I have never seen such devastation. On the other hand, I have never witnessed such tremendous courage as that displayed by individuals who are beginning to rebuild their lives.

Mike Espy
Secretary of Agriculture
Chair, Flood Recovery Task Force
November 10, 1993

Floods are a function of the location, intensity, volume, and duration of rainfall and snowmelt. Other factors include the characteristics of a region's topography, its land-cover conditions, and the capacity of its floodplain to convey or store water. In 1993 a singular combination of these factors resulted in one of the most costly flood disasters in U.S. history. This chapter surveys the damages prevented and the record damages reported in the 1993 flooding of the upper Mississippi River Basin. It also addresses the response and recovery costs for affected towns, cities, and states and for the nation.

THE BASIN

The upper Mississippi River Basin is physiographically, ecologically, and climatologically diverse. Physiographically it ranges from the Rocky Mountains to the Ozark Plateau to the Glaciated Plains and central lowlands. Climatologically it ranges from the semi-arid basins and plains of eastern Colorado and Wyoming to the humid-temperate margins of the Great lakes. Geographic analysis divides this region into 70 terrain units defined by distinct combinations of physical, geologic, soil, ecological, climate, and land-use characteristics. Each unit is subject to different combinations and intensities of hydrologic and geomorphic processes. Individual areas respond differently to storm events and land treatments. The Mississippi River rises at the outlet of Lake Itasca in the lake and forest country of north-central Minnesota and empties into the Gulf of Mexico in the marshy delta just below Head-of-Passes, Louisiana. Over its journey of 2,320 miles, the Mississippi River falls 1,463 feet and drains 1.25 million square miles (sq. mi.) or 41 percent of the land area of the 48 contiguous United States. That portion of the Mississippi River drainage lying above its confluence with the Ohio River and referred to as the upper Mississippi River Basin is the focus of this report. It is in this basin where the deluge of rain and consequent record flooding occurred during the spring, summer and fall of 1993.

Draining all or part of 13 states, the upper Mississippi River Basin encompasses approximately 714,000 square miles. It comprises 57 percent of the total Mississippi River Basin and 23 percent of the area in the contiguous United States. From its source at Lake Itaska, Minnesota, to its confluence with Ohio River at Cairo, Illinois, the Mississippi River courses a distance of 1,366 miles. Its principal tributary is the Missouri River, which drains 529,300 sq. mi. above its mouth at St Louis, Missouri, including 9700 sq. mi. in Canada.

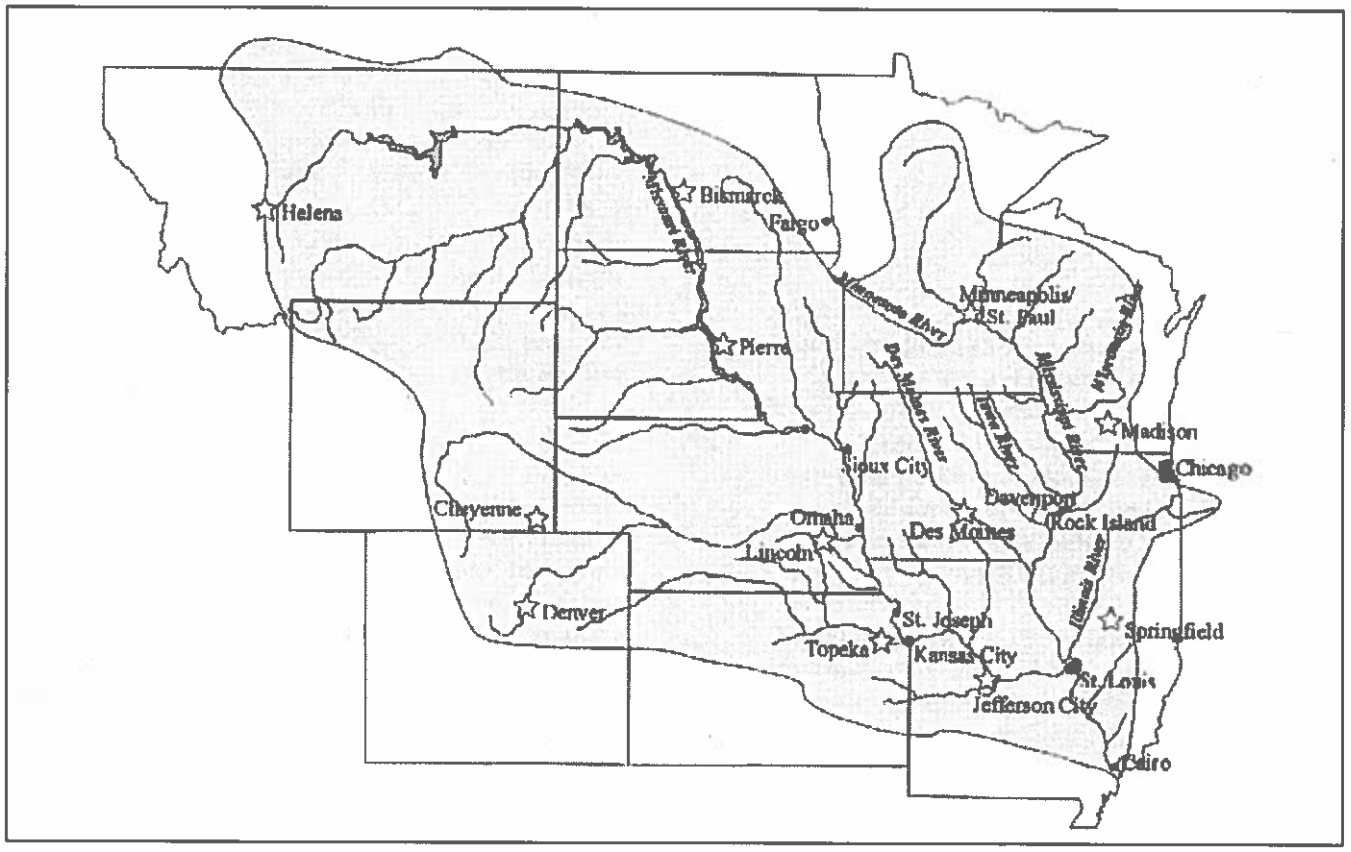
UPPER, LOWER, MIDDLE?

Lending confusion to a discussion of the Mississippi River and its drainage basin is the fact that hydrologists divide the basin, including tributary basins, into two parts: the upper and the lower; and the river into three reaches -- the upper, middle, and lower. Division between the upper basin and lower basin is at Cairo (above the mouth of the Ohio River). For the Mississippi River itself, the reach upstream from St. Louis is called the upper Mississippi River (upper Miss.), the reach between St. Louis and Cairo is the middle Mississippi River (middle Miss.), and the reach downstream from Cairo is called the lower Mississippi River (lower Miss.).

Other major tributaries include the Minnesota, Wisconsin, Iowa, Des Moines, and Illinois rivers, all of which drain watersheds greater than 10,000 sq. mi. in area (Figure 1.1).

The Missouri River, which drains all or part of ten states and 74 percent of the upper Mississippi River Basin, contributes only 42 percent of the long-term average annual flow of the Mississippi River at St. Louis. The Missouri River does contribute the most sediment in the upper Mississippi River Basin. Hydrologically the Missouri River Basin is divided into upper and lower portions with demarcation at Sioux City, Iowa. The upper and lower basins contain 314,600 sq. mi. and 214,700 sq. mi. respectively.

Runoff from the upper basin is controlled in great measure by regulation of six large dam and reservoir projects on the main stem Missouri River operated by the U.S. Army Corps of Engineers (USACE). The drainage area (279,400 sq. mi.) above Gavins Point Dam, the dam furthest downstream, encompasses about 90 percent of the upper Missouri River Basin and over 50 percent of the total Missouri River Basin area. The amount of water that runs off the upper basin annually averages 24.6 million acre-feet.[1]



History of Development

The upper Mississippi River valley was settled by European immigrants during the 18th and 19th centuries. By 1824 early steamboat travel and commerce created a demand for navigation improvements. Urban and rural populations continued to grow, creating an increased demand for forest lumber resources and agricultural products. Most early urban settlements were located on or near rivers to be close to water supplies and transportation arteries. By the late 1800s, settlers had cleared and drained many wetlands for agriculture and planted higher floodplain areas to crops.[2]

VOLUMES OF WATER

When quantifying large volumes of water, a measuring unit as small as a gallon results in numbers in the billions or trillions and makes perception difficult. Water engineers and scientists have adopted a larger unit and, therefore, employ smaller, somewhat more readily envisioned numbers. That unit is the acre-foot and represents the volume of water standing one foot deep over an area of one acre. Thus the mean annual volume of water that runs off the upper Missouri River Basin can be expressed as 25 million acre-feet rather than 8,145,720,000,000 gallons.

Figure 1.1 Upper Mississippi River Basin

Some areas were protected with agricultural levees.

Early development of the basin was closely tied to the river system, and many navigation and local flood-control efforts were installed without federal assistance. By the early 1900s, the basin's fisheries resources were declining as a result of various environmental perturbations, sedimentation, pollution, and water-leverl fluctuations caursed by deforestation and agricultural development. Between 1930 and 1950, extensive modification continued on tmain rivers, while upland areas continued to be drained for agricultural purposes. Major urban areas such as St. Louis, Kansas City, and Minneapolis/St. Paul developed as business and industry centers.

The Midwest Flood of 1993, one of the most costly flood events in this nation's history, flooded over 6.6 million acres in the 419 counties in the study area.[3] The damages experienced reflected the land-use and settlement patterns within and adjacent to the floodplain. The floodplains

along the main stem Mississippi and Missouri rivers and the major tributaries that were inundated generally are used for agriculture, and most areas are sparsely populated. Throughout most of the area, river towns are protected by urban levees, or they are located primarily on a bluff. Floodwaters thus inundated neighborhoods rather than entire communities. Residences, businesses, and industries did receive extensive damages in bottomland areas and along tributaries near Kansas and St. Louis. Development in these urban areas, however, is largely in the uplands or protected by urban levees that provided flood protection. As a point of comparison, significantly fewer people were impacted by the Midwest Flood of 1993 than were impacted by the 1927 flood on the lower Mississippi River.

Floodplain land-use patterns. Above Rock Island, Illinois, the Mississippi River valley is relatively narrow and bottomlands are filled to a large extend by navigation pools -- the slack water pools that form behind navigation dams. Most of the remaining floodplain in this area is contained in wildlife refuges with limited agriculture. Along this reach of the river are scattered towns settled during the steamboat era that have developed as market centers and service areas for agricultural hinterlands. Industries were established in many of these towns to take advantage of river navigation and the railroads that later followed the river valleys. Such towns generally have been protected b urban levees or are largely out of the floodplain. Below Rock Island the valley widens out to as much as six miles. The extensive bottomlands in these areas are protected by agricultural levees and used for crops. The leveed areas include farmsteads and a few small farm communities entirely within the floodplain.

Missouri River bottomlands, used predominantly for agriculture, are protected to varying degrees by levees. On the fringes of the bottomlands are small farm communities. In the adjoining uplands a number of larger communities are located on the bluffs above the valley.

Developed floodplains with larger urban areas such as Omaha/Council Bluffs, Kansas City, and St. Louis are largely protected by levees. Near Kansas City and St. Louis, several residential, industrial, and commercial areas are built on floodplains behind levees that overtopped or failed in 1993. Other residential, industrial, or commercial areas were flooded along the larger tributary streams in these urban areas. Rural subdivisions are scattered along the river, many of which began as hunting and fishing camps and evolved into year-around communities. These subdivisions provide inexpensive housing in part because of cheap land, lack of services such as sewer and water, limited land-use controls, and few building requirements.

On the major tributaries, the patterns of development are much the same as along the Mississippi and Missouri main stems, although the bottomlands are narrower with fewer farmsteads. The small towns along these tributaries often have floodprone neighborhoods, but most of the population lives in the adjoining uplands. Table 1.1 includes information on land use and land cover categories for the floodplain and the flood extent for the study area. The estimates of land use and land cover were developed using satellite imagery.

Population trends. In general rural counties declared disaster areas in the nine states affected by the 1993 flood are losing population. No data are available on gain or loss of floodplain populations during this period. The only comparable data from the 1980 Census and the 1990 Census are aggregated by county or community. Population increases that have occurred are generally in the suburban counties of major urban areas such as Minneapolis/St. Paul, Des Moines, Kansas City, and St. Louis. Loss of population in rural areas is the result of farm consolidation, lack of employment opportunities, and improvements in transportation. Fewer farmers mean a lower demand for local goods and services, which has a ripple effect on the local economy. Those who remain on the land drive to larger communities to shop and for many of the services previously provided by farm towns. Such trends, not unlike those occurring throughout the nation, are limiting development pressure within the floodplain. Figure 1.2 shows the population gain or loss by county in the flood-affected 9-state region between 1980 and 1990.

Table 1.1 Land Use and Land Cover in the Floodplain and Areal Extent of Flooding in 1993.

Land use/cover category	Floodplain (acres)	Use in floodplain (%)	Flood extent (acres)	Use in flood extent (%)
Urban built-u	518,891	5.0	165,980	2.5
Agriculture	7,073,696	68.8	4,155,830	63.4
Water	933,085	9.1	956,983	14.6
Wetland/forested wetland	1,435,411	13.9	882,174	13.5
Other	321,906	3.1	394,109	6.0
Total	10,282,989		6,555,076	

Source: Federal Emergency Management Agency contract with Earth Satellite Corporation, April 1994.

Note: The land use and land cover categories in the table are Anderson Level One used by the U.S. Geologic Survey (Anderson, James R., Ernest E. Hardy, John T. roach, and Richard E. Witmer, U.S. Geological Survey Professional Paper No. 964, 1976). The floodplain was identified using landform analysis and includes areas protected by levees and areas above the elevation of the 1993 flood. The flood extent is the area flooded and includes some ponding in upland areas not in the geomorphologic floodplain.

Population characteristics. The Review Committee found during visits to over 60 communities in the flood-affected region that the floodplain neighborhoods and rural subdivisions tended to be lower income neighborhoods of the community. These neighborhoods appear to have a higher percentage of rental properties, more elderly residents, more young families more people on assistance, and lower value housing. It is common to find homes in the floodplains of these communities that have market values of less than $25,000 and often as low as $10,000 or $5,000.

In part these neighborhoods may be low-income because they contain older housing and because they are floodprone. In many of these communities these floodplain neighborhoods are an important source of affordable housing for low and moderate income families. The U.S. Census data shown in Table 1.2 tend to confirm these observations.[4] The data for the study area, however, is available only by community and by Census Block Group. These geographic areas will generally include both floodplain and upland areas. Demographic differences

must be recognized and floodplain policies must be carefully designed to prevent inequities.[5]

THE FLOOD EVENT

The National Weather Service (NWS) reported that the Flood of 1993 caused at least 38 deaths, severe damages, and extreme hardship for the people of the Midwest. Agricultural damages exceeded 50 percent of the total, but less than 30 percent of such damages were in the floodplains of the main stem rivers. The majority of agricultural damages were in the uplands where the cause was wet soil conditions rather than inundation. The duration of flooding caused people to be driven from their homes and businesses for an extended period. In the major cities, such as St. Louis and Kansas City, damages were prevented by flood-control improvements. In many areas past policies of federal, state, and local governments avoided potential damage by preventing development in the floodplain.

The Flood of 1993 in the Midwest was a hydrometeorological event without precedent in modern times. In terms of precipitation amounts, record river levels, flood duration, area of flooding, and economic losses, it surpassed all previous floods in the United States. During the period from June through September, record and near record precipitation fell on soil already saturated by previous seasonal rainfall and spring snowmelt, resulting in flooding along major rivers and their tributaries in the upper Mississippi River Basin.

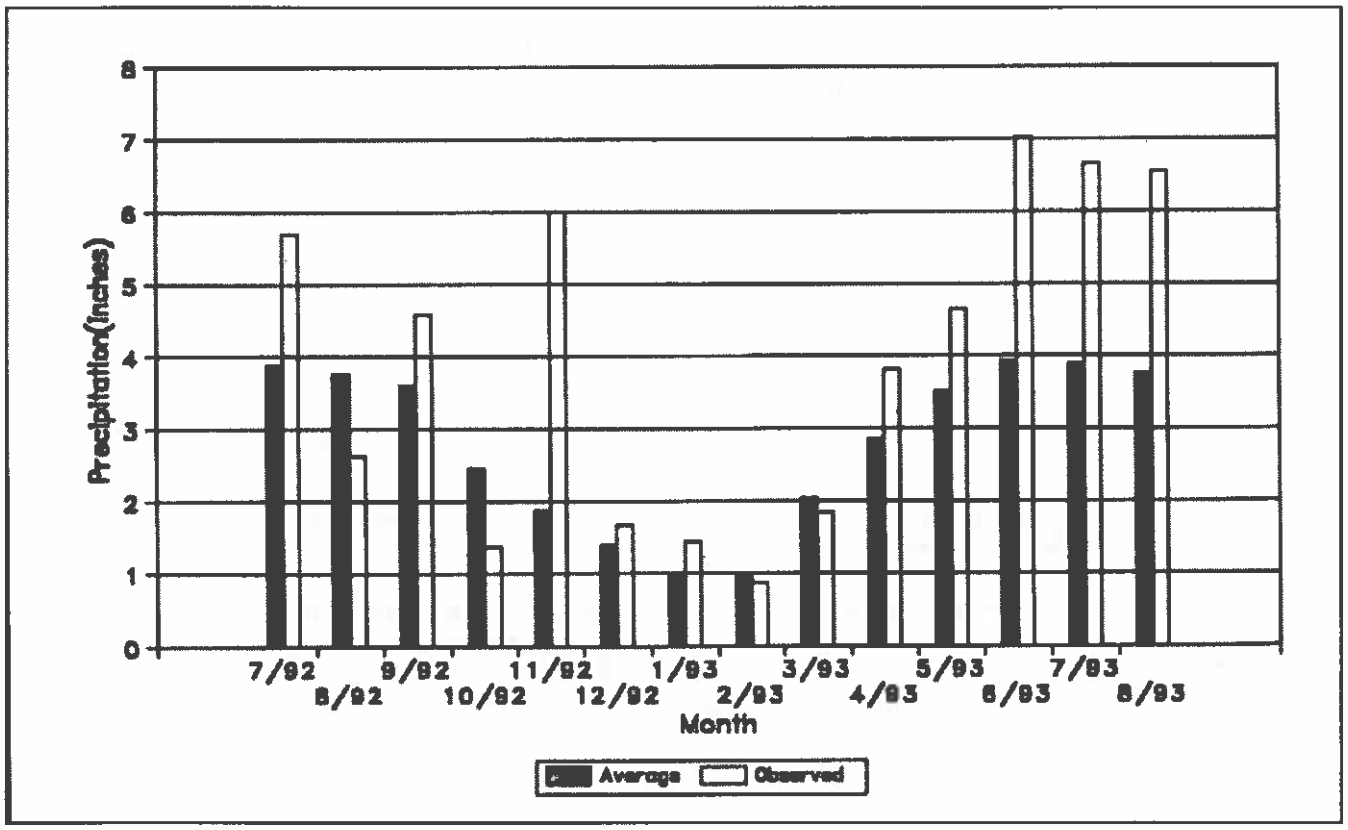
Table 1.2 Papulation Characteristics of the Study Area.

	Upland CBGs	Flood Extent/Floodplain CGBs in MSAs	Flood Extent/Floodplain CBGs in non-MSAs
Age Over 65	13.4 %	10.8 %	16.7 %
Public Assistance	5.9 %	5.7 %	6.7 %
Per Capita Income	$12,636	$10,635	$10,542
Median Household Income	$27,953	$22,629	$21,249
Mobile Homes	4.8 %	10.8 %	12.3 %

Source: U.S. Bureau of Census, 1990.

Notes: (1) CBGs = Census Block Groups; MSAs = Metropolitan Statistical Areas.
(2) Per capita and median household income are lower for CBGs within the flood extent. Mobile homes represent a considerably higher percentage of the housing units, another indication of a lower income population.

River levels exceeded flood stage at approximately 500 NWS river forecast points and record flooding occurred at 95 forecast points throughout the flood-affected region.6 At 45 U.S. Geological Survey (USGS) streamflow gaging stations, the peak discharge rate (flowrate) exceeded that of the 1-percent annual-chance (100-year) flood value. 7 Not only extensive in magnitude and area, the 1993 flood was prolonged in time as evidenced by many locations that remained above flood stage for weeks, with some remaining for as long as five straight months.



Soil Conditions Prior to the 1993 Flood

The antecedent conditions that gave rise to the Flood of 1993 include, in addition to record rainfalls, wet soil conditions that began in the central Great Plains during the summer of 1992 and rose rapidly with the increasing precipitation and cooling air temperatures of late 1992. July, September, and especially November 1992 were much wetter than normal over the upper Mississippi River Basin. That winter precipitation was near normal, but a wet spring followed. By late March, extremely moist conditions covered much of the region as a result of the wet fall and spring snowmelt runoff.8 Iowa, which was centrally located in the area of heaviest flooding, experienced the second wettest November -- April period in 121 years of record. This period was followed by above-normal precipitation over the upper Mississippi River Basin during April and May (Figure 1.3). The April -- June period was the wettest observed in the upper Mississippi River Basin in the last 99 years. Consequently even before the onset of the heavy summer rains, most upper basin soils were saturated, and many streams and rivers were flowing at well above seasonal normal levels.

Rainfall

During much of the summer of 1993, a persistent atmospheric pattern of excessive rainfall occurred across much of the upper Mississippi River Basin.9 The major river flooding resulted primarily from numerous series of heavy rainfall events from June through late July. The recurrence of heavy rainfall was the direct result of a stable upper-level atmospheric circulation pattern with a deep trough to the west of the upper Mississippi valley and a strong ridge along the East Coast (Figure 1.4). In late July and early August, a change in the upper air circulation pattern brought drier conditions to the Midwest as the trough shifted eastward. Locally heavy thunderstorms generated some additional flooding in parts of the soaked upper Mississippi River Basin during mid-August;

Figure 1.3 Average and Observed Monthly Precipitation Totals for the Upper Mississippi River Basin

Source: U.S. Department of commerce, NOAA, National Weather Service.*

however, these rains were associated with a typical summertime pattern and not a return to the anomalous and persistent June and July atmospheric conditions.

During the June-August 1993 period, rainfall totals surpassed 12 inches across the eastern Dakotas, southern Minnesota, eastern Nebraska, and most of Wisconsin, Kansas Iowa, Missouri, Illinois, and Indiana. Over 24 inches of rain fell on central and northeastern Kansas, northern and central Missouri, most of Iowa, southern Minnesota, and southeastern Nebraska. Up to 38.4 inches fell in east-central Iowa. Generally precipitation amounts were 200 to 350 percent of normal from the northern plains southeastward into the central Corn Belt.

Rainfall amounts over the upper Mississippi River Basin during the May-August 1993 period are unmatched in the historical records of the central United States. In July broad areas in the lower Missouri River Basin experienced rainfall amounting to four times normal. The series of storms producing these record rainfalls were remarkable not only in their magnitude but also for their broad regional extent; record wetness existed over 26,000 sq. mi. of the upper Mississippi River Basin. Seasonal rainfall records were shattered in all rainfall amounts equaled those computed for storm frequencies having 75-year to 300-year recurrence intervals. Figure 1.4 shows the weather pattern that existed in 1993.

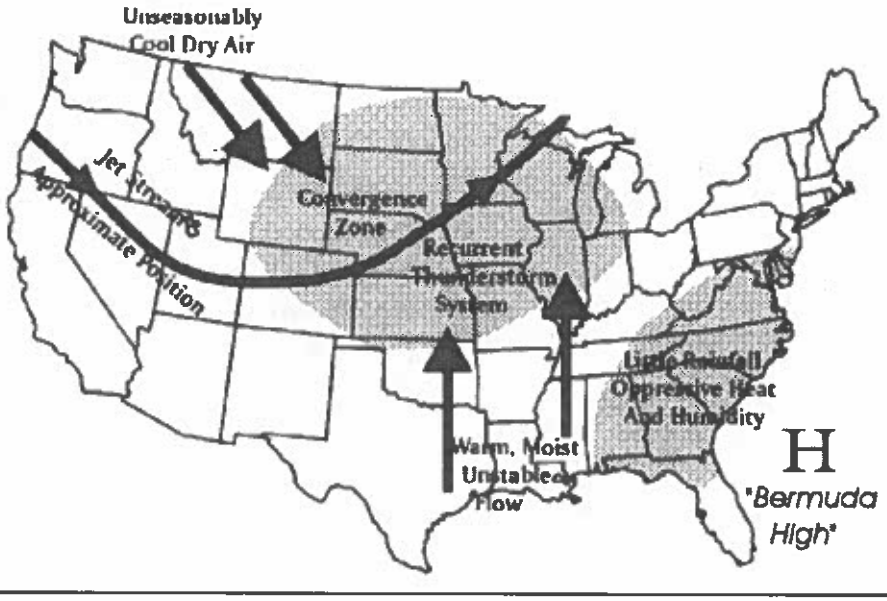
INCREDIENTS FOR A MAJOR FLOOD

The following weather facts tell why Iowa flooded in 1993:

Wettest period. Precipitation from January through September 1993 was the greatest amount, 44.5 inches, in 121 years of record; the previous record was 44.2 inches in 1881.

Wettest 12 months. Precipitation from September 1992 through August 1993 was the greatest amount in history, 54 inches; previous record was 49 inches in 1881

Unusual persistence of rainfall. The Midwest had no previous record for such a sustained period of precipitation.



Highest soil moisture. Soil moisture readings in August 1993 were the highest in history.

Cloudiest period. Cloud cover from November 1992 through August 1993 was the greatest for that time period on record.

Lowest evaporation. Evaporation was the lowest in history.

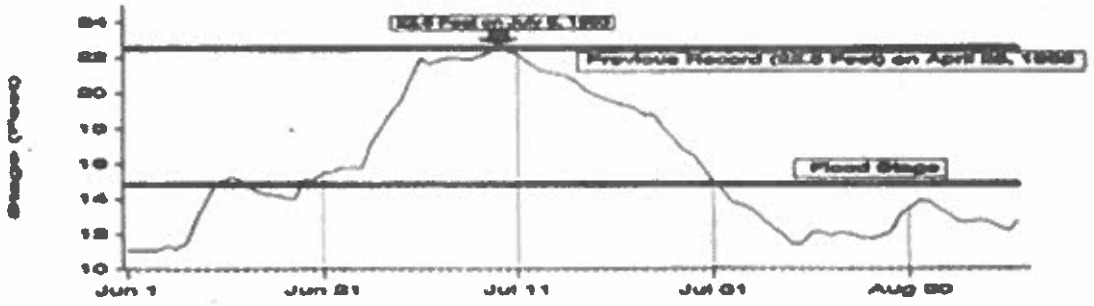
River Flow

The deluge across the upper Mississippi River Basin produced record setting peak flow rates and water levels in many tributaries and in the main stem rivers, including a large reach of the upper Mississippi, over the full reach of the middle Mississippi, and over much of the length of the lower Missouri River. Flooding began in the northern portion of the upper Mississippi River Basin in June and then moved southward with the shifting of the storm-producing weather pattern and the travel of the flood flows downstream as summer progressed.

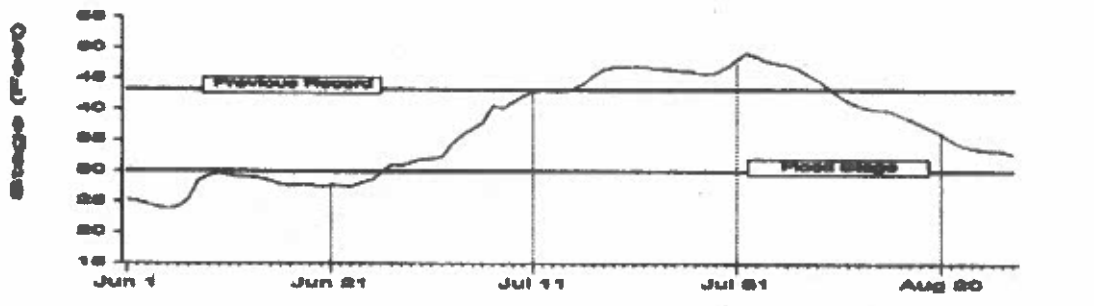
Rainfall was particularly heavy between June 17 and 20 in southwest Minnesota and northwest Iowa, causing record flooding on the Minnesota River. The next major pulse of precipitation occurred from June 23-25. Runoff from these rains combined with flood flows from the Minnesota River to initiate the first flood crest that moved down the upper Mississippi River.

Following a short, dry period, a prolonged siege of heavy precipitation occurred from June 30 to July 11. This included extreme amounts of rainfall on July 9 in Iowa, which produced record flooding on the Raccoon and Des Moines rivers. Just as the crests from these two rivers reached Des Moines, a relatively small, convective pocket dumped several inches of rain on the crests rapidly boosting the river levels and flooding the city's water treatment plant. The intense rainfall during this period also led to record flooding on portions of the lower Missouri River and combined with the crest already rolling down the Mississippi to establish record river stages from the Quad Cities area on the upper Mississippi River downstream to Thebes, Illinois, on the middle Mississippi River.



Another major precipitation event occurred from July 21-25. The heaviest rains were focused farther south than the earlier events, with especially heavy rain falling over eastern Nebraska and Kansas, leading to the second major crests on both the Missouri and Mississippi rivers. Hydrographs, of river stages (elevations) over time for the Missouri River at Kansas City and the upper Mississippi River at the Quad Cities are shown in Figure 1.5.

The Kansas City graph shows two flood peaks, one caused by the June 30 to July 11 rainfall and the other by rain falling from July 21-25. The Quad Cities graph shows only the single peak from the earlier period. This comparison demonstrates the generally southern focus of this second event. Both peaks are evident on the hydrograph for the Mississippi River at St. Louis (Figure 1.5). While flooding from the latter rainfall period did not extend as far upstream on the Mississippi River, new record river levels occurred at many locations downstream and on much of that portion of the Missouri River that flows through Missouri. Figure 1.6 shows those reaches of main stem and tributary rivers where peak stages exceeded previous record levels and where they reached unusually high but not record levels.



Above normal rains continued to occur over pats of the flood-affected region during August, especially over Iowa where accumulations were twice the normal monthly amount over much of the state. By mid-September, however, rainfall began to diminish and rivers began to recede. Then, at the end of September, a strong system of thunderstorms deposited 1 to 3 inches of rain over the State of Missouri and 7 inches or more from the central part of the state eastward. The consequence was major flash flooding on many tributaries and new flood crests on the lower Missouri and middle Mississippi rivers. Farmlands behind previously breached levees were reflooded and two people drowned in separate incidents. Many roads were washed out and there was much damage to property in Missouri.

Conclusion: ***Wet antecedent soil and swollen river conditions, record rainfall, and significant upland runoff resulted in 1993 flood flows that ranged from below the 100- year up to the 500-year recurrence interval magnitude at many locations.***

DAMAGES REPORTED

Estimates of total damages in the Midwest from weather events during 1993 range between $12 billion and $16 billion. Over half of these were agricultural damages to crops, livestock, fields, levees, farm buildings, and equipment. The remaining damages were primarily to residences, businesses, public facilities, or transportation. Much of the agricultural damage occurred in upland areas as the result of wet fields and a short growing season rather than inundation by floodwaters. Similarly a portion of residential and business damages was caused by basement flooding due to high groundwater and sewer back-up in areas outside the floodplain.

The NWS has estimated damages for the Midwest flood at $15.7 billion based on information provided by its field offices.[10] This estimate was based on totals by state, but did not include breakdowns of damage by type. In August 1993 The New York Times published an estimate of nearly $12 billion in damages based on information it obtained from state and federal officials.[11] State and federal officials could not assess all damages until floodwaters receded, and the full extent of agricultural damages was not known until after the end of the growing season. Most of the affected states have updated their damage estimates, and the total ranges from $12 billion to $13 billion. The available estimates are summarized in Table 1.3.

The Review Committee developed an estimate of flood damages using federal payments and making assumptions as to what percentage of damages those payments represent. This information indicates that total damages were ore than $12 billion with as much as $4 billion to $5 billion of that total being agricultural damages in upland areas.

Table 1.3 Damage Estimates for 1993 Midwest Flooding, in Millions of Dollars

State	NWS Totals	State Totals	State Agriculture	NY Times Totals	NY Times Agriculture
Illinois	2,640	1,000-2,000	565	1,535	605
Iowa	5,740	>3,400	na	2,200	1,200
Kansas	551	>500	441	574	434
Minnesota	964	1,700	1,500	1,023	800
Missouri	3,430	3,000	1,790	3,000	1,800

Total	15,701	12,000-13,000	na	11,683	7,231

Sources [12]
Note: "na" means not available

Damage estimates for the Midwest flood show marked inconsistencies. No federal agency is responsible for developing accurate assessments of flood damages, nor is funded to do so. The affected states and the Federal Emergency Management Agency (FEMA) conduct preliminary damage assessments to determine if a Presidential disaster declaration is warranted and to estimate the resources necessary for response and recovery. Once sufficient damage has been identified that justifies a declaration on once FEMA has a general idea of how resources should be allocated, federal agencies have little incentive to expend resources updating preliminary assessments. Resources are instead focused on tracking and projecting expenditures. The NWS is not funded to estimate total damages but does so to support other missions. The USACE, which in the past estimated flood damages, is no longer funded to do so. The Review Committee is concerned that decisions involving hundreds of millions of dollars often are being made without systematic assessments of flood damages and without a clear understanding of the nature and extent of those damages.

Agriculture

Agricultural damages from the Flood of 1993 had two primary causes: excessive moisture that prevented planting and reduced yields in upland and floodplain areas and actual flooding that destroyed crops and severely damaged many acres of fertile floodplain cropland. It is difficult to separate the factors that influenced crop production during the 1993 growing season in the 9-state region. They included rain, low temperatures, early frost, and floods. More then 70 percent of the crop disaster assistance payments, however, were made to counties in upland areas -- not in main stem river floodplains.[13]

Agricultural damages directly attributed to actual flooding totaled more than $2.5 billion, with an estimated $1.4 billion in lost corn and soybean sales. Most of these losses were restricted to 1993 as the productive capacity of the land was unchanged. There were, however, damages to field fertility and farm infrastructure of at least $100 million.

Each state suffered different types of losses. For example, Missouri with 34 percent of its cropland (5.1 million acres) in the floodplain , had crop damages from flooding on 3.1 million acres causing $247 million in lost sales.[14]

In Illinois, only 3 percent of the state's corn and soybean acreage (312,000 and 276,000 acres respectively) were lost to flooding with a loss in sales of $153.4 million.[15] Minnesota farmers lost $500 million in crop sales, but most of the damage was caused by wet conditions rather than riverine flooding. [16]

Damage from scour and deposition affected 455,000 acres on the Missouri River floodplain representing 20 percent of the flooded cropland along the Missouri and Mississippi rivers. [17] Drainage ditches were filled with sediments, and other agricultural infrastructure was destroyed. Almost 60,000 acres have sand deposition more than 24 inches thick and reclamation costs to restore fertility to damaged cropland are approximately $190/acre.[18] If cropland restoration requires removal of sand, it would cost approximately $3,200 to remove each acre-foot of sand. [19] It will cost $10.8 million to remove sediment and debris from ditches.[20]

Secondary impacts of agricultural losses to a local economy vary substantially with the dependence of that economy on the agricultural sector. Immediate losses are due to lost sales and unemployment. In the long run, the assessed value of land that sustained long-term damage may be reduced which will affect the property tax base of affected communities.

Another secondary effect was a reduction in crop-support payments after prices adjusted to the reduced production caused by wet weather in the Midwest and drought in the Southeast in 1993. This loss to farmers was a gain for

taxpayers since subsidies represent transfer payments. For corn, these deficiency payments were reduced by more than $2.6 billion.[21] These price effects and subsequent reduction in deficiency payments will be temporary, if the 1994 crop supply returns to past levels.

Conclusion: ***The majority of 1993 agricultural damages in the Midwest were caused by wet soil conditions and inundation in upland areas. Damage to inundated cropland in the floodplain was significant with almost complete crop losses behind failed levees. Areas affected***

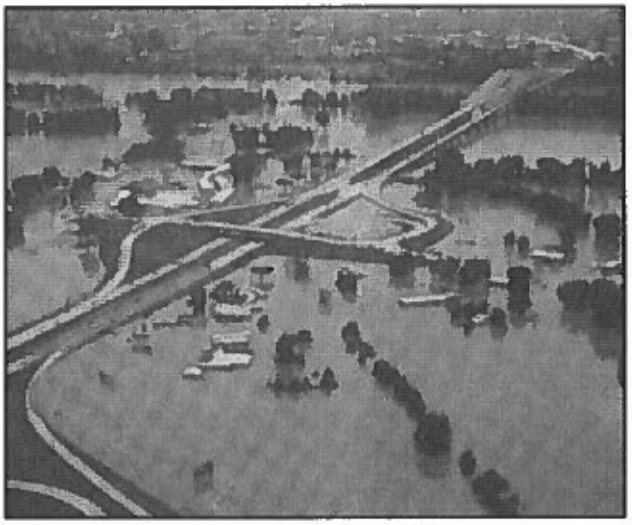
by severe erosion and deposition may suffer long-term loss of productivity.

Residences and Businesses

Estimates vary on the number of homes flooded and families impacted by the Midwest flood. Surveys made by Red Cross workers immediately after the floods identified more than 55,000 flooded residences.[22] FEMA subsequently verified these damages with Red Cross chapters and developed an updated estimate of 70,545 residences.[23] The New York Times estimated that more than 84,000 residences were damaged.[24] As of April 11, 1994, the federal government had received 167,224 registrations for individual assistance and 112,042 applications for the Disaster Housing Program. Among this latter group, 89,734 applications have been approved. The Disaster Housing Program data indicates that more than 100,000 residences were flooded. [25]

The fluctuating numbers illustrate an overlooked characteristic of this flood. While the media focused on flooding of communities along the main stem Mississippi and Missouri rivers and their major tributaries, at least as many families were impacted by flooded basements due to high groundwater, overloaded storm sewer systems, or sewer back-up. Many of the homes with flooded basements were not in the 100-year floodplain or behind levees that overtopped or failed. In Cook County, Illinois, for instance, large numbers of homes on the south and west sides of Chicago had basement flooding due to storm water and sewer back-up caused by heavy rainfall which overwhelmed the city's combined storm and sanitary sewer system. The county was eventually added to the Illinois disaster declaration even though this type of damage generally does not warrant inclusion. Over half of the 60,448 registrations for individual disaster assistance in Illinois and 20 Percent of the registrations for the entire 9-state region were in Cook County.[26]

Businesses sustained significant physical damages particularly in urban areas such as St. Louis County and the Kansas City areas of Missouri. Much of this damage occurred behind levees that failed or were overtopped. The 1996 National Flood Insurance Program (NFIP) claims payments made to small businesses26 and the 4,667 Small Business Administration (SBA) loans for



damages to businesses26 indicate that in excess of 5,000 individual businesses were damaged. No overall damage estimates for businesses are available, but a measure of this damages, SBA loans to businesses, exceeded $334 million for physical damage29 and economic injury. Add to these loans NFIP flood insurance payments for small businesses and other non-residential buildings that exceed $94 million, 30 and the total exceeds $431 million. In addition to physical damage to buildings and their contents, lost profits and wages from businesses closed by the flood had local and regional impacts. For example, an American Cyanamid Plant near Hannibal, Missouri, was protected by its own levee and not damaged by floodwaters, but the plant was shut down for nearly three month because its access road was inundated when an agricultural levee failed.

Transportation Systems

Rivers and river valleys historically have been major transportation routes, particularly in the area impacted by the 1993 flood. In the Midwest, transcontinental railroads, interstate highways, and other road systems either follow river valleys or cross them. As a result, physical damages to transportation systems form a significant percentage of total flood damages. In addition to direct damages, indirect costs accrue when transportation routes are inundated by floodwaters, and traffic is halted or detoured.

A major portion of flood damages to public facilities I n1993 involved roads and bridges. These damages ranged from blown culverts and wash-outs on rural roads and city streets to loss of bridges and damages to interstate highways inundated by floodwaters. The repair of flood-damaged roads and bridges generally is funded through the FEMA Public Assistance Program or the Department of Transportation. Funds expended by those agencies when added to the state/local cost share for public assistance indicated that total physical damages to roads and bridge exceeded $250 million. [31]

Road and bridge flooding caused indirect losses related to increased transportation costs. In extreme cases, detours of 100 miles were required to travel between adjoining

communities that had been connected by a bridge. Often bridges were elevated high above the river to allow for navigation or to minimize hydraulic impacts of floods, but bridge approaches built at or near the natural elevation of the floodplain were inundated by floodwaters. Even though the bridge was undamaged and the approach damage was minimal, the economic impacts on the communities served by the bridge could be extreme, particularly for a long duration flood such as occurred in 1993. For example, Keokuk, Iowa, was cut off from market areas in Illinois and Missouri for several weeks when the approaches to bridges over the Mississippi and Des Moines rivers were inundated. This resulted in serious economic impacts on local businesses. Flooding of the approaches to the bridge over the Mississippi River at Quincy, Illinois, for 73 days resulted in an estimated $30 million in lost business to Quincy merchants.[32] In addition, many people who lived in Missouri and could not commute to work in Illinois were temporarily unemployed. Ferries were eventually established to address part of this problem. The full magnitude of these losses are reflected in over 36,000 claims approved for a total of $92 million in Disaster Unemployment Assistance.[33]

Historically railroads were built in floodplains and river valleys to minimize construction and fuel costs. Main lines continue to parallel both the Missouri and

Mississippi rivers. Although generally tracks are elevated on embankments above the elevation of most floods or are located behind levees, they remain subject to major flood events. In 1993 over 800 miles of track were flooded and several main lines were inundated for varying periods of time, but most trains were routed around flooded areas. The Association of American Railroads estimates that railroad damages totaled $182 million, including $131 million in physical damages to tracks, bridges, signals, communication lines, switches, locomotives, rolling stock, and buildings. Additional cost of $51 million resulted from detouring trains around sections of flooded track.[34] Repair costs are generally borne by the railroads themselves although $21 million was distributed to railroads through the Supplemental Appropriation for Local Rail Freight Assistance.[35]

Airports often are located in floodplains because of the flat terrain and close proximity to urban areas. The Federal Aviation Administration (FAA) has identified 33 airports with varying degrees of flood damages. Estimated repair costs exceed $5.4 million. The airports range in size from the Spirit of St. Louis Airport in St. Louis Country, Missouri, to airports that are little more than grass landing strips with a few hangars for private aviation. Most of the flooded airports were in Missouri (16) and Iowa (12). The Spirit of St. Louis Airport, and alternate for Lambert-St. Louis Airport, sustained $1.7 million in damages when the Monarch-Chesterfield Levee failed. Other major airports that were flooded included those at Creve Couer and Jefferson City and the Kansas City Downtown Airport. Several smaller airports remain closed and may not reopen.[36]

Navigation

Most of the main stem rivers were closed to barge traffic from July 11 until August 15, 1993, and severe limitations on barge traffic continued through September, October, and November. The Maritime Administration estimated that losses of revenue to the navigation industry were $300 million per month.[37] More than $165 million were lost in Illinois alone. Regional impacts on jobs from barge and port disruptions were also greatest in Illinois.[38]

Public Facilities

The Midwest flood caused extensive damages to water and wastewater treatment plants and other public facilities. Damages to utilities, including water and wastewater treatment facilities and storm sewer systems, exceeded $84 million. [39] Water treatment plants often are located in floodplains to be near well fields or the surface water that supplies the system. In addition, water supply lines must cross floodplains to serve floodplain residents. The EPA has identified 200 municipal water systems impacted to some degree by the flood.[40] The most prominent example is the Des Moines Water Works that serves the City of Des Moines and adjoining communities. The plant was flooded and remained out of operation for 12 days, and water from it was not safe to drink for another seven days. In addition to physical damages of $12 million, significant impacts were felt in the service area.[41] Businesses and government offices closed because of lack of fire protection, and bottled water and portable toilets had to be provided for residents. The economic impact of the shutdown may far exceed thee cost repair of the physical damage.

Wastewater treatment plants tend to be located in floodplains which are generally the lowest point in a community and offer the advantage of gravity flow. Furthermore the effluent from these plants is discharged into major rivers or streams. The impact of flooding ranges from temporary plant shutdown and the discharge of raw sewage into the river during the flood to physical damage that results in extended plant shutdowns and continued discharges of raw sewage or partially treated effluent until such time as the plant can be repaired. A total of 388 wastewater facilities were impacted by the flood. [42]

Damages to public buildings exceeded $27 million. Water control facilities had more than $20 million in damages, and facilities such as parks and other recreation facilities

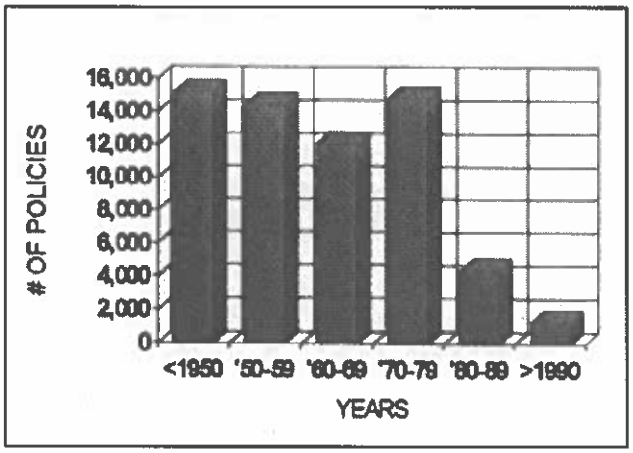
recorded more than $22 million. These estimates are based on FEMA projections of infrastructure spending that include a 10-percent local cost share. [43]

DAMAGES PREVENTED

Management and structural practices prevented damages from being worse than they were. These practices involved nonstructural solutions, upland conservation treatment, and major flood control projects.

Nonstructural Flood Protection

The term "nonstructural measures" is used to describe techniques that "modify susceptibility to flooding (such as regulation, floodplain acquisition, and flood proofing techniques)."[44] A nonstructural approach to flood damage prevention was effective in the town of Prairie Du Chein, Wisconsin where the flood was a 40- to 50- year event. Prairie du Chein was the site of the first relocation project undertaken by the USACE and carried out between 1978 and 1984. A measure of the project's success was reported by the Red Cross workers came to town but left within two weeks because no one needed their help.[45] Relocation had freed citizens of anxiety about the risk of flood damage to their home and businesses. Nonstructural land management applications such as the Minnesota Valley National Wildlife Refuge and the Upper Mississippi River Wildlife and Fish Refuge provided for storage and conveyance of a portion of the 1993 floodwaters within the floodplains of the lower Minnesota and upper Mississippi River valleys. Refuges, parklands, green ways, and agriculture are examples of appropriate floodplain uses that reduce flood damages by minimizing the number of structures at risk.



The National Flood Insurance Program. The NFIP has not encouraged floodplain development in the Midwest and, in combination with state and local floodplain management programs, appears to have discouraged it. The NFIP has discouraged floodplain development by (1) increasing awareness of flooding by identifying and mapping the flood hazard, (2) internalizing the cost of floodplain occupancy, making development in the floodplain more costly (i.e., added cost of protecting buildings from flooding and the added cost of the NFIP flood insurance premium), and (3) requiring additional permitting and engineering studies that developers and individuals may choose to avoid.

The Review Committee met with a number of communities in the Midwest, large and small, that actively discourage development in their floodplains even if permitted by federal or state regulations. This "steering" of development to flood-free locations has deterred new floodplain development in these communities.

Approximately 93 percent of the properties which are located in the 100-year floodplain in the flooded area and are currently insured by the NFIP were constructed before the issuance of a Flood Insurance Rate Map (FIRM) for the community and conversion of the community to the Regular Program of the NFIP, [46] i.e., between December 31, 1974 and the early to mid-1980's. Floodplain management regulations appear to have prevented or reduced damages to new construction (post-FIRM construction). These buildings sustained proportionally fewer losses than older buildings even though the flood elevations exceeded the 100-year design standard in many locations. These new buildings comprise 6.4 percent of the insured floodplain buildings in the declared counties, but account for only 3.2 percent of the losses.[47]

Figure 1.7 indicates a significant reduction in the number of buildings built in the floodplain after 1980. Since insured buildings tend to include newer, more expensive buildings with mortgages subject to the mandatory flood insurance purchase requirement, the percentage and numbers of all buildings built prior to enactment of the NFIP are likely to be even higher.

Figure 1.7 Construction Dates NFIP Insured Buildings in the Nine Midwest States

Source: Federal Emergency Management Agency, Federal Insurance Administration. Computer Printout, March 28, 1994.

Acquisition and relocation. Acquisition or relocation of floodprone building through federal programs or state and local initiatives continues to be an important strategy for reducing potential flood damages. Successful buy-out programs normally are a response to a flood or series of floods. Implementation occurs over a multi-year period, as funding becomes available. The Review Committee identified more than 600 buildings in the upper Mississippi River Basin which have been acquired and relocated out of floodprone areas over the past 20 years. Most of these buildings had been damaged previously by floods and would have been severely damaged by the higher waters of the Flood of 1993.

Upland Watershed Treatment

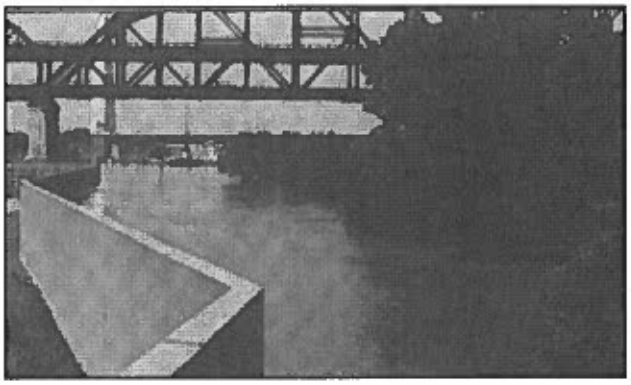
The Flood of 1993 demonstrated the value of f installing flood-prevention measures and of improving land treatment practices on agricultural lands throughout the watershed. In upland watershed areas, the Soil Conservation Service (SCS) small watershed projects prevented damages estimated at $400 million. Crop losses to landowners were lower in areas with upland watershed treatment. An example is the SCS project on the Grindstone-lost Muddy Watershed Project that protects approximately 60 percent of Dekalb County and portions of Clinton, Gentry, and Davies counties in Missouri. Flood protection on the 326-sq. mi. watershed includes land treatment, flood prevention, multi-purpose flood control reservoirs, and erosion grade control structures. The project area recorded two storms exceeding the 1-percent chance of occurrence in July and September 1993. Estimated agricultural benefits accrued were $915,900 for the July storm and $989,700 for September storm with road and bridge benefits of $66,000 and $70,000. Agricultural disaster payments per acre in Dekalb County were less than half those paid in neighboring counties. Since the storm, local people have donated $2,000 to purchase landrights for construction of remaining flood control reservoirs.

Flood Damage Reduction Projects

The USACE estimates that flood-control facilities in place during the 1993 flood prevented $19.1 billion in damages.[48] Of that total, $11.5 billion in damages were prevented along the Missouri River. Damages prevented by the water control management of flood storage reservoirs amounted to $7.4 billion in the Missouri River Basin; $4.0 billion by the storage of flood water in the six main stem Missouri River reservoirs on the tributaries. The other 4.1 billion in damages prevented along Missouri River is attributed to levee projects. USACE and Bureau of Reclamation flood control reservoirs on the main stem and tributaries in the Missouri River Basin reduced peak discharges on the Missouri River by storing over 17 million acre-feet of flood water between June and August.[49] In the St. Louis metropolitan area, a combination of upstream reservoirs, levees, and floodwall prevented damages of approximately $3 billion. Upstream reservoirs and levees also prevented damages of about 5.6 billion at Kansas City.

Conclusion: ***Damages from the 1993 flood were reduced significantly through use of non-structural and structural measures.***

RESPONSE AND RECOVERY COSTS



By the end of the flood, nine state disaster declarations included more than 525 counties. Current estimated federal response and recovery cost include 4.2 billion in direct federal expenditures, $1.3 billion in payments from federal insurance programs, and more that $621 million in federal loans to individuals, businesses, and communities.

A review of the types and amounts of federal response and recovery cost by state illustrate again the differences in types of damages among the nine states.

In the upper basin states of Minnesota, Nebraska, North Dakota, and South Dakota and in Wisconsin and northern Iowa, the losses were primarily to agriculture, much of it in upland areas. Along the main stems of the Mississippi and Missouri rivers and their major tributaries in Missouri, Illinois, and central Iowa, significant losses occurred in agriculture as a result of bottomland flooding, but urban areas also recorded damages.

Federal Expenditures

Federal expenditures represent disaster response and recovery cost borne by the federal government. Among these are disaster assistance payments to individuals and farmers, costs to repair levees and other infrastructure, costs to provide health and social services; and cost associated with hazard mitigation, housing, and community development. Å summary of federal expenditures for the Midwest flood is included in Table 1.4

Crop disaster payments. Disaster payments are made for production and quality losses of most commercially grown crops when losses are caused by damaging weather and related condition. Production losses related to prevented planting and low yield are eligible for compensation. The Agricultural Stabilization and Conservation Service of USDA can authorize crop disaster payments without a Presidential Disaster Declaration. Participation in price-support programs does not affect eligibility or payment levels. Producers with crop insurance qualify if losses are greater than 35 percent of expected production; and those without crop insurance qualify if losses are greater than 40 percent. For most crops grown in the 9-state region, payments are calculated by determining the eligible amount of loss and multiplying it by 65 percent. As a general rule of thumb, farmers can expect disaster payments to cover 40 percent of expected cash receipts. 50 For 1993, yields less than 9 bushels an acre of corn or 4 bushels per acre of wheat counted as total losses for calculation of disaster payments. Figure 1.8 shows the location of crop disaster payments in the 9-state region. More than 70 percent (1.02 billion) went to the prairie pothole

region of the Dakotas, Minnesota, Wisconsin, and northern Iowa. [53] Cropland in this area of hydric soils and excessive rainfall does not drain well. The majority of payments went to farmers participating in commodity programs (Table 1.5), but damages would have been higher without farmer enrollment because the 6 million acres of land set aside (the 1993 requirement for program participation) would have incurred crop losses if production has been allowed.

Federal Insurance Programs

The federal government operates two insurance programs that provided claims payments to those impacted by the Midwest flood; the National Flood Insurance Program (NFIP) and the Federal Crop Insurance Program. Claims payments by federal insurance programs are distinct from federal expenditures. Table 1.6 summarizes claims payments from these programs by state. Under both programs, individuals pay an annual insurance premium to the government and the government provides insurance coverage. Tables showing insurance payments from the NFIP and the Federal Crop Insurance Corporation (FCIC) follow.

National Flood Insurance Program. Flood Insurance coverage on buildings and their contents is available through the NFIP participating communities. Under

the NFIP insurance premiums for buildings that predate the identification of the flood hazard in a particular community are subsidized, but for buildings built after that date, premiums are based on full actuarial rates. All costs of administering the program, including the costs of floodplain mapping and salaries of federal employees are charged to policyholders. The Midwest flood was the third most costly in terms of NFIP payments, exceeded only by Hurricane Hugo and the December 1992 coastal storm that struck New York, New Jersey, Massachusetts, Delaware, and Connecticut. In 1993, over half of the losses and two thirds of the payments were in Missouri. States in the upper basin had lower average payments since buildings were generally subjects to shallow flooding along tributaries which flooded basements and some first floors. States in the lower basin had much higher average losses reflecting the deep flooding in the bottoms along the main stems of the Mississippi and Missouri rivers (Table 1.7 and Figure 1.9). High average payments in Missouri also reflect large payments to small businesses and other non-residential building, particularly in Chesterfield and elsewhere in St. Louis County. Even in the counties with disaster status, in excess of 80,000 insured properties did not overtop or fail, but most were on tributaries that did not flood or where flooding was of less than 100 year frequency.

Federal Crop Insurance Program. Farmers can protect themselves from actual crop losses or prevented planting caused by uncontrollable natural events through purchase of crop insurance from the FCIC. This government corporation within the USDA provides coverage for 51 crops in the event of loss from drought, excess soil moisture, flood, frost, hail, wind, insects, and other natural perils. Historically drought has been the major cause of crop loss (55 percent) while floods represent only two percent of claims. Excess soil moisture, however, represents 16 percent of losses.

Farmers must purchase the insurance early in the crop year. For example, a policy to cover a corn crop planted in 1994 in the Midwest would have to be purchased by April 15. Farmers can choose the level of insurance that they wish to purchase, but they are not able to insure their crop for the full value. Maximum coverage is 75 percent of expected crop yield.[54] To encourage participation, the federal government subsidizes crop insurance premiums up to 30 percent and pays administrative, actuarial, underwriting, and selling expenses.

Table 1.8 shows the participation rate for crop insurance purchases in the 9-state area for 1993 as well as the indemnities paid to policyholders. Participation is lowest in the corn/soybean region and highest where

Table 1.7 NFIP Flood Insurance Losses for the Period from April 1 Through September 30, 1993 by State for the 1993 Midwest Floods.

State	Policies 1/31/94	Loss Count	Total Payments ($)	Average Payment ($)	Losses (%)	Payments (%)
Illinois	36,844	3,624	61,389,123	16,939.60	22	21
Iowa	8,689	1,390	23,378,415	13,833.38	10	8
Kansas	11065	1,071	10,702,780	9,993.26	7	4
Minnesota	3,472	372	1,712,960	4,604.73	2	>1
Missouri	20,981	8,271	192,296,740	23,249.52	5	65
Nebraska	6,652	503	4,833,133	9,608.61	3	2
North Dakota	3,008	198	285,572	1,442.28	1	>1
South Dakota	1,313	115	745,309	6,408.95	2	>1
Wisconsin	7,096	323	1,999,654	6,190.88	2	>1
Total	99,120	16,167	297,343,686	18,392.01

wheat is the principal crop. The largest claims were in the prairie pothole region (as were the bulk of the crop disaster payments) rather than in the floodplains. The probability of participation in the crop insurance program is lower for floodplain farmers than for those in the upland because flood damage is, in general, more localized than drought which is the primary hazard in the Midwest.

Loans. Federal agencies have approved $623 million in loans to individuals, businesses, and communities impacted by the Midwest flood. These loans, which must be repaid, as a federal expenditure only to the degree that interest rates are subsidized, borrowers default on loans, and administrative costs are incurred (See Table 1.9). The primary source of the loans is the Small Business Administration (SBA) Disaster Loan Program, which provided $597 million in loans to flood-affected homeowners and renters, businesses of all sizes, and non-profit organizations. Interest subsidies, defaults, and administrative costs amount to approximately 30 percent of the loans.[55] Farmers Home Administration (FmHA) is the source of agricultural loans because SBA is prohibited from making loans to farmers.

Federal income tax deductions. Uninsured and otherwise unreimbursed losses resulting from casualties such as a flood are deductible for Federal Income Tax purposes to the extent that they exceed 10 percent of Federal Adjusted Gross Income plus 100. ˇHis deduction results in decreased tax revenue to the federal government. The Internal Revenue Service provides tax counseling to disaster victims to assist them in applying for refunds by amending their previous years tax return when a major disaster is declared. The loss of tax revenue has not been quantified for the Midwest flood. Due to the amount of insurance and disaster assistance payments, the income levels of many of the flood victims, and requirement that the loss exceed 10 percent of adjusted gross income, the loss may not be substantial. The casualty loss deduction, however, does act as an additional mechanism for transferring the costs of flood damage from the private sector to the federal government.

State and Local Costs

The Midwest flood was also costly for state and local governments. Because the FEMA provided assistance at a 90/10 cost share, the state/local share was approximately $42 million for Public Assistance and nearly the same amount for assistance to indivuduals.56 States and communities also had unreimbursed expenses associated with response and recovery. State and local costs for the restoration of damaged levees and watershed exceeded 130 million. These expenditures were part of the USACE 80/20 and the SCS 75/25 required cost shares.

Of greater concern to some communities is the short and long-term reductions in real estate tax revenues as properties are reassessed to reflect flood damages to building and agricultural lands or losses in market value due to the increased awareness of the flood hazard. In those areas, where homes are not being rebuilt and fields are not being restored, these losses will be permanent. Impact aid from the U.S. Department of Education, currently budgeted at $70 million, will replace a part of the lost tax revenues that would have gone to schools.[57] At the state level, losses in tax revenue may result from lost profits and wages. Partial compensation for these losses may come in part from the increased economic activity of the recovery effort and from federal assistance.

Non-Quantifiable Costs

The EPA determined that 59 Superfund sites experienced flooding; however, impacts to the sites were minimal and corrective measures have been completed on sites requiring them.[58] In addition, 73 solid waste treatment,[59] storage, and disposal sites were also flooded,[60] and large propane tanks that were dislodged floated downriver creating the potential for massive explosions. Besides the large propane tanks, the states collected over 18,000 orphaned drums[61] -- each with a potential hazardous or toxic substance -- and a large amount of household hazardous wastes whose disposal was necessitated by the flooding. Daily loads of agricultural chemicals (herbicides and Nitrates) transported by the Mississippi River were large relative to previous years; record flooding did not dilute the concentrations of herbicides.[62] Concentrations of two herbicides (altrazine and cyanazine) in some samples from the Mississippi River exceeded health-based limits for drinking water; however, the annual concentration was not expected to exceed those limits for 1993.[63] The cumulative impact of any flood-related releases of hazardous materials, including pesticides, herbicides, and other toxic materials has not been established.

The effects of flooding on groundwater hydrology and groundwater quality have yet to be determined. In response to concerns regarding the safety of private wells, the Administration established a well-water contamination survey in coordination with the nine-flood states.[64] The EPA performed floodwater quality sampling around major metropolitan areas on the Missouri River. In some cases, drinking water standards were exceeded, but the majority of the readings posed no health risk.[65] Results from sampling of treated drinking water revealed three location where Maximum Contaminant Levels were exceeded although results from a single sample do not necessarily indicate a problem.[66] USGS and National Oceanic and Atmospheric (NOAA) have not found significant changes in water chemistry since the 1993 flood.[67]

Impacts of the flooding on the distribution of contaminated river sediments is also unknown. Studies are underway to determine sediment chemistry and characterize sediment deposition patterns in rivers and streams.[68]

Effects of the flood on public and mental health are largely anecdotal. Some communities noted increases in spousal and child abuse and numbers of calls for police response. Mental health effects of community and individual buyout/relocation are poorly understood. Several studies are currently being completed to assess the human response to the 1993 flood and to evaluate the factors that strain the ability of families to function adaptively to the event.[69] Experience with other floods indicates that out breaks of Equine, Western, and St. Louis encephalitidies can be expected two years after flooding event (due to the lag time in amplification of disease vectors).[70] The length of time between the flood event and the appearance of disease adds to the problem of attributing costs.

The flood took its toll on historic and cultural resources

Table 1.9 Summary of Amount of Federal Loans by State for the 1993 Midwest Flood in Millions of Dollars

Program	Total	IL	IA	KS	MN	MO	NE	ND	SE	WI
Small Business Administration Disaster Loans	597.3	134.7	108.55	31.6	27.4	235.3	14.2	16.1	16.7	12.8

Farmers Home Administration Emergency Disaster Loans	14.7	2.1	7.3	0.1	2.4	0.9	0.1	0.2	0.9	0.8
Total Amount Approved	621.3	136.8	122.5	32.9	29.8	236.9	14.4	16.3	18.2	13.6

Source: Kuilik, Bernard, Associate Administrator for Disaster Assistance, U.S. Small Business Administration, personal communication, May 3, 1994; U.S. Department of Agriculture, Flood Information Center, "USDA Emercency Assistance Paid to Flood States," April 4, 1994.

in the area. Historic homes in Grafton, Illinois and Ste. Genevieve, Missouri and a church in Portage des Sioux were damaged. A cemetery in Hardin, Missouri was inundated which disinterred over 500 bodies. There were several American Indian tribes affected by the Flood of 1993. The SAC and Fox of the Mississippi in Iowa (Mesquakie) lost 10 homes and the ceremonial area of their Pow-wow grounds.[71] The Kickapoo Tribe in Kansas had damages to their crops, bridges, roads, and water systems.[72] Indian lands in the prairie pothole are were saturated by frequent rains. Local lakes flooded homes on the shore and contaminated drinking water wells. Well and lake water continue to be monitored for pesticides, animal wastes, and other pollutants potentially carried by runoff to the upland lakes.[73] Preliminary field investigations by state and federal forestry staff in Mississippi River navigation pools 25 and 26 revealed that all hackberry and sugarberry and a large percentage of sycamore appeared to be dead or dying at those locations. Similar effects might be expected elsewhere in the Basin's floodplain where flood duration coincided with the entire growing season. Hackberry and sugarberry are important mast-producing trees, and mature sycamore are frequently selected by species of colonial nesting birds.[74] The full effects on forest canopy and subcanopy structure will not be know for years to come.

Conclusion: ***Not all costs of the Flood of 1993 can be quantified in monetary terms, but bot quantifiable and non-quantifiable costs were significant in magnitude and importance.***

BENEFICIAL EFFECTS

Flooding is a natural phenomenon of every river. Historically, floodwater enriched bottomlands and provided spawning habitats for native fish. The ecological value of maintaining connections between the river and its floodplain and the flood-pulse advantage are among the benefits conveyed by a flood.[75] The 1993 flood connected many midwestern rivers with their floodplains, and for the first time in decades this flood coincided with the natural spawning period of riverine fishes. The benefits of this inundation to fisheries and aquatic resources was evidenced anecdotally in reports of fishermen utilizing newly created scour holes, and empirically in fisheries samples collected as part of the fall fish sampling for the cooperative interagency (USACE, FWS, and 5 states) upper Mississippi River System Long Term Resource Monitoring Program (LTRMP). Catches of young-of-the-year fish in fall 1993 samples (after the flood) were greater than numbers of such fish collected in all samples for the entire 1992 samplings year (before the flood).[76]

ENDNOTES

1. U.S. Army Corps of Engineers, Missouri River Division, Reservoir Control Center, *1993-1994 Missouri River Mianstem Reservoirs Annual Operating Plan,* December 1994.

2. U.S. Arm Corps of Engineers, Kansas City District, maps of the Missouri River from Rulo, Nebreska to St. Louis, Missouri 1879-1954.

3. The Fema study area was selected in the early phases of the response and recovery effort and included 419 contiguous counties in the upper Mississippi and Missouri River basins believed at the time to be most severely impacted by the 1993 flood.

4. The analysis was based on those Census Block Groups (CBGs) whose centroids were in the flood extent and the floodplain as mapped by the SAST team. These CBGs then were compared to CBGs with their centroids in uplands. Although most of the CBGs with centroids within the flood extent and floodplain contain extensive upland areas, the data are an indicator that areas inundated by the Midwest flood differ from the upland areas. The data were developed for both CBGs within Metropolitan Statistical Areas (MSA) and those outside of those areas.

5. The Executive Order on Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations (EO 128-98, February 11, 1994) requires agencies to conduct activities related to human health and the environment in a manner that does not have the effect of discriminating against low-income and minority populations.

Labor data-Personal communication, Tom Edwards, ETA Public Affairs, May 13, 1994.

53. FMRC analysis of USDA/ASCS count-level data.

54. The amount paid for a claim is based on loss below the coverage amount. For example, a farmer with a 65 percent level of crop insurance who lost half of his or her crop would be compensated for 15 percent of the crop value (65% - 50% = %15). A farmer with a 35 percent level (the minimum) would get no compensation. The price paid per unit of eligible crop loss can be selected as the market price or as a percentage of an established. The insurance premium depends both the chosen yield coverage and price election.

Chapter 2

IMPACTS OF HUMAN INTERVENTION

In the matter of floodplain management, most people agree that some combination of structural and nonstructural methods are probably a better approach than the previous complete reliance on dams and levees.

Luna B. Leopold
Water Resources Update, Issue No. 95: Spring, 1994

HISTORY

The rivers and streams of the Midwest were focal points for early settlement because they provided sources of drinking water and avenues for transportation and trade. Once settlements were established along rivers, the problem of controlling floods to protect human life and investments became readily apparent. At first small mounds of dirt were thrown up to divert water away from towns, and over the course of time, these mounds became levees and floodwalls. Many people living in floodplains behind those levees and floodwalls remain at risk because of decisions made many years ago. The modern challenge is to reduce those risks.

As settlers spread west they altered prairie, forest, meandering streams, and free-flowing river landscapes to provide arable farmland, raw materials for homes and industry, and transportation. Federal policies encouraged extensive private land development which then required construction of reservoirs and levees for flood protection. Human use thus changed midwestern landscapes to the detriment of natural ecological systems. The Flood of 1993 raised questions as tow what extent these landscape changes have contributed to flood frequency and duration.

Agricultural Policy and Farm Production

Since the 1930s, when one quarter of the population lived on farms, U.S. farm policy has used a system of price supports (loans, purchases, payments, or a combination of methods) to improve farm income and promote conservation, while assuring a dependable Food supply for the United States. The Food, Agriculture, Conservation, and Trade Ace of 1990 (FACTA) continued the market orientation of its predecessor, the Food Security Act of 1985. Stated goals of the 1990 Farm Bill (FACTA) were to ease financial stress on farmers, reduce government costs, reduce crop surpluses, maintain export competitiveness, and enhance environmental quality. Among the best know features of the farm policy are the Production Adjustment/Price Support Programs administered by the Agricultural Stabilization and Conservation Service of the U.S. Department of Agriculture (USDA). Appendix C provides an example of how price supports operate.

Agriculture is the leading industry in most counties of the nine states affected by the Flood of 1993 (See Table 2.1).

PRODUCTION DIFFERENCES OF FLOODPLAINS VS. OTHER AREAS

Agricultural production in floodplains of the nine midwestern states affected by the flood is focused on commodity crops such as corn and soybeans. Corn yields in well-drained floodplains uniformly average 15 percent higher than the state average in Missouri. Production on portions of the floodplains, however, can be reduced by poor drainage. Upland production yields are variable, depending on soil type and location. The highest upland corn yields are 16 percent higher than the highest floodplain yields; however, high-yield upland areas are presently I full production. Any additional production in upland areas would be in areas with yields averaging 14-26 percent lower than the average well-drained floodplain yield.

The area's 208 million cropland acres represent 32 percent of the nation's farm acreage, 35 percent of total agricultural sales, and almost 60 percent of total national corn, wheat, and soybean acreage.[1] Combined production from Illinois and Iowa alone represent 33 percent of corn and 30 percent of soybean acreage in the United States, but dominant crops and yields vary by state throughout the region. Floodplains comprise approximately 11 percent of total acreage affected by the 1993 flood and 66 percent of this acreage is in agricultural production. [2]

Navigation

There are two types of navigation projects present in the Basin. One, on the upper Mississippi River, is slack water navigation created and controlled by a system of locks and dams. The other, open water navigation, is utilized on the Missouri River and middle Mississippi River.

Upper Mississippi River. The upper Mississippi River navigation system provides a variety of uses: commercial transportation, recreation, environmental resources, water supplies for domestic and industrial use, and energy production. The Water Resource Development Act of 1986 declared the upper Mississippi River system to be a nationally significant ecosystem and a nationally significant commercial navigation system.

Navigation on the Mississippi River was a primary factor in settlement of the valley. The federal government began to support commercial navigation actively in 1824; first with 4-foot channels. The navigation channel projects, authorized by Congress in the 1930s for the Mississippi and Illinois Rivers, extended 9-foot draft navigation upstream to Minneapolis/St. Paul and connected the St. Lawrence-Great Lakes with the Mississippi-Ohio-Missouri navigation systems (Figure 2.1)

The upper Mississippi River 9-foot navigation project has converted the Mississippi River (St. Louis to Minneapolis/St. Paul into a series of pools at low and normal flow (Figure 2.2). Navigation dams, each consisting of a row of gates mounted between piers over a low sill, are used to maintain sufficient water depth for navigation. During periods of high flow, the navigation gates are completely opened to allow passage of the flood flows.

Construction of the 29 lock and dam projects on the Mississippi River north of St. Louis was completed by 1950. These locks are nearing the end of their economic life span and may soon start to require

Table 2.1 Agricultural Characteristics of Flood Affected States

expensive replacement. Locks and dam 26 near Alton, Illinois, was replaced during the early 1980s at a cost of nearly $1 billion. Below the southernmost lock, Lock 27 at Granite City, Illinois, navigation is maintained through placement of flow regulating structures such as wing dikes and by dredging that channelize, narrow, and deepen the river.

Maintenance of the upper Mississippi River navigation system requires periodic dredging at over 200 sites, removing an average of 9.5 million cubic yards of material annually. Additionally, about 2,400 submergent and 700 emergent wing dikes are maintained to reduce main-channel sedimentation and 420 miles of bank line stabilization are maintained to prevent shoreline erosion.[3]

Illinois River. Two construction projects have supported navigation activities on the Illinois River. The first, the Chicago sanitary and Ship Canal, completed in 1900, diverted water from Lake Michigan into the Illinois River. The second, a modern lock and dam system, similar to that in operation on the upper Mississippi River, consists of seven separate navigation locks. This system was completed in 1965.

Missouri River. In 1945 congress authorized a comprehensive navigation plan for the Missouri River system. The result was a 9-foot channel navigation project to channelize and deepen the river from St. Louis upstream to Sioux City, Iowa. Six multi-purpose mainstream reservoirs, affecting over 900 river miles, were developed above Gavins Point Dam. One purpose was to provide a regulated release of water for downstream navigation. Downstream of Gavins Point Dam, the river consists largely of a 735-mile navigation channel maintained with wing dikes, channel stabilization and other erosion and sedimentation control devices. Annual water release for navigation is based upon available water supplies. Navigation needs combined with winter releases for waste supply and hydropower demands obligate all available water during a normal year. The navigation season on the Missouri River is limited to the ice-free season between April 1 and December 1.

Flood Damage Reduction

A flood in 1927 affected millions of people throughout the Mississippi River Basin and demonstrated the inadequacy of the pattern of private flood damage reduction measures begun in 1879. It became a milestone event leading to major changes in national floodplain management policy. The 1928 Flood control Act, which established the lower Mississippi River flood damage reduction system, and the 1936 Flood Control Act were the first codification of the

Figure 2.2 Typical Upper Mississippi River Lock and Dam.

federal interest in the coordinated development and installation of flood damage reduction measures. The primary method used to prevent damages in those early years was floodplain levees. Starting in 1936 the USAE responsibilities were focused on major rivers and development of congressionally approved plans for reservoirs, levees, channelization, and diversions. The method s used were those determined to be most cost effective for preventing flood damages.

The USACE has constructed 76 reservoirs in the upper Mississippi River Basin. These control a drainage area of almost 370,000 square miles and contain a total flood storage volume of 40 million acre-feet of water.[4] Forty-nine are located in the Missouri River Basin where the USACE also operates 22 Bureau of Reclamation reservoirs for flood storage. The majority of the reservoirs are operated to provide benefit s on the tributaries where they are located; some are operated to benefit the main stem rivers.

In addition to the reservoirs, the USACE has constructed or improved over 2,200 miles of levees for the protection of communities and agriculture in the upper Mississippi River Basin. Though records on the federal levees are kept by the USACE (Table 2.2), there is no known inventory about the estimated 5800 miles of non-federal levees that are in the upper basin.

Flood damage reduction-related activities of the SCS began nationally in 1944 with passage of PL 78-534 authorizing installation of upland treatment and flood damage reduction work selected watersheds. The Watershed Protection and Flood Prevention Act of 1954 (PL 83-566, referred to herein as PL-566) expanded the SCS flood damage reduction program to the entire nation. During the past 40 years, in the nine midwestern states affected by the Flood 1993, the SCS has planned and evaluated 316 watershed projects covering 40,000 sq.mi. (25.5 million acres). Locally sponsored PL-566 projects have resulted in the installation of 2,964 reservoirs that influence the drainage of over 5 million upland acres, and 818 miles of channel work, 75 percent of which is located in North Dakota, Minnesota, and Illinois. The SCS requires 75 percent of the land above a proposed reservoir site to be treated before construction. It is estimated that PL-566 has resulted in soil and water conservation treatments on more than 3 million upland acres.

Although flood damage reduction reservoirs and levees reduce the risk of flooding, they do not eliminate it. Given enough rainfall the flood damage reduction storage capacity of a reservoir can be exceeded and water will overtop the spillway. Local flooding may then occur downstream; its extent will depend upon the condition of the stream when

Table 2.2 Levee Constructed or Improved by the USACE in the Upper Mississippi River Basin.

the overtopping occurs. Throughout the basin, the Flood of 1993 exceeded the design capacity of many levees and the flood storage capacity of some reservoirs, flooding lands and property of persons who may have thought they were not at risk.

Wetland Losses

Wetlands occur in poorly drained soils and in areas where water is found at or near the ground surface. Between 1780 and 1980 an estimated 53 percent of the nation's original 221 million acres of wetlands were drained.[5] In the nine mid western states affected by flood 57 percent of the wetlands have been converted to other uses (Figure 2.3). The SwampLand Acts of 1849, 1850, and 1860 resulted in the transfer of nearly 65 million acres of wetlands in 15 states from federal state administration for the purpose of expediting their drainage.[6]

United States policy from the mid to the late 1800s has been to cede "overflow and swampy" lands to the states and to convert these lands to productive use.[7]

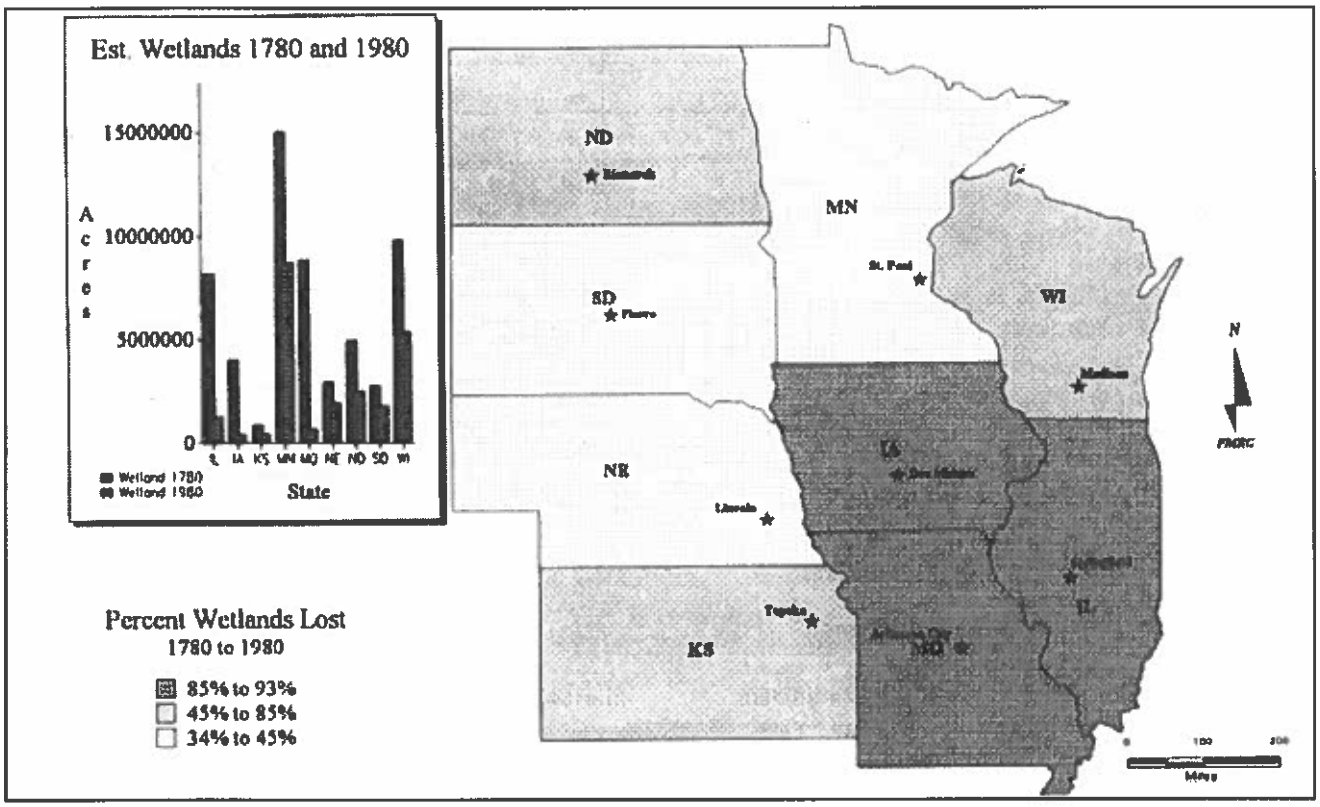
Substantial bottomland timber harvesting began with arrival of pioneers, and by the 1930s, most wetlands had been converted to from natural to agricultural used and over 84 million acres nationwide had been included in regional enterprises known as drainage districts.

By the 1950s, forested wetlands had been reduced to 66.7 million acres, and by the mid-1970s in additional 6.5 million acres had disappeared.[8]

Between the mid-1950s and 1970s an average of 458,000 wetland acres were lost each year in the coterminous United States. Agricultural development was responsible for 87 percent of the loss as wetlands were drained, filled, or otherwise converted to cropland.

IMPACT AND EFFECT

Development in the upper Mississippi River Basin for agriculture and other economic activity, flood damage reduction and navigation has greatly altered the original landscape. The characteristics of Food events and the modification of the basin's natural resources reflect these changes.

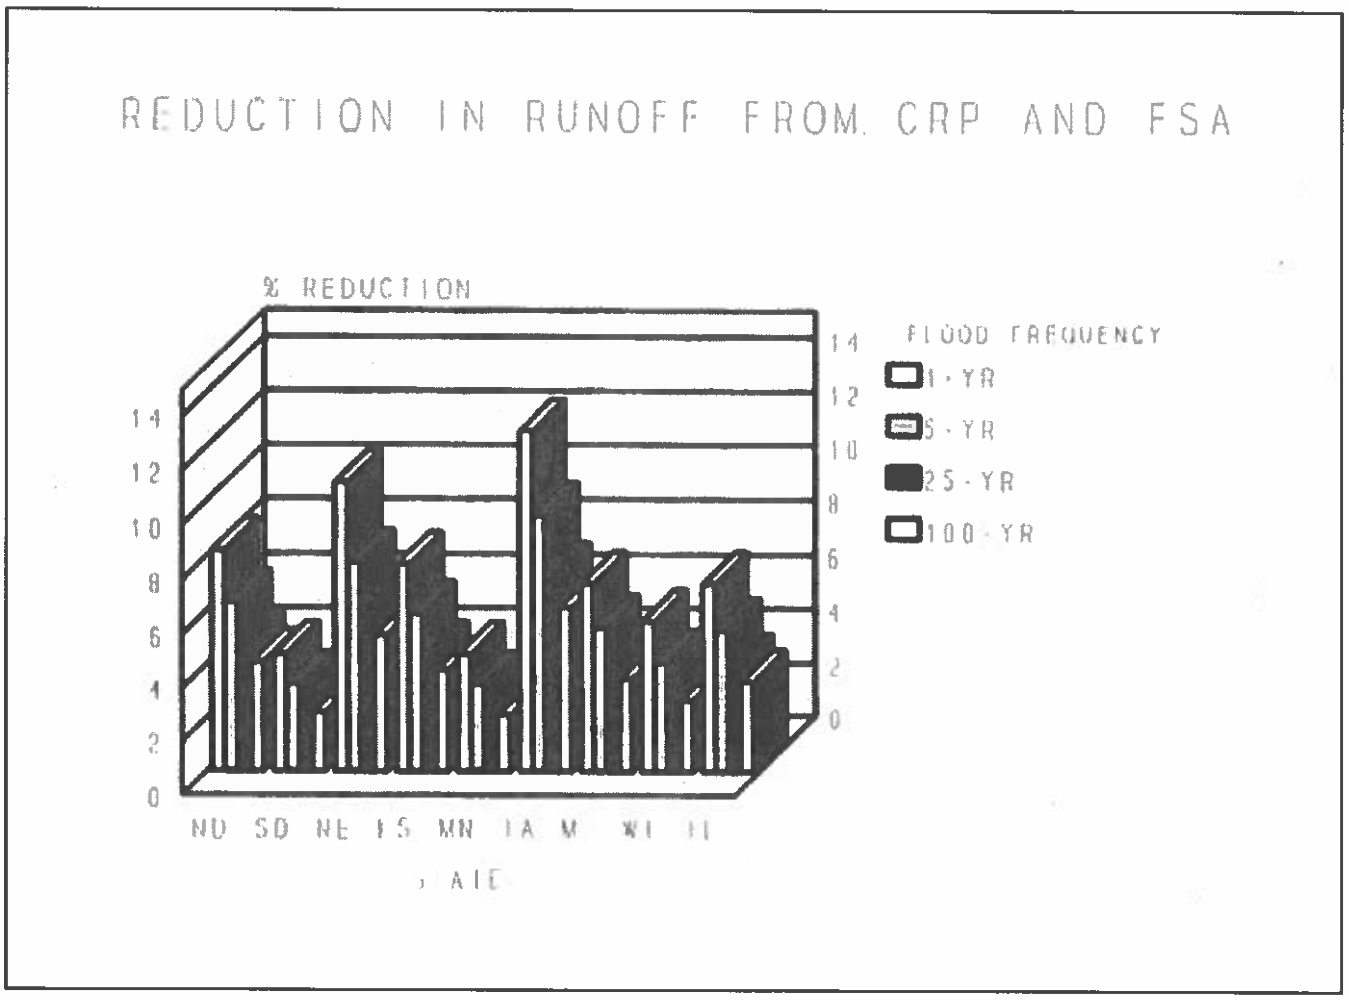


Upland Treatment and Runoff

Upstream land use and land treatment affect downstream flow regimes of rivers and floodplains. In considering floods and floodplain management, knowledge of where and how runoff occurs and which land practices can hold the rain where it falls for as long as possible become critical. Proper management can greatly affect the quantity and quality of water and sediment transported by floodwaters. Factors influencing the amount and velocity of run off include the amount and intensity of precipitation, soil type, land slope, available storage and land cover.

Proper management of agricultural lands requires use of protective cover or land conversation practices. In the Midwest cropland erosion can be reduced by using measures such as conservation tillage, terraces, crop rotation, field border, sediment and debris basins, strip cropping, and permanent vegetation. Such land use practices increase infiltration rates and help hold both water and soil in place. It is estimated that 37 percent of the nation's croplands have adequate land treatment installed.[9]

Figure 2.3 Estimated Wetland Losses, 1780 Through 1980



Source: Based on GAO/RCED-92-79FS, Report fo November 1991.

The 1985 Food Security Act (1985 Farm Bill) mandated treatment of all highly erodible land (HEL) with conservation measures needed to reduce erosion. The Conservation Reserve Program (CRP) established by the Act was intended to encourage landowners to retire highly erodible and other environmentally fragile land from crop production for ten years. In the upper Mississippi River Basin, over 200,000 CRP contracts were signed and 10.9 million acres were converted from cropland to grass or tree cover at a ten year cost of $11.3 billion. This has r educed the average erosion rate from 18.6 tons per acre per year. Assuming normal antecedent soil moisture conditions, CRT lands reduced runoff volumes by approximately 6-12 percent for the 1-year event, 3-8 percent for the 25-year event, and 2-4 percent for the 100-year event.[19] In the case of the 1993 flood, soils were saturated and the quantity and intensity of rainfall so great that runoff reduction attributable to land treatment was minimal (Figure 2.4)

Figure 2.4 Effects of the Food Security Act.

As CRP contracts begin to expire in September 1995, a large portion of enrolled acres is expected to revert to cereal, row-crop, and forage production. Current estimates are that 63 percent of land under contracts will revert to cropland and 23 percent to grazing and pastureland. The remainder is expected to remain in permanent grass and trees and other miscellaneous uses.[11] Conversion of these lands to cropland is expected to increase storm runoff even allowing for installation of proper conservation practices.

Conclusion: ***Upland watershed treatments such as conservation tillage practices and CRP land easements are effective in reducing upland runoff, especially for smaller storm events, for large events like the 1993 flood, upland treatments had little effect.***

Wetlands and Flood Storage

Pre-1850 historical records indicate that even prior to the clearing of wetland areas major floods occurred in the Mississippi River Basin. As part of economic development in the Midwest a substantial percentage of agricultural lands were created by drainage of wetlands and hydric soils. Hydic soils, good indicators of past and present wetland locations, total 10.4 percent of Mississippi and Missouri basin soils.[12] The review Committee heard numerous times that flooding would have been reduced had more wetlands been available for rainfall and runoff storage. An evaluation of the upper Mississippi River Basin's capacity to store rainfall runoff estimates that the soil profile has 10 times more storage capacity than above ground storage in depressional potholes.[13] Because much of the basin was depleted and unable to store water from the rains of June and July.[14]

Surface depressions or potholes occur throughout the glacial landscapes of north central Iowa, east South Dakota, and North Dakota. When these depressions fill, surface waters flow from pothole to pothole through an ill-defined network, eventually finding an outlet to a surface stream. This intricate network of depressions slows runoff. A different pattern of runoff occurs in the remainder of the basin. There surface runoff flows through and open network of streams, with only minor areas of surface water storage available. Historically, shallow wetlands and wet prairies, which occurred in these areas, served a similar, but less effective, function to that of potholes.

Topography has a direct impact on water movement and soil formation. The upper Mississippi River Basin is characterized by two distinct kinds of landscape: open systems, which drain externally and closed systems where drainage is trapped within a common depository. Due to the extended period of rain preceding the 1993 flood, the impacted area became completely saturated and surface depressions filled; therefore, storage available for additional runoff could only be found in the deep depressional areas located in the prairie pothole region of the Dakotas, Minnesota and Iowa.

Hydrologic mode studies of four watersheds that are representative of distinctly different upper Mississippi River Basin areas or terrain units were completed in 1994.[15] The modeled watersheds represent only 5 of the 70 terrain types in the basin and therefore information derived from these modes has limited applicability to assessing flood flow reductions basin-wide. The following watersheds were selected for hydrologic studies:

- Boone River near Webster City, Iowa –a Central Towa and MinnesotaTill Prairie with a relatively steep 380 sq.mi. watershed with well incised drainage.

- White Creek near Dallas, Iowa—an Illinois and Iowa Deep Loess and Drift and Iowa and Missouri Heavy Till Plain with a relative steep 380-sq. mi. watershed with well incised drainage.

- West Fork Cedar River near Finchford, Iowa—a Eastern Iowa and Missouri with Prairie with a flat 850 sq.mi.watershed but having well defined drainage system.

- Redwood River Watershed above Redwood Falls, Minnesota -- a Central Iowa and Minnesota Till Prairie and Loess Uplands and Till Plain with both high relief and low relief pothole areas of a 700 sq.mi.watershed.

For the analysis all model runs used antecedent moisture condition II for the start of modeling conditions Condition II is defined as the average soil condition prior to the annual flood event. For the 1993 flood antecedent conditions were condition III in most areas. Condition III indicates near saturated soils prior to the storm and gives significantly higher runoff that antecedent II. Because the model analysis used a lower antecedent moisture condition than was actually experienced in the 1993 flood, the peak discharge reductions resulting from the model analysis are greater than would have occurred.

In areas where opportunity exists, wetlands and small detention structures can aid in lowering peaks. However, flood peak discharge reduction is dependent on the topography of the watershed, the percentage of the basin containing deep depressional storage, and the intensity and volume of the rainfall.

In the watersheds modeled the maximum reduction for floodplain wetlands was 6 percent of 25- and 100-year storm event. Wetlands are more effective in upland areas with more deeply incised potholes, such as the Redwood River watershed. Where reductions were 23 percent of the 1-year event, 11 percent of the 25-year event, and 10 percent of the 100-year event. In areas of shallow depressions, such as the Boone River watershed, restored wetlands reduced peak discharge by 9 percent of 1-year event, 7 percent of the 25-year event, and 5 percent of the 100-year event.

With the installation of a combination of land treatment measures and restored wetlands in the watershed, the models indicate runoff reductions of 12 to 18 percent are possible for the 25-year or less event. This indicates these practices could be effective for the smaller storm events.

Wetland restorations in the uplands could function much the same as small upland reservoirs. It was shown more than three decades ago that small flood damage reductions dams are effective in the reach of stream immediately downstream but their effect diminishes rapidly with distance. As far as a series of small headwater dams is concerned, they are essentially ineffective under conditions in which major floods occur on large rivers.[16]

A State of Illinois report concluded that for certain watersheds, peak flow decreases as wetland areas increase. In very small watersheds (less than 100 sq.mi.), peak flowrates decreased by an average of 3.7 percent for each increase in wetland area equivalent to one percent of the area of the watershed. Applicability of this report may be limited only to the study areas. While wetlands may have some impact on peak flow in the smaller watersheds during smaller storms, their effects in larger watersheds during smaller storms, their effects in larger during larger events has not been sufficiently documented and needs further study.

Previous watershed evaluations, such as the study of Devils Lake in North Dakota (a closed basin), indicate reductions of peak flowrates up to 41 percent for 1 100-year storm. These widely ranging results from the aforementioned studies demonstrate that alternative watershed practices produce varying degrees of success in reducing flood runoff rates depending (in addition to the magnitude and intensity of the rainfall and antecedent moisture conditions) on the percentage of the basin treated and basin topography. Generally, as drainage areas increase, upland treatment measures, wetlands, and small detention structures have less effect in decreasing peak flowrates. In short, land treatment and detention storage (upland wetlands) can play a role in reducing peak runoff in some watersheds but are not a panacea for solving flood problems. Only a combination of upland and floodplain management practices can reduce floodplain damages in the future.

Conclusion: ***Upland wetlands restoration can be effective for smaller floods but diminishes in value as storage capacity is exceeded in larger floods such as the Flood of 1993. Present evaluations of the effect that wetland restoration would have on peak flows for large floods on main rivers and tributaries are inconclusive.***

Flood-storage Reservoirs

The 1993 flood demonstrated that dams and reservoirs, engineered and built to store and regulate floodwater discharge, could reduce flood damages. All federally funded flood storage reservoirs operated as planned during the 1993 flood. At some facilities, such as Tuttle Creek Reservoir (Kansas) and Coralville reservoir (Iowa), emergency spillway flows occurred when inflow volume exceeded reservoir storage capacity, the storage space allocated in a typical reservoir and effect of flood storage is depicted in Figure 2.5. During the period of peak flooding (April 1 to August 1, 1993), the USACE reservoirs stored 22.2 million acre-feet of flood water.[17] Approximately 18.7 million acre-feet were stored in the Missouri Basin, half of which was stored in the 6 main stem.

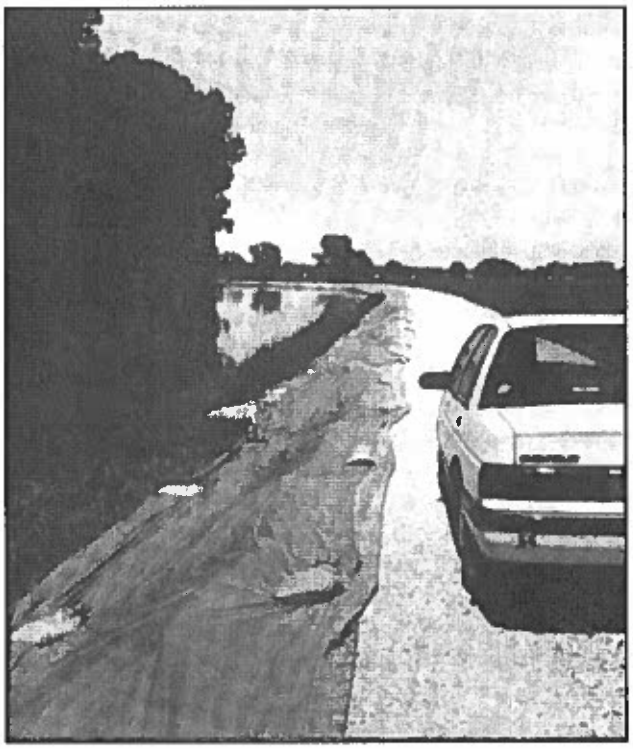
RESERVOIR OPERATIONS

Flood control reservoirs temporarily store a part of the flood flow for later release so that peak downstream flows will be reduced. Food-storage capacity is always located above sediment and multi-purpose pool elevations. Food damage reduction reservoirs have emergency spillways that allow safe passage of flows that exceed storage capacity. All managed flood damage reduction reservoirs are operated pursuant to a water control management plan. In no case will the peak discharge from the dam exceed that which would have occurred without the dam.

Missouri River reservoirs. Most of the remainder was stored in tributary reservoirs of Kansas and Osage rivers. About 3.5 million acre-feet of water was stored in the Mississippi River Basin and an additional 1.1 million acre-feet were stored in 2,964 small PL-566 upland flood damage reduction reservoirs. Flood damages reduction reservoirs effectively controlled excess runoff and reduced damages to downstream floodplains during the 1993 flood event. The combined effect of the storage of flood waters in the federal flood damage-reduction reservoirs in the Missouri River basin reduced the average discharge of the Missouri River near it mouth, during the month of July, by 211,000 cfs. This had the effect of lowering the peak stage of the Mississippi River at St. Louis by 5 feet.

Levees

Federally constructed levees, in concert with upstream flood-storage reservoirs, protect many large urban areas from potentially significant damage. For example, without levees or floodwalls, portions of low-lying areas in Rock Island and Moline, Illinois, and Kansas City would have been devastated. At St. Louis the Mississippi River crested at 49.6 feet on the USGS gage, almost 20 feet above stage, yet that portion of the city protected by the large flood wall escaped inundation.



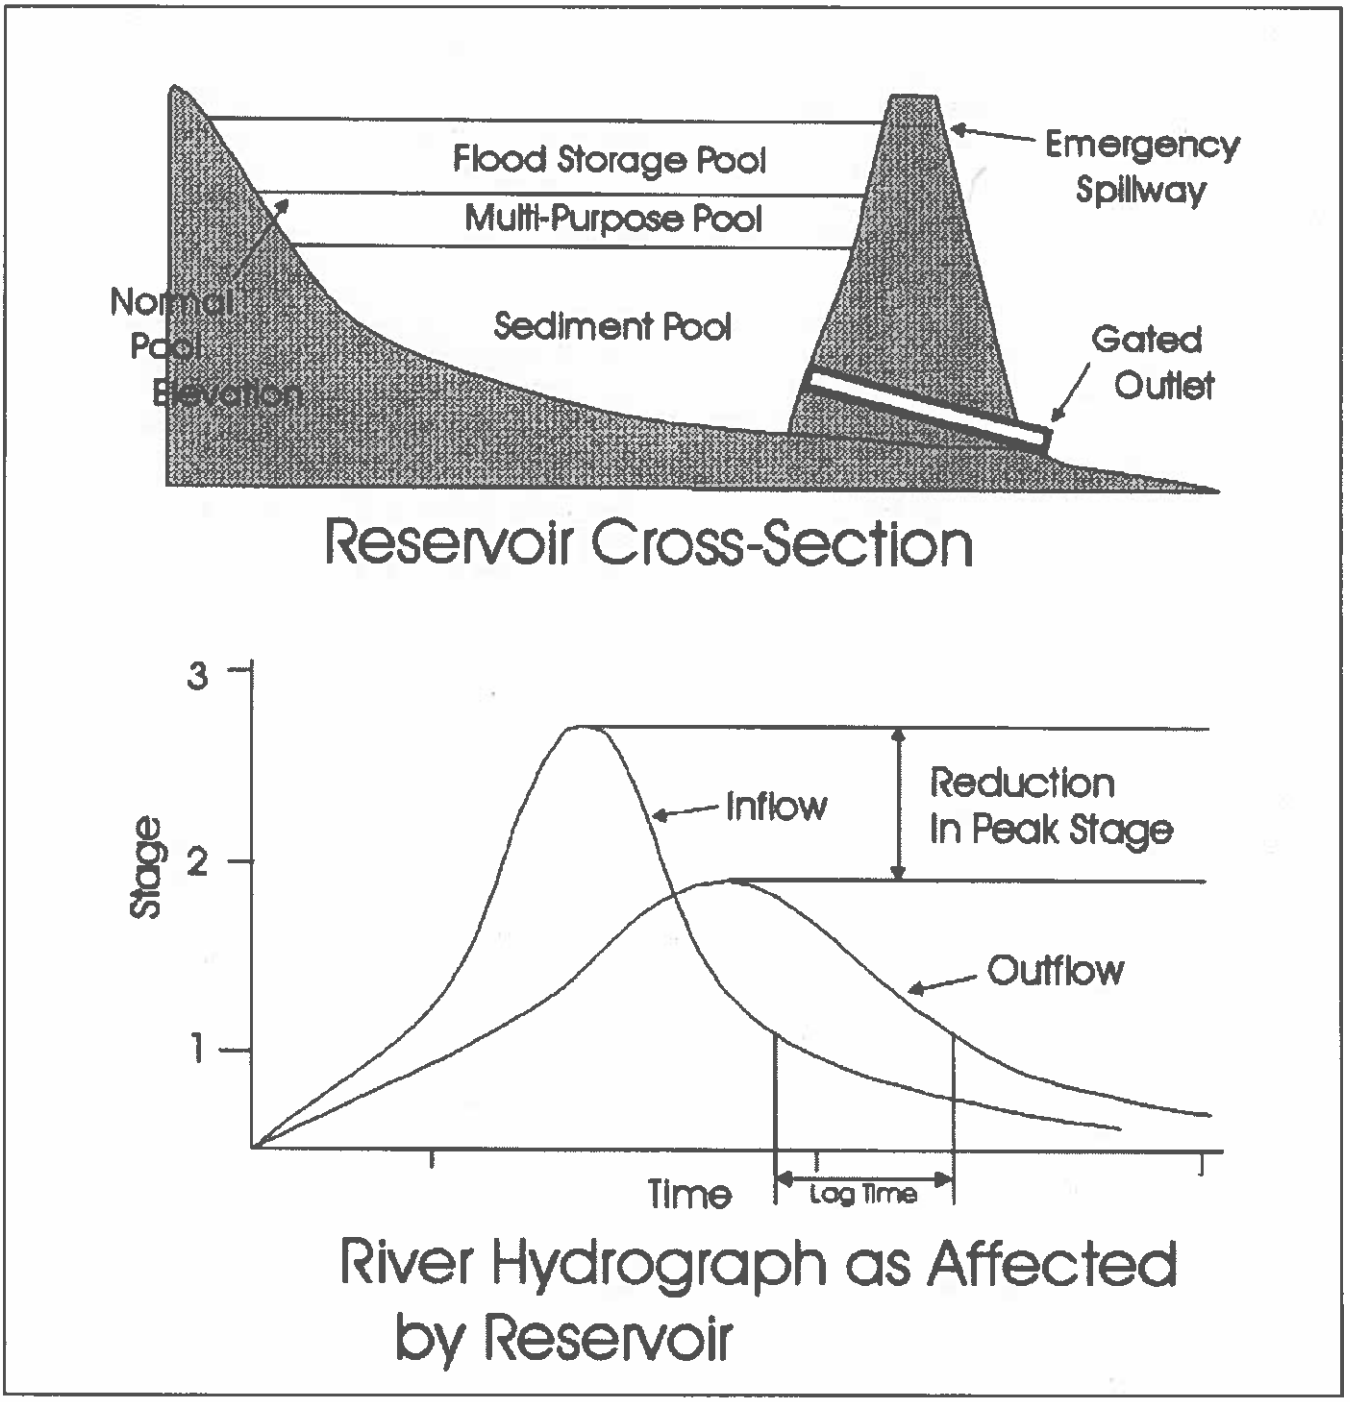


Figure 2.5 Typical Reservoir Cross Section and Hydrograph.

Source: Floodplain Management Review Committee. Adaption

Much of the speculation about the effect of levees on flood levels during the 1993 flood was based upon inferences drawn from comparisons between recent event data, obtained from systematically-measure d river flow (discharge) and river level (stage) records, and similar data for historical floods. Such discussions fail to recognize that significant differences in data quality exist between the modern (after 1930) and the historic record.[18] In addition, many other changes have occurred in the upper Mississippi River Basin which have created differences in flow regimes over time.

To ascertain the actual effect existing levees had on peak 1993 Mississippi and Missouri river flood stages, the UNET model, which analyzes unsteady state river flow condition,[19] was applied to the river reaches where cross-sectional data were available:

(1) the Mississippi River between Hannibal, Missouri, and Cairo, Illinois,

(2) the Missouri River between Hermann, Missouri, and the mouth at St. Louis, and

(3) the Illinois River Between Meredosia , Illinois, and the mouth above St.Louis.

The analysis used flow data from 1993, 1986, and 1973 floods and developed water surface profiles resulting from the same flood flows without levees. The model was calibrated and a range of possible floodplain ground covers was used.[20] The analysis suggested that if all the levees (other than urban levees) were absent, the peak stage at St. Louis in 1993 would have been reduced by 2.5 feet, but still more than 17 feet above flood stage and almost 4 feet higher than the previous known maximum level recorded during the 1973 event. This model scenario assumes the improbable condition of a totally open floodplain covered only with bare soil or short grass cover. If one assumes existing levees would have constructed to contain all flows, peak stages at St. Louis would have been increased by 2.3 feet.

An independent model commissioned by the *St. Louis Post-Dispatch* showed that the overtopping and breaching of two levees downstream from St. Louis at Columbia and Harrisonville, Illinois, reduced peak stage at St. Louis by 1.6 feet.[21] This analysis used steady-state model applied to a short stretch of the river and lends support to the UNET findings.

A physical model study conducted at the Waterway Experiment Station (WES) in 1979 by Foster and Allen[22] showed that the removal of the trees between the river bank and levee along the middle Mississippi River between St. Louis and Cape Girardeau would lower the stage at St. Louis about 2.5 feet for the 1973 flood, which corresponds with the mathematical (UNET) model results for the fully open, treeless floodplain assumption.

Farther downstream along the middle Mississippi River, the UNET mode predicted that there would have been a sizeable local drop in river levels in the absence of levee under the most conducive flow scenario. At Chester, Illinois, the stage of the Mississippi River during the 1993 flood would have been approximately 11 feet lower if the levees containing the river were removed. But the floodplain would have been under water. The mode predicted that there would be no stage reduction if the entire floodplain were covered dense forest or brush -- a scenario representing a least conducive flow condition. It is expected that a typical floodplain without levees would contain a mix of uses and associated land covers such as sloughs, side channels, forested and non-forested wetlands and agriculture.

Conclusion: ***Levees did not cause the 1993 flood. During large events such as occurred in 1993, levees have minor overall effects on floodstage, but may have significant localized effects.***

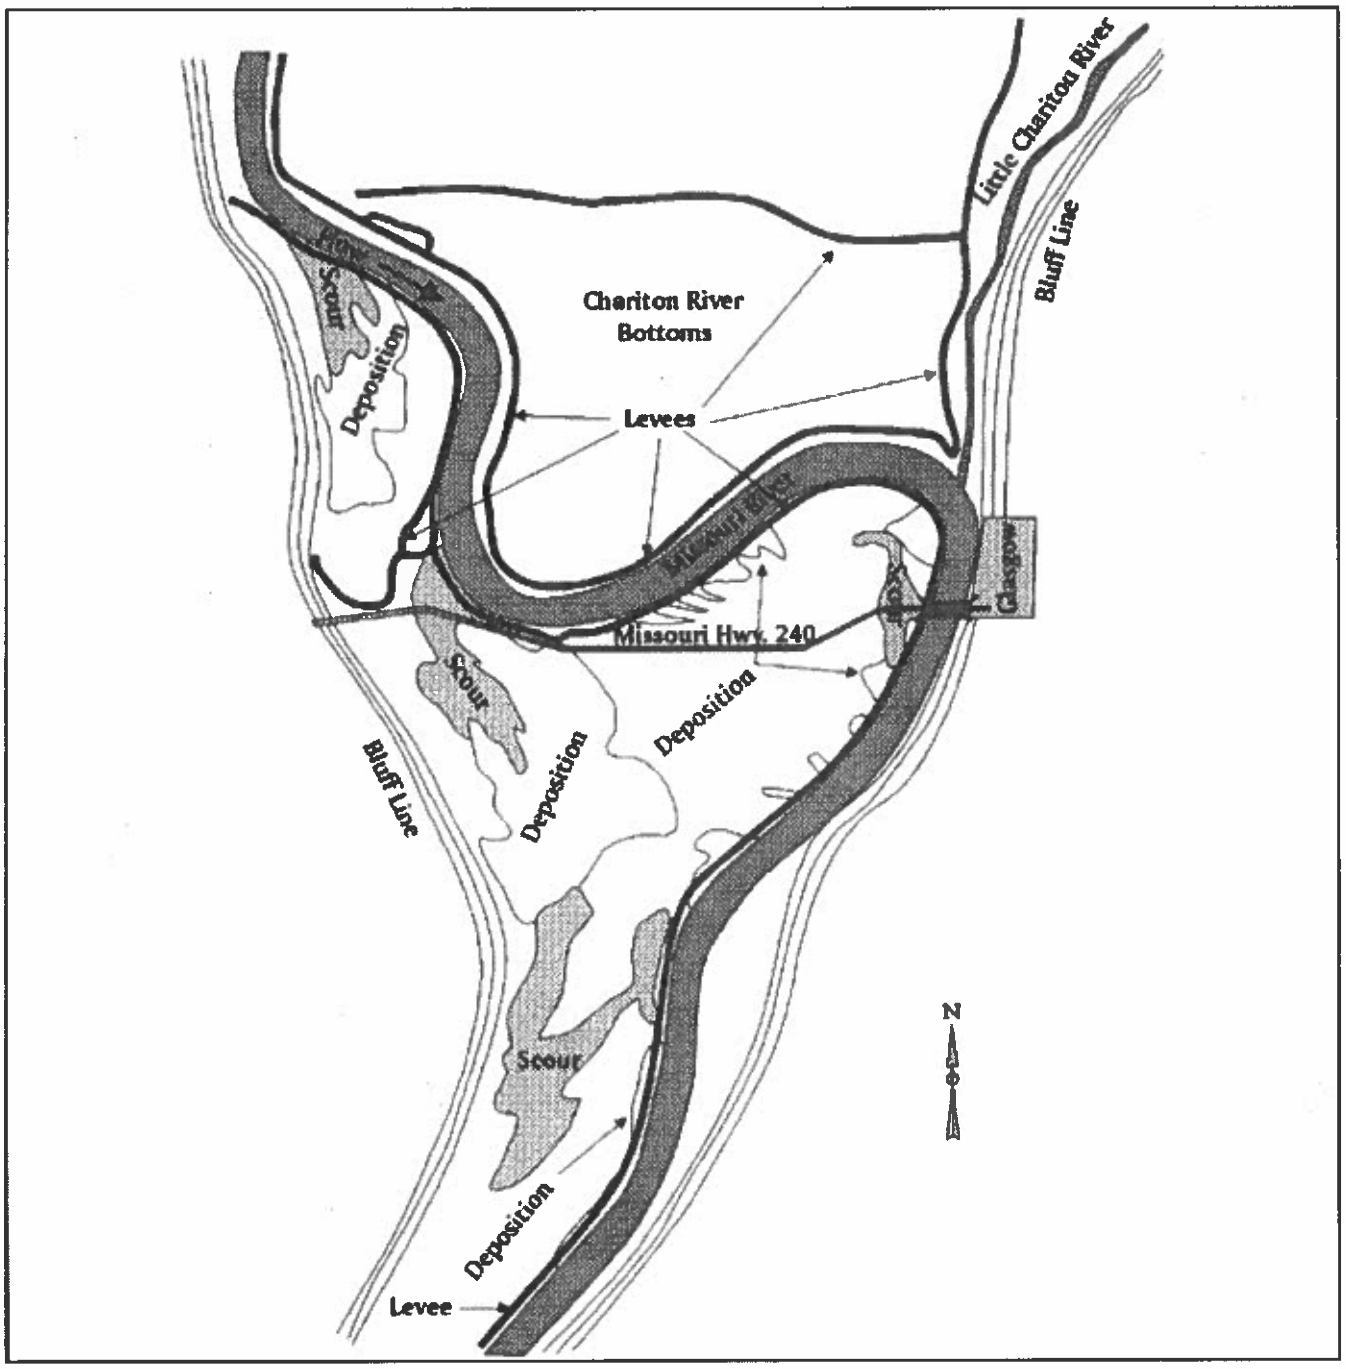
Erosion and Sedimentation

Upland erosion and the sedimentation in downstream areas are major causes of reduced water quality and habitat destruction in most midwestern rivers and streams. Sedimentation in the backwaters of the upper Mississippi River is the most significant problem in that river. In recent years, Missouri, Minnesota and Wisconsin have developed watershed management programs to reduce runoff and erosion. Land use planning and land stewardship are key nonstructural factors in reducing runoff and downstream flooding.

Significant floodplain erosion and deposition occurred during the 1993 flood, principally on floodplain agricultural lands along the Missouri River. Preliminary analyses of aerial photography, satellite imagery, and historic Missouri River floodplain maps reveal that more than 90 percent of the areas affected by significant erosion and deposition are associated with breached levees situated in active, high-energy floodplain zones.[23] Review of the history of levee failures in this area shows levees have been breached repeatedly at sites of natural river cutoffs or chutes in the past three decades. Construction of levees across these high energy channels is a risky investment which has required repetitive repair.

In most cases where levees breached, scour holes, locally known as blow holes or blue holes, occurred. These holes, typically 25 to 50 feet deep, are caused by scouring of alluvial soils underlying the levees and farm fields and are caused when the head of water exceeds the height of a levee or its ability to withstand water pressure, overtopping or breaching the levee and releasing river water through the constricted levee breach with velocities similar to that of a dam break flood wave. This sudden release of energy scours tremendous volumes of materials creating both new aquatic and terrestrial habitat. Erosional zones of scour and stripping can extend as far as one mile downstream from the larger breaches (Figure 2.6). Locally constricted floodflows in breaches through railway embankments and in the vicinity of railroad and highway bridges act in a similar manner.

Comparison of the effects of the 1993 floods on the upper Mississippi and Missouri rivers shows that river reaches in broadly similar physiographic regions may respond very differently to floods. The annual discharges of the upper Mississippi River are generally comparable to those of the Missouri River, but sediment yields of the Missouri average more than five times those of the Upper Mississippi. Average slope of the lower Missouri River floodplain (upstream of St. Louis) is about twice that of the middle Mississippi River floodplain (downstream from St. Louis). Levee breaches along the lower Missouri commonly resulted in high-velocity flows across its relatively narrow and relatively steep (high gradient) floodplain, contributing to extensive deep scour and thick sand deposition across agricultural lands located there. In contrast, levee breaches along the middle Mississippi produced less intense erosion and sedimentation; impacts were largely limited to passive inundation of large bottomland tracts.



The Pick-Sloan plan authorized by Congress in 1944 called for the creation of a floodway from 3,000 to 5,000 feet wide between levees along the Missouri River from Sioux City, Iowa, to the mouth near St. Louis, Missouri. The purpose of this floodway was to provide sufficient space for flood waters to pass and reduce potential damage to adjacent farmlands. For a number of reasons, this plan was never implemented. The Flood of 1993 demonstrated the need for some form of floodway to provide greater capacity to convey flood flows. Implementation of any future flood damage reduction plan should recognize that in lieu of a standard setback distance, the floodway should coincide with the natural high-energy zone of the river, which commonly is wide in areas of large meanders and narrow in straighter portion of the river.

Conclusion: ***Levee location and height are factors in determining erosion and deposition in the floodplain. There are certain locations where levees should not be constructed. In these cases set-back levees might allow normal river functions. Each situation needs to be evaluated on its own merits.***

Navigation

The Review Committee received numerous suggestions that the flood crest could be lowered significantly by opening navigation dam gates before the arrival of flood waters. Hydraulic investigations by the University of Iowa,[24] and evaluations of the 1993 flood show that navigation dams cause slight, localized increases in

Figure 2.6 Reach of the Missouri River Bottoms Showing "High Energy" Erosion and Deposition Zones.

Source: Floodplain Management Review Committee. Adapted from SAST data, 1994

Flood height just upstream of a dam. They do not cause increases in flood elevations for the entire Mississippi River System. In the middle Mississippi (from St. Louis to the confluence with the Ohio River) and on the Missouri River, navigation channels have no locks and dams, and the dikes and revetments which are in place cause little or no restriction to flow.

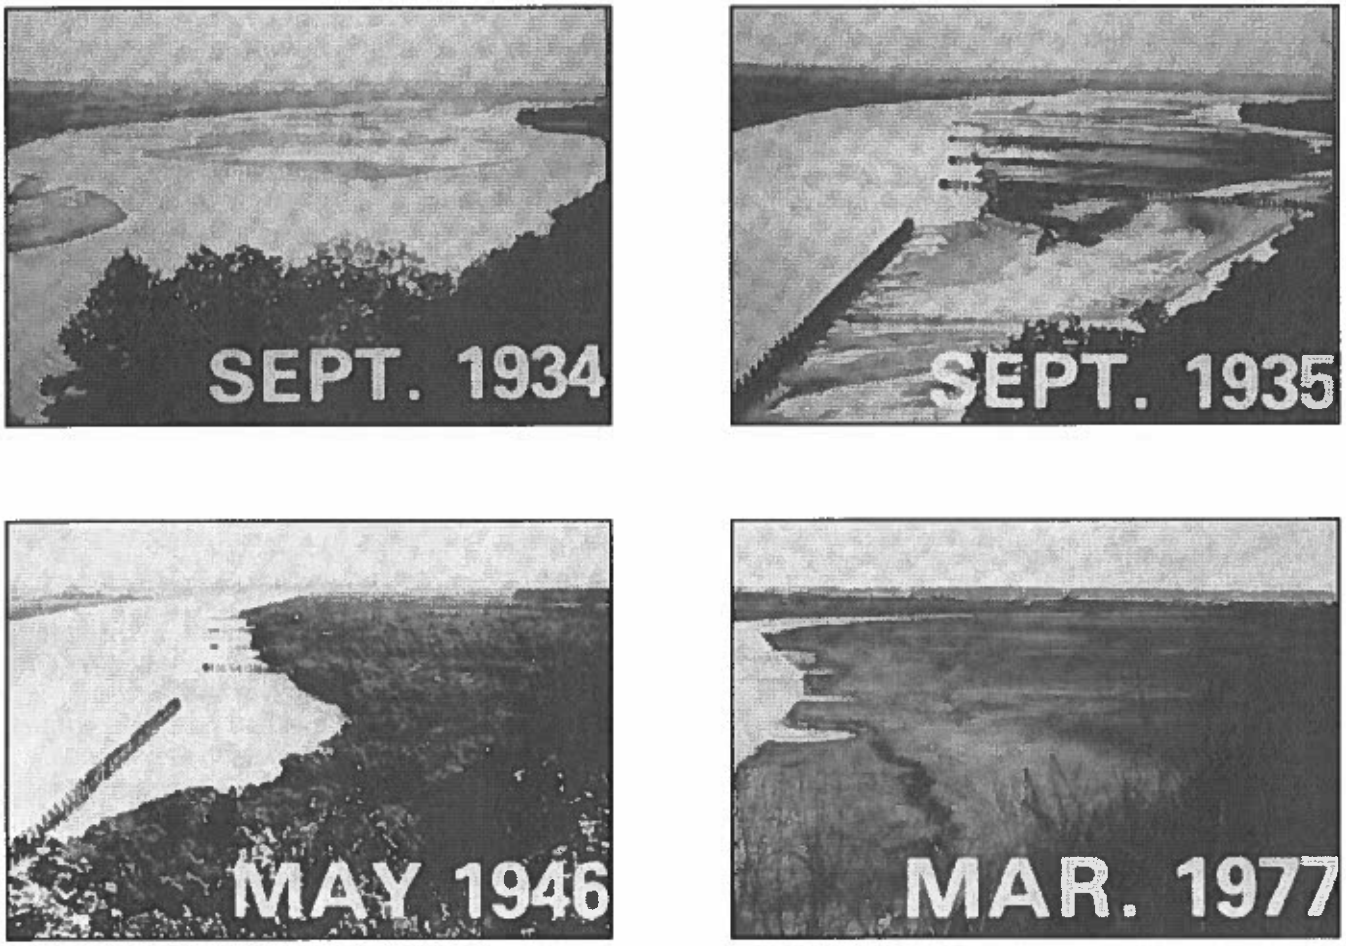
Conclusion: ***Navigation dams and locks did not cause an increase in the stage heights of the 1993 flood.***

Habitat Loss

Fish and wildlife resources in the upper Mississippi River Basin have been significantly affected by the loss of wetlands and other terrestrial and aquatic habitats due to construction for navigation and flood damage reduction structures.

Upper Mississippi River. The upper Mississippi River was originally a free-flowing, alluvial riverine environment with associated riparian habitats. Construction of navigation control structures (rock dikes) and installation of the slackwater navigation dams have created habitat types substantially different from those found in a free-flowing alluvial river.

Habitat types within the upper Mississippi River slackwater navigation pools are created by coincident physical, water quality, and botanical characteristics. River position, depth, water-surface area, stage and discharge, vegetation, river-bottom types, water quality, and the superimposed structural elements within the river define the various habitats. Three distinct habitat zones occur in the slackwater navigation pools. The upper end of each pool is like the original river although subject to exaggerated water level fluctuations from the upstream dam releases. March development is limited. In the middle portion of the pools, downstream impoundment backs water up and over the islands and old hay meadows, creating large areas of shallow water. This section has the best marsh development, and some deep sloughs and wooded islands can be found. In the lower end, immediately above each dam, wide open water lake-like areas occur (Figure 2.2).



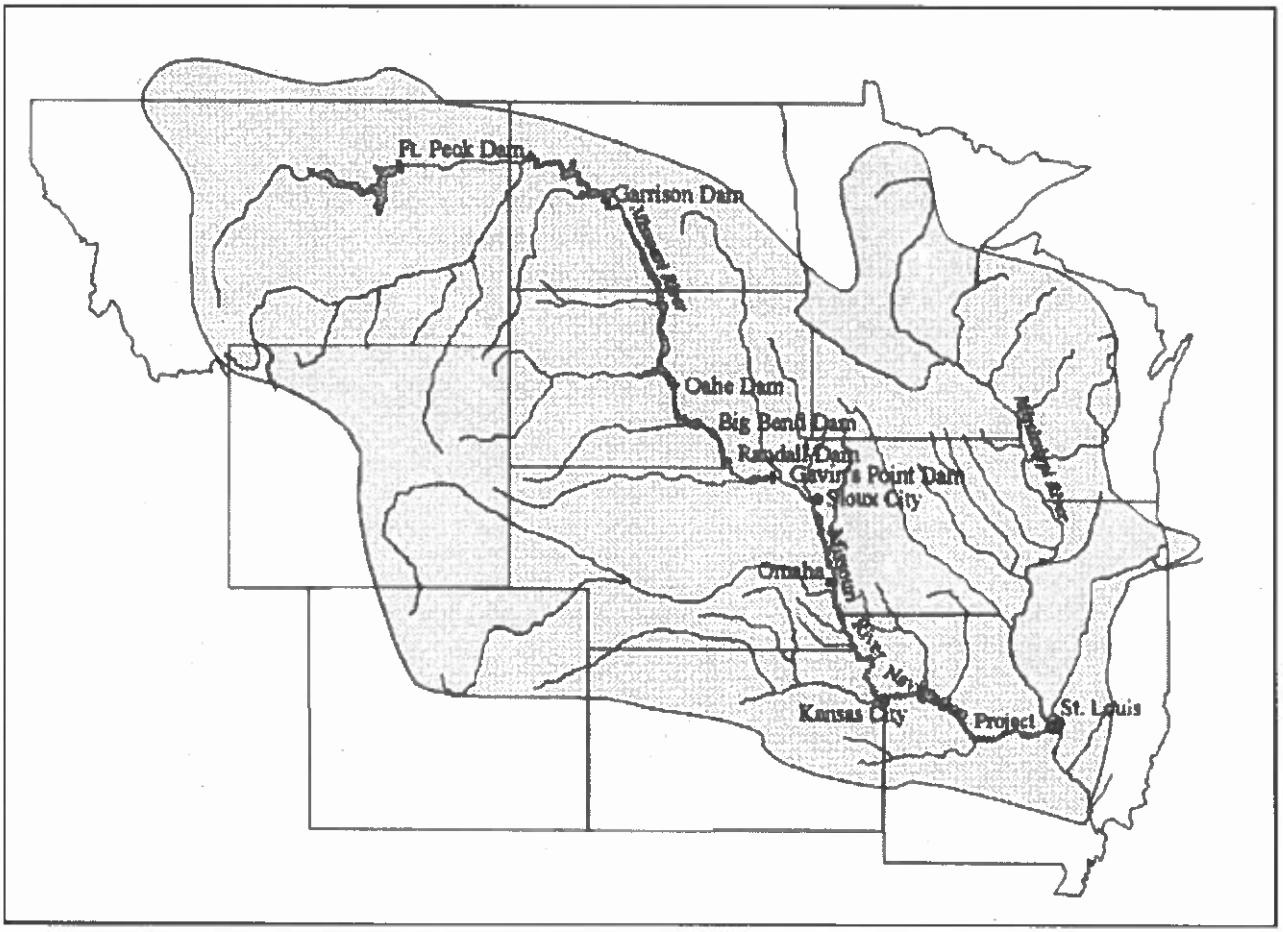
While impoundment of the upper Mississippi River for slackwater navigation created a variety of backwater and side-channel habitats, these dams also slowed river currents, starting the irreversible process of sedimentation. Many backwater habitats are filling with sediments from the erosion of upland agricultural and developed lands. Rock dikes and channel maintenance dredging also contribute to the problem. Mississippi River backwaters shill provide critical fish production and nursery habitats, but may be lost to sedimentation and eutrophication within 60 yrs.[25]

Downstream from its confluence with the Missouri River, the upper Mississippi River takes on a very different character, similar to that of the Missouri (see Missouri River habitat description). Forth-six species of Mississippi River fish, virtually all of which have been affected by flood damage reduction measures and navigation, are listed by basin states as rare, threatened, endangered, or a species of special concern.[26]

Missouri River. Parts of the Missouri River were well known as a braided river with swift, muddy flows. The historic floodplain was a ribbon of islands, chutes, oxbow lakes, backwaters, marshes, grasslands, and forests. Sandbars and wooded islands dotted the channel. Between 1879 and 1954, human actions and natural changes shortened the river by 45.6 miles, reduced river surface area by over 50,000 acres, reduced the number of islands from 161 (24,419 acres) to 18 (419 acres), and converted nearly 67,000 acres of river habitat from public to private ownership, most to agriculture.[27]

Nearly one-third of the Missouri River has been impounded, another one-third channelized, and the hydrologic cycle, including temporal flow volume and sediment transport, has been altered on the remainder. The Missouri River formerly had peak run-off during two periods, March-April and June. Prior to 1954 flushing flows, known as dominant discharge, occurred every 1.5 years. The river was in a state of equilibrium; net sediment entering a reach replaced an equal amount leaving allowing for ample habitat

Figure 2.7 Changes in Channel Morphology Following the Addition of Navigation Dikes, Indian Cave Bend, Missouri River, North of Rulo, Nebraska.



Source: USACE

development, and aquatic nutrition. Loss of sediment load let to channel degradation which contributed to the loss of off-channel habitat and further severed the river from its floodplain. Since the early 1950s the Missouri River has thus been deprived of a floodplain in most reaches. Water temperature, photoperiod, and run-off cues have been altered by reservoir releases for navigation and other purposes.[29]

Changes in basin and floodplain physiography and channel morphology have reduced commercial fish harvest by more than 80 percent and are implicated in the demise of native species. The Missouri River's natural riparian ecosystem has been nearly eliminated and presently consists of a discontinuous, single row of trees. Missouri River floodplain forest coverage decreased from 76 percent in 1826 to 13 percent in 1972, while cultivated lands increased from 18 percent to 83 percent.

Figure 2.8 Missouri River Reservoirs and Navigation System.

Thirty-four species of Missouri River Basin stream fish are listed by basin states as rare, threatened, endangered, or as species of special concern.[29] The pallid sturgeon, piping plover, least tern, and bald eagle are all native Missouri River species listed as endangered by the U. S. Fish & Wildlife Service (FWS).[30] Population densities of five species of chubs[31] and two species of minnows[32] have been reduced by as much as 95 percent since 1971.[33] Burbot have been nearly extirpated, sauger have been greatly reduced, and blue catfish are rare.

The Master Water Control Manual for the six Missouri River main stem reservoirs is currently under review by the USACE. Decisions made with regard to this manual are important to the future of the Missouri River ecosystem. For example reservoir water releases could be adjusted to simulate natural hydrographs and, in combination with riparian land acquisition, be used to restore many of the river's natural functions including low-level flooding of riparian lands.

Illinois River. Aquatic and terrestrial habitats of the Illinois River Valley have suffered a series of cataclysmic events since 1900: (1) permanent rise in water level from water diverted from Lake Michigan, (2) the draining of more than half of the 400,000 acre floodplain through the construction of levees and pumping stations, (3) an upsurge in untreated urban and industrial pollution during the 1920s, (4) the creation of a 9 ft. channel and its attendant navigation dams in the 1930s, and (5) an acceleration in sedimentation rates following World War II, apparently resulting from an increase in the amount of open row crops grown within the basin.[34] As an example, in 1908, a 200-mile reach of the Illinois River produced 10% of the total U. S. catch of freshwater fish (employing 2,000 commercial fishermen and yielding 24 million lbs. of fish annually). Commercial fish yield totaled about 178 lbs/ac of permenent water, but by the 1950s yield had dropped to 38 lbs/ac and by the 1970s to 4 lbs/ac, totaling 0.32% of the total U.S. freshwater harvest.[35]

Conclusion: ***Alteration of Mississippi, Illinois and Missouri Rivers and floodplains has resulted in significant changes or losses of habitat. The disruption of natural ecosystems has caused the destruction of many native species populations and has caused an increasing number to be listed as threatened or endangered.***

19. The UNET Model is a computer program that solves unsteady state flow equations to describe floodflow conditions. Unsteady state means that the depth of flow changes with both distance along the channel and with time. The model uses a network approach to solving the unsteady state flow relationships. UNET is a 1-dimensional model and assumes that the calculated velocity at a cross-section exists across the entire river. The area behind levees are modeled as storage cells. After calibration using flow data observed in the 1993, 1986, and 1973 flows with pre-flood conditions of levee development in the floodplain, the model analyzed the water surface profiles that would result from those same flood flows assuming levees were absent. Under such a scenario, land use in most areas would be different than presently exists as would ground cover types. Because the hydraulic roughness (resistance to flow) of the floodplain cross-section must be represented in the model, a range of possible ground cover types was used, from bare soil or short grass to dense forest or dense brush. A floodplain absent of levees would likely have a mix of ground cover types ranging between and including these extremes.

Chapter 3

FUTURE FLOOD POTENTIAL

After the 1965 flood, they told us this wouldn't happen again for another 100 years.

Midwestern mayor
July 1993

This quote illustrates the lack of understanding by many individuals concerning flood potential. Many people think of flooding only in relation to a flood of a 100-year magnitude. They overlook the fact that although government regulators have selected the 100-year flood as a reasonable regulatory standard, it is not the only magnitude of flood that can occur. Floods are random, variable events. Through frequency analysis, hydrologists can characterize them as a 50-year flood, 100-year flood, or 500-year flood. The Midwest flood of 1993 varied from less than a 50-year flood at St. Paul, Minnesota, to less than a 100-year flood at Lincoln, Nebraska,[1] to over a 100-year flood at St. Louis, Missouri.[2] No one -- especially those living at risk in floodplains -- should be misled into believing that a 100-year flood occurs only once in a century. What happened in the Midwest in 1993 could happen again at any time!

WHAT IS A 100-YEAR FLOOD EVENT?

The American people have heard quite a bit recently about a 100-year flood. What exactly is it? A 100-year flood has a 1-percent chance of being equaled or exceeded in any given year. It has a 26-percent chance of occurring over the life of a 30-year mortgage, and a 63-percent chance of occurring over the next 100 years. The terminology used to describe the 100-year frequency flood, 1-percent flood, 1-percent annual chance flood, and base flood, which all refer to the same event, are often used interchangeable. Confusion can result because the 100-year flood is usually the only type people hear about, even though larger and smaller floods are likely to occur.

As commonly applied, the concepts of a 100-year flood and 100-year floodplain can be misleading. Technically only the outer edge of a 100-year floodplain has a risk of one percent. The risk rises for sites closer to a river, ocean or other water feature, and also at lower elevations, yet most people think of the entire area between the water body and the outer edge of the 100-year floodplain as subject to the same risk.[3] Variation of risk is not usually shown on floodplain maps. There are areas within the mapped 100-year floodplain that may flood more frequently and to greater depths than others.

Uncertainties surround 100-year discharges and elevations, and mapping 100-year floodplain boundaries is at best an imperfect science. Estimates of the 100-year flood discharge (or flowrate) can be based on a range of techniques, and current techniques provide estimates that could be off as much as 5 to 45 percent.[4] Factors such as the size of the watershed, the availability and length of streamgaging records, and the level of detail of mapping for use in determining model parameters contribute to the uncertainty in a 100-year flood discharge estimate. Flood discharges associated with

infrequent events, such as the 500-year flood discharge, are more difficult to predict and have more uncertainty associated with them. Even if a fairly accurate 100-year discharge is determined, it may subsequently change due to land-use changes in the watershed and natural and human changes to the channel and floodplain.

After determining a discharge rate, this figure is entered into a hydraulic model to determine the elevation of the 100-year flood. Hydraulic models, depending upon the level of accuracy of information on topography, friction losses, and hydrology, can produce estimates of 100-year flood elevations within 0.5 to 2 feet.[5]

Once the elevation of the 100-year flood has been determined, the extent of the floodplain can be mapped. Topographic maps vary in precision and level of detail.

The accuracy of the floodplain boundary line is influenced most strongly by the quality of the 100-year flood discharge estimate. The next most significant factor is the quality of the topographic mapping. Research suggests that the probable nationwide standard error for base (100-year) flood elevation mapping is 23 percent of the base (100-year) flood depth. This value, translated into an average depth, amounts to about 3 feet.[6] Thus, the floodplain boundary line shown on a map is not absolute and structures located within several feet (vertically) of the 100-year floodplain are still at risk. In flat areas, structures located within several hundred feet (horizontally) of the 100-year floodplain also may be at risk.

MARBLES AND FLOODS

At one of the public meetings attended by the Review Committee, a young Missouri farmer provided a correct explanation of the possibility of experiencing a 100-year flood. He described a bag full of 100 marbles with 99 clear marbles and one black marble. Every time you pull one of those marbles out, and it's black, you've got a 100-year flood. After each draw, you put all 100 marbles back in the bag and shake it up. It's possible that you could pull the black one out two or even three times in a row. To represent the uncertainty of estimating a 100-year flood, it's also possible that the bag could hold two or three black marbles.

STANDARD PROJECT FLOOD

Another magnitude of flood that can occur is one that results from the standard project flood (SPF) discharge. This event is not assigned a frequency or recurrence interval, although it is often used by hydrologic engineers to approximate the 0.2 percent annual chance (500-year) flood. The SPF discharge in a river represents the flow that can be expected from the most severe combination of meteorologic and hydrologic conditions reasonable characteristic of the geographic region involved. SPF discharges exclude extremely rare combinations. The SPF procedure is used in lieu of the discharge-frequency approach because of the unreliability inherent in estimating large magnitude infrequent events from short record, or even regional, discharge-frequency analyses.

The SPF discharge is currently used for design of engineered structures which, if compromised, could result in catastrophic flooding. The SPF discharge is generally used to determine the level of protection for urban population centers where there is great threat of loss of life and of damage to critical infrastructure.

RESIDUAL RISK BEHIND LEVEES

Risk exists in all areas within a floodplain -- both areas protected by channel modifications, dams, or levees and areas outside the 100-year floodplain. Levees built to provide a 100-year level of protection modify the natural overflow boundary of the 100-year floodplain and the boundaries for lesser floods. Individuals and businesses remaining in what was once the 100-year floodplain, are not required to carry flood insurance even though the chance of a flood greater than the 100-year flood occurring in the next 30 years is about 1 in 4. Uncertainties also surround a levee's level of protection. Engineers may account for discharge and elevation uncertainties in the design of levee by the use of freeboard -- the difference between the top of the levee and the design flood height. Even though areas protected by levees are considered safe, the potential for catastrophic loss still exists. If floodwaters overtop a levee, flooding in the protected area could reach depths equaling or exceeding the levee's height. Higher levees reduce risk but could increase potential damage.

CLIMATE CHANGE

Climate change could increase flood risk. Although considerable uncertainty exists, climate change could bring about more-frequent and/or more intense floods. Given that development in and near floodplains is expected to last considerable period of time and that the nation's ability to predict the magnitude and frequency of future events is still limited, it may be prudent to consider the potential effects of climate change when decisions are made (or revised) about the type and amount of development allowed in vulnerable areas. In the absence of sufficient data, flexible and cautious policies are preferred.

U.S. Congress, Office of Technology Assessment
Preparing for an Uncertain Climate ---- Volume I

FUTURE FLOODS

Not every state and local government regulates storm water runoff, and the volume of runoff and flood peaks may increase in the future because of urbanization. The streets, parking lots, gutter, drains, and storm sewers accompanying urbanization convey rainfall rapidly to stream channels. Natural channels are often straightened, deepened of lined, transmitting flood waves downstream more quickly. Storm waters can therefore accumulate downstream more quickly than in natural river systems and produce higher, shaper flood peaks. Unless steps are taken to mitigate the impacts of urbanization, flood volumes and peaks will continue to increase.

FUTURE FLOOD POTENTIAL

Current flood records are limited by their length. As flood records for more years become available, current estimates of flood discharge, volume, stage, and duration will change.

In the 1993 flood, out of more than 500 USGS gaging stations in the area of flooding streams,[7] 45 exceeded the 100-year discharge,[8] but at least 450 did not. Many people think that the entire upper Mississippi River Basin experienced a 500-year flood, when setimates indicated that only the research of the Mississippi River from Keithsburg, Illinois, to above St. Louis and the reach of the Missouri River from Rulo, Nebraska, to above Hermann, Missouri, endured such a flood.[9] Since 1900, St. Louis has experienced large floods in 1903, 1909, 1927,1973, and 1993. The communities in the Midwest that experienced a 10- to 50-year flood in 1993, may experience a 100- to 500-year flood in the near future. There is no question that flooding is inevitable. The open questions are when? Where? And how much?

Conclusion: ***Floods equal to and greater than the flood of 1993 will continue to occur across the nation. It is difficult to predict precisely when and on what rivers these large events will happen.***

Part II

A BLUEPRINT FOR THE FUTURE

Chapter 4

A VISION FOR THE FLOODPLAIN

The Congress...declares that it is the continuing policy of the Federal Government, in cooperation with State and local governments, and other concerned public and private organizations, to use all practicable means and measures, including financial and technical assistance, in a manner calculated to foster and promote the general welfare, to create and maintain conditions under which man and nature can exist in productive harmony, and full till the social, economic, and other requirements of present and future generations of American.

Section 101, National Environmental Policy Act of 1969

...it is the sense of Congress that flood control on navigable waters or their tributaries is a proper activity of the Federal Government in cooperation with the States, their political sub-divisions, and localities thereof, for flood control purposes are in the interest of the general welfare; that the Federal Government should improve or participate in the improvement of navigable waters of their tributaries, including watersheds thereof, for flood control purposes if the benefits to whomsoever they may accrue are in excess of the estimated costs, and if the lives and social security of people are otherwise adversely affected.

Section 1, Flood Control Act of 1936

The United States, as it moves into 21st century, is at a crossroads in the use of its floodplains. The nation may choose to use these flood-prone lands for the primary purpose of economic development, or it may take action to better balance their economic and environmental outputs. Floodplain resources can be shared by human occupants and natural systems. Over the last century, in the upper Mississippi River Basin, while human activities have produced significant economic and social benefits, some of these activities have placed both human and nature at risk.

Flood control works have allowed cities to grow in the face of periodic high waters. Until the middle of this century, the nation did little to control the clearing of lands of the floodplains. Subsequent increases in runoff generated the need for additional flood damage reduction activities. Levees, built by both the federal government and private lawn owners, helped agriculture flourish in the fertile bottomland environment; however, the overtopping of these levees by floodwater created major economic losses. Reservoirs, like levees, reduce the flood threat to many downstream communities, but the reduction in flood flows simultaneously creates incentives for many people to settle riverbanks and become subject to the impacts of the next major flood. The promise of post-flood support from government and private agencies may encourage people to continue occupying land at frequent risk of flooding.

In recognition of this continuing vulnerability to flooding, watershed-focused programs are now emerging, and the United States has begun to move in a new direction. Concern for the environment and sustainable development as well as recognition of the severe limits on federal spending and of funding opportunities lost in flood recovery speak clearly to the need for reexamining the nation's flood damage reduction strategy.

This reexamination must acknowledge that the current state of floodplains reflects in part a succession of political decisions made at the national level. Much of the flood-control effort of the last half-century in combination with other infrastructure development had major land-development implications. Many people moved to or remained in the floodplain with the understanding that the federal government was providing them flood protection. Others saw upstream activity, over which they had no control, increasing their hazard. As the nations seeks a new approach for floodplain management, it must not lose sight of the realities of the past.

Recognition in the early 1960's of the natural functions and resources of the floodplain -- habitat, scenic beauty, water filtration, storm buffer, groundwater recharge, and floodwater storage -- caused the nation to reconsider its policy of supporting wholesale conversation of natural areas to other uses. Persistent flood losses during a half century of flood-control programs raise serious questions concerning the long-term efficiency of such programs. A movement to reduce flood damages through nonstructural means, limiting unwise development of the floodplain and evacuating those at most risk, gradually has become a viable alternative to the construction of dams, levees, and floodwalls.

DEFINING THE VISION

The National Commission on the Environment, a non-profit group, proposes a concept of sustainable development to accomplish economic progress by protecting and restoring the quality of the natural environment, improving the quality of life for individuals, and broadening the prospects for future generations.[1] Effective floodplain management embodies these very concepts by seeking to balance competing uses in a way that maximizes the net benefits to society.

What then should be the national vision for use of the floodplains? To assist in developing this vision, the Floodplain Management Review Committee reviewed the literature on early and recent goals of the nation's floodplain management. Committee members consulted with interest groups at national, regional, and local levels and discussed possible goals with citizens affected by the flood of 1993. The governors of the 9 flood-affected states in the Midwest provided their vision of future floodplain activity. The Review Committee looked to the *National Assessment* and the accompanying *Action Agenda* prepared by the Federal Interagency Floodplain Management Task Force definition.[2] Based on this input, the Review Committee proposes strategic and operational goals for the nation's future use of its floodplains and management of that use:

Strategic Goals

Reduce the vulnerability of the nation to the dangers and damages that result from floods.

Reduce the vulnerability to urban areas, industry and agriculture, when such reduction is justified and reasonable; avoid new development when reduction is not appropriate. As appropriate, move those currently at risk from the floodplain. Strive to eliminate threats to life, property, and the environment, and to the mental health

and well being of floodplain occupants. Ensure the viability of critical infrastructure and the regional economy.

Preserve and enhance the natural resources and functions of floodplains.

Treat the floodplain as part of a physical and biological system that includes the floodplain within the larger contact of its watershed. Seek to identify and enhance the cultural, historic, and aesthetic values of floodplains. Where appropriate, restore and enhance bottomland and related upland habitat and flood storage. Use existing government and private programs to acquire, over time, environmental interest in these lands from willing sellers. Ensure the consideration of social and environmental factors in all actions relating to the floodplain.

Operational Goals

Streamline the floodplain management process.

Implement consistent, equitable, flexible, cost-shared, and efficient floodplain management by improving the National Flood Insurance Program, federal-state-tribal-local-individual relationships, and the conduct of mitigation and disaster planning and execution. Ensure federal-state-tribal-local-individual collaboration and accountability in a bottom-up, shared planning and decisionmaking process. Reduce the cost to the nation of flood damages. Share the risk among all levels of government and among flood-affected individuals.

Capitalize on technology to provide information required to manage the floodplain.

Provide timely and accurate information to assists in identifying hazards, determining impacts of proposed actions, and developing a temporal and spatial basis for long-term action strategies. Leverage the strength of geographic information systems .

FLOODPLAIN OF THE FUTURE

If this vision was implemented, how would the floodplain of the future appear and how would it be managed? Human activity in the floor plain would continue (Figure 4.1) but with a clear recognition that any such activity would be subject to the residual risk of flooding and assumption of the costs of this risk by those sponsoring the activity, Determining future activities would depend on historical settlement, on a balancing of the economic, social, and environmental impacts of an activity together with a recognition of its place in the hydrologic and hydraulic regime of the river basin and what physical impacts its existence has on other segments of that basin.

Urban centers whose existence depends on a river for commerce or whose locational advantage is tied historically to a floor plain would be protected from the ravages of devastating floods by means of levees, floodwalls, upstream reservoirs, or floor water storage in managed upland and floodplain natural areas. Sections of communities with frequently flooded businesses or homes would become river-focused parks and recreation areas as former occupants relocated to safer areas on higher ground.

In areas outside of these highly protected communities, where land elevation provided natural protection from floods, state and local officials would control new construction by requiring it to be at elevations well out of harm's way. Those who were at risk in low-lying areas would be relocated, over time, to other areas. Higher land in these alluvial areas would continue to produce rich harvests. Outside of the urban areas, industry would protect its own facilities against major floods.. Critical infrastructure, such as water and wastewater treatment plants, power plants, and major highways and bridges would either elevated out of the flood's reach or protected against its ravages. Much of the infrastructure, as well as the homes, businesses, and agricultural activities located behind lower levees, would be insured against flooding through full participation in commercial or federally supported insurance programs.

At the upstream end of many levees, federally built water-control structures would permit river waters to keep sloughs wet though out the year maintaining and restoring aquatic habitat with resultant benefits for fisheries, waterfowl, and other wildlife. Levees would be modified to provide for controlled overtopping in the event of major high waters, eliminating the catastrophic failures that have occurred in the past.

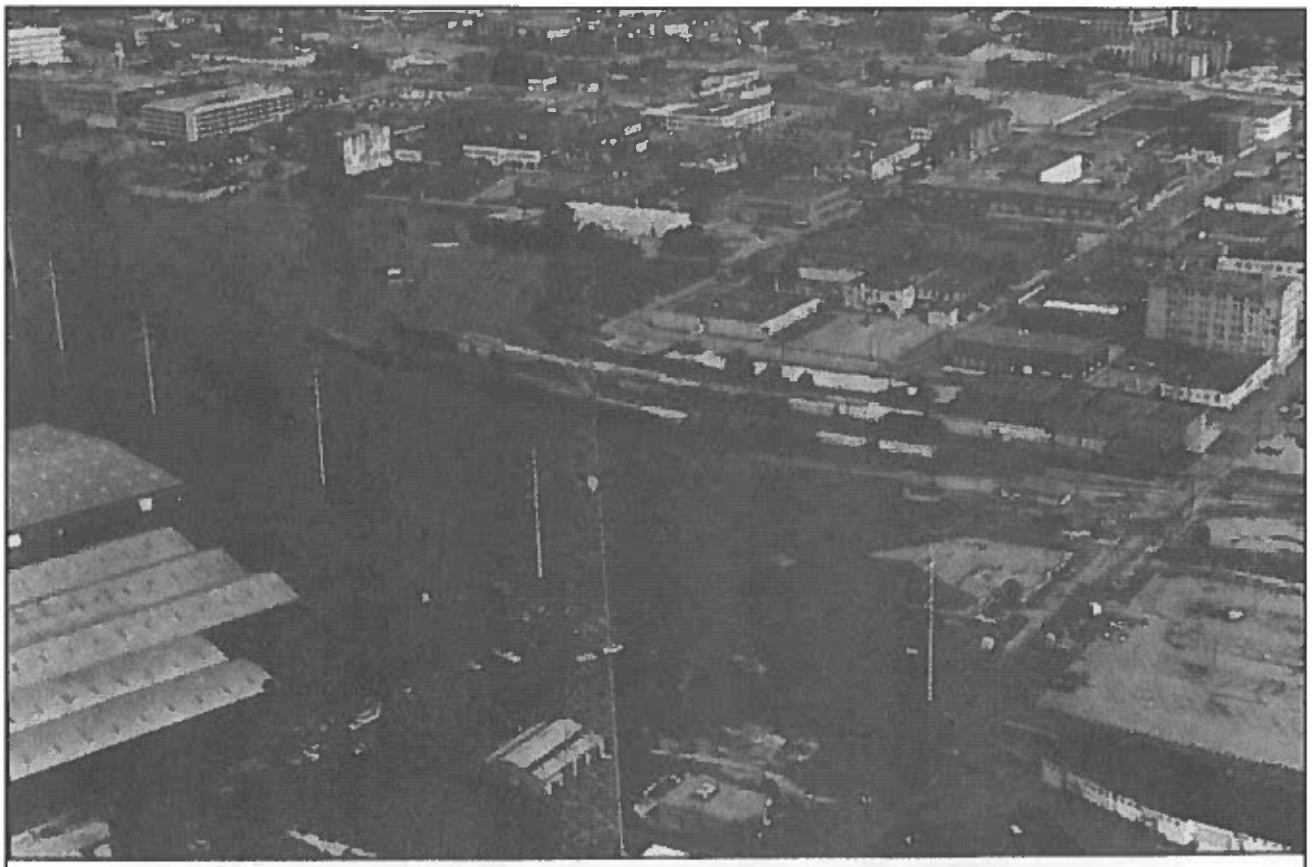
Some bottomland owners behind modified levees would choose to convert from crops to alternative crops or silviculture or to return their lands to a natural state under federal or state easements. Owners would base their decisions on private and government analyses that found their land too wet for farming or in a location where levee protection was impossible to maintain.

Upland of the floodplain, federal-state-tribal-local programs to improve the treatment of lands, control new runoff, and restore wetlands, would reduce the flows during frequent floods and shave the peaks off larger events.

Both commercial and recreational vessels would continue to ply the river's waters, operating in a navigation system that would enhance river line ecosystems through water-level adjustments and control. Modifications in river-control structures would continue to increase fisheries and wildlife habitat.

Floodplain activity would guided by broad-based plans of federal-state-tribal-local governments working together as partners in a streamlined floodplain management effort. Operation of the waterway and the levee systems, with their attendant environmental components, would be focused in a single agency that would collaborate with other interested agencies. Levees along main stem rivers and principal tributaries would be maintained on a cost-shared basis by federal and state governments and local levee boards. Decisions concerning activities in and near the water would be assessed using computer models to indicate the effects of such actions on other regions of the river basin. Forecasts of river conditions would reflect the availability of basin-wide data and the rapid processing of these data. Use of high technology remote sensing platforms and data-filled geographic information systems would provide highly accurate information on which to base key decisions for both planning and crisis management.

A New Approach



Through most of the past two centuries, the nation's approach to floodplain management has focused on reducing flood impacts through structural means. Floodplain management has been flood control. In the 19th century and the first half of this century, the debate was whether or not a levees-only policy should be pursued. Only in the last 30 years has the nation moved to increase the use of nonstructural approaches.

To achieve the goals of floodplain management, the nation must adopt a new approach -- one that takes full advantage of all methods available to reduce vulnerabilities to damages and, in parallel, to protect and enhance the natural resources and functions of the floodplain. Translated into actions this approach, espoused in the draft 1994 Unified National Program, would achieve floodplain management through:

- Avoiding the risks of the floodplain;
- Minimizing the impact of those risks when they cannot be avoided;
- Mitigating the impacts of damages when they occur; and
- Accomplishing the above in a manner that concurrently protects and enhances the natural environment.

The citizens of the nation bear a responsibility to exercise good judgement in their use of the floodplain and to share in the costs of their judgements. Under this approach, state and local governments serve as the principal managers of the land. The federal government provides support for state and local floodplain management, establishes broad national goals, and, by its own actions, sets an example. Federal actions will continue given the interstate nature of water and the related impact of all riverine activity on these waters, the ever-present potential for catastrophic floods, and the federal government's long-standing commitment to flood-control activities as being in the interest of the general welfare.

Figure 4.1 A Typical Reach of a 21st Century Floodplain.

Reducing the Vulnerability of the Nation to Flood Damages

Individuals and their investments in the floodplain will always be at risk. Though it is impossible to remove the risk completely and remain in the floodplain, it is possible to reduce the degree of risk.

One solution is to evacuate floodplains and move people and their public and private investments out of harm's way. This is not always a viable or desirable solution. Techniques that either modify the susceptibility to flood damage and disruption or modify the extent of the flooding may be more reasonable for cases in which evacuation is not feasible. The new vision seeks to reduce the vulnerability whose floodplain residents and activities whose continuing presence in the floodplain makes economic, social, and environmental sense.

The lessons of the flood of 1993 are clear. The United States should not continue to tolerate the loss of life and the damage to cites, rural communities, and farms caused by major flooding, nor should the nation carry the burden of massive federal flood disaster relief costs that current policies generate each time a major flood occurs. Even with a large infusion of federal funds, private donations, and volunteer assistance, the 9-state area still has not returned to normal. Individuals, communities, and agricultural sector will experience the long-term effects of the flood for years. Many of these damages could be avoided through vulnerability reduction measures.

This chapter addresses the vulnerability reduction goals that the Review Committee seeks to achieve with the new vision. Subsequent chapters will address, given the experiences of 1993, the strategies for achieving these goals.

Defining the Risk

Against what magnitude of flooding should damage reduction programs be focused? The answer depends on the social, environmental, and economic assets of the flood-prone area. This will be reflected by the use being made of land, as well as the amount of human activity and critical infrastructure located in the area.

Risk of damage or loss from flooding is greatest where human life and property are concentrated in highly populated areas on the floodplain. For any years following the passage of the Flood Control Act of 1936, the federal government focused its efforts on protecting communities at risk from the largest flood they could expect to encounter. Over time, with limited federal monies available for flood damage reduction purposes, selection of this high level of protection came to be driven more by benefit-cost analyses. Communities with little at economic risk received less protection that those with more. Today many cities and towns are able to see major floods move by with minimal effect. Others could not survive a lesser event without experiencing major trauma. Had the 1993 flood been centered slightly to the north, several urban centers would have been inundated. Given the social and economic consequences of such flooding in affected communities floodplain management activities need to focus on reducing the vulnerability of population concentrations to the most significant flood event expected to occur. Reducing the vulnerability of communities, where appropriate, to the discharge associated with standard project flood (SPF) provides a greater reduction in residual risk than is provided by using the 1 percent annual chance (100-year) flood discharge. The SPF serves as a practicable expression of the discharge to be considered in evaluating alternatives to reduce the vulnerability of activities associated with communities where large population and high-value property are involved. In most cases the SPF approximates the 0.2 percent chance (500-year) discharge.[3]

Recommendation 4.1: *Reduce the vulnerability of population centers to damages from the standard project flood discharge.*

The identification of a target flood does not represent a call for new levees or floodwalls. In fact, given this target discharge, floodplain managers would develop a strategy for evaluating vulnerability reduction considering all of the nonstructural and structural approaches available. Planning for the future may move a community to first seek funding for mitigation activities such as relocation or elevation. Availability of land in the watershed or in the floodplain may result in upstream storage or riverine floodways being considered better approaches. When other approaches have been reviewed, higher or upgraded levees or floodwalls might also be considered. The costs and benefits of each approach would determine whether the vulnerability would be eliminated, reduced, or the status quo maintained.

Critical Infrastructure

The risk of imposing severe hardship on the public or endangering public health and safety arises when infrastructure critical to maintaining the wellbeing of a community, region or nation is damaged. This is especially true in floods of long duration, such as the one that occurred in the Midwest in 1993. For example, when the city of Quincy, Illinois, lost both of its crossings over the Mississippi River, it faced the situation of having no open bridge across the river between Iowa and St. Louis, Missouri, for over two months. People were put out of work, local businesses were isolated from their market areas, and the local economy was disrupted.

Recommendation 4.2: *Reduce the vulnerability of critical infrastructure to damage from the standard project flood discharge.*

Critical infrastructure can be defined as structures, facilities, and installations of the following type and function:

- Those that, if rendered unserviceable, would impose significant hardship on the public, or
- Those that, if flooded, would pose a threat to public health, public safety, and/or the environment.

Critical infrastructure could include, on a situation-dependent basis, municipal drinking water facilities, stations, major highways bridges, major passenger and freight railroads, critical access roads running through or over floodplains, major airports, hospitals and related medical care facilities, electricity generating plants, and facilities that generate, store, or dispose of hazardous, toxic, or radioactive materials. For many of these facilities, such as roads, the element of flood duration must be considered in determining the applicability of the definition. A road out for five hours may not be critical, but one out for three months might be. The only road to a county hospital might be critical under any circumstances.

Where feasible, critical infrastructure should be located outside the floodplain. Critical infrastructure, which must be situated in the floodplain, should be evaluated for protection against the SPF discharge. This issue is not new. Floodplain Management Guidelines for implementing Executive Order (EO) 11988, issued by the Water Resources Council in February 1978, require that critical high-risk activities be protected at a minimum against the 0.2 percent annual chance (500-year) flood. They also provide planners assistance in determining whether infrastructure should be considered critical.[4] In 1982, a National Academy of Science panel concurred and recommended that critical infrastructure be protected against, at a minimum, the 0.2 percent annual chance flood.[5]

Vulnerability of Other Areas

If the goal of floodplain management is to reduce the vulnerability of population centers and critical infrastructure to damages from an SPF discharge, what should it be for areas that do not fall into these categories? While extending an SPF goal to all areas might seem equitable to many, such an action is neither physically, economically, environmentally, nor socially feasible. The strategy for damage reduction

and the target flood against which the strategy is based must be determined on a case-by-case basis using modern planning techniques and methods of analysis. In the long term, much human habitation and related businesses might move to higher ground leaving only agriculture, silviculture, and natural use behind existing levees. Where such an approach is not feasible or desirable and structural solutions appear appropriate, the hard facts of benefit-cost analysis normally will preclude using the SPF discharge as a basis for federally supported increases in protection.

The level of protection provided these areas would be determined considering social and environmental values as well as the economic benefits and costs. Depending on the mix of population, infrastructure industry, and agriculture, the level of protection will vary.

Sharing the Challenge -- Government, Business, Citizen

Since passage of the flood control act of 1936, the federal government has for the most part, dominated the nation's flood control efforts and as a result the nation's floodplain management activity. Structural programs needed for flood damage reduction were also the principal sources of funds for any efforts to stem the rising tide of flood losses. Many states and local governments have developed and carried out floodplain management efforts that both reduced flood damages and enhanced the natural functions of the floodplain; but in carrying out these programs they were hampered by the diversity that hindered efficient floodplain management. The dominant federal role in funding flood damage reduction and recovery activities limited the incentive for many state and local governments, businesses, and private citizens to share responsibility for making wise decisions concerning floodplain activity. Now is the time to:

- Share responsibility and accountability for accomplishing floodplain management among all levels of government and with the citizens of the nation.

- Organize the federal government and its programs to provide the support and tool necessary to carry out effective floodplain management.

Succeeding chapters detail how the nation should organize for successful floodplain management and then, by improving the efficiency and effectiveness of programs already in existence, reduce the vulnerability of the nation to flood damages in the years ahead.

Chapter 5

ORGANIZING FLOODPLAIN MANAGEMENT FOR SUCCESS

...it is hereby declared to be the policy of the congress to encourage the conservation, development, and utilization of water and related land resources of the United States on a comprehensive and coordinated basis by the Federal Government, States, localities...

Section 2, Water Resources planning Act of July 21, 1965

The current system for managing floodplains and protecting the nation from impacts of unwise use is piecemeal. It is dispersed among a variety of agencies at federal, state, and local levels. The Unified National Program was intended to correct this...that program has not succeeded...the Unified national Program is neither unified nor national. In several respects if falls short of achieving the goals set out for it by the Congress and previous administrations.

Gilbert whit, et al.
Actin Agenda for Managing the Nation's' Foodplain
March 1992

The test of how well floodplain management activities are being carried out is in what happens at the level of individual farms, households, and local communities.[1] The 1993 Midwest flooding illustrates where local, state and nationa; efforts succeeded and failed. Progress has been short of what is desirable or possible or of what was anticipated when current policies and activities were initiated.[2]

The collective floodplain management efforts of federal, state, tribal and local governments, individuals, and the private sector must be improved. Together they can use the regionally and nationally significant assets of watersheds and associated floodplains to reduce risk, achieve economic efficiency, and enhance natural resources and functions. The current floodplain management infrastructure has the capability and the responsibility to influence floodplain development and recovery from floods. At issue is the appropriate distribution of responsibilities across and creation of accountability for governments and individuals.

DEFINE FEDERAL-STATE-TRIBAL-LOCAL RELATIONSHIPS AND RESPONSIBILITIES

The strengths fo the federal government -- nationwide experience; ability to examine issues from a national, inter-state and systems perspective; and multi-disciplinary technical expertise -- should guide strategic decisions regarding its obligations and duties. Since the Water Resources Council ceased operations in 1981, however, activities of the federal government have offered little leadership or guidance in resolving interstate waste-resource issues.

Management of the nation's water resources is provided by several agencies. Yet water resource issues are inextricably linked and accomplishedment of agency mandates requires coordination and collaboration among agencies. The National Flood Insurance Act of 1968 required reports to Congress analyzing the implementation of current programs and recommending actions needed to achieve a unified program of planning and action at all levels of government to reduce flood losses and losses of floodplain natural values.[3] Despite these *Unified National Program for Floodplain Management* reports, the United States, in practice, has no unified national program for floodplain management.[4] This stems in part from ambiguity in national goals.[5] If limited resources of money and people are to be utilized effectively, the vision articulated in this Report needs to be accepted and adopted by the populace and assimulated into all levels of government.

A major component of floodplain management is land-use control, which is the sole responsibility of state, tribal, and local entities. The local process for land use and construction decisions (i.e., what, where and how to build) is supplemented in some states by state floodplain permit programs. The federal responsibility rests with providing leadership, technical information, data, and advice to assist the states in their pursuit of sound floodplain management. The federal government is also a partner with states, tribes, and communities in funding floodplain management activities. Where the federal government is contributing finds to protect local communities, however, there is a compelling interest that the finds do not spur increased development in vulnerable locations and that local jurisdictions assume greater responsibility in their land use planning to not increase potential losses. The federal government should not undertake actions that lower the incentive for those in the floodplain to avoid risk because they know the federal government will provide compensation for damages resulting from the risk (see Chapter 14). The floes while promoting and assuring interstate commerce, national econimic development including a viable agriculture industry, and national environmental quality including the enhancement of the quality of the human environment. Congress established the federal interest in flood damage reduction.[6] This interest complements the fundamental state, tribal, and local interest in flood damage reduction.

Action 5.1: *Enact a national Floodplain Management Act to define governmental responsibilities, strengthen federal-state coordination and assure accountability.*

The Administration should propose enactment of a Floodplain Management Act to declare a national policy and goals for floodplain management. These should reflect the vision articulated in Chapter 4 and move the nation toward implementation of a new floodplain management vision that:

- Reduces vulnerability to flooding by avoiding of flood risk through watershed planning, buyout of structures in the floodplain, and mitigation;

- Reduces vulnerability to flooding by modifying flood risk or protecting against floods by minimizing risk to existing population centers (such as cities), protecting existingcritical infrastructure, and protecting the nation from flood-related releases of hazardous materials; and

- Recognizes that floods will continue to occur but that the residual risk in floodplains can be reduced by insuring against flood loss and rebuilding properly when flood losses occur.

The purpose of the Act should be to provide incentives including funding for state and local entities to develop and implement floodplain management plans and increase their accountability for actions in the floodplain. This should be achieved by assigning primary responsibility for floodplain management to states and providing federal guidance and technical and financial assistance to them for development and implementation of floodplain management programs meeting minimum federal standards. The act should authorize funds to supplement state efforts to build and institute effective floodplain management programs. Participation in on-going, non-disaster flood damage reduction and mitigation activities could be withheld from those states that do not conduct floodplain management planning. To support local planning and emphasize state leadership, the Act should require that federal activities affecting floodplains be consistent to the maximum extent practicable with federally approved state programs. The fundamental components of the proposed Floodplain Management Act are found in Appendix D.

...there needs to be a fundamental change in the federal flood protection role. This new role must be to facilitate and to assist state and local government in the implementation of these multi-objective programs.

Doug Plasencia, P.E.
Chair, Association of State Floodplain Managers
Testimony before Congress, October 27, 1993

IMPROVE FEDERAL COORDINATION, EFFICIENCY AND FEDERAL-STATE-TRIBAL PLANNING

The 1965 federal Water Resource Planning Act established the U.S. Water Resources Council (WRC).[7] However, the WRC ceased operations in the early 1980s when funding was discontinued. Lost with the WRC funding was its ability to provide interagency coordination, technology transfer, and data and information services. Deficiencies inheret in the original WRC which established a command-and-control, top-down approach to achieve consistency in federal water resources activities should not be repeated.[8] Nevertheless, the WRC provided an avenue to bring together federal agencies to address water resources issues, in general, and floodplain management, in particular. The Midwest Flood of 1993 illustrates the need to move toward the unified nation program of floodplain management that the nation has sought since, at least, 1968.

Some federal agancies and states, numerous organizations and individuals noted to the Review Committee the continued need to revive the WRC or some WRC-type of organization to provide a coordination function. Many examples demonstrate why a WRC, composed of department and agency heads, is needed to provide policy-level coordination of cross-cutting issues of floodplain management and other water resource issues:

- Federal agencies continue to fail to comply with the spirit and letter of Executive Order 11988, Floodplain Management, by locating or funding nonfloodplain dependent activities in floodplains putting federal investments at considerable risk (this issue is further discissed below);

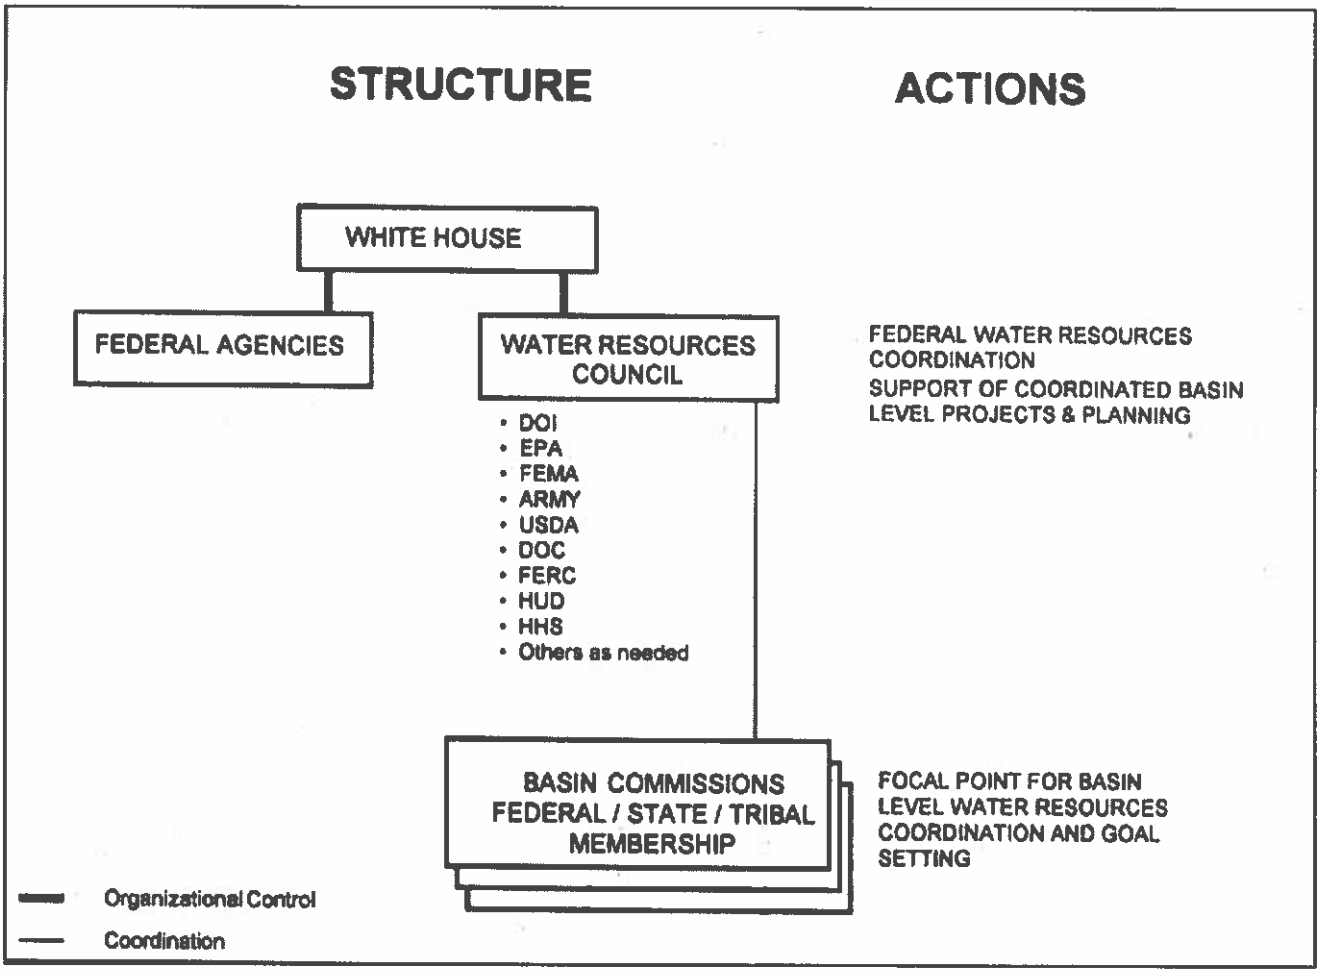
- The shortcomings of and opportunities for increasing the effectiveness of floodplain management identified by the Federal Interagency Floodplain Management task Force in 1992 in its *Floodplain Management in the United States: An Assessment Report* have not been acted upon. No entity exhists to act upon those recommendations.

- The Unified National Program is neither unified nor national -- it does not adequately integrate either the numerous program aimms that have been set forth or the efforts of those charged with implementing them. There is no central direction for the Unified National Program.[9]

A minimal staff would facilitate operations of the Council and would prepare, based on input form federal agencies and states, items for discussion or action by the Council.

Action 5.2: *Revitalize the Water Resources Council.*

Immediate revitalization of the WRC would launch and promote cooperation among federal agencies and the states-tribes. The WRC would, among other things, serve to align federal floodplain management goals with other broad national goals; provide a single point of focus to assist coordination and resolution of interstate water resource management issues; serve as an innovative planning and technology center, including intergovernmental data gatehering and dissemination activities; and facilitate resoulution of federal agency issues. The Secretary of the Interior, as designated chairwoman of the WRC, should request that the Administrator of the EPA and the Director tof the FEMA become full-time participants on the Council. Other full-time members, as established by the 1965 federal Water Resources Planning Act, are the secretaries of Army; Agriculture; Commerce; Housing and Urban Development (HUD); and, Helath and Human Services and the Chair of the Federal Energy Regulatory Commission. The Secretary of the Interior, as the Chair of the WRC, should restaff the Council. A small staff and budget to support pursuit of the Council's mandate is suggested. Appendix I provides additional details about this proposal.



The 1965 federal Water Resource Planning Act also authorized creation of federal-state-tribe basin commissions and authorized financila assistance to states-tribes for water planning.[10] The individual basin commissions produced comprehesive, coordinated plans for water and related land resources that were advisory to federal, state, tribal and local authorities. The basin commissions established pusuant to the Act were abolished, along with federal funding, in 1981.[11] While several interstate organizations evolved to fill, in part, the gap left by the demise of the basin commissions, federal participation is limited to non-voting membership. A mechanism is needed to facilitate enhanced federal presence among continuing participation with these groups.[12] Basin commissions provide a means of preserving and enhancing the state and local attention to floodplain management as well as broader water and natural resource issues, while providing a mechanism to involve or enroll appropriate federal agencies in state and local floodplain management activities. Because watersheds and associated ecosystems do not coincide with, nor do water resources and environmental protection problems respect, political boundaries, a vechicle is needed to integrate federal-multi-jurisdictional examination of issues and solutions. This basis for formation of basin commissions remains valid.

Action 5.3: *Reestablish basin commissions in a revised form reflecting current needs.*

The president should reestablish basin commissions to provide a forum for coordinaated federal and state planning. Basin commissions are not needed everywhere. Basin commissions would be formed in consultation with the governors of states for those areas where the governors determine that interstate or federal-state coordination of several activities was needed or appropriate. The states, in consultation with the WRC, would define the geographical

extent of each proposed basin commission. Each basin commission would serve as the principal agency for the coordination of federal, state-tribe, interstate, local and non-governmental plans for their designated areas and would indertake other activities pursuant to Title II of the Water Resources Planning Act of 1965. Their focus should be results oriented and their process collaborative. Their charters should look beyond traditional water and flood management challenges to allow the commsiisions to address regional issues of biodiversity conservation, water quality, sustainable development, and other environmental goals. Each basin commission would be co-chaired by a state and federal representative and would operate with a limited staff of four to five professionals. While many federal agencies would participate on the commissions, that voice could be limited to increase state significance and responsibility in addressing land-use planning issues. The basin commissions would use federal and state agencies, working within exhisting programs and structures to realize commission responsibilities. Actual staffing requirements, therefore, would be small. Public participation and comment should be vital aspects of their functions. The above changes are proposed to address criticisms of the original basin commissions. Funding of

Figure 5.1 Proposed Institutional Framework for Water Resource Council, River Basin Commissions, and Federal Agencies.

the commissions would be shared by federal and state governments. It is anticipated that no increase in costs to state will occur for those states currently participating in river basin associations; however, the federal government would have to contribute some funding.[13] Appendix I describes in greater detail the Review Committee's concept of revived basin commissions.

FEDERAL ACTIONS IN THE FLOODPLAIN -- SETTING AN EXAMPLE

In 1977 with issuance of Executive Order (EO)11988, Floodplain Management, Presudent Carter raised federal agency attention to issues of floodplain use.[14] With time, however, it has become apparent that some federal agencies either are unaware of or misunderstand the requirements fo the EO and either build or support building in floodplains. Under the EO, federal agencies must

- Demonstrate that no practible alternative site exhists outside of the floodplain, and

- If no alternative exhists, take steps to minimize direct and indirect impacts of the proposed action and no restore and preserve the floodplain.

Review Committee visits to the Midwest and discusses with the FEMA, USACE, and state floodplain manager revealed several examples of apparent non-compliance by federal agencies with the EO. While responsible agencies no doubt believe they have complied with the EO, these developments point our some of the deficiencies with the EO. Among the most notable examples were a low-income housing project finded by HUD and a federally funded state prision within floodplains, and a proposed construction of a federal weather station behind an uncertified levee. The Association of State Floodplain Mangers report that such federal activities occur nationwide. This type of activity lessens the capacity of the federal government to demonstrate leadership in floodplain management.

The EO also requires that federal agencies with responsibility for federal real property and facilities in the floodplain comply with the National Environmental Policy Act (NEOA) requirements and the construction standards of the NFIP. This task if evaluating cumulative, direct, and indirect impacts and risks associated with individual projects within a floodplain requires scientific and technical expertise beyond the capacity of a single reviewer, and often requires consultation with FEMA or USACE.

The EO applies to all feseral agency activities including the acquisition, management, and disposition of lands and facilities. It covers federally undertaken, financed, or assisted construction and improvements and federal activities and programs affecting land use. Thise include but are not limited to water and related land resources planning, regulation, and licensing activities. One objective of the EO is to ensure that all federal agencies aviod, to the extent possible, the long- and short-term adverse impacts associated with the occupancy of floodplains.

Federal activities that induce development weaken the effectiveness of exhisting local or state floodplain management regulations and place pressure on local governments to relax their regulations. Conversely an active federal program to undertake activities outside the floodplain sets an example and encourages the establishment and implementation of state and local programs. A number of states and communitiies have enacted floodplain management regulations, some of which are more stringent than those issued by FEMA.[15] The EO does not explicitly recognize the exhistence of local or state floodplain regulations or the effect federal actions may have on them. Neither are federal agencies required to consult with state floodplain managers concerning floodplain activities. Fedreal leadership in floodplain management requires an adjustment in the way that federal activities are undertaken in the floodplain.

The EO does not explicitly recognize that certain federal actions or activities in the floodplain are critical to the health and welfare of floodplain inhabitants. The extended closure of transportation systems, pipelines, dispersal of hazardous materials, and power outages caused by the

1993 flood demonstrated the vulnerability of floodplain infrastructure. The destruction or disruption of critical infrastructure can have a widespread impact on a community or region. The current definition of critical actions contained in the EO Guidelines, "those for which even a slight chance of flooding would be too great," suggests that critical actions not be undertaken in any area subject to flooding of greater than a 500-year frequency. The guidelines, which fail to recognize that flood events differ in frequency, duration, and type, must be made more flexible.[16]

Federal and federally sponsored facilities, including critical infrastructure, remain at risk. To reduce the possibility of major losses, the vulnerability of these existing buildings and infrastructure should be assesed. Federal agencies that provide funds for improvements to previous investments in the floodplain fall under the EO requirements and accordingly should take measures to reduce the risk of flood loss and minimize the impact of floods on human safety, health, and welfare. There is an opportunity to mitigate the impacts of federal activities completed prior to the creation of the NFIP and the EO that may have resulted in flow constrictions that increased flood risk.[17] Continuing improvements to federal facilities in the floodplain, such as the Defense Mapping Agency's facility in St. Louis that was severly flooded and damaged in the 1993 flood, also require consideration of the EO. Federal programs that are delegated to or assume by states may fall outside the EO. Examples of the latter are stating revolving authorized by the EPA and Rural Development Administration or situations where the use of federal funds is at the discretion of state or local governments. These federal funds may directly or indirectly affect development in floodplains in ways that are inconsistent with the intent of the EO.

The federal government also leases some of its property in floodplains for seasonal recreational cottage use. Some leasees are using the cottages on a full-time basis. In St. Charels County, Missouri, 13 percent of the repetitive NFIP claims are from properties on land leased from the federal government.[18] These leases appear to contradict the EO mandate that the government "take action to reduce the risk of flood loss to minimize the impact of floods on human safety, health, and welfare"; however, Section 1134 of the Water Resourced Development Act of 1986 directed the Secretary of the Army to extend the leases until such time as they are terminated by the leaseholder or their assigns.

Action 5.4: *Issue a new Executive Order to reaffirm the federal government's commitment to floodplain management with an expanded scope.*

A new EO, built upon EO 11988, will reaffirm the federal commitment to floodplain management by addressing the full scope of federal activities, particularly critical infrastructure, acknowledging uncertainties of scientific information, stating the economic policy implications of floodplain development, and requiring an interagency consultative process. The EO would provide a means to clearly articulate and thereby institutionalize the new vision of floodplain management. It would emphasize avoidance of federal activities in the floodplain. Requiring federal agencies to evaluate all structures during maintenance and repair activities to determine the feasibility of mitigating flow constrictions or undertaking other mitigating measures will reduce the risk of flooding and minimize the impacts of floods. Requiring federal activities to comply with state and local regulations when more stringent than national standards will affirm the states role as floodplain manager. The revision will aslo require each agency to prepare new implementing guidelines for activities potentially occuring in or affecting floodplains, increasing agency awareness of the issue, and allowing agencies to address issues unique to their programs. It would also require that federal spending does not increase development in sites vulnerable to flood damages. The FEMA will provide oversite of EO compliance as described in Appendix G.

Action 5.5: *OMB should direct all federal agencies to conduct an assesment of the vulnerability of flooding using a scientific sample of federal facilities and those state and local facilities constructed wholly or in part with federal aid.*

This vulnerability assessment should identify and quantify the total federal investment subject to flood damage. The target flood for protecting critical infrastructure (i.e., SPF or 500-year) should be considered in the assesment. The assesment also should contain recommendations on mitigation measures to protect federal facilities currently at risk. The results of this study would be used to make decisions regarding the need, if any, to take mitigative measures.

Action 5.6: *Seek revision of Section 1134 of the Water Resources Development Act of 1986 to provide for phase-out of federal leases in the floodplain.*

The Administration should seek reivsion of Section 1134 which requires continuation of leases of federal lands. Then the Administration should phase out leases along the Mississippi River to reduce the risk of flood loss and minimize the impact of floodx on human safety. The USACE should enforce provisions of the leases prohibiting year-round occupancy. In the interim community floodplain management ordinances should apply.[19]

The EPA's regualtions for the Resource Conservation and Recovery Act (RCRA) on permitting hazardous materials treatment, storage, or disposal facilities have locational standards; but these standards appear inconsistent with the EO guidelines for critical actions.[20] The EPA, in draft regulations (1978), proposed design standards for facilities located in the 500-year floodplain. Public comment on the draft reflected dificulties with identifying the 500-year floodplain and a concernthat the EPA was holding these facilities to a higher standard than that required by EO 11988. The final regulations addressing flood design require that no wash out of hazardous materials occurs. Therefore they apply only to those facilities located in the areas with a 1 percent annual chance of flooding.[21] The EPA requires that permitted facilities have contingency plans addressing notification and response for any unplanned sudden or non-sudden release. The regulations do not specifically require that the plans address flooding events, even for facilities in areas with 1 percent annual chance of flooding where an obvious cause of releases could be flooding.[22] Furthermore, there exists no feedback mechanism regarding plan effectiveness in the event of a hazardous material release.

Recommendation 5.1: *Revise the RCRA locational standards and contingency planning regulations for consideration of flood hazards in areas impacted by the Standard Project Flood.*

Revision of the site regulations to recognize that releases of hazardous materials are critical actions for which "even a slight chance of flooding is too great" would provide a greater level of environmental protection and public health and safety and would be consistent with implementing guidelines for EO 11988.[23] Revision of the EO would automatically trigger this action. Specifically requiring contingency plans to reflect the special activities and coordination required in the event of flooding would also decrease the risk of hazardous material releases and enhance governmental response. An additional requirement for review of contingency plans after hazardous material releases would provide the means to enhance pre-disaster planning.

STATES LEAD THE WAY

The state should be the entity best able to coordinate the overall watershed and floodplain management activities occurring within its borders. Communities deal with local problems and solutions. Active involvement by the states is necessary to develop flood-reduction projects consisent with multiple floodplain and watershed amanagement goals as well as other state natural resource and economic goals. States need to be more involved in setting floodplain management priorities, adjudicating intrastate issues regarding priorities and determining impacts of floodplain management projects, and in brokering federal assistance. Currently, the extent of state involvement in locally sponsored flood-reduction projects is highly variable, ranging from requiring approval of the governor

at the end of project planning to multiple agency collaborative commitment throughout project planning. In many areas state-level leadership and coordination is vital: flood-fighting, repair activities, buyouts, hazard mitigation, permitting of levees and other structures that impact beyond the local area. State involvement in levee programs should be increased. The Association of State Floodplain Managers notes that only 16 of the contiguous states regulate levees -- five of which are Midwest states.

States floodplain management programs vary within the region and the nation. Several of the states in the upper Midwest are pioneers in floodplain management and have programs that pre-date the NFIP. These states have adopted floodplain management laws and minimum floodplain management regulations implemented with state funds. They provide technical assistance to communities and undertake other activities that are critical to achieving the vision articulated in this report. Other states in the region have minimal state floodplain management programs. In these states floodplain management is often incidental to other resource and emergency management. Appendix F summarizes state floodplain management activities.

Prior to the 1993 flood, states took little cognizance of the fact that many levees repair program. States need to be more involved in coordinating floodlight to ensure that these efforts do not harm other parties, that they are focused to ensure greatest public benefit, and that they have no long-term adverse effect on floodplain management. Several midwesten communities noted that because they did not belong to a levee district offering some level of protection, they were not involved in levee maintenance or floodfight decisions. State involvement could raise community issues to the attention of federal officials. State involvement in coordinating levee repairs needs to be enhanced. Some states did not assume an active role, so the USACE and USDA levee repair programs had to work directly with local entities. An example of more appropriate state involvement is the PL-566 watershed program wherein each governor makes recommendation and sets priorities for proposed local watershed projects.

Increasing state involvement will require greater state technical capabilities in floodplain management. Few incentives exist, however, for the state to build this expertise. The federal government currently provides technical assistance directly to local entities and/or states through the USACE Floodplain Management Services and Planning Assistance to States Programs, the SCS PI-566 Program, and the Tennessee Valley Authority (TVA) programs. Provision of technical assistance directly to individuals and local communities does not build and, in fact, detracts from state capabilities. The FEMA Community Assistance Program provides technical assistance to local entities through the states. The TVA, in a self-review to increase customer service, determined that provision of assistance directly to individuals was not the most efficient use of federal resources and decided to focus its assistance on states.24

Recommendations 5.2: *Increase the state role in all floodplain management activities including, but not limited to, floodfighting, recovery, hazard mitigation, buyout, floodplain regulation, levee permitting zoning, enforcement, and planning.*

A shift towards a state role from what is now primarily a federal-local relationship is necessary to set priorities, adjudicate intrastate issues regarding priorities and impacts of floodplain management projects, and broker federal assistance. This could be accomplished for all federally assisted or funded floodfight, repair and recovery, flood damage reduction, and other floodplain activities by requiring:

- State sponsorship or co-sponsorship in conjunction with local sponsorship or
- Prior state approval.

The non-federal cost share could be provided by either or both the state and local entity or both.

Recommendation 5.3: ***Restructure and refine the scope of federal technical services programs and increase funding for the USACE in the areas of Floodplain Management Services and Planning Assistance to the States programs and increase funding for states through the FEMA Community Assistance Program.***

By altering the focus of technical and planning assistance for floodplain management from individual and local assistance to state assistance for coordinated dispersal to local areas, federal programs can create an incentive for states to build these types of expertise. Federal information transfer and training for the states for subsequent transmittal to local governments are far more efficient uses of federal expertise and limited federal funds because the same information reaches more people and provides a public service. In its most recent testimony to Congress, the Association of State Floodplain Managers indicated that floodplain management funding and planning assistance for states are not sufficient to provide dissemination of critical data necessary to support sound decisions at the local and state level. This viewpoint was echoed by state officials in the in the Midwest. The federal government receives far more requests for assistance from local governments and individuals than can be accommodated given current funding constraints. The inability t to provide assistance in some situations can lead to inappropriate floodplain development decisions and, therefore, increased long-term costs. Additional funding would allow federal agencies to provide and analyze pertinent data necessary for state and local governments to make sound floodplain management decisions.

INCREASE THE STATE-LOCAL STAKE IN FLOODPLAIN MANAGEMENT

Ultimate responsibility for floodplain management rests with individuals and local government through local land use planning decisions. The federal government must ensure that it provides incentives for, and no disincentives to, community-based floodplain management. Cost sharing is essential to maintain the state and local stake in all floodplain management activities and should be retained.

In the series of recent disasters impacting large populations (I.E., Hurricane Andrew, the Midwest flooding, and Northridge earthquake), non- –federal cost-share requirements were decreased to respond to state and local financial constraints. Disaster-specific changes in federal/non-federal cost-share percentages for FEMA disaster assistance may have an adverse effect on floodplain management. The federal-state cost-share originally 75/25 was adjusted for all three disasters to a 90/10 basis. These cost-share changes have two potentially significant consequences. First they set up an expectation of similar treatment in subsequent disasters and increase political pressure to provide a lower non-federal share. This perpetuates the dominant federal role in recovery and increases federal costs. Second they may defeat the fundamental purpose behind cost sharing which is to increase the amount of local involvement, responsibility, and accountability. By lessening the non-federal investment, state and local governments have less at stake and, therefore, may have a lower incentive to develop and adopt sound floodplain management policies and practices.25Community consequences for choosing not to participate in the NFIP are limited because FEMA disaster assistance pays for damages to all public (i.e., community) facilities and infrastructure other than buildings regardless of whether a community is participating in the NFIP. In non-participating communities individual citizens suffer the consequences. Few, if any, incentives exist for communities to seek private insurance for damages to community facilities; rather, most communities rely solely on FEMA to provide reparation. This is inconsistent with the philosophy that federal disaster assistance should be provided in situation where communities and states, due to the magnitude of damages, will exhaust their resources and not have the capability to recover on their own.

PRIVATE INSURANCE HELPS CITY COVER ITS LOSSES

In July 1993 the Des Moines Water Works was inundated and put out of commission for two weeks. The damage totaled $12 million, $9.9 million of which will be covered by private insurance previously obtained by the water works. This resulted in minimizing federal public assistance costs to $2.1 million. Although the insurance carrier would not renew their insurance, the water works was able to acquire new insurance for the water treatment plant. The new private insurance premium of $1,720 per year purchased $10 million of flood insurance. Subsequent to the flood of 1993, the levees surrounding the plant have been raised six feet and concrete floodgates have been constructed to close the gap made by the roadway into the plant.

Recommendation 5.4: *Hold FEMA's existing disaster assistance cost-sharing requirements to no more than 75/25; seek to make other agencies disaster programs' cost-share requirements consistent at 75/25.*

By retaining 75/25 as the basic FEMA disaster assistance cost-share for mitigation and disaster, non-federal investments will serve as an incentive for non non-federal interests to pursue means to protect those investments through more effective floodplain management. Cost-sharing requirements by other federal programs for flood-fighting and repair should be consistent. Circumstances may occur where changes in the cost-share ratio are justified; further evaluation of how to define those circumstances is warranted.

Action 5.7: *For communities not participating in the NFP, limit public assistance grants.*

Create additional incentives for communities to participate in the NFIP by limiting public assistance given to on-NFIP communities to rescue and emergency operations only. Participation in the NFIP will help assure that new infrastructure complies with basic floodplain management requirements and does not adversely impact other development.

Action 5.8: *Encourage communities to obtain private affordable insurance for infrastructure as a prerequisite to receiving public assistance.*

Require a community desiring public assistance to demonstrate that it had done all it could to secure affordable private insurance for public facilities. This would help to increase community responsibility and accountability and would reduce the federal taxpayer burden associated with risky behavior in floodplains.

FUNDING FOR PUBLIC FACILITIES

Concerns have been expressed that the current FEMA public assistance program may provide disincentives for communities to take actions to protect public infrastructure from flood damages or to relocate those facilities out of the floodplain. Public Assistance funds the repair of damaged public facilities under a 75/25 cost share formula (although a 90/10 cost share was used for the Midwest flood). A local cost share of less than the cost of relocating the facility out of the floodplain or protecting the facility from flood damages, creates a disincentive for the community to mitigate. A further concern is that communities may not budget adequate funds for the maintenance and upgrading of infrastructure and other public facilities are damaged, a portion of the damage may be due to deferred maintenance or to the community's failure to upgrade or properly size the infrastructure. Although FEMA can reduce the amount of the grant to account for deferred maintenance, it is often difficult to make this distinction and the community receives a windfall in the form of a new or repaired facility.

A further problem is that storm and sanitary sewer systems were inadequate to handle the high groundwater and rainfall that occurred in many areas of the Midwest in 1993. This resulted in flooding and sewer back up into the basements of thousands of homes and businesses. The public assistance program currently will provide funds to repair sewer systems to their pre-flood conditions but not to up grade those systems so that they are adequately sized to handle similar storm events with minimal damages.

The Review Committee considered a recommendation that all public assistance to communities for the repair or upgrading of infrastructure or other public facilities be in the form of loan rather than grants to remove these disincentives, but loans may not be practicable for a community devastated by a major disaster.

FEMA can provide limited funds through the public assistance program for cost effective mitigation measures that will reduce future damages to a facility. In addition a community can decide not to repair, restore, reconstruct, or replace a facility at its existing location and obtain up to 90 percent of the federal share of repair cost to expand alternate facilities, build a new facility, or fund hazard mitigation measures. However, the community must pay any additional cost to relocate or upgrade the facility. If it can not afford to do so, the facility is then repaired to its pre-flood condition at its current location and remains vulnerable to further flood damage. Some funds may also be available through FEMA Section 404 Hazard Mitigation Grant Program to upgrade these systems. However, these funds are often fully allocated for other purposes and are not available for public facilities.

States and communities should undertake efforts to identify vulnerable facilities in the floodplain. This inventory would help target priorities for pre-disaster mitigation and would be necessary to determine insurance needs.

Action 5.9: *Provide loans for the upgrade of infrastructure and other public facilities.*

A loan program would encourage and enable communities to undertake action during recovery to reduce future damages to public facilities by relocating or protecting those facilities rather tan repairing the facility at its current location. In addition such a program would assist communities to upgrade undersized storm sewer systems or other flood control facilities. Because upgrades are capital improvements that have long term benefits for the community, loans are more appropriate than grants. The loan program can be established to allow flexible terms based on the communities' ability to pay (e.g., zero or low interest rates and long repayment period). The Administration should seek Congressional action to establish such a program.

PROVIDE A BALANCED FOCUS IN THE PLANNING PROCESS

Federal actions taken to develop water resources reflect the objectives set over several decades by the Congress. Various Administration s have defined federal water resources objectives.[26] The two most significant publications on federal water resources development are *Principles and Standards for Planning Water and Related Land Resources* commonly referred to as *Principles and Standards* or *P&S,* published in 1973, and *Econimic and Environmental Principles and Guidelines for Water and related Land Resources Implementation Studies* commonly referred to as *Principles and Guidelines* or *P&G* published in 1983. The *P&S* was a rule applied to water and land programs, projects, and activities carried out by the federal government and non-federal entities with federal financial or technical assistance the rule guided formulation and evaluation of projects to enhance national economic development (NED) and the quality of the environment. When the *P&S* was superseded by *P&G* in 1983, rules became guidelines. The *P&G* contain a single objective for planning of water resource s projects: "contribute to national economic development consistent with protecting the Nation's environment, pursuant to national output of goods and services, expressed in monetary units. Under *P&G,* alternative plans can reduce net NED benefits to further address other federal, state, local, and international concerns not fully addressed by the NED plan. A plan recommending federal action is to be that with "the greatest net economic benefit consistent with protecting g the nation's environment" (the NED plan), unless the Secretary of a department or head of an independent agency grants an exception to this rule. Exceptions require overriding reasons for recommending another plan, based on other federal, state, local, and international concerns. Since 1983, exceptions to the NED plan have been limited.

Calculations of NED are meant to include all environmental and social benefits and costs which monetary values can be obtained. The monetary focus on NED, however, does not give adequate consideration to unquantifiable environment and social values.

Because of their non-market nature,environmental quality, ecosystem health, the existence of endangered species, and other social effects are not as easily quantified in monetary values.[27] This limits formulation and acceptance of projects capable of striking a better balance between flood damage reduction or other water resources development and the environment.

Action 5.10: *Establish as the new, co-equal objectives for planning water resources projects under Principles and Guidelines:*

- ***To enhance national economic development by increasing the value of the Nation's output of goods and services and improving national economic efficiency, and***

- ***To enhance the quality of the environment by the management, conservation, preservation, creation, restoration, or improvement of the quality of natural and cultural resources and ecological systems.***

The current nationaleconomic develpoment objective of the *P&G* should be revised immediately through the issuance of an executive order. This will provide a balanced focus for guiding decision making.

Update *Principles and Guidelines*

The *P&G* are now more than ten years old, and several areas are in need of thorough review. Critics of the *P&G* see a bias toward structural solution to flooding problems and a failure to evaluate nonstructural alternatives in the same way as structural alternatives, such as levees. One of the differences in the evaluation is that for structural alternatives the reduction in flood damages is included as a measure of the benefits of a project, while for some nonstructural alternatives, such as evacuation of structures from the floodplain, reduced damages must be separated

into internalized and externalized damages. Then, only the externalized damages prevented (those borne by other than the floodplain residents) are claimed as benefits for the nonstructural evacuation alternative. There is an economic rationale for doing this, but the concern still exists that it results in a bias against nonstructural projects. In addition, many social benefits of removing people at risk from the floodplain and environmental benefits of a natural floodplain are not included adequately within the evaluation. Although the *P&G* do not exclude these considerations, application deficiencies exist because of the non-market nature of the impacts. Because of these application deficiencies, research is recommended in Chapter 11 to allow greater consideration of difficult to quantify inputs for which no market system exists and to improve techniques for measuring social or environmental outputs that result from alternative actions.

A system-of-accounts analysis can provide critical information on market and non-quantifiable, non-market impacts necessary to provide the basis for trade-off. Such analysis can support a sound formulation-of –alternatives process that includes quantified impacts where available as well as qualitative impacts and displays beneficial and adverse effects of each alternative considered on the following accounts: national economic development; regional economic development; other social effects; and environmental quality of various project alternatives. The *P&G* do not require the system-of accounts; however, some agencies strongly encourage this comparison of impacts to these four areas within agency rules. The system of accounts or something similar is needed to help ensure balanced planning.

SHIFTING THE PROJECT ANALYSIS PARADIGAM

Utilizing benefit-cost analysis under the existing system, net monetary benefits must exceed zero. Under the proposed approach, the sum of net monetary benefits and society's value of net nonmonetary benefits must be greater than zero

The *P&G* require the responsible federal agency to contact the governor or designated agency for each affected state before initiating a study. It requires the federal planning agency to provide the state agency or agencies responsible for or concerned with water planning with opportunities to participate in defining the problems with opportunities in scoping the study and in review and consultation. A truly collaborative approach, however, is not required or encouraged. The *P&G* also states that interested and affected agencies groups, and individuals should be provided opportunities to participate throughout the planning process and that a coordinated public participation program should be established with willing agencies and groups. This falls short of establishing partnerships and collaborating within an ecosystem context on major watershed efforts. Benefits of collaborative approaches include improved efficiency and cooperation (both within and across agencies) and improved service to the public. The approach also serves to crystallize public opinion regarding problems and builds consensus for solutions. Criteria should be established to indicate where collaborative approaches are appropriate and recommend a mechanism for implementation to include single or separate agency funding of participation in the collaborative efforts. For cost-shared feasibility studies, a determination should be made as to whether it is reasonable to require participation in collaborative funding by the non-federal cost-sharing sponsor.

The *P&G* provides and overriding philosophy and process for formulating alternative plans an weighing the impacts of each alternative to select a recommended plan for meeting the study needs. The requirements of the NEPA are included as part of the *P&G* process. This process can be applied to all federal agency evaluations of alternatives to most efficiently allocate scarce resources to meet the needs of the nation.

Currently the only federal agencies required to use *P&G* are the USACE, the SCS, the TVA, and the Bureau of Reclamation. To increase efficient resource allocation,

P&G should be extended. It should apply to the planning and evaluation of the effects of water and land programs, projects, and activities carried out by the federal government and by the states or other entities with federal financial or technical assistance.

Action 5.11: ***Establish an interdisciplinary, interagency review of the P&G by affected agency representatives to address:***

- ***Structural versus nonstructural project bias;***
- ***Inclusion of system of accounts or a similar mechanism for displaying impacts;***
- ***Inclusion of collaborative planning in an ecosystems context for major studies; and***
- ***Expansion of the application of the revised P&G to water and land program, projects, and activities to include:***
  - ***All federally constructed watershed and water and land programs;***
  - ***National parks and recreation areas;***
  - ***Wild, scenic, recreational rivers and wilderness areas;***
  - ***Wetland and estuary projects and coastal zones; and National refuges***

An interdisciplinary, interagency committee of individuals from potentially affected federal agencies should be established to focus on the new broadened objectives, and to make specific recommendations for revisions to the current *P&G,* based on the four areas identified above an any others as appropriate. Revision must be consistent with the intent of EDO 12893, Principles for Federal infrastructure Investments, and EO 12898, Environmental Justice, both issued in 1994. This committee should be convened as soon as possible with a goal of making all necessary revisions by December 1994. To ensure that coordination of planning principles occurs at the state, tribal, and local level and that a balanced approach is taken, any revisions to *P&G* should be published and provided for public review and comment prior to finalizing.

COLLABORATIVE EFFORTS

Ecosystem, watershed, and large-scale river studies lend themselves to collaborative approaches by virtue of their scope. Only by working in partnerships with other federal agencies, state agencies, tribes, local governments, and private organizations can individual agencies look beyond their defined missions. A collaborative approach in an ecosystem context is needed for major watershed and floodplain management planning to move agencies away from single-agency problem solving. A more comprehensive evaluation of problems and solutions is likely is if a collaborative approach includes governmental parties at all levels as well as public and private stakeholders. Such collaborative partnerships also constitute a means of leveraging limited funds to implement projects with multiple benefits. Collaborative efforts require more than consultation, coordination, seeking public input; they require a commitment to working collectively to solve complex, interrelated concerns.

The ongoing USACE 18-month Floodplain Management Assessment study provides an opportunity to include other agencies as partners in a collaborative atmosphere. The study is being coordinated federal agencies, many of which would prefer to participate as a partner in the Assessment. By redirecting the current planning process, the Assessment can become a partnership of federal

agencies in a collaborative effort to assess the floodplain management objectives of the basin. Funding for this collaborative planning effort may necessitate a supplemental appropriation. If necessary, funds would be dispersed at the discretion of USACE, the lead agency, after consultation with collaborating agencies. If the supplemental request is not approved, USAC E should provide the opportunity for other agency collaboration of the expense of each individual agency. Active involvement by multi-agency participants in all aspects of the USACE Floodplain Management Assessment would ensure a holistic review of the area's floodplain management issues. A collaborative approach would identify a broader set of alternative solutions that address problems or multiple state and local objectives. It would build greater trust in a support for findings and recommendations o of the Assessment.

In keeping with the trend toward ecosystem-or watershed based planning federal agencies are expected to work as partners or to collaborate. Currently funding constraints limits the ability or most federal agencies to participate without reprogramming their funds. The USACE districts are particularly limited by the project-specific nature of their funding. Feasibility studies are cost-shared with the non-federal sponsor on a 50-50 basis, and partner interests are more likely to be limited to the study area than to the entire watershed. Additional funding is needed for all federal agencies for the purpose of collaborative planning. While it will cost more initially, collaborative planning is an investment in the future that will reduce future project-specific planning expenditures.

Recommendation 5.5: *The Administration should seek increased funding for federal agencies to support collaborative planning participation with other federal agencies.*

For major ecosystem or watershed planning studies, the lead federal agency should budget for adequate funding to reimburse other key federal agencies for their collaborative participation. Studies that are not watershed in scope or that have not been adequately funded to support a multi-agency collaborative effort may require that individual agencies budget their own participation monies.

Programmatic NEPA Documents

The Review Committee heard comments that requiring independent NEPA documents on similar but individual projects can be an inefficient and time-consuming approach to decision making. Efficiencies can be realized by analyzing all the anticipated actions as a group and applying NEPA on a programmatic basis before proceeding on individual projects requiring site-specific NEPA compliance. Application of multi-agency programmatic environmental impact analyses performed at the watershed scale allows agencies to focus on issues that are geographically related or have timing, impact, or other subject matter similarities. In addition the programmatic NEPA process provides a formal public involvement mechanism to address strategic decisions. Subsequent impact analyses would only focus on project-specific purposes and needs and those issues n need of decisions.[28] Where subsequent plans are consistent with the programmatic analysis, further analysis would be focused, costs reduced, and planning made more efficient.

The Council on Environmental Quality (CEQ) needs to actively pursue use of programmatic NEPA documents and issue a directive to agencies to also increase their emphasis on this approach.

Recommendation 5.6: *Promote the use of programmatic NEPA documents in the planning process.*

A workshop should be sponsored on strategic and programmatic application of NEPA by CEQ so that success stories in this area can be shared. This will build knowledge about the applicability of these approaches. Their utility, and the means of undertaking broad programs-level analyses. The CEQ should explore other means to pursue strategic programmatic analysis of problems.

Federal Agency NEPA Participation

Currently lead agencies designate those agencies that should cooperate in the NEPA process. Where agencies have not been designated by the lead agency but specially request participation due to a vested interest, these agencies should be allowed to cooperate in the process. No mechanism exists to require the lead agency to include these other requesting agencies in the process. The CEO should revise the regulations implementing NEPA to require the lead agency to designate those federal agencies formally requesting cooperating agency status, where appropriate. This would further the goal of establishing collaborative planning among pertinent federal agencies.

REEVALUATING WATER RESOURCES PROJECTS

Many of the nation's water resources projects were constructed a number of years ago. The Review Committee heard concerns that: (1) these projects will eventually need major maintenance expenditures, (2) conditions have changed that make them less effective (such as headwater development that increases runoff and flood stages causing protection downstream to be lessened, and (3) consideration is not adequately given to changing societal goals with regard to potential modifications to the projects themselves or modifications in the operation of them.

Recommendation 5.7: ***OMB should issue a directive that requires periodic reevaluation of federal water resources project to include potential operation and maintenance modifications.***

Projects for which construction was completed 40 or more years ago should be reevaluated to consider potential project modification and insure project integrity. Other projects less than 40 years old should be reevaluated when know major problems exist, where conditions have changed that impact the effectiveness of the project, or where changing societal goals demand that modification be considered. Specific procedures tied to the new *P&G* should be established and a directive issued by OMB. Legislation should be provided in a Water Resources Development Act or other act to give water resources construction agencies the blanket authority to address these issues, where appropriate, without the need for project-specific study authorizations Congress.

FUNDING CONSIDERATIONS FOR PROJECTSTHAT INCLUDE FUTURE DEVELOPMENT

Some flood damage reduction projects, in their effort to reduce damages for existing floodplain structures, also provide protection for undeveloped land areas that have a high potential for future development. In these cases, future development savings resulting from the project are estimated and included in the benefit-cost ratio. A separate accounting of existing and future benefits is required by P&G to provide decisions makers with the information necessary to make informed decision. The total benefit-cost ratio, however, is reported in the feasibility report and usually used for budgetary considerations in establishing funding priorities.

Recommendation 5.8: ***OMB should use only the benefit-cost ratio for damage reductions to existing development in establishing Administration funding priorities unless a standard project flood level of protection is provided.***

The Office of Management and Budget should give more detailed consideration to the type of project benefits being claimed for each individual project recommendation. Future development benefits should not be used as the basis for increasing the funding priority of flood damage reduction projects unless a standard project flood level of protection is provided.

Chapter 6

AVOIDING VULNERABILITY THROUGH PLANNING

Throughout human history it has been the way of nature to visit us on occasions with disaster, without apparent cause, without explanation, often without mercy, always reminding us that we need to live our lives with a little more humility and always understanding that we are not in full control...We know we cannot contain the fury of a river.

President Clinton
Remarks on signing flood relief legislation at a tribute to flood heros in St. Louis, Missouri, August 12, 1993

The goals of floodplain management are to reduce the nation's vulnerability to floods while concurrently integrating preservation and enhancement of the natural resources and functions of the floodplain. The basic tenet of reducing vulnerability is to avoid risks as much as possible in the planning stage. Moving people out of harm's way or limiting development in the floodplains lessens risks from flood damages. Planning on the watershed level can balance competing and compatible uses of the floodplain to meet social, environmental, economic, and other community goals.

For planning to be effective, it needs to be coupled with an educational program for local people involved with planning activities as well as landowners. Once communities and individuals understand the residual risk inherent in floodplain use, and once they understand how natural and hydraulic systems operate, they can make more informed decisions that balance multiple objectives.

With planning and education as the cornerstones of floodplain management, the nation can further reduce risks through watershed management, programs such as the NFIP, and acquisition of flood prone lands. By pursuing planning efforts in a collaborative and coordinated fashion, the nation can reduce its vulnerability to flooding substantially.

MANAGING FLOODPLAINS AS WATERSHED COMPONENTS

What happens in the larger watershed affects what happens in the floodplain. The upper Mississippi River Basin consists of watersheds of varying size. Each watershed is a physically discrete hydrologic unit in which water is channeled from upland areas to lower areas and eventually into main stem rivers. The flood stage, frequency, and duration normally are influenced by the degree to which rainfall is captured and released in the uplands. As discussed in Chapter 2, wetland restoration and maintenance and upland treatment can be effective for smaller floods with lesser impacts on larger floods. The correlation between upland rainfall capture and release and

downstream flood stage, though complex and incompletely understood, indicates that well-managed watersheds reduce downstream flood stages with concomitant reductions in flood damages and increases n water quality and ecosystem benefits.

A number of Midwest communities flooded in 1993 reported to the Review Committee that they perceived an increase in flood stages and frequencies over the past few decides. Some attribute this to structural flood control (levees), and others to changed land use practices in upland areas of the watershed. Among the changes they mentioned were agricultural development and paving of residential and industrial areas -- both of which reduce storage capacity and increase runoff. People rarely consider the downstream cumulative effects of individual activities, in large part because water sheds typically encompass a number of political jurisdictions with differing economic interests.

Watersheds have long been recognized as the optimal management unit for water resources planning. As early as the 1970s, the USACE was performing analyses of water quality and supply using watersheds as the basic planning unit.[1] The USDA for decades has recognized benefits of watershed planning under its PL 566 program and through the Forest Service.[2] More recently within the Department of the Interior, the National Park Service and the Fish and Wildlife Service have instituted watershed management programs, and the Environmental Protection Agency has begun using watersheds as the most practical unit to resolve problems that traditional programs have been unable to address adequately.[3]

Federal watershed programs and policies suffer from a lack of coordination and a failure to develop achievable multiple objectives. Many of these programs focus exclusively on water quality or habitat improvements derived from watershed management but disregard flood damage reduction benefits. Federal watershed programs primarily operate in rural areas, neglecting non-agricultural urban and suburban land uses. Program eligibility requirements and incentives also differ among agencies. The regional of most federal agencies, tied to state boundaries, complicates the ability to focus on watersheds.

Any pending legislation dealing with watershed planning and management should consider achieving multiple objectives, including flood damage reduction as an element of watershed management and incentives based upon demonstrated flood reduction. Legislation should also consider opportunities to trade for flood control, such as payments from floodplain farmers to induce upland farmers to install land-management practices that reduce flood peak and frequency. Currently, pending legislation (S. 2093, formally S. 1114; President Clinton's Clean Water Initiative; and H.R. 3938)[4] considers the achievement of multiple objectives for watershed, although flood control management activities and incentives are not explicitly stated.

The best parts of federal programs must be merged to encompass a holistic and synergistic approach to watershed management. Opportunities for change include current congressional action n the Clean Water Act and reauthorization of the Farm Bill due in 1995. To capitalize on potentially forthcoming legislative authority, the federal government must build on going watershed programs, focusing on the most effective means of achieving multiple objectives, and targeting conservation programs to complement watershed management goals.

Action 6.1: *The Administration should establish an interagency task fore, jointly chaired by the USDA and EPA, to formulate a coordinated, comprehensive approach to multiple objective watershed management.*

Many federal agencies undertake watershed programs to achieve goals consistent with their primary mission. Such goals may be inconsistent with local, regional, or basin-level ecosystem needs. Currently, success is measured by achieving agency goals irrespective of other attainable benefits. For example, the Forest Service watershed program seeks to improve stream habitat through reduced siltation and temperature reduction. Success is measured by increases in fish population. Flood damage reduction and water quality -- goals that could be accomplished with small incremental expenditures of expertise and money -- are not factors in determining program success.

The recommended task force would provide an overview of federal watershed management programs to ascertain their effectiveness and identify areas for improvements. The task force will necessarily include the USACE and the DOI due to their missions and jurisdiction in water resources activities. Task force members could identify areas in which interagency missions coincide and are achievable through watershed management on a collaborative level. The task force should also follow up on the demonstration project discussed in Chapter 11 under the section on hydrologic and hydraulic benefits of natural floodplain functions.

Enhancing Stream and Riparian Areas

Stream and riparian restoration vital to watershed management holds, for a relatively small investment, promise of improved water quality, wildlife habitat, and reduced runoff. Federal efforts designed to restore non-urban stream and riparian areas include those of the Bureau of Land Management, the National Park Service, the Soil Conservation Service, and the Forest Service. Nonprofit groups and private and local interests have also focused on similar activities. Unfortunately many stream and riparian sites located within urban and suburban areas are degraded, undervalued, and ignored by federal programs. Properly restored urban streams provide the same benefits as restored rural streams, often becoming centerpieces for urban revitalization. Recognizing the need for stream and riparian restoration, Congress recently introduced legislation to establish a national urban watershed restoration program.[5] On the national level, current stream and riparian restoration is largely uncoordinated; federal expertise is decentralized and underutilized; and valuable information on costs, techniques, and effects is unavailable.

Action 6.2: *The DOI, USDA, and EPA should coordinate and support federal riverine and riparian area restoration.*

Because of the importance of stream and riparian restoration to water resource management, the Administration should establish a stream and riparian restoration program with DOI, USDA, and EPA cooperating to provide technical assistance for state, tribal, local, and private restoration.

Enhancing Agricultural Conservation Programs

The Food Security Act of 1985, and the Food, Agriculture, Conservation, and Trade Act of 1990, the last comprehensive congressional actions on agricultural policy, contained strong conservation measures to reduce soil loss and improve water quality by creating incentives and disincentives, primarily through cross-compliance with other agricultural programs. Two programs were of particular importance: the Conservation Reserve Program (CRP), introduced in 1985, provided payments to farm operators who agreed to protect temporarily highly erodible lands, and the Wetland Reserve Program (WRP), established in 1990, acquires conservation easements on agricultural lands from voluntary sellers and restores wetland conditions. About 36.4 million acres currently enrolled in the CRP will begin to come out of the program in 1995. Even with application of conservation practices, conversion of these acres to cropland will increase runoff.

The emergency supplemental appropriation for the Midwest floods established an Emergency Wetlands Reserve Program (EWRP) applicable to farmland damaged by flooding in the nine affected Midwest states. The Review Committee suggests that the authority for the WERP be continued in some form to provide an alternative means of recovery for farmers. Other programs within the Agricultural Resource Conservation Program of the USDA also are used to protect wetlands from development and degradation.

The USDA found many acres that met program criteria, but funding constraints precluded enrolling all of the eligible land. Conservation programs need to target limited funds to acquire critical lands that offer the greatest benefits per federal dollar. Present selection criteria, which consider natural characteristics on a site-by-site basis, do not recognize flood control benefits as an objective. Other benefits of the programs are well documented.[6] A systems approach to watershed management would consider a wider range of environmental objectives within enrollment criteria.

Action 6.3: ***The Administration's legislative proposals for the 1995 Farm Bill should support continuation and expansion of conservation and voluntary acquisition programs focused on critical lands within watersheds. The proposal should support technical and financial assistance for implementation of watershed management, riparian enhancement, wetland restoration, and upland treatment measures.***

STREAMLINING DISASTER PLANNING

A floodplain management plan that attains the national goals described in Chapter 4 is dependent on the ability to tie together pre-disaster, response, recovery, and mitigation programs with long-term floodplain planning efforts. Many federal agencies have programs designed to help disaster-stricken areas. Such programs can be improved by streamlining the system so that pre-disaster and post-disaster efforts are natural extensions of each other. Comprehensive pre-disaster planning and mitigation efforts will reduce risks and damages during the emergency, and recovery efforts will be consistent with long-term floodplain management goals. Improvements in federal coordination made before the 193 flood led communities to report that things worked "better than expected."

Pre-Disaster Planning

Pre-disaster planning needs to coordinate individual, business, community, state, tribal, and federal personnel and activities to minimize health and safety impacts and environmental risks. Such planning will help ensure adequate response. Awareness of flood threat, the first step in pre-disaster planning, relies on individuals who understand their risk and plan for disasters. Individual responsibility in knowing what to do, such as closing household gas lines, and when and where to evacuate in the event of a flood or other emergency is essential. The Review Committee heard from communities where owners did not remove mobile home trailers on wheels and farm equipment from low-lying areas. Some individuals refused to evacuate voluntarily when access was open and later required evacuation by air or boat, endangering both themselves and their rescuers. For better participation by individuals in pre-disaster planning, federal agencies must undertake education and outreach.

Pre-disaster planning is also a corporate responsibility. Operators of facilities generating, storing, or disposing of hazardous materials -- including farmers who use herbicides, pesticides, and fertilizers -- need plans for removing such materials should the facility lack the capability of assuring that no materials will be released. Local emergency managers need to be aware of locations of hazardous materials within their jurisdiction; local hospitals, fire companies, and others potentially involved with response need to be knowledgeable about threats posed by hazardous materials, their treatment, containment, and removal n the event of an unplanned release. Several emergency managers working in the Midwest flood reported the need for more pre-disaster information about facilities where hazardous wastes are generated, stored, and disposed. Siting issues should go hand in hand with pre-disaster planning.

Planners also need to consider how to safeguard valuable assets, such as cultural and historical properties. Communities should identify these properties prior to a disaster and coordinate with emergency managers, local government officials, federal agencies, and other following and event.

Pre-disaster planning requires action, involvement, and cooperation among not only floodplain residents, tribes, businesses, and industries but also across local, state, and federal government agencies. Application of advanced geographic information systems technology will increase efficiency and facilitate coordination.

Recommendation 6.1: *Enhance pre-disaster planning and training.*

The FEMA, in coordination with the EPA, UACE, USDA, DOT, and other federal agencies involved with aspects of emergency response, should increase state, tribal, local, public, and corporate awareness of risk. Those involved should practice implementation of pre-disaster plans. The EPA should work with the FEMA and states to emphasize local pre-disaster planning, including notification and coordination procedures for responding to releases of hazardous materials. Pre-disaster plans for spilled hazardous materials must identify suitable containment areas and develop a coordinated response of the emergency network. All agencies should encourage the use of geographic information systems to link data sources.

FLOODPLAIN PLANNING AND THE NATIONAL FLOOD INSURANCE PROGRAM

The National Flood Insurance Program (NFIP) is a primary component of the nation's floodplain management strategy. The congress created the NFIP in 1968 in response to mounting flood losses and escalating costs to the general taxpayer for disaster relief. Federal flood insurance is available only in communities that adopt and enforce floodplain management regulations that meet minimum NFIP requirements.

Building on NFIP Floodplain Management Requirements

The NFIP provides a framework for protecting new construction from flood damages through its floodplain management requirements that communities adopt and enforce as a condition of program participation. New and substantially improved residential buildings must be elevated to or above the elevation of the 100-year flood and non-residential buildings must be elevated or flood proofed at least to that elevation. Flood insurance premiums support floodplain mapping. In riverine floodplains, encroachments in the floodway are prohibited if they will result in any increase in flood stages. This limits development in areas of the floodplain adjacent to the river channel.

Flood insurance rates reinforce NFIP floodplain management requirements. Rates on new buildings are actuarial (based on the risk of flooding). When a structure is built in compliance with a community ordinance, the flood insurance premium is generally affordable. When a building violates a community ordinance, the flood insurance premium can increase to thousands of dollars a year or the building can be denied insurance at the request of the community

In the Midwest, the NFIP tends to discourage floodplain development through the increased costs in meeting floodplain management requirements and the cost of an annual flood insurance premium, although this may not be the case elsewhere in the nation. Individuals and developers appear to choose locations out of the floodplain to avoid these costs. Developers have the added incentive of wanting to avoid marketing flood prone property. Many communities visited by the Review Committee actively discourage floodplain development.

The NFIP, however, has its limitations. NFIP requirements are minimum standards applied throughout the nation in areas subject to very different flooding conditions. Requirements that are reasonable and prudent in some parts of the nation are not reasonable in others. As a result minimum standards tend to be just that. An example of a requirement that might be reasonable to apply in some areas of the country but not in others, is access to subdivisions and other new development at or near the elevation of the 100-year flood. While access to buildings may not be a critical issue in areas of the country subject to shallow or short-duration flooding, it is critical in the bottomlands of the Mississippi and Missouri rivers. A home elevated to above the flood elevation is of little use to a family if the house cannot be occupied for weeks at a time because it is cut off by floodwaters. Provisions of emergency services to these areas also can be a burden on a community. These issues are best addressed at the state or community level, not through a minimum federal regulation. Several states in the Midwest have more restrictive state floodplain management regulations that address a number of these issues.

NFIP requirements dictate how the structures are to be built to minimize property damage but not whether the location is appropriate given the flood risk and the overall objectives of the community. Because land use planning is traditionally a responsibility of state and local governments, the NFIP does not require that communities undertake these decisionmaking processes that are a necessary part of an effective floodplain management program. Decisions such as subdivision approval and providing capital improvements for roads and sewer, water, and other utilities are critical to the location of development. Such decisions largely determine the uses of the floodplain. Land-use controls, including techniques such as density controls, cluster development, performance zoning, dedication of floodplain lands, and maintenance of greenways and buffers, can result in development that avoids or minimizes impacts on the floodplain but ensures property owners and developers an adequate return on their investment.

The NFIP Community Rating System (CRS) provides discounts on flood insurance premiums in those communities that have floodplain management programs above and beyond NFIP minimum requirements. The CRS recognizes those communities that have developed floodplain management plans and in some instances encourages communities to undertake new floodplain management initiatives. These premium discounts, however, are not sufficient to encourage widespread participation in the Midwest. New initiatives are needed to encourage local floodplain management planning.

Addressing Issues Raised by States and Communities

One state expressed a concern to the Review Committee that NFIP requirements were not being enforced by some communities. Although most communities visited by the Review Committee had little new floodplain development since joining the NFIP, without a review of permit files, it is difficult to determine how well these communities were implementing floodplain management requirements that applied to buildings substantially damaged by the Midwest flood. FEMA regional staff have conducted systematic visits to NFIP communities impacted by the flood to monitor enforcement of local floodplain management ordinances. Preliminary results from these visits indicate that many communities are not enforcing their ordinances adequately, often because they do not understand the program requirements or the long-term benefits of reducing flood damages. This finding indicates the continuing need for federal or state agencies to provide technical assistance to communities and to monitor their compliance. The enactment and funding of the Floodplain Management Act called for in Action 5.1 of this report will enable states to provide significantly increased levels of technical assistance to communities. This assistance will improve implementation by communities of floodplain management programs and compliance with NFIP requirements.

States and communities have suggested that the FEMA amend its minimum floodplain management criteria to provide freeboard and a more restrictive floodway requirement. They also advocate discontinuing the practice of issuing Letters of Map Revision that remove from the floodplain those properties elevated on fill. Other issues of concern include access above the 100-year flood elevation to all subdivisions and other development in areas subject to deep flooding and appropriate require-

ments for agricultural buildings. The FEMA should review these issues in the context of its minimum criteria for floodplain management with consideration given to hydraulics and environmental effects.

Action 6.4: *Promote the NFIP Community Rating System as a means of encouraging communities to develop floodplain management and hazard mitigation plans and incorporate floodplain management concerns into their ongoing community planning and decision making.*

The NFIP Community Rating System (CRS) credits many of the more restrictive floodplain management requirements suggested by states and communities currently. The CRS provides discounts on flood insurance premiums in those communities that implement floodplain management programs exceeding the NFIP minimum.

The CRS should provide additional credits to encourage comprehensive planning at the community level to incorporate floodplain management into day-to-day decisions on capital improvements and land development.

Action 6.5: *Provide funding for the development of state and community floodplain management and hazard mitigation plans.*

The development and implementation of state and community floodplain management and hazard mitigation plans can reduce significantly federal expenditures of future disasters. Funding should be provided to encourage these planning initiatives. One source of this funding could be a mitigation fund established using NFIP premiums (such as that provided for in S. 1405 and H.R. 3191 both entitled the National Flood Insurance Reform Act of 1994). An additional source of funding could be a portion of the monies appropriated for the FEMA Disaster Fund or other appropriated funds.

Recommendation 6.2: *The FEMA should review its policy of issuing revisions to flood insurance maps which remove property from the floodplain based on fill.*

Under current NFIP policy, if floodplain areas are filled to above the 100-year flood elevation, the property be removed from the floodplain by revising the flood insurance map for the community. Within these areas, floodplain management measures and the mandatory flood insurance purchase requirement do not apply. This policy may encourage the filling of floodplains by developers to avoid community floodplain management requirements and to assist in marketing flood prone properties. It also may result in individuals making decisions to purchase a property without full knowledge of the residual risk of flooding, the advisability of obtaining flood insurance coverage, or access problems during floods. FEMA's review of this policy should include consideration of all program and engineering issues.

Identifying Those at Risk

State and local officials are concerned that some sparsely populated rural counties with occupied floodplains have not been mapped by FEMA. The agency did not map these areas because their low populations and minimal development did not warrant the expenditure or because base mapping was not available when the initial identification of flood prone communities was made in the mid-1970s. Funding constraints have limited the agency's subsequent ability to map these communities given the priority for communities with more concentrated development. Without floodplain maps federal sanctions do not encourage community participation. In the nine Midwest states, 209 counties have not been mapped, including 108 that were declared as disaster areas due to the 1993 floods.

Action 6.6: *Map all communities with flood hazard areas that are developed or could be developed.*

The FEMA should review flood prone communities that have never been mapped, and map those communities with flood hazard areas that are developed or have potential for development. NFIP communities then would have the information necessary to enforce floodplain management regulations and to ensure that individuals at risk purchase flood insurance. Mapping the floodplain will provide an incentive for non-participating communities to join the program because federal assistance for acquisition and construction of buildings is not available in designated flood hazard areas unless a community is participating in the NFIP.

Improving Accuracy and Timeliness in NFIP Mapping

The nation must have an adequate floodplain mapping program to achieve its floodplain management goals. At the core of any floodplain management program is knowledge of the risk-floodplain boundary and flood elevations.

The flood risk information on the NFI Flood Insurance Rate Map (FIRM) forms the technical basis for administering federal flood insurance and is utilized nationwide. Since creation of the NFIP 25 years ago, it has identified approximately 22,000 communities as flood prone. Nearly 21,000 of these have been mapped, and over 18,300 are participating in the NFIP.[7]

States and communities indicated to the Review Committee that for some areas, NFIP maps are out of date, inaccurate, take too long to get revised, or may not exist. Others encountered difficulty in obtaining copies of the maps. The program for maintaining and distributing maps if funded entirely by flood insurance policyholders through a $25 surcharge on each policy. The annual mapping budget is $35 million.[8] This surcharge covers administrative costs as well. This funding allows the FEMA to initiate about 250 studies per year and to respond to requests to update maps based on local or state date.[9] A small portion of the budget goes to the digital conversion of the maps. About $4 million annually covers the printing and distribution of the maps.[10]

The FEMA is striving to automate the mapping process as much as possible under current funding constraints. Beginning in FY 1995, all engineering studies contracted by the FEMA will be submitted in digital format. A tool for automated review of engineering models has been developed. The mapping program recognizes the benefits derived from using digital technology but has not implemented it through to the final phase of the map production process. Because a large inventory of old, traditionally mapped FIRMs do not meet national map accuracy standards, the addition of horizontal control to the FIRM has become part of the digital conversion process. The current level of production is slightly over 2,000 digital map panels per year.[11] With current funding and procedures, it would take 40 years to complete the digital conversion of 80,000 map panels nationwide. The FEMA is drafting a plan for flood studies maintenance that would inventory and prioritize nationwide floodplain mapping needs every five years.

Action 6.7: *To improve and accelerate delivery of NFIP map products, the Administration should propose supplementing those funds obtained for floodplain mapping from NFIP policyholders with appropriated funds.*

Current NFIP funding derived from the $25 federal policy charge is not adequate for maintaining and updating floodplain management maps. Raising this surcharge may undermine efforts to market flood insurance and would not be equitable since policyholders are only one user of these maps. Since the maps are critical for floodplain and emergency management, Congress should supplement policyholder dollars with appropriated funds. Flood insurance claims payments for the 1993 Midwest flood totaled $297 million,[12] a small percentage of the federal payments for this disaster. The federal government has an interest in maintaining and updating the NFIP'S $1 billion investment in floodplain mapping to ensure that all levels of government and individuals have the information necessary to manage their floodplains and reduce future damages.[13]

USERS AND USES OF NFIP MAPS

WHO	WHY
Communities participating in the NFIP	Enforce floodplain management ordinances
State and local floodplain managers	Enforce regulations and land use decisionmaking
State and local emergency managers	Response and recovery planning
Federal Agencies	Compliance with EO 11988
Federal Insurance Administration	Establish insurance rates
Insurance companies and agents	Rate flood insurance policies
Lenders	Comply with mandatory purchase requirements
Designers of floodplain development	Determine design requirements
Disaster response agencies	Coordinate disaster response and recovery
Real estate brokers and agents	Disclosure of the flood risk

Action 6.8: *Utilize technology to improve floodplain mapping.*

The FEMA should investigate alternative methods of expediting the conversion of FIRMs to digital format. Digital conversion will result in a long-term cost savings because of reduced ongoing map maintenance requirements. The digital format will enable the efficient accommodation of large as well as small changes and will result in more accurate maps. Digital floodplain boundary information combined with land parcel records from a community or street address range data, such as are available from the U.S. Bureau of the Census TIGER files, will facilitate applications under floodplain and emergency management. The simplest and most common use is to look up the flood risk data for a specific address. Some areas in which the FEMA would realize savings and increase efficiency are in processing certain revisions, verifying insurance ratings, analyzing repetitive loss data, assuring local compliance, and marketing. Digital FIRMs will also facilitate the completion of a national inventory of floodprone structures, which is recommended in Action 11.2 of this report.

INCREASING EDUCATION AND OUTREACH EFFORTS

If individuals and communities are going to participate in pre-disaster, response, recovery, and mitigation efforts, then awareness of natural hazards should be the first step in pre-disaster planning. This is especially true for flood hazards since individuals have to make decisions that affect their vulnerability. To increase awareness, the

federal government should pursue education and outreach activities.

Because the general populace may not have a complete understanding of natural physical processes, such as the hydrologic cycle and river hydraulics, and of geomorphology, they poorly grasp their vulnerability to flooding and the economic, environmental, and social benefits of alternative strategies to avoid or reduce risk. Unawareness of flood vulnerability results in the inappropriate development of floodprone areas. Another result is that only a portion of the public responds appropriately to flood warnings, and this lack of response can have grave results.[14]

Floodplain information is not distributed widely beyond floodplain regulators, federal and state agencies, and the insurance and lending industries. Many individuals may not even be aware that flood and other hazard information exists for their community. Success stories of local efforts in the area of zoning, pre-disaster planning, biotechnical engineering, and collaborative programs should be distributed and shared with all levels of government in an effort to achieve widespread application of successful floodplain management strategies and tools.

Recommendation 6.3: *Federal agencies involved in floodplain management should include information regarding floodplain management and pat and probable future flood heights and extents in their education and public affairs initiatives.*

Floodplain information should be available to the general public in formats that the average person can understand and use. All agencies involved in floodplain management should continue efforts to inform and educate the public about the nature of flood hazards, the natural resources and functions of floodplains, and the various strategies and tools available for comprehensive floodplain management.[15] Agencies should adhere to guidance given in EO11988 (or in a revised EO on floodplain management) regarding the conspicuous delineation of past and probable flood heights on property used by the general public.

Recommendation 6.4: *State floodplain management officials should encourage local school districts to include natural hazard education in their curricula.*

Education regarding the existence of natural hazards, such as floods, should be introduced into the elementary and secondary education curricula to provide an early awareness and understanding of how and why floods occur. Information should include what to do in the event of a natural hazard emergency. If educated from an early age, adults will be better able to participate in pre-disaster, response, recovery, and mitigation efforts.

Chapter 7

FOCUSING ON ENVIRONMENTAL ENHANCEMENT

Even before the Great Flood of '93, we had started to realize that some of the areas within our levees should have never been cleared for farming. The events of the last year have driven this point home. Many farmers with marginal and sub marginal land are tired of fighting the river and want to find a way to get out from under their financial burdens.

Letter from Union County Board of Commissioners
to U.S. Senator Paul Simon (D-IL), April 1994.

During the 1993 flood, environmental easement and land acquisition programs became tools in assisting recovery and in removing people from long-term flood vulnerability. In addition to meeting the needs of disaster relief victims, these programs can be effective in achieving the nation's environmental goals. Environmental enhancement and mitigation programs essential to ecosystem management are often part of federal development projects. In the past, though, such programs have been delayed, under funded, or not funded at all. Had they been implemented before the 1993 flood, these programs would have restored natural lands and provided a measure of flood protection through reduced runoff and increased floodwater storage. Environmental mitigation programs also have tended to be site-specific rather than focusing on broader ecosystem goals. This chapter recommends ways to use federal environmental programs in ecosystem management to meet the needs of human development and the environment.

ESTABLISHING A LEAD AGENCY FOR LAND ACQUISTIONS

Following a disaster like the 1993 flood, landowners can benefit from a number of federal assistance programs, such as fee title or land easement acquisitions. During the early post-flood response period, land acquisition did not emerge as a viable risk-reduction option for a number of reasons: limited funds, lack of a participatory mechanism for mixing funds from different agencies, and lack of a focal point within the government for such action. Part of the problem is that no single federal agency has authority to coordinate existing land buyout or easement programs for environmentally related acquisitions, such as the USDA Wetland Reserve Program, Emergency Wetland Reserve Program, and FS forest acquisition program; the USACE Missouri River Mitigation Project; and the FWS National Wildlife Refuge acquisition program.

Federal acquisitions and easement programs share capabilities to restore habitats for native fish and

FEDERAL AGENCIES COMPETING FOR THE SAME LAND

Stan Hinnah's farm on e Missouri River near Glasgow, Missouri, was devastated by the 1993 flood. His farm lies in one of the river's high energy zones on the site of an old channel bed. When Mr. Hinnah's levee broke, a surge of water scoured out unconsolidated sands from the old channel and deposited them across the remainder of his fields. Mr. Hinnah owns other lands in the nearby uplands and would like to sell his Missouri River bottomlland and get on with his farm operations at another location "out of harm's way," as he put it. When Review Committee members spoke with him, he was frustrated because even though several federal and state acquisition programs were available, none were clearly defined, and none were able to get funding approved and released to complete the sale. Mr. Hinnah was confused by the number of governmental units involved in buyouts, and he was hesitant to make a deal with any one of them and miss a better deal.

wildlife species of special federal interest. Such programs can address the needs of landowners who may wish to discontinue row cropping or who may simply wish to sell fee title interest altogether. One way to overcome problems associated with these programs is to involve non-governmental organizations (NGOs) that can contribute financially to the federal buyout process and act as a catalyst between landowners and government agencies.

During visits with government agencies and landowners, the Review Committee found an interest in establishing on federal agency as the lead for environmental land acquisitions.

Action 7.1: *The Administration should establish a lead agency for coordinating acquisition of title and easements to lands acquired for environmental purposes.*

Several federal agencies have land acquisition authority, but lack of coordination between them creates confusion and provides opportunities for landowners to shop around, promoting potential bidding wars between interested agencies. Taken together, government land acquisition-easement programs provide an opportunity to address both landowner and ecosystem needs. Several programs already exist to address these needs, but coordination among the primary agencies -- DOI, USDE, and USACE -- would improve efficiency. Because the mission of the FWS within the DOI "...is to conserve, protect and enhance the Nation's fish, wildlife and habitat for the continuing benefit of the American people...", the Review Committee suggests that the DOI coordinate federal acquisitions of environmental lands. this role does not imply ultimate exclusive ownership or management by the DOI but provides for leadership in identifying the capabilities and interests of other federal agencies, states, tribes, and local resource managers, as well as individual landowners.

The recommended cooperative land acquisition-easement program would develop Memoranda of Agreement (MOA) between the DOI, USDA, USACE and other agencies. Federal land acquisition agencies would establish rules for acquisitions and easements based on program authority. Transfer of acquisition funds to the DOI would be made, as appropriate, under Cooperative Agreements (CAs). When such CAs have been completed, agencies would provide

PRIVATE INVOLVEMENT IN PUBLIC BUYOUTS

NGOs, such as the Iowa Natural Heritage Foundation and the Conservation Fund, played significant roles in acquisition of the Louisa No. 8 Levee District on the Iowa River near its confluence with the Mississippi River. Louisa No. 8 had a history of repair from past floods, and, although it was eligible for repair under the USACE PL 84-99 program, affected landowners expressed an interest in alternatives to continued farming. Administrative and authority limits in the land acquisition programs of federal Disaster Field Office participants prevented federal agencies from pooling funds to initiate land acquisition. By utilizing their funds, the Iowa Natural Heritage Foundation and the Conservation Fund were able to step in and purchase the land, holding it until federal funds were released to finish the buyout. This allowed landowners to get on with their lives.

oversight and would assist the DOI with landowner contacts to assure that all federal mandates are met. The DOI would not be involved in non-environmental land acquisitions, such as the purchase of construction sites or FEMA sturture-buyouts that offer no special potential for environmental enhancement.

The nation needs a coordinated program to maximize federal use of funding for programs such as the FWS refuge acquisition program, the USACE Missouri River Mitigation Project and the USDA Wetland Reserve Program. Coordinated leadership would help ensure that federal environmental land acquisition programs focus on ecosystem management to meet the needs of interjurisdictional, native, and threatened and endangered species. it would help guard against acquisitions or easement involving disconnected or disaggregated lands that are checkerboard in appearance and difficult to manage.

Federal land acquisitions would be coordinated with existing state and local programs to avoid conflicts, as well as complement and further their environmental activities. In addition, the DOI would not necessarily maintain fee title and operation and maintenance responsibility for acquired lands. When appropriate, a cooperating agency or state would assume ownership and operation-maintenance responsibility, although the DOI would maintain those lands critical to federally listed threatened and endangered species.

PROTECTING THE TAX BASE OF LOCAL GOVERNMENTS

During discussions with individuals and local governments regarding federal land acquisitions, the Review Committee learned that lost tax revenues from acquired lands are an issue. For acquisitions involving the DOI, Congress designed the Refuge Revenue Sharing Act (RRSA)_ to reduce the financial hardship lost tax revenues by providing government payments in lieu of taxes. Inadequate funding of the RRSA program, however, has limited the attractiveness of federal land acquisition in various areas of the country.

Recommendation 7.1: ***The Administration should support increased funding for the Refuge Revenue Sharing Act.***

Increased funding of the RRSA, in conjunction with review and revision of implementing regulations, would assist in equitable distribution of funds among different regions of the country and would address of concerns of local governments regarding tax base impacts that negatively affect schools and infrastructure.

ALLOWING AGENCIES PROCEDURAL FLEXIBILITY IN DISASTERS

In examining the federal flood response, the Review Committee learned of difficulties encountered by agencies in their efforts to enhance natural resources while considering landowner needs. Uncertainty among landowners about the ability of federal agencies to execute timely real estate actions limited their interest in full or partial land sale or easement acquisition. Statutory feature of easement-acquisition authorities for federal agencies prevent spending without first completing full procedural cycles. In a disaster response situation, procedural flexibility would be advantageous for federal agencies and economically distressed landowners.

Action 7.2: ***The Administration should develop emergency implementation procedures to organize federal agencies for environmental land acquisitions.***

The waiver of certain procedural components of land acquisition programs that require extended intra- and interagency review and comment would improve response to economic hardships during immediate post-disaster periods. The Administration should direct the DOI, in cooperation with other federal land acquisition agencies, to develop an interagency, programmatic environmental land acquisition plan that could be implemented during emergency situations.

All agencies with jurisdiction or special expertise in land acquisition should participate in the DOI interagency plan. Agencies will have program-specific interests in a planning area, but, within the context of a programmatic document, they can integrate their interests to articulate the range of federal, tribal, state, and local options. Following disasters, the federal government could use available funds to immediately acquire lands with pre-identified environmental values and hazard plans. This approach, similar to one used by the FWS for acquiring available parcels within pre-identified Waterfowl Production Areas, would involve a larger group of agencies.

Recovery Operations

The 1993 flood caused major infrastructure damage throughout the upper Mississippi River basin. An August 1993 interagency letter of cooperation' signaled the Administration's awareness that disaster response must provide innovative actions using various federal programs, such as the USDA Emergency Wetland Reserve Program, Section 1135 of the Water Resources Development Act (WRDA) of 1986, and public-private partnerships. The acquisition of the Louisa No. 8 Drainage District exemplifies this partnership. Although the lack of experience and institutionalization of buyouts limited actions similar to the Louisa No. 8 buyout, this situation could be improved if the ad hoc relationship established by the aforementioned letter were formalized.

Action 7.3: ***The DOI should formalize environmental considerations in multi-agency disaster recovery land restoration activity through a coordinated Memorandum of Agreement.***

The Administration should direct the DOI to use the Louisa No. 8 project as an example to develop a MOA

between agencies for post-disaster recovery. Formalization of working relationships would expedite recovery efforts by providing coordination points and a central clearinghouse for information on buyout options, sources of funds, and a list of potential cooperators.

Emergency Funding

PL 84-99 provides the USACE with flexibility to quickly reprogram funds from agency accounts to fund Presidentially declared flood disaster response efforts. This enables the USACE to use appropriated funds to address emergencies and disaster response in a timely manner.

Action 7.4: *Seek legislative authority for flexibility in use of programmed funds in emergency situations.*

The Congress should provide legislative authority and flexibility, similar to that provided the USACE by PL 84-99, to other agencies and programs. Such flexibility would expedite landowner relief and enhance the federal ability to capitalize on environmental enhancement opportunities. Funds used could be reimbursed, if necessary, from supplemental appropriations, when they became available and, as appropriate, by reprogramming funds from other sources within agency. As an example, following the 1993 flood, the FWS was unable to access several million dollars of appropriated Land & Water Conservation (LAWCON) funds. If the FWS had been able to access those funds, which were earmarked for other uses, the agency could have offered landowners an immediate alternative to realigning and repairing levees. The opportunity to restore wildlife habitats was missed. The LAWCON account could have been reimbursed subsequently either by special appropriation or transfer from other accounts.

ACQUIRING AND RESTORING LAND ON PROBLEM RIVER REACHES

Federal agencies are focusing on ecosystem management in recognition of the functional relationships between living resources and physical features of the landscape. This is evidenced by the March 1994 concept document *Ecosystem Approach to Fish and Wildlife Conservation* circulated by the FWS; the April 1993 *Ecosystem Management Principles and Applications* document prepared by the FS for the Eastside Forest Ecosystem Health Assessment, and the *Reinventing Environmental Management* document prepared by the National Performance Review (NPR) in September 1993. These documents call for interagency coordination and a resultant collaborative approach to managing the health of whole ecosystems, such as the upper Mississippi River Basin.

Ecosystem management is in its infancy, and federal agencies have just begun ecosystem planning and related programs. Explicit funding for ecosystem management remains minimal and plan development incomplete. In the absence of plans and funding, the DOI, as the recommended lead agency for environmental land acquisitions and easements, should focus federal acquisitions and easements on problem river reaches with known habitat values and threatened and endangered species.

Action 7.5: *The DOI should focus land acquisition efforts on river reaches and areas with significant habitat values or resource impacts.*

The Administration should provide funding for and the DOI should develop and implement cooperative ecosystem management plans with the states and other agencies. The NBS currently operates a major GIS system for the upper Mississippi River main stem and is in the process of developing GIS capability for the Missouri River main stem. The Congress should appropriate funds to expand these facilities to survey the natural resources of the entire upper Mississippi River Basin. The NBS should work in collaboration with the states, NGOs, and other agencies to identify critical habitats, significantly impacted ecosystems, and opportunities for ecosystem management. Participating states and agencies should evaluate site-specific, collaborative management plans developed as part of their own operations for use in ecosystem management.

The Accompanying Report on the DOI by the NPR[2] identified several factors that prevent the agency from making long-term decisions that provide for wise ecosystem planning and management. In response, the NPR indicated that the DOI should be able to acquire lands using a comprehensive approach and that it should have a set amount of discretionary funds so that the Secretaries of the Interior and Agriculture can take advantage of unforeseen opportunities or urgent acquisition developments. The NPR Action for this issue stated: "the Secretaries of the Interior and Agriculture and the Director of OMB should modify the process for determining land acquisition priorities and modify current procedures." The Review Committee endorses this action as a key component in providing better focus for such acquisitions.

USING O&M FUNDS TO MANAGE ECOSYSTEMS

Construction of various federal navigation and flood control projects have impacted federal trust resources in many rivers of the upper Mississippi River Basin.[3] Operation and maintenance of some of these projects continue to impact fish and wildlife resources and, in some cases, may accelerate those losses. In the 1970s and 1980s, concerns related to these impacts on the upper Mississippi River resulted in formation of cooperative interagency management efforts, such as the Great River Study,[4] Upper Mississippi River Master Plan,[5] and Upper Mississippi River Environmental Management Program.[6] These programs, which address both development and natural resource needs, have resolved many interagency conflicts and problems.

Across the upper Mississippi River Basin, though, federal agencies need to develop and implement ecosystem management plans. Especially on the Missouri River, such plans would help ensure protection of fragile ecosystems and address the needs of plant and animal species that are of interjurisdictional federal interest. Presently a funding mechanism to develop and implement ecosystem management plans does not exist.

As a matter of practice, agencies responsible for operating and maintaining major development projects should procure funding for representation and participation of other federal agencies in their major study and implementation efforts. The USACE-FWS Memorandum of Agreement for fund transfers related to Fish and Wildlife Coordination Act compliance makes such participation possible during the planning process, but no authority exists to transfer funds for support of post-construction ecosystem planning. Similarly no funding mechanisms exist for state or local participation in either the planning or post-construction phases of federal water resources development.

Action 7.6: *Require agencies to co-fund ecosystem management using Operation and Maintenance funds.*

Ecosystem management planning would document natural resource needs and identify actions that federal agencies can take to offset development impacts and enhance ecosystem sustainability. Funding for development and implementation of ecosystem management plans should be an annual standard component of each federal agency's operation/maintenance/construction budgets along with annual funding for development projects, which often impact the ecosystem. Funds should provide for participation of outside agencies and the states. Once costs of minimizing environmental impacts become a standard part of project costs, they can be reflected more closely in federal benefit-cost ratios.

EXPANDING FEDERAL, STATE, AND NGO COST-SHARING

Many levee and drainage districts contain remnant natural features, such as oxbow lakes and sloughs, that were hydraulically disconnected from the main stem river either by natural processes or by levee construction. Structural modifications to these levees would allow periodic, controlled flows between the river and former oxbows or channels. By providing these connections, off-channel habitat could be available during spawning periods. Such area could contribute to the river fishery and increase seasonal wetland values.

During the PL 84-99 review process, resource agencies and landowners sought to use levee modifications to reconnect some oxbows and sloughs to the river, but they were unable to do so because Congress authorized PL 84-99 only for emergency structural repair and not for modification to serviceable projects. New construction for other purposes was simply not possible. On the other hand, the USACE environmental enhancement authority provided by Section 1135 of the 1986 WRDA includes new construction as an option. Additionally, Section 906 of the 1986 WRDA provides general authority to undertake mitigation measures for projects, whether completed, underway or unstarted, including acquisition of any needed related lands. Section 906 provides for mitigation cost-sharing consistent with other project purposes. The review Committee found that potential activities authorized by Section 906 have not been pursued.

It was brought to the Review Committee's attention that current reporting and approval processes require multi-level review of Section 1135 projects within USACE. This may discourage pursuit of small scope projects. it is anticipated that many small projects could be pursued at lower administrative costs with abbreviated report requirements and decentralized approval authority. In discussions of the Section 1135 option with several landowners and drainage district representatives, the USACE found that many did not accept it because of the cost-share burden added under PL 84-99. The USACE could not overcome the cost-sharing problem because other federal agencies, such as the FWS, are not able to participate as cost-share sponsors.

Action 7.7: *Enact legislation allowing cost-share participation and eligibility requirements under Sections 906 and 1135 of the 1986 WRDA to include federal, state, and non-governmental contributions as well as work in-kind.*

By expanding the array of possible cost-share sponsors and by providing for cost-sharing consistency in Section 906, more enhancement opportunities can be leveraged by cooperating federal, state, and non-governmental organizations. Permitting work in-kind to qualify as local sponsor cost-share contributions would expand the availability of Section 1135 for environmental restoration activities.

MOVING MITIGATION AT THE SAME RATE AS DEVELOPMENT

Development projects often require agreement to purchase mitigation lands before project construction plans receive approval. Although authority exists for mitigation measures and acquisition of mitigation lands and although agency policy encourages concurrent mitigation, funding of mitigation land acquisition has not proceeded on the same schedule as construction funding. In some cases this lack of funding has led to unmet mitigation over periods of years.

Action 7.8: *Allocate funds for mitigation lands in concert with and at the same pace as project construction.*

The Administration through OMB must assure anequitable funding stream where mitigation is required as part of authorized projects.

Chapter 8

MINIMIZING THE VULNERABILITY OF EXISTING DEVELOPMENT

Floods are an act of God; flood damages result from acts of men.

House Document 465, 89th Congress, 2d Session
A Unified National Program for Managing Flood Losses, August 1966

Development will continue to occur in the nation's floodplains. Two fundamental strategies -- protection or removal -- can minimize the vulnerability to floods in these lowlands. Each strategy is appropriate in different circumstances. The nation should discourage new development in floodplains. For areas with existing concentrated development, such as cities where removal is impracticable, combine structural and nonstructural measures to protect existing development.

In the past structural measures were the primary approach to flood damage reduction. Throughout history, well-designed and well-sited structural measures have demonstrated their effectiveness in protecting property and saving lives. The traditional structural strategies to modify flooding have relied on the following tools: dams and reservoirs; urban stormwater management systems; dikes, levees, and floodwalls; channel alternations; and diversions, spillways, and floodways.

Each of these measures carry environmental and social impacts that may limit their future applicability. While they work well, they also create problems. Structural approaches, particularly those taken prior to implementation of federal environmental protection statutes, have caused or contributed to environmental degradation. The 1993 flood demonstrated not only the strengths of structural approaches but also their weaknesses, particularly those of levees.

Another approach to minimizing vulnerability, not widely used in the past, is the removal of vulnerable populations from the floodplain. Because of the severity and duration of the 1993 flood, the general public has taken a new interest in this strategy. Building on its experience with the NFIP, the FEMA capitalized on this interest in removals. The Administration responded by targeting federal recovery programs that support buyouts and relocation of floodplain populations. The fundamental value of buyouts over structural approaches is that they completely eliminate flood risk for affected individuals and, at the same time, may have environmental and hydrologic benefits. Relocation associated with buyouts can, however, involve social, environmental, or hydrological impacts. For federal relocations, compliance with the NEPA would identify and help to avoid such impacts. Careful planning by state and local agencies should also identify these issues.

ADOPTING A SYSTEMS APPROACH

The first step in minimizing flood vulnerability is to approach the problem from a systems perspective. Determining the array of potential solutions requires an understanding of the source of the vulnerability and the current risk that flooding poses. Is the risk one of debris-laden flows from highly erodible canyons? Is it increased runoff? Is it changed river hydrology? Is it flash floods or slowly rising waters? The best solution to a localized flooding problem may be watershed management rather than channelization. The flooding river cannot be analyzed separately from its watershed and ecosystems. The initial focus ought not be exclusively on structural

flood damage-reduction projects. The situation calls for a system-wide approach that accounts for basin hydrology, hydraulics, and ecosystem concerns. Such an approach will identify the nature of the flooding problem and help in the selection of the most appropriate combination of flood damage reduction measures. A systems approach allows planners to address flood vulnerability and identify the best means for minimizing flood impacts, when they do occur. The systems approach brings to the forefront the ecosystem effects of flood damage-reduction projects, and it allows for avoiding, minimizing, and compensating for adverse effects and capitalizing on environmental opportunities.

The next step in changing the historic approach to flood damage reduction is to equally consider structural and non-structural approaches. Objective consideration of the various flood damage reduction options looks at their short- and long-term engineering and their environmental, social, and economic feasibility. Such a consideration is vital to achieving a new pattern of flood vulnerability reduction. The revisions proposed by the Review Committee for the *Principles and Guidelines* would facilitate this type of consideration. If structural alternatives provide the only means to address a local flooding problem, they need to be considered within the context of the larger systems of the river and its watershed. The direct and incremental impact of each structure on river hydrology, hydraulics, and ecology needs evaluation and balancing. By understanding the system and designing and constructing in response to that system, more efficient opportunities to reduce the vulnerability of flood impacts can be found.

Existing and future damage reduction strategies must consider the impact on upland and riparian areas of the ecosystem. The design, operation, and repair of flood damage reduction systems can lessen these impacts and may, in some circumstances, enhance the environment. Chapter 7 focused on flood damage reduction measures that also protect and improve wildlife habitat.

Recommendation 8.1: ***Federal agencies should capitalize on opportunities, within existing authorities and resources, to enhance the environment when reviewing operations or undertaking repairs or improvements to existing flood damage reduction programs.***

IMPROVING STRUCTURAL MEASURES

Levees will continue to serve as a means of minimizing flood vulnerability. Of the approximately 8,000 miles of levees in the upper Mississippi River Basin, roughly half were constructed by the federal government or meet federal standards and thus receive support from the federal government in post-disaster situations. Some new levees may be built to protect critical infrastructure, but the remainder of these structural flood damage reduction facilities with their numerous strengths may also have room for improvements.

Constructing and Repairing Levees

Five different federal agencies are engaged in the repair of federal and non-federal levees damaged by the 1993 flood. These agencies are involved in funding, design, construction, or a combination of the three. The water resources design and construction agencies, the USACE and SCS, have been joined in the levee repair and construction business by the FEMA, EDA and HUD, through their public assistance and grant programs. Normally only the USACE and SCS construct levees as part of projects authorized by Congress, although in recent years, SCS levee construction has significantly declined.

These agencies have not used the same engineering standards or methods of economic analysis in carrying out their programs. Some of the differences rest with the purpose of the programs and the varying nature of the levees. Nevertheless these differences cause confusion among those dealing with the multiple programs. The nation cannot afford to have this duplication of effort in

the federal system. The costs to the nation of this multi-agency approach, measured in dollars or social and environmental impacts, remain large.

Action 8.1: *Establish the USACE as the principal federal levee construction agency.*

This action is not a call for new levee construction, but a recognition that when repairs or construction are authorized, the USACE would be the principal agency for the work on major rivers and tributaries. The USACE, with its long history of levee building and repair, has the in-house expertise to serve as the federal government's principal representative pertaining to major levee construction and repair. The SCS has the history and expertise for assistance pertaining to small agricultural levees in small watersheds and assistance to individual landowners. To coordinate their different responsibilities and engineering and evaluation guidelines, the USACE and the SCS should review and modify, as appropriate, the existing 1986 Memorandum of Agreement (MOA). When complete this MOA should be provided to all states and appropriate levee districts. Other government agencies wishing to pursue levee construction must arrange planning, design, and construction through the USACE which will follow the revised *P&G* procedures. For small agricultural projects, the USACE would coordinate the action with the SCS.

While multiple federal agencies currently participate in levee construction and repair, this report recommends in Action 8.1 that USACE be established as the principal federal levee construction agency. If this recommendation is implemented, cost-sharing inconsistencies between different federal agencies currently involved in levee construction would be resolved. If the recommendation is not implemented, cost-sharing inconsistencies exist that should be rectified to eliminate shopping by non-federal sponsors for the best federal deal. Regardless of the decision made on levees, inconsistencies between federal agencies for similar types of activities also exist for other federal water resources projects. One example is under the SCS PL 83-566 program, in which non-federal sponsors provide the lands necessary for project construction, but 100 percent of the cost for flood damage reduction is provided by the federal government. Non-federal sponsors of flood damage reduction projects constructed by the USACE are required to pay a minimum of 25 percent of the total project cost and a maximum of 50 percent. A minimum cash contribution of 5 percent of the total project cost is required as a part of this cost-share. In addition, the USACE requires a 50 percent cost-sharing for feasibility studies while the SCS feasibility studies are at 100 percent federal cost. The SCS multi-purpose projects involve non-federal cost-sharing but SCS allows credit for in-kind services in meeting that requirement. The USACE allows credit for in-kind services only for meeting a portion of study cost-sharing requirements. The SCS multi-purpose projects involve non-federal cost-sharing but SCS allows credit for in-kind services in meeting that requirement. The USACE allows credit for in-kind services only for meeting study cost-sharing requirements.

Another example is in relation to the levee rehabilitation program. The SCS Emergency Watershed Protection Program requires a non-federal cost-share of 25 percent of the cost of the project which excludes inspections and design. Under the USACE PL 84-99 program, there is no cost-sharing for federally built levees. However, the non-federal cost-share for qualified non-federally constructed levees is 20 percent of the cost of the project to include inspections and design. The FEMA and the EDA also are players in levee repair with non-federal shares of 25 percent for the FEMA repairs (although this was modified to 10 percent for the 1993 flood) and 20 to 25 percent for the EDA repairs. Other examples of inconsistencies also exist but are not elaborated on in this document.

Recommendation 8.2: *The Administration should propose legislation that establishes consistent cost-sharing across agencies for non-federal participation in like activities.*

Affected federal agencies should coordinate with each other to identify all differences in cost-sharing and in-kind services and provide documentation of inconsistencies to the Administration. For those flood damage reduction activities where multiple federal agencies will still be participating, consistent cost-sharing is recommended. In addition, consistent approaches should be taken regarding

non-federal credit for in-kind services in meeting the cost-sharing requirement.

Performing Emergency Repairs

The federal review of levees impacted by the Midwest Flood of 1993 provided valuable lessons in applying the USACE emergency flood-control repair program under PL 84-99. Approximately 1,600 levees (1,400 of them non-federal) were damaged to the point of requiring some form of rehabilitation or repair.[1] Less than 500 of these levees are under the USACE program, and of these, only 229 were federally constructed. Many levees which had been under the USACE program in the past were not under it at the time of the flood for various reasons, such as responsible parties failure to operate and maintain the levee properly, individual decisions not to participate, lack of a public sponsor, or inability to meet required engineering criteria. In the past, benefit-cost analyses have not included consideration of previous levee failures and the potential for future failures.

Given the seriousness of this situation and the fact that less than 15 percent of the non-federal levees that were damaged qualified for repair consideration under the USACE program, the Administration and Congress provided supplemental funding for levee repair. Even with the waiver of the USACE requirements, the Administration and Congress stipulated that levee districts or sponsors would have to meet the following requirements to receive federal funding: agree to join the USACE program and, within two years, provide public sponsorship, ensure levee maintenance, and meet engineering, environmental and other eligibility requirements of the program.

The USACE program should continue in the future. The Review Committee reviewed the eligibility requirements of the program and found them to be reasonable. Even though the 1993 flood was not a typical flood, this is no reason to deviate from the established and sound principles of the levee program. Waivers of these requirements may send the wrong message to levee sponsors. It is in the interest of the nation to provide incentives to ensure the integrity of public levees. This can best be accomplished by the participation of levee sponsors in the USACE program. It must be clear that the federal government will provide repair assistance in the future only to levees enrolled in the program and that the risks associated with non-participation are simply too great to take.

Action 8.2: *The Administration should reaffirm its support for the USACE criteria under the PL 84-99 levee repair program and send a clear message that future exceptions will not be made.*

In addition to the specific requirements of the USACE program, the USACE should ensure that levees are properly located and aligned to reduce the probability of repetitive losses and do not adversely impact river hydraulics and other properties. Benefit-cost analyses should be expanded to include consideration of environmental and social benefits and costs, in addition to the traditionally quantifiable benefits and costs. Where levees have a history of failures and realignment is not feasible, the benefit-cost analysis should consider the greater risk of failure, adjusting operation and maintenance cost estimates appropriately. Where the site is unsuitable, no federal support should be provided.

Design Considerations to Lessen Levee Overtopping Impacts

During the 1993 flood, many levees were overtopped and catastrophic damages occurred from scour and sand deposition. There are various methods for lessening these types of impacts such as use of spillways, control structures, and levee superiority (choosing where a levee should overtop first).

Recommendation 8.3: *The USACE should investigate procedures to minimize impacts associated with levee overtoppings.*

Differing methods to lessen levee overtopping impacts should be investigated. A report should be prepared by USACE that details preferred engineering techniques to improve current levee structures, where appropriate.

Coordinating Economic Evaluation Criteria

Both the SCS and USACE have requirements for economic feasibility with regard to potential levee repairs. Differences exist in the detail of analysis, period of analysis, and interest rate used for each of these programs.

Recommendation 8.4: *The USACE should coordinate with the SCS to decide on appropriate criteria for evaluating the economics of levee repairs.*

The Review Committee recommends that one agency, the USACE, be the principal federal levee repair and construction agency. Past differences in the evaluations by the two agencies suggest that coordination of methods could lead to an improved procedure.

Floodfighting on Levees

Threatened communities and owners of agricultural levees conducted heroic levee floodfighting during the Flood of 1993. They took action, however, without knowledge or consideration of the effects that keeping the water off their portion of the floodplain would have on the river level in proximity to that location. The act of raising a levee during rising flood conditions has the effect of increasing the river level in the immediate area and possibly upstream and downstream as well. The magnitude of the increase could be minor or significant, depending on hydraulic factors pertinent to the affected levee and river reach. If the water level raise is significant, it could cause greater damage than otherwise would have occurred to nearby lands, especially if levee raising results in the failure of a neighboring levee.

Action 8.3: *Federal and state officials should restrict support of floodfighting to those levees that have been approved for floodfighting by the USACE.*

The USACE would determine by advance planning, with the benefit of river hydraulic modeling analysis, those levees that can and those that cannot be floodfought without significant adverse impacts on other properties in the floodplain. This action would not prevent floodfights which are consistent with state and local floodplain management regulations under the National Flood Insurance Program (NFIP).

Floodfight Controls

In 1978, during federal construction of an agricultural levee on the Missouri River downstream of Brunswick, Missouri, the USACE, FEMA, the City of Brunswick, and the levee sponsor agreed to limit the height of the levee being constructed to a 25-year protection level and that the levee district would not increase the levee height during a flood event. This agreement was to prevent the levee from raising upstream flood elevations more than one foot, especially at Brunswick. During the 1993 flood, the USACE provided technical assistance to the Brunswick Dalton Drainage District in its efforts to fill in low spots in the levee -- locations where the levee elevations were below the authorized project levels. Therefore, in accordance with the agreement, the levee sponsor did not raise any sections of the levee above the design grade. In late July, the levee overtopped.

Urban Stormwater Management

The use of detention basins as a type of structural flood damage reduction measure has greatly increased over the last 20 years. Many local ordinances now require "zero-increment" runoff for new development, which means that on-site detention must be provided. State and federal government involvement in runoff management is typically limited to managing stormwater runoff from roads and highways. The *Floodplain Management in the United States* report indicates that federal and state governments have increased attention to this problem due to an awareness that a large percentage of flood insurance claims come from areas not identified as floodplains.

Flooding can be increased significantly by the runoff from land that has been stripped of vegetation or covered with buildings, pavement, and other impervious materials. Historically the approach to such runoff has been to confine and transport that water as quickly as possible. As urbanization spread, this approach contributed significantly to increased magnitude and frequency of downstream flooding and the construction of flood damage reduction structures. Reduced groundwater supplies and degraded water quality are frequent byproducts of this approach. New efforts to handle runoff from frequent storms (e.g., 2- to 10-year events) include on-site detention or retention though a variety of measures and management of total runoff within a watershed to ensure that discharges from watershed sub-units reach the main channel at different times and, therefore, reduce peak flows in downstream areas. Most on-site detention measures typically provide little protection from large, infrequent events such as those that caused the Midwest flood because their capacity is exceeded.

While the main objective of on-site detention is to prevent excessive runoff from developed areas, a secondary benefit is that on-site detention measures can be designed to trap pollutants and, therefore, improve water quality. Throughout the country there is considerable interest in using natural wetlands or creating wetlands to help manage stormwater runoff.

EXPANDING NONSTRUCTURAL MEAUSRES

Hazard mitigation includes those action taken by individuals and communities to reduce damages from such hazards as earthquakes, tornados, and floods. Examples of actions commonly taken after a flood are buyouts, elevation or floodproofing of damaged buildings, structural flood protection, flood-warning systems, and flood hazard awareness programs. There are ways to reduce the vulnerability of floodplain structures through design for all flood loads, selection of flood-resistant materials, and use of flood-resistant construction practices.

The Administration established buyouts of flood-damaged properties as the first priority for mitigation funds available for the Midwest flood. As of April 25, 1994, the federal government had approved applications from 61 communities for acquisition or relocation of 4,181 buildings. Other applications are pending, and as many as 6,000 buildings will be acquired or relocated.[2] This initiative represents a turning point in flood recovery policy, since it is the first time that buyouts have been attempted on such a large scale.

Buyouts are an appropriate federal response for the Midwest flood and for floods like it. Many of the buyout neighborhoods have been damaged repetitively by flooding. Subject to deep and long-duration flooding, they were isolated by floodwaters for extended periods of time. In addition, a significant percentage contain older, lower value housing, much of it of poor quality and in need of rehabilitation. Under the right circumstances, the buyouts will not only reduce flood damages and protect people and property, but also achieve other objectives such as improving the quality of affordable housing, increasing recreational opportunities and wildlife values, and general betterment of the community.

A TEAM EFFORT

The Home Life Restoration Committee, a local citizen's group in Hannibal, Missouri, and the Missouri Housing Development Office joined forces to assist four families whose homes had been severely damaged in the flood of 1993 to move into new housing outside the floodplain. Bridge loans of up to $5,000, bearing interest of 1%, were provided to each family through a program of the Housing Development Office. The Committee members, in conjunction with another charitable group, the Natural Resources Community Action Coalition, solicited a total of $50,000 in donations from local business and industry. This joint state/local effort enabled four homes outside the floodplain to be acquired and rehabilitated. The state loans will be forgiven if these families remain in their new homes for five years.

Buyouts and Other Hazard Mitigation Actions Following a Flood

Prior to the current buyout initiative, the primary federal response to mitigating damages to flooded structures was the substantial damage requirement implemented by communities participating in the NFIP. Buildings damaged so that the cost of repair is equal to or greater than 50 percent of the market value prior to the flood must meet program requirements for new construction, such as elevating above the 100-year flood elevation. Substantially damaged structures also become subject to actuarial rates under the NFIP.

While enforcing a substantial damage requirement is critical to achieving long-term objectives of reducing flood damages, financial assistance will be required to assist property owners who cannot afford to elevate or relocate their buildings or obtain replacement housing. The buyout initiative, in part, meets this need.

Individuals and communities impacted by the Midwest flood appear to be far more receptive to buyouts than after past floods. Often in the past, people regarded a flood as a one-time event. Any interest in acquisition or relocation waned with time as memories of the flood faded. But with the Midwest flood, the duration of the flooding and the multiple flood crests and floodfights created stress for floodplain occupants and communities. By the end of the summer, floodplain occupants just wanted out.

Implementation of buyouts has not been without problems. Federal agencies had to overcome significant obstacles to make the initiative work. This resulted in confusion and uncertainty among states, communities, and individuals. Since no federal or state agency had ever attempted buyouts on this scale, agencies had to invent policies and procedures and establish relationships between programs. They had to create mechanisms to coordinate programs and provide technical assistance to small communities with limited resources and expertise. They also had to develop expedited procedures for compliance with the NEPA, historic preservation, and other federal mandates.

A common theme throughout the Review Committee's meetings with states, communities, organizations, and interest groups has been the need for common policies and procedures among federal agencies participating in buyouts and other mitigation activities,. The current initiative with multiple programs, applications, and eligibility requirements is overwhelming to communities, even with the improvements made to date. A corollary need is for sufficient flexibility in these programs to respond to a variety of flooding conditions or other circumstances, including responding to other types of disasters.

Expedited decisions on buyouts would reduce the uncertainty of property owners and avoid needless

PRINCIPAL SOURCES OF FUNDING FOR BUYOUTS

The following federal programs provide funding for buyouts following a disaster such as the Midwest Flood of 1993:

Department of Housing and Urban Development Community Development Block Grants (CDBG). The 1993 Supplemental Appropriation included $200 million for the CDBG program to assist in acquisition and relocation and in meeting other housing needs. The 1994 Earthquake Supplemental included an additional $250 million for a total of $450 million.

Federal Emergency Agency Section 404 Hazard Mitigation Grants. The Hazard Mitigation and Relocation Assistance Act of 1993, signed into law on December 7, 1993, revised the formula for determining the amount of the Section 404 Hazard Mitigation Grant in the Stafford Act and changed the cost share to 75/25. Under the revised formula the FEMA estimates that $134.9 million will be available through the Hazard Mitigation Grant Program funds for the Midwest flood.

Economic Development Administration (EDA) Grants. The 1993 Supplemental Appropriation included $200 million for EDA for grants to states and communities to preserve or create jobs or upgrade infrastructure. The funds can be used to assist in the relocation of businesses or for the infrastructure needed to support those businesses.

National Flood Insurance Program Section 1362 Flood Damaged Property Purchase Program. Several million dollars are available from the appropriation for the NFIP Section 1362 program for acquisition of insured properties. These funds are paid from the National Flood Insurance Fund, using premium dollars.

Other Programs. Funds were available from other programs such as the FEMA Public Assistance Program to assist in various aspects of buyouts and relocation. SBA loans are available to help individual property owners not eligible for CDBG monies.

expenditures for repairs to houses that are subsequently purchased. This duplication cannot be entirely avoided. It takes time to properly conduct a buyout, particularly for relocation of buildings or neighborhoods. Situations will continue to occur where making minimal repairs to a structure will be more cost-effective than providing rental assistance through the FEMA Disaster Housing Program.

While the Review Committee applauds the work of federal and state agencies in adapting existing programs to make buyouts work, these gains need to be consolidated to position the government for future buyouts and other hazard mitigation initiatives. A critical issue is how to transfer the buyout experience and other mitigation actions of the 1993 flood to other floods. The Midwest flood, a unique event covering a 9-state area and impacting over a thousand communities, required large supplemental appropriations. For more typical floods without supplemental appropriations, funding for mitigation must come from the FEMA Section 404 Hazard Mitigation Grant Program, the NFIP Section 1362 program, and other existing programs.

Recommendation 8.5: *Maintain flexibility in hazard mitigation programs to promote cost-effective and appropriate mitigation techniques.*

Buyouts are the optimal solution for many neighborhoods impacted by the Midwest flood. Circumstances arise, however, where other mitigation techniques may be the most cost-effective method for reducing flood damages with the least impacts on the community and the environment. In areas of shallow, short-duration flooding, elevation of structures on site may be the preferred alternative. Where high groundwater or sewer backups flood basements in or out of identified flood hazard areas, the optimal mitigation action could be making drainage improvements, upgrading sewer systems, or installing backwater valves. Future mitigation initiatives must be flexible enough to respond appropriately to these differences.

Action 8.4: *Establish a task force to develop common procedures for federal buyouts and mitigation programs.*

A federal interagency task force should coordinate pre- and post-disaster buyouts and other hazard mitigation actions. This task force should include representatives of agencies that could be involved in a buyout program as well as agencies with responsibilities for consultation and oversight on compliance with laws and executive orders. The task force should build on the Midwest flood experience to accomplish the following objectives:

- Develop common policies and procedures among agencies for buyouts and provide for increased flexibility in programs to respond to the unique circumstances of a disaster;

- Address compliance with the NEPA, applicable executive orders, historic preservation requirements, and other federal mandates during multi-agency buyouts;

- Design delivery systems to expedite buyout decisions to be responsive to disaster victims and minimize duplication of assistance in instances where properties are to be bought out;

- Identify statutory barriers buyouts and other mitigation actions and propose changes where appropriate; and

- Make recommendations on how supplemental appropriations would be channeled through a single program such as the FEMA Section 404 Hazard Mitigation Grant Program rather than being provided through multiple agencies and programs.

Coordination issues that arise during future disasters should be resolved through the Interagency Hazard Mitigation Task Force.

Recommendation 8.6: *Encourage establishment of state-chaired task forces to coordinate buyout and implementation of other hazard mitigation activities.*

One of the success stories of the Midwest flood is the creation and operation of state task forces to coordinate buyouts and other mitigation actions. These task forces include participation by representatives of state agencies and of field offices of various federal agencies. In some cases communities have had to make only one application to the task force, which then determined the funding sources and amounts available to the community. These task force have proved to be important forums for resolving differences between agencies and for coordinating buyout programs. They have provided the additional benefit of involving agencies that previously had not conducted floodplain management. Operating at the state level, they could effectively coordinate future buyout programs and package FEMA Section 404 funds with other available state and federal funds.

Action 8.5: *Provide states the option of receiving FEMA Section 404 Hazard Mitigation Grants as a block grant.*

A number of states have indicated an interest in coordinating buyouts and other mitigation actions after disasters. They feel that they could be more responsive to communities and could expedite decisions if they received

FEMA Section 404 Hazard Mitigation Grants in the form of a block grant. Under the current program, states already are given considerable latitude in establishing priorities and allocating Section 404 Hazard Mitigation Grant Program monies. A block grant also may provide greater flexibility to use these funds in conjunction with other federal, state, and local funds. The Review Committee suggests that block grants be offered as an option for those states that have adopted approved floodplain management or hazard mitigation plans. Block grants are consistent with the Review Committee's call for an expanded state role in floodplain management and hazard mitigation.

The block grants should be subject to the current cost share and to general federal requirements, including the establishment of overall priorities for hazard mitigation actions. Issues such as compliance with the NEPA, the Endangered Species Act, Historical Preservation, EO 11988 and other Federal mandates require resolution. For the CDBG program, the HUD is authorized to delegate these responsibilities to states and communities, but the FEMA is not.

Action 8.6: *Provide funds in major disasters where supplemental appropriations are made for buyouts and hazard mitigation, through FEMA's Section 404 Hazard Mitigation Grant Program.*

The federal government is providing funds for buyouts and other hazard mitigation activities for the Midwest flood through several agencies and programs. For major disasters that require supplemental appropriations, a better approach would be to make supplemental appropriations to the Section 404 Hazard Mitigation Grant Program. The FEMA should issue mission assignments to other agencies with expertise in community development and in providing technical support to states and communities in developing buyout programs. Providing funds to a single agency would invoke a single set of policies and procedures.

Action 8.7: *Establish a programmatic buyout and hazard mitigation program with funding authorities independent of disaster declarations.*

The current buyout program is funded primarily through supplemental appropriations made only after extraordinary floods and other disasters. Most flood events impact on much smaller geographic areas and may or may not result in a Presidential disaster declaration. Programs need to be in place to accomplish buyouts and other appropriate mitigation for such floods on an on-going basis.

Money currently available for mitigation activities includes funds from existing programs -- such as the FEMA Section 404 Hazard Mitigation Grant Program, the NFIP Section 1362 program, SBA loans to individuals, and any monies remaining available from funds allocated to states and communities through CDBG and EDA. Recent changes to the Section 404 Hazard Mitigation Grant Program to increase available funding will help.

Mitigation insurance coverage through the NFIP and cost-shared mitigation grants for states communities for on-going hazard mitigation planning and actions also should be components of such a program. Such funding measures are included in pending legislation.

In addition to this NFIP mitigation fund, the FEMA should have authority to allocate a percentage of its annual Disaster Assistance Fund appropriation to states for community hazard mitigation plans and action.

Recommendation 8.7: *Encourage use of CDBG, EDA, and other funding to acquire and relocate or take other mitigation actions where consistent with program objectives.*

The Midwest Flood of 1993 demonstrates a commonality of objectives between mitigation actions to protect neighborhoods and businesses from flooding and

ON-GOING ACQUISITION AND RELOCATION PROGRAMS

A number of communities in the nine states affected by the Midwest flood have undertaken systematic programs to acquire or relocate buildings in their floodplains. Two examples are Beatrice, Nebraska and Austin, Minnesota.

Beatrice, Nebraska. Over a multi-year period, the City of Beatrice, Nebraska, obtained annual Community Development Block Grants (CDBG) totaling about $3 million to purchase owner occupied floodplain properties from willing sellers. The city usually purchased these properties when they became vacant which minimized acquisition costs. Between 85 and 90 properties were acquired. More recently the city has acquired an additional 20 to 25 properties using their own funds. The lands acquired have been converted to parks.

Austin, Minnesota. After a 1978 flood, the city of Austin, Minnesota, consulted with the USACE over construction of a flood damage reduction project but decided that the best alternative was to clear out the floodplain. At that time the city obtained $1.4 million in CDBG money and acquired 44 homes, 16 of which were relocated. In 1983 the city initiated an NFIP Section 1362 project to acquire flood-damaged buildings covered by flood insurance. The city made offers on 11 home and eventually acquired 6 of them. Others dropped out because they had spent their insurance/disaster assistance and could not afford to move. The city is currently putting together an application for another relocation project for another 40-50 homes that were damaged by the 1993 flood.

the missions of federal housing and development programs intended to provide safe and sanitary affordable housing and to create and preserve jobs. For example, many of the neighborhoods most severely impacted by the Midwest flood are low-income neighborhoods with substandard housing. Often these neighborhoods further deteriorate as a result of floods or the threat of floods. Similarly, efforts to create or preserve jobs are made more difficult in communities where business expansion is prevented or results in the relocation of these businesses to other communities or regions. Agencies administering these programs should continue to be active participants in floodplain management and to seek out opportunities for reducing flood losses.

Reducing Risks to Insured Buildings Substantially or Repetitively Damaged

NFIP minimum criteria require that substantially improved buildings, including those substantially damaged, meet most requirements for new construction, including the requirement that residential structures be elevated to or above the elevation of the 100-year flood. The substantial damage requirement is an integral part of the NFIP strategy to reduce future damages to existing floodprone development. The substantial damage requirement has been difficult to enforce because property owners often do not have the funds necessary to meet it or to obtain replacement housing.

PENDING LEGISLATION ON FLOOD INSURANCE

Legislative initiatives are pending in the Congress that would provide for increased financial assistance for mitigating flood damages. The National Flood Insurance Reform Act (S. 1405) has passed the Senate as Title VI of S 3474, the Community Development, Credit Enhancement, and Regulatory Improvement Act of 1994. The bill provides for mitigation insurance that would pay for the additional costs of elevation, floodproofing, demolishing or relocating substantially damaged or repetitively damaged building (two damages in 5 years averaging 25 percent of the value of the property) as a standard benefit to the policy holder. A mitigation program funded by $20 million from the National Flood Insurance Fund would be established at a 75/25 match for state and community mitigation projects to reduce damages to other insured buildings. A portion of these funds would be available for state and community mitigation planning.

The House of Representatives has passed H.R. 3191, also called the National Flood Insurance Reform Act of 1994, which provides for a study of mitigation insurance and establishes a mitigation fund of more than $30 million per year for state and community mitigation projects and planning. H.R. 3191 would provide grants from the Mitigation Fund, through an application process, to be available to individuals for floodproofing, demolishing or relocating substantially damaged or repetitively damaged buildings. These projects and activities would be funded through a surcharge on flood insurance policies. Neither bill addresses mitigation for uninsured buildings.

For the Midwest flood and for several other recent catastrophic disasters, the FEMA has allowed communities to use replacement cost instead of market value for calculating substantial damage except where state regulations are more restrictive. The use of replacement cost usually means that far fewer structures will be deemed as substantially damaged. This change has been a source of controversy in the Midwest. Because the agency did not communicate the change to communities early enough, some communities, after making determinations based on market value, had to recalculate based on replacement cost to placate affected property owners. Because fewer buildings are considered substantially damaged using replacement cost, some states and communities believed that the change was inconsistent with sound floodplain management as it resulted in fewer buildings being elevated, demolished, or relocated.

Persuasive arguments can be made for using either market value or replacement cost to define substantial damage. The FEMA needs to decide on a definition and be consistent.

A related issue is that of repetitively damaged structures, i.e., those damaged on two or more occasions since 1978. These buildings currently account for 35.9 percent of all NFIP losses and 44.2 percent of all payments.[3] Unless these buildings are substantially damaged by one flood, no regulatory requirements apply and flood insurance continues to be available at highly subsidized rates. Significant numbers of these repetitive loss buildings, including buildings that have had as many as eight losses, can be found in areas in Missouri and Illinois.

St. Charles County, Missouri, alone has 1,055 of these repetitively damaged buildings which have sustained a total of 3,625 losses.[4] Other communities in the surrounding counties of Missouri and Illinois also have large numbers of these buildings in areas with chronic flooding problems. Because repetitive-loss buildings were substantially damaged by the Midwest flood, rigorous implementation of the requirement should reduce the numbers of these buildings.

Action 8.8: *The FEMA should continue to enforce substantial damage requirements, but decide on a definition of substantial damage and stick to that definition.*

The NFIP substantial damage requirement is crucial to reducing flood damages to structures built prior to the adoption of floodplain management regulations in participating communities. The FEMA should decide on a definition of substantial damage/substantial improvement and consistently apply that definition in disaster and non-disaster situations. This will eliminate confusion and improve the overall level of compliance with NFIP regulations.

Action 8.9: *The Administration should support insurance coverage for mitigation actions necessary to comply with local floodplain management regulations.*

Critical to continued enforcement of the substantial damage requirement is providing NFIP flood insurance coverage for the costs of elevating, floodproofing, or relocating substantially damaged buildings. Currently flood insurance pays only for the repair of physical damage to the building. Mitigation insurance would provide coverage that pays the costs of bringing insured buildings that are substantially damaged by floods into compliance with community floodplain management regulations either by elevating, floodproofing, demolishing, or relocating the building. The coverage would be funded by flood insurance premiums and be part of the claims adjustment process. Mitigation insurance has a number of advantages:

- It supports consistent enforcement of the substantial damage regulatory requirements;
- It more fully indemnifies policyholders from flood-related losses;
- It is funded by flood insurance premiums and not by appropriated funds;
- It would reduce over time the subsidy for these pre-FIRM buildings; and
- The flood insurance claims adjustment procedure is an efficient way to deliver assistance.

The National Flood Insurance Reform Act of 1993 (S. 1405 which has passed the Senate) authorizes the NFIP to provide mitigation insurance. Similar legislation that has passed the House of Representatives (H.R. 3191) provides for a study of mitigation insurance.

Action 8.10: *Develop a program to reduce losses to repetitively damaged insured properties through insurance surcharges, increased deductibles, mitigation insurance, and/or mitigation actions.*

Repetitive loss buildings account for a disproportionate percentage of NFIP losses and represent a significant liability for the program. The FEMA should develop a comprehensive strategy to address these losses, including flood insurance premium surcharges and increased deductibles. Such a strategy should reflect more accurately the increased risk to these buildings and provide an incentive for protecting the buildings from flooding. Mitigation insurance should cover the cost of mitigation for the most vulnerable structures. Buyouts and other mitigation initiatives should place a high priority on these buildings. When such structures are substantially damaged, the FEMA should enforce this requirement rigorously.

The flood insurance program should include cost-shared funding for on-going pro-active planning and mitigation independent of disasters. This element should include provision for a mitigation fund financed out of NFIP premiums (such as that provided for in S. 1405 and H.R. 3191 both entitled the National Flood Insurance

Table 8.1 NFIP-insured Buildings with Repetitive Losses, Midwest States, 1978-1993.

State	Buildings with Repetitive Losses	Number of Losses for Such Buildings

Reform Act of 1994) for state and community mitigation projects and planning. Since the source of these funds is NFIP premiums, projects financed by the mitigation fund should mitigate damages to insured buildings. Any assistance to uninsured buildings should be incidental and necessary to the success of the project.

ENDNOTES

1. Some estimate the total at approximately 2,200 levees which would mean approximately 2,000 non-federal levees.

Chapter 9

MITIGATING FLOOD IMPACTS THROUGH RECOVERY AND INSURANCE

Keep in mind, we can't hold harmless everybody from every loss...there are programs to help businesses, farms, communities, and individuals who are out of work and who have no means of support.

President Clinton
Interview with Larry King, July 20, 1993

Despite efforts on the part of the government and affected individuals to reduce vulnerability, flood disasters will continue to occur. The eventuality of flooding carries with it the necessity to have a coherent and coordinated disaster response and recovery strategy and effective insurance programs. The National Flood Insurance Program indemnifies individual property owners for their losses without requiring costly disaster assistance expenditures. The Federal Crop Insurance Corporation provides partial coverage for crop losses caused by natural perils. The challenge to the federal government is to develop a cooperative framework under which federal, state, and local entities can marshal their forces to address emergency response and recovery issues. At the federal level, the Review Committee is calling for a streamlining of disaster-related activities to avoid duplication of effort or working at cross purposes. In addition, the Review Committee seeks to encourage those who voluntarily chose to live in a floodplain to purchase NFIP coverage so that they can bear, to the degree possible, the costs associated with the risks. Ultimately, flood insurance will reduce disaster payments by internalizing the costs of living in the floodplain and by creating an incentive to move out of harm's way.

REORGANIZING DISASTER RECOVERY

The key to mitigating damages during recovery, especially after a disaster such as the Flood of 1993, is in organizing the recovery effort to establish leadership at the federal level and to involve fully all appropriate federal, state, and local government agencies.

Integrating Flood Response and Recovery under a Single Federal Agency

Congress established the FEMA in 1979 to consolidate emergency management programs that previous were scattered among multiple agencies. Over the last several years, the federal government has assigned other agencies the leadership responsibility for the recovery portion of disaster response following larger disasters in an attempt to provide a more responsive system.[1] These agencies, however, do not have the collective experience in disaster recovery offered by the FEMA, nor do they have an expansive knowledge of federal floodplain management goals or existing recovery and hazard mitigation programs, including multiple hazards. The nation needs a single agency to coordinate federal flood response and recovery because the two are integrally linked. A single agency also can develop and maintain a core knowledge of the full suite of federal programs available to help recovery.

By decoupling flood response from flood recovery, the nation is losing opportunities for hazard mitigation and floodplain management. Response activities that occur without regard to potential recovery alternatives may foreclose opportunities to lessen future damages. This may leave people and property at risk and potentially increase future disaster support. The federal government must strike a balance between being responsive and adding to the inherent confusion resulting from any disaster.

Recommendation 9.1: *Integrate federal flood response and recovery under the FEMA.*

The Review Committee suggests that the FEMA be the federal agency coordinating response and recovery to help achieve floodplain management goals. Development of a federal response and recovery plan would incorporate national floodplain management goals and reflect state floodplain management responsibilities by identifying federal and state agency roles and responsibilities and establishing consistent rules and priorities, thus streamlining both response and recovery by the federal government.

Linking Response and Recovery with Floodplain Management

In 1980 the Office of Management and Budget established a FEMA-led Interagency Hazard Mitigation Task Force through a Memorandum of Agreement (MOA) to coordinate federal post-disaster recovery and to identify means to mitigate hazards.[2] Thirteen federal agencies agreed to participate in the task force and on interagency hazard mitigation teams activated for each flood disaster.[3] The USACE, SCS, and NWS have participated regularly on these teams as have state agencies. The FEMA encouraged states to lead these teams and, in the process, to build expertise transferable to disasters not needing federal disaster assistance. Participation by other federal agencies has been limited (see Table 9.1) by lack of staff and travel funds, a perception that the teams are tangential to an agency's mission, and the lack of high level support.

Most federal agencies participated on hazard mitigation teams for the Midwest flooding. Although activation of a 13-agency team is not necessary for each Presidentially declared disaster, regional coordination is desirable to review and determine each agency's involvement in such disasters.

While the Federal Interagency Floodplain Management Task Force and the Interagency Hazard Mitigation Task Force provide for interagency exchange of information, neither has successfully created the interagency dynamic and commonality of purpose needed for floodplain management activities.[4] Separation of the two task forces perpetuates a distinction between hazard mitigation and floodplain management when, in fact, the former is a key component of the latter. Neither has provided a link between emergency response and recovery, hazard mitigation including multiple hazards, and floodplain management at large. While both provide some information transfer, they do not coordinate federal funding to focus on priority problems, nor do they provide research oversight, planning advice, or issue resolution.

Between emergencies, federal agencies need to improve their coordination. In the aftermath of an emergency, the priority issues of that emergency soon fade into an agency's daily activities with little resolution. In 1986, the USACE and the SCS signed a Memorandum of Agreement to establish engineering standards for levees and levee repair responsibilities. But when the 1993 flood occurred, the two agencies had not yet set levee standards and did not fully delineate their separate responsibilities until months into the flood recovery, creating additional confusion.[5]

Recommendation 9.2: *Enhance the linkage among response, recovery, and floodplain management.*

Coordinating the Interagency Hazard Mitigation Task Force, the Interagency Floodplain Management Task Force, and other groups involved with emergency response will help link disaster response into a seamless set of functions. In the intervals between disasters, the increased support and interest by all federal agencies

would facilitate all facets of floodplain management, including disaster planning, recovery, and hazard mitigation.

Action 9.1: *Hold an interagency strategic planning meeting for those Presidentially declared disasters that require a multi-agency recovery effort.*

Coincident with deliberations regarding each proposal for a Presidential disaster declaration, the FEMA should hold an interagency strategic planning meeting to review and determine the necessary or desired involvement of each agency. At such a meeting, the FEMA could brief each agency on the situation and figure out its involvement. More efficient interagency coordination, early enlistment of agencies, and clear direction regarding agency involvement should result.

Recommendation 9.3: *Continue to seek federal-state co-leadership of an interagency hazard mitigation team.*

State co-leadership of hazard mitigation teams formed in response to a Presidentially declared disaster recognizes the responsibility of the states for floodplain management. In addition the experience gained by state participants increases opportunities for hazard mitigation in state or locally declared disasters and should decrease federal expenditures for hazard mitigation in the future.

REBUILDING MORE EFFICIENTLY

As part of flood response and recovery, the federal government should offer individuals and communities that choose to relocate or rebuild opportunities to integrate energy efficient technologies, such as solar devices and more efficient lighting, into the design and construction of new structures. For example, the town of Valmeyer, Illinois, received assistance from the Department of Energy to integrate more energy-efficient standards into building designs. Relocations, in particular, offer a unique opportunity to start from scratch in planning and constructing to assure that sustainable development becomes an integral part of the entire community. Each community would choose the characteristics it values such as an agricultural base, the historic or rural nature of the town, affordable housing, energy and/or water efficiency, diversity of species, or natural resources. Communities would incorporate these into planning and construction. Individuals also would use energy-efficient technologies to conserve limited natural resources with resultant cost savings. Rebuilding also offers an opportunity for reducing potential damages from hazards other than floods and for increasing awareness of these hazards. As part of response and recovery, a team of federal experts would work through state agencies to provide communities and individuals technical assistance and information on the use of more innovative technologies.

MITIGATING LOSSES THROUGH FLOOD INSURANCE

The National Flood Insurance Program was created by Congress in 1968 in response to mounting flood losses and escalating costs to the general taxpayer for disaster relief in the belief that flood insurance is preferable to disaster assistance. To encourage participation in the NFIP by communities and purchase of flood insurance by individuals, the federal government subsidizes the premiums for buildings constructed prior to the issuance of a FEMA Flood Insurance Rate Map (FIRM). This subsidy also recognizes that many floodplain buildings were built or purchased without knowledge of the flood risk. New construction (post-FIRM) is charged an actuarial premium that reflects the property's risk of flooding. Currently 59 percent of NFIP policyholders pay a full actuarial rate and 41 percent are subsidized.*

If the NFIP is to be successful in indemnifying property owners from flood losses and reducing federal expenditures for disaster assistance, a high percentage of property owners must purchase and maintain flood insurance coverage. The program depends on the mandatory flood insurance purchase requirement contained in the Flood Disaster Protection Act of 1973 and voluntary purchase by other property owners at risk. The 1973 Act requires the purchase of flood insurance by property owners who receive federal grants or loans, or loans from a federally supervised, regulated, or insured lender for the acquisition, construction, or improvement of structures located in identified special flood hazard areas (the 100-year floodplain). In the 9-state region affected by the 1993 flood, only about 20 percent of structures in the floodplain carried flood insurance, a rate well below optimal levels.

FLOOD INSURANCE VS. DISASTER PAYMENTS

The federal government should encourage the purchase of flood insurance because it internalizes the risk of locating investments in the floodplain, and it more adequately indemnifies property owners from flood losses. The Midwest flood confirms the Congressional findings in the Flood Disaster Protection Act of 1973, which states:

...the Nation cannot afford the tragic losses of life caused annually by flood occurrences, nor the increasing losses of property suffered by flood victims, most of whom are still inadequately compensated despite the provisions of costly disaster relief benefits; and it is in the public interest for persons already living in floodprone areas to have both an opportunity to purchase flood insurance and access to more adequate limits of coverage, so that they will be indemnified for their losses in the event of future flood disasters.

NFIP Market Penetration

The NFIP has not achieved the public participation needed to reach its objectives. This situation is evidenced by the assistance provided to individuals and businesses during the Midwest flood. Although policyholders filed 16,167 flood insurance claims,[7] the FEMA approved 89,734 applications for the Disaster Housing Program and 38,423 applications for Individual and Family Grants. The SBA approved 20,285 loans for individuals and businesses.[8] Many of these applications or loan approvals were for persons outside of identified flood hazard areas or from renters who do not normally purchase flood insurance. Others, including many of those who obtained SBA loans, should have had flood insurance either because it was required or because they were at risk. Some of those who obtained SBA loans may have had flood insurance, but their coverage may not have been sufficient to cover their losses.

Estimates of those covered by flood insurance nationwide range from 20 to 30 percent of the insurable buildings in identified flood hazard areas. Initial estimates in the Midwest flood area ranged from below 10 percent up to 20 percent. None of the estimates are authoritative, since no nationwide inventory of floodprone structures exists. The Review Committee obtained reliable structure counts for a number of Midwest communities. Sources of these data included inventories conducted by state and federal agencies, data from community geographic information systems, data submitted by communities participating in the NFIP Community Rating System, and counts obtained by Review committee members on visits to Midwest communities. Market penetration in these communities ranges from less than 5 percent to more than 50 percent. Based on this information, the Review Committee believes that market penetration in small rural communities is probably less than 10 percent. For most medium to large communities, market penetration appears to be in the 20 to 30 percent rage. For a few large communities with middle-income floodplain populations and a high degree of flood hazard awareness among community officials, lenders, and property owners, market penetration can exceed 30 percent and, in one instance, 50 percent.

FLOOD INSURANCE COVERAGE IN THE MIDWEST

Although the nation lacks the structure inventories necessary for a reliable estimate of NFIP market penetration, the Review Committee obtained inventories for individual communities and groups of communities in the Midwest. These data indicate that market penetration is highly variable, depending on the size of the community, the history of flooding, the economic status of floodplain occupants, and the awareness of flood hazards among community officials, lenders, and individual property owners.

State or Community	Buildings Zone A	Policies Zone A	Market Penetration Zone A
Austin, Minnesota	316	174	55.1%
Lincoln, Nebraska (1-4 family)	2,076	475	22.8%
17 Midwest NFIP CRS Communities	14,876	4,467	30.0%
North Dakota (1-4 family)	13,907	3,933	28.3%
23 Minnesota Communities	1,095	157	14.3%

Source: Building counts provided by states, communities, the USACE, and the FEMA; NFIP policy data are from the NFIP Community Information System.

Increasing Flood Insurance Purchase

Lender compliance to the requirement for mandatory flood insurance has been receiving a considerable amount of attention during hearings on pending legislation. The concern is that lenders do not require purchase of flood insurance at closing, nor do they ensure that property owners maintain flood insurance coverage for the life of a loan. Despite differences of opinion over how well lenders comply with the mandatory purchase requirement, most people agree on the need for improvement and for increased compliance to increase NFIP market penetration. However, the current dependence on the mandatory purchase requirement to drive high levels of market penetration may be unrealistic. According to the 1989 American Housing Survey, 42.4 percent of owner-occupied housing in the nation is owned free and clear of mortgages.[9] An additional percentage of those that are mortgaged were financed by

sellers, other individuals, lenders not covered by the mandatory purchase requirement, or they were financed prior to implementation of the requirement. For the nation as a whole, it appears that over half of owner-occupied properties are not subject to the mandatory purchase requirement.

Reasons other than lender noncompliance contribute to low levels of NFIP market penetration in the Midwest flood area. The most striking characteristic about the floodplain sections of communities visited by the Review Committee is that they appear to be predominantly low-income areas, whose populations have higher than usual percentages of renters, elderly, public assistance recipients, and property owners without mortgages. Housing ownership and sales in small rural communities differ from those in urban or suburban communities. Sales in small rural communities occur less frequently, often as cash sales or as sales financed through land contracts, loans from lenders who are not federally insured or regulated, or loans from family members. These small communities are precisely the areas where the mandatory purchase requirement would be applied least often and where voluntary purchase of flood insurance is least likely.

In the view of the Review Committee, other explanations for low market penetration in the upper Midwest include the false sense of security due to levees, particularly agricultural levees along the main stems of the Mississippi and Missouri rivers, the reluctance of insurance agents to market flood insurance in communities with few potential buyers, and a low level of awareness of the risk to those on the fringes of the floodplain.

Recommendations 9.4: *States should actively encourage flood insurance purchase by their citizens.*

States must play an active role in improving market penetration for flood insurance by working with communities and lenders and by assisting in education efforts. Fiscal assistance to states for floodplain management under a Floodplain Management Act should take into account a state's willingness to undertake this effort.

Action 9.2: *Increase NFIP market penetration through improved lender compliance with the mandatory purchase requirement.*

The Review Committee supports current attempts in pending legislation (S. 1405 and H.R. 3191, both entitled the National Flood Insurance Reform Act of 1994) to improve the level of lender compliance. This should include establishment of penalties for lenders who do not require the purchase or maintenance of flood insurance coverage.

Action 9.3: *Provide for the escrow of flood insurance premiums or payment plans to help make flood insurance affordable.*

The escrow of flood insurance premiums in those instances where the lender escrows property taxes and hazard insurance would ensure that coverage is maintained over the life of a mortgage. Additionally, those who may not be able to afford a one-time annual payment of a flood insurance premium would be more likely to purchase and maintain flood insurance coverage, if it were possible to spread the cost of the premium through the escrow of flood insurance premiums. The NFIP should provide payment plans for those who do not have mortgages and voluntarily purchase flood insurance.

Action 9.4: *Develop improved marketing techniques.*

Although improved lender compliance is critical to achieving increased market penetration, it will not by itself drive insurance purchase to the levels necessary to achieve program objectives. The program requires additional measures to increase voluntary purchase of flood insurance by those property owners not subject to the mandatory purchase requirement.

Counteracting Negative Incentives for Insurance Purchase

A perception persists that disaster assistance compensates homeowners as fully as flood insurance coverage. This may or may not be true depending on the value of the property affected and the income of the owner. A particular concern expressed by communities and others after the Midwest flood is that disaster victims, particularly those with lower incomes, who obtain disaster assistance from the Individual and Family Grant Program, the Disaster Housing Program, the Red Cross, and other programs may end up as well off as those who purchase flood insurance and receive payment for claims. Generous disaster assistance creates negative incentives for the purchase of flood insurance. The government and the insurance industry must ensure that the public is fully aware of the advantages of flood insurance and the limitations of disaster assistance. They must work to ensure that disaster benefit payments do not approach or exceed flood insurance benefits. Floodplain occupants must be aware that disaster assistance is only available during a Presidentially declared disaster, while flood insurance claims are paid any time a general condition of flooding occurs.

Action 9.5: *Reduce the amount of post-disaster support to those who could have bought flood insurance but did not, to that level needed to provide for immediate health, safety, and welfare; provide a safety net for low-income victims.*

The FEMA should seek authority to limit the amount of disaster assistance to individuals in the 100-year floodplain who have not purchased flood insurance and investigate approaches that could be used to provide a safety net for those not able to afford flood insurance premiums.

Insuring Those Behind Levees

The Midwest flood brought to the forefront issues regarding the residual risk behind levees, the catastrophic damages that can occur, and the false sense of security that develops among floodplain occupants. Most of the levees that were overtopped or failed were agricultural levees not credited as providing 100-year flood protection, but some credited 100-year levees were overtopped or failed, such as a local levee at Chesterfield, Missouri, and a federal levee at Elwood, Kansas. The mandatory NFIP purchase requirement and floodplain management regulations do not apply behind credited 100-year levees. New structures were not protected from flood damage, and many buildings were not insured. Flooding threatened other credited levees that protect urban areas, and they too could have overtopped or failed had floodwaters been higher.

Currently if a levee meets minimum criteria established by the FEMA, that levee is credited as providing flood protection, and the application of floodplain management requirements and the purchase of flood insurance are not mandatory. The FEMA criteria require that the levee be at or above the elevation of the 100-year flood plus three feet of freeboard and meet certain structural requirements. Levees built by the USACE or other federal agencies are certified by the sponsoring agency.

The Review Committee is concerned that the minimum level of protection recognized by NFIP levee criteria and the level of protection that could result form current USACE procedures for selecting the design level for a federally constructed levee are not sufficient, given the residual risk to new and existing buildings behind levees. The residual risk to a building constructed behind a levee designed to provide protection from a 100-year flood is substantially greater than the risk to a building elevated to or above the 100-year flood elevation. This difference in residual risk, produced by the catastrophic damage that would occur if the levee is overtopped or fails, warrants a reevaluation of current federal policies toward levees and levee construction. Residual risk further warrants designating areas behind levees as flood hazard areas subject to the mandatory flood insurance purchase requirement.

PAYING CLAIMS BEHIND THE MONARCH-CHESTERFIELD LEVEE

The Monarch-Chesterfield Levee at Chesterfield, Missouri, is an example of a levee that induced floodplain development and of the residual risks that result from depending on a levee for flood protection. The Monarch Levee was an agricultural levee with an extensive emergency repair history that was upgraded during the 1980s to meet early NFIP standards. Subsequent to the completion of the levee and its being credited by the NFIP as providing 100-year protection, an industrial area developed behind the levee. In 1993 when it became apparent that the levee might overtop or fail, many property owners were able to purchase flood insurance and later to receive claims payments. Other property owners did not have flood insurance or did not meet the 5-day waiting period for coverage. The Review Committee identified at least 67 flood insurance claims payments behind the Monarch Levee that totaled $13.2 million. This represents nearly 5 percent of the total flood insurance payments for the 9-state region. The flooding of this industrial area had severe impacts to the area not only from insured and uninsured damages but also from the temporary or permanent loss of jobs.

SOURCE: FEMA Federal Insurance Administration, claims data for 1993, geocoding by the Floodplain Management Review Committee.

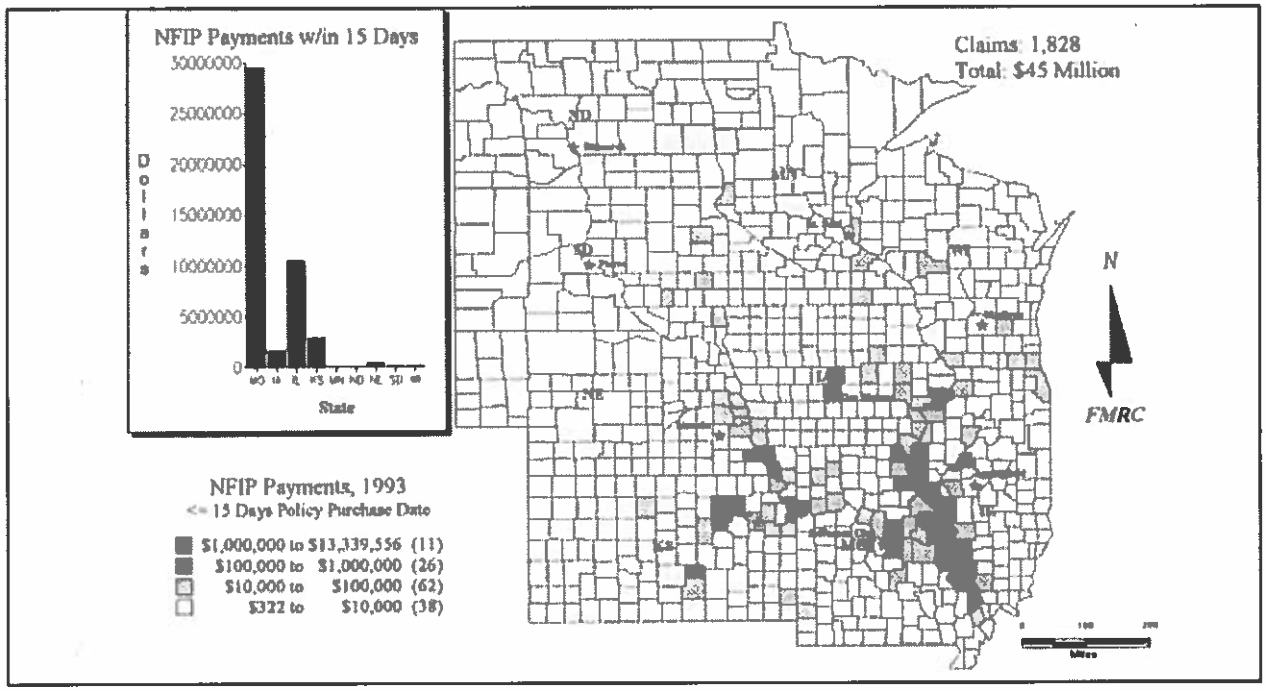
Action 9.6: *Require actuarial-based flood insurance behind all levees that provide protection less than the standard project.*

The FEMA should designate as AL zones those areas behind levees designed to meet current minimum NFIP criteria but which do not provide protection from the Standard Project Flood (SPF) discharge. The AL zone would include those areas landward of the levee that are below the 100-year flood elevation. The mandatory flood insurance purchase requirement would apply within this AL zone, and new buildings would pay flood insurance premiums based on actuarial rates. The FEMA could establish floodplain management requirements for these areas, although elevation or floodproofing to or above the 100-year flood elevation should not be mandatory. This recommendation is similar to one in the 1982 National Academy of Science's National Research Council report, *A Levee Policy for the National Flood Insurance Program.*

A mandatory flood insurance purchase requirement behind such levees would provide a number of benefits to the public and to property owners:

- Property owners would be insured against the real possibility that a levee will be overtopped or will fail,
- Federal expenditures for disaster assistance would decline,
- Property owners would be more fully aware of the residual risk in building or locating behind a levee, and
- Communities would have an incentive to seek higher levels of protection

Existing Flood Insurance Rate Maps should be revised where appropriate to reflect AL zones. The FEMA should obtain a legal opinion on whether this designation could be made based on residual risk of catastrophic loss, or if it would require legislation.



Increasing the Waiting Period for Flood Insurance

The NFIP requires a 5-day waiting period between the time of purchase of a flood insurance policy and when coverage becomes effective. At the closing on the sale of a property, flood insurance can be purchased with coverage effective immediately. The intent of the waiting period is to ensure that property owners cannot wait and purchase flood insurance only when floodwaters threaten their building.

The Midwest flood demonstrates that a 5-day waiting period before flood insurance becomes effective is insufficient for main stem flooding. In the Midwest flood, 13,310 losses resulted in claims payments totaling $297 million. Over a third of these claims were for losses that occurred within 60 days of the purchase of the initial flood insurance policy for the property. If a 15-day waiting period had been in effect for the Midwest flood, 1,828 fewer claims would have qualified, and claims payments would have been $45 million less (Figure 9.1). If the waiting period had been 30 days, 3,390 fewer claims would have qualified, and claims payments would have been $82 million less. If the waiting period had been 60 days, 4,588 fewer claims would have qualified, and claims payments would have been $105 million less.[10]

Most of these losses were for properties in downstream areas behind levees in Illinois and Missouri. Owners of these properties purchased flood insurance after watching upstream levees overtop and fail. In at least one instance, a community undertook a gallant floodfight not in expectation of protecting a school but rather to keep it from flooding until the 5-day waiting period had expired. The 5-day waiting period creates an incentive to purchase flood insurance coverage on watching upstream levees overtop and fail, and only when flooding is imminent. It is also inequitable for those policyholders who have

Figure 9.1 NFIP Payments for 1993 Losses that Occurred Within 15 Days of the Purchase of the Policy.

bought and maintained coverage for a period of years. If the practice became widespread, it could threaten the fiscal soundness of the National Flood Insurance Fund. One consequence of this flood is that some policyholders in the lower basin may drop their coverage in expectation of having time to purchase coverage based on flood forecast.

Action 9.7: ***Increase the 5-day waiting period for flood insurance coverage to at least 15 days.***

The 5-day waiting period for flood insurance coverage is too short for main stem riverine flooding and should be increased to at least 15 days. At the closing on the sale of a property, coverage should continue to become effective immediately. A 15-day waiting period would introduce sufficient uncertainty to ensure that property owners did not purchase flood insurance only when flooding was imminent. Data from the Midwest flood alone would warrant a 30-day waiting period. FEMA should balance the benefits of a 30-day waiting period against possible impacts on the marketing for flood insurance.

IMPROVING THE FEDERAL CROP INSURANCE PROGRAM

Multiple Peril Crop Insurance has been available to farmers for more than 50 years. There have been substantial changes in the program, however, during the intervening years. The Federal Crop Insurance Act of 1980 (PL 96-365) was the last major overhaul of the way insurance is offered to farmers. The purpose of the legislation was to create an insurance program that was almost actuarially sound and had limited government financing and to completely replace ad hoc disaster payments.[11] In the 1970s the existing policy for agricultural crop disaster assistance was expensive and encouraged production in high-risk areas.[12] However, the results of the 1980 reform were disappointing. The program suffered from poor actuarial performance and limited participation, and failed to eliminate federal crop disaster assistance. In fact, disaster payments exceeded $6.9 billion from 1980 to 1989.[13] The current insurance program subsidizes the transfer of risk from farmers to the government rather than being an efficient risk-sharing mechanism.[14]

The Administration has proposed to reform the Federal Crop Insurance Program as a result of these longstanding problems and as a direct response to problems experienced by farmers in 1993 who had crop insurance and were flooded. The Administration's Federal Crop Insurance Reform Act was submitted to Congress in March 1994 by the Secretary of Agriculture. The Act contains several features that promise to improve the crop insurance program as a risk-sharing mechanism. It also proposes to repeal standing disaster assistance authority and require that crop insurance coverage be linked to obtaining farm program benefits and FmHA loans.

Data on participation in the current program by floodplain farmers are not available. Discussions with floodplain residents indicate that few farmers choose to participate in the crop insurance program because they consider the 75 percent maximum coverage too low, flooding is relatively rare, and disaster assistance is available that almost equals the insurance indemnity. Drought is the primary natural peril for which farmers make claims, and floodplain farmers are less at risk for the effects of drought than upland farmers. On average, floods represent only 2 percent of the FCIC insurance payments.[15]

Action 9.8: ***The Administration should continue to support reform of Federal Crop Insurance that limits crop disaster assistance payments, increases participation, and makes the program more actuarially sound.***

The Review Committee supports the current initiatives by the Administration to pass the Federal Crop Insurance Reform Act of 1994. It is proposed that FCIC modify its process to make crop insurance actuarially sound. Insurance participation will be increased if coverage is a prerequisite for participation in other USDA programs and will bring more floodplain farmers into the program. The Act also attempts to reduce the demand for ad hoc disaster assistance.

ENDNOTES

1. In 1992 after Hurricane Andrew, President Bush tasked the Secretary of Transportation with recovery and in response to the 1993 flooding disasters, the secretary of Agriculture was tasked.

2. Director of the Office of Management and Budget; memorandum to heads of agencies on non-structural floodplain measures and flood disaster recovery, July 10, 1980.

3. Memorandum of Agreement on Interagency Hazard Mitigation. Signed by 13 federal agencies, December 16, 1980.

4. The Federal Interagency Floodplain Management Task Force was established in 1975 within the U.S. Water Resources Council. In 1982, OMB assigned its responsibilities to FEMA, which assumed the role of chair. Part III

A FRAMEWORK PLAN FOR THE UPPER MISSISSIPPI RIVER BASIN

Chapter 10

A NEW APPROACH FOR THE UPPER MISSISSIPPI RIVER BASIN

...we need a comprehensive strategy to substitute for what has been the piece-by-piece building of our levee system in the Upper Mississippi. The River is a single system. Actions in one place to keep water out mean that pressure elsewhere along the system increases, often with adverse effects on other communities...

Richard Gephardt
House Majority Leader
October 1993

Earlier chapters of this report have suggested a new approach for floodplain management, including collaborative planning by all stakeholders, i.e. local, tribal state, and federal governments, businesses, and the people who occupy floodplains either through choice or happenstance. The Review Committee has addressed floodplain management issues from both a national perspective and as they apply to the flood-affected nine-state area. This chapter, in response to the Committee's charge, considers the current state of the upper Mississippi River Basin, considers improvements to the present situation, and suggests ways to apply new approach to those improvements.

DEALING WITH THE RIVER SYSTEM AS A WHOLE

The upper Mississippi River Basin is affected by a complex of independently managed federal programs for navigation and flood damage reduction, water quality improvement, natural resources protection and enhancement, and agricultural production. To coordinate and sustain water resources development consistent with national floodplain management goals, these programs need to be integrated using existing or modified institutional arrangements among federal, state, tribal, and local agencies. The federal sector, however, must first set an example by coordinating programs across its agencies.

Currently no single entity has federal or federal-state oversight responsibility for the range of activities within the upper Mississippi River basin, or for ensuring that funding and performance among programs are commensurate with national goals. The Review Committee found no single hydraulic or hydrologic model and no system-wide flood reduction strategy or ecosystem management strategy within the basin. Linkage exists among system components, but separate federal agencies deal with component problems independently. With the demise of the river basin planning institution embodied in the Water

Resources Planning Act of 1965 (PL 89-80), the coordinated basin-scale approach lost prominence in American water resources planning in favor of more generic and site-specific solutions.[1] This state of affairs exists despite the tenets of the *P&G* and the NEPA that call for direct, indirect, and cumulative impact analyses and integration of regional federal actions. The situation is exemplified by the number of separate activities currently underway in the basin, such as the Missouri River Master Manual Review and Update Study, the Upper Mississippi River-Illinois Waterway Navigation Study, the Upper Mississippi River Basin Floodplain Management Assessment, the Missouri River Mitigation Project, the Upper Mississippi River Environmental Management Program, and many USACE studies directed at improving or building individual levee projects in the basin.

REDUCING THE VULNERABILITY OF THOSE IN THE FLOODPLAIN

Three situations made evident by the 1993 flood point to the need for reducing the vulnerability of those in the floodplain of the upper Mississippi River Basin. First is the hazard of being in the floodplain. The 1993 flood was a major natural event but floods of even greater magnitude or over a larger area could occur any time. USGS staff reported to the Review Committee that only 30 percent of the streamgaging stations in the flood-affected area recorded discharges having greater than a 10-year recurrence interval and less than one in ten recorded flowrates greater than that of the 100-year flood. Another factor to consider is the presence of the New Madrid Fault, which has potential to create seismic damage to structures over an area encompassing many of the 1993 flood-affected states. This points to the need for multi-hazard planning in known hazard zones. Second, the federal government is being asked to restore much of the pre-flood structural system on an individual project basis without knowledge of system-wide benefits or costs. Structures, lives, and livelihoods will remain vulnerable to damage even with complete restoration of levees and despite buyouts and relocations. Third, the flood-related, landscape-shaping processes witnessed in the 1993 flood will recur, and these processes will help define compatible uses of the floodplain. Some areas will remain more inherently risky to occupy or develop than other areas.

Current Approaches To Flood Damage Reduction

Development of flood damage reduction strategies in the upper Mississippi River Basin contrasts sharply with that in the lower basin. From the mouth of the Ohio River downstream almost to the Gulf of Mexico, the nation has an integrated system of federally planned, designed, constructed, and maintained facilities. The system includes main stem and tributary levees, floodway bypasses, interior drainage pumping stations and flood storage dams. In the upper Mississippi River Basin, most flood damage reduction facilities were not constructed in accordance with any system plan but were developed on a project basis by a host of individuals, drainage and levee districts, and the federal government.

Major tributary and main stem flood storage reservoirs in the Missouri River Basin were developed by the USACE and the Bureau of Reclamation as part of the Pick-Sloan Plan (Chapter 2). However, the systematic approach for building main stem levees offered by the Pick-Sloan was never fully implemented. Many levees were constructed by local owners without consideration of the Plan's provision to set levees sufficiently back from the riverbank to retain the floodplain's capacity to convey floods. The result is a collection of federal and non-federal facilities of greatly varying structural integrity, providing widely varying levels of protection for similar land uses, and placed, in some cases, upon the floodplain without full regard to their impacts on the river upstream, across or downstream. Some levees were sited without adequate consideration of physiographic features, the forces the river itself imposes upon them during flood, or their riparian environment. For most of the past 60 years, construction of structural measures was the primary method chosen for flood damage reduction. Under the new approach, nonstructural measures, consideration of

basin-wide hydrologic and river hydraulic processes and ecosystem functions would weigh heavily in project planning and design. Structural flood damage reduction projects have been built throughout the upper Mississippi River Basin. These projects should be reviewed and in-depth consideration given to modifications that will achieve floodplain management goals.

Levees

By some counts, over 8,000 miles of levees of various descriptions exist in the upper Mississippi River Basin (Chapter 2). They represent a mix of age, ownership, size, purpose, and quality. Most levees, other than those connected with the navigation system, have their origins in effort by communities, individuals, and groups to protect their land from flooding. They date back, in many cases, to early settlement. Since passage of the 1936 Flood Control Act, many levees have been upgraded or replaced by federal construction and are maintained by local owners or sponsors. Others, built and maintained by local owners, are eligible for post-flood emergency repair under the USACE PL 84-99 program. Eligibility for inclusion in the USACE program requires that a levee be a primary one that provides an adequate level of protection, that it be sponsored by a public entity, that the sponsor maintain the levee to a standard established by USACE, and that the cost of any levee repair be shared: 20 percent by the local sponsor and 80 percent by the federal government. Local sponsors also provide all lands, easements, and rights-of-way needed for repairs. Levees not in the USACE program tend to be smaller, single-owner structures of those publicly sponsored levees whose sponsors did not desire to maintain them to USACE standards.

These levees constructed by different agencies and individuals at various times and under various times and under various programs, have very few common characteristics. Their physical composition varies by reach of the river. Some are on the riverbank while others are set back appropriately to permit flood flow conveyance. Many of those built in areas subject to swift currents during floods or over formerly active channels are destined to fail again and again. Most non-federal levees were built without any substantive understanding about impacts on river hydraulics and the riparian environment. Many of the federal levees were built prior to the availability of river hydraulic models and geologic maps that could provide such needed information. In some cases flows have increased for the same meteorological conditions because of upstream development. Determination of the level of protection provided by a levee is an important piece of information frequently difficult to obtain.

Natural Resources

From the ecosystem perspective, current flood-reduction strategies have direct effects on the floodplain resources and functions at locations where they were implemented, and indirect effects elsewhere in the system (Chapter 2). The lower Mississippi River currently is receiving hydrologic restoration through installation of water control structures in selected interior areas. The upper Mississippi River is receiving ecosystem restoration attention through the Environmental Management Program. The Missouri River, however, remains one of the most highly impacted and least attended floodplain ecosystems. The watersheds of those floodplains receive varied attention through federal programs.

The assemblage of levees described in the preceding section may be considered a metaphor for natural resource management on these rivers. System-wide, coordinated, and integrated management of the Mississippi River ecosystem is not currently a defined objective of any agency, nor is such an approach a part of agency operational plans at the regional or local levels.[2] The Review Committee has found this to be a case with the Missouri River as well. Although several federal agencies have complementary goals and the NEPA establishes a common environmental goal for all federal agencies, no single agency serves as the necessary focal point for ecosystem protection needs in ongoing water management decisions.[3] Separate government programs address land use, nonpoint source pollution, major point sources of pollution, wetlands, and a host of other environmental concerns. Failure to integrate such programs makes it difficult for land and water managers to achieve their goals.[4]

System Integration

It is now recognized that the combination of existing levees requires a systematic hydrologic and hydraulic analysis to determine flood-damage reduction efficiency. Federal agencies must become partners in conducting a system analysis of basin hydrology, hydraulics, and overall ecosystem condition. Future decisions regarding federal, state, and local investments will require assessment of the following:

- Impacts that levees may create as physical factors having hydraulic and ecological consequence,

- Effects of river regulation as a hydraulic and hydrologic factor having ecological and flood consequences,

- Effects of watershed condition as a hydrologic factor having ecologic and flood consequences, and

- Impacts of physical and hydrologic characteristics on economic productivity and of government policies as incentives or disincentives on decisions to develop the floodplain.

Detailed analysis of system hydrology and hydraulics will result in the means to evaluate levees for a variety of factors, such as current protection level, flood insurance, rate mapping, habitat restoration, flood storage and/or conveyance, and design modification to achieve any combination of objectives. At the same time, an ecological inventory and analysis of species-habitat relationships will provide a sound basis for cooperative decisions regarding river regulation, land acquisition, watershed planning, flood damage reduction, and mitigation activities. The assessment of economic productivity and effects of government policies will determine tradeoffs inherent in watershed planning choices. Many operational and administrative efficiencies should be realized subsequent to completion of system-wide analyses.

Administrative integration

To organize ongoing activities, the Review Committee sees the need for two levels of activity:

- A strategic level that will result in development of comprehensive plans for water and related land resource development. This strategy is embodied in the authorities of the basin commissions established under Title II of PL 89-80;

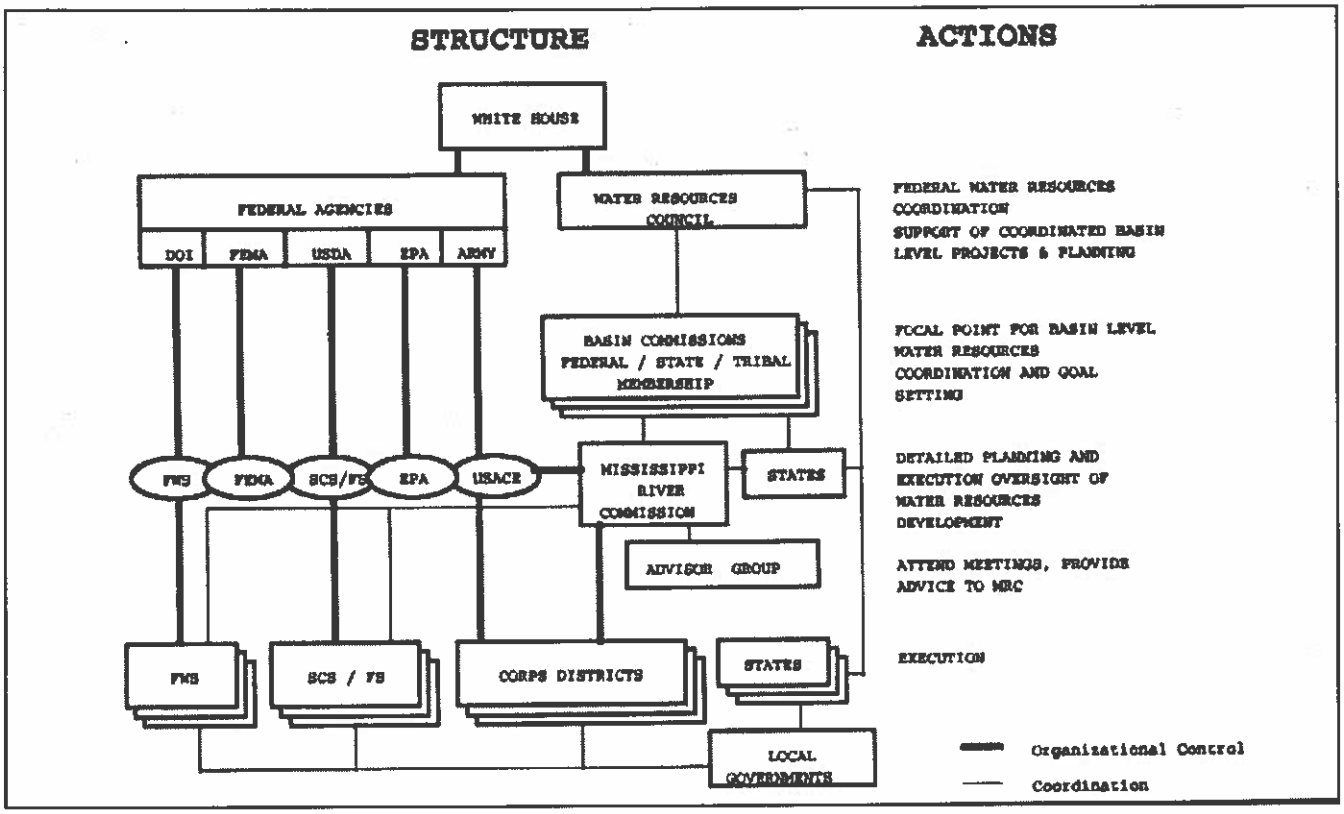
- An operational level such as that of the Mississippi River Commission, but with an expanded focus to include stewardship of the ecosystem that supports current and desired levels of development.

At the strategic level, utilization of a regional institutional framework for comprehensive planning was exemplified by the Upper Mississippi River Basin Commission (UMRBC). The UMRBC prepared a Comprehensive Master Plan for Management of the upper Mississippi River system in response to Section 101 of the Inland Waterways Authorization Act of 1978 (PL 95-502). Termination of the UMRBC and five other basin commissions by EO 12319 in 1981 complicated implementation of the master plan, which represented a successfully integrated federal-state-local planning effort with substantial public input. PL 99-88 and PL 99-662 ultimately authorized implementation of portions of the master plan, one element of which is the Environmental Management Program. This requires federal and state agency input to the USACE through the Upper Mississippi River Basin Association (UMRBA) is basically a policy research and coordination forum for the upper Mississippi River basin states. Because the UMRBA is a state initiative, the federal government has no voice in planning activities.

Action 10.1: *Establish upper Mississippi and Missouri basin commissions with a charge to coordinate development and maintenance of comprehensive water resources management plans to include, among other purposes, ecosystem management, flood damage reduction, and navigation.*

Reestablishment of the basin commissions will help decisionmakers reach fully coordinated floodplain management decisions within the larger context of

basin-level water resources planning and goals. Through minimal staffing with qualified leadership, the basin commission format, authority, and funding mechanisms provided by PL 89-80 will stimulate non-federal attention to timely completion, update, and implementation of multiple-use plans (Figure 10.1). The Review Committee considers basin commissions to be a necessary link between federal and state agencies and a coordination forum for implementing national policy. The basin commission structure is described in detail in Appendix I.



At the operational level, an institutional framework is currently in place to effect operational modifications of flood damage reduction and navigation facilities throughout the basin. The foundation of this framework is the technical capability on water resources found within the USACE. Beyond this technical capability, Congress provided for detailed project planning and implementation oversight on the Mississippi River by establishing the Mississippi River Commission (MRC) in 1879. The MRC Act authorized the Commission to extend its activities "between the Head of Passes near its mouth to it (Mississippi River) headwaters." Until the late 1920s the MRC was based in Saint Louis, Missouri, and was active in mapping the entire river. In 1928 the current Mississippi River and Tributaries (MR&T) project was authorized for the lower Mississippi River basin as a result of the devastating 1927 flood. Since then the MRC, which relocated to Vicksburg, Mississippi, has focused on the MR&T project, though it did continue to build levees in the upper Mississippi River Basin as far north as Rock Island, Illinois, until the early 1950s. For more than 60 years the MRC has focused attention on the MR&T project, but its authority still extends to the Mississippi River headwaters. The MRC reports program performance directly to the USACE Chief of Engineers and the White House. No similar framework or technical foundation is in place within one agency or between agencies responsible for natural resource protection or management within the upper Mississippi River basin. Of major importance, no direct connection exists between natural resource management and management of the river and floodplain for other uses.

Action 10.2: ***The Administration should expand the mission of the Mississippi River Commission to include the upper Mississippi and Missouri rivers. Further, to recognize ecosystem management as a co-equal federal interest with flood damage reduction and navigation, the Administration should request legislative change to expand commission membership to include the DOI.***

The Review Committee heard from a number of groups who expressed a desire for establishment of a coordinating body. Conversely many groups have expressed concern over this recommendation. Both pro and con positions are based on perceptions of the MRC and past action under MRC oversight, primarily the MR&T project. To many the MRC has been synonymous with big levees, uniform main stem river protection, and loss of habitat. The MR&T project began its 70-year development with a structural focus on navigation and a uniform level of flood protection on the main stem Mississippi River. In furtherance of national goals, the MR&T project supported development of agriculture. Environmental resources and natural floodplain functions were foregone. Over the last 20 years, in response to a shift in national goals toward environmental quality, the MRC has been adjusting the MR&T project to provide habitat restoration and environmental enhancement.

The expanded commission will provide for detailed planning and execution oversight of water resources development project, and it will assure appropriate fiscal attention to programs necessary for achievement of national floodplain management goals. The USACE Chief of Engineers and the Secretary of the Interior will receive annual commission reports on the performance of navigation, flood damage reduction, and ecosystem management projects. Because of the direct relationship between basin hydrology, river hydraulics, and floodplain ecosystem function, expanded membership of the commission will ensure coordination between multiple-use interests. The principal utility of the MRC

Figure 10.1 Proposed Institutional Framework

model is accountability. It is anticipated that multiple program integration and performance will be assured by assigning responsibility to a single entity, which answers directly to the public and the Administration. DOI membership is provided to ensure that its programs for ecosystem stewardship are fully integrated with other activities under MRC oversight. Because of the interrelationship of missions and responsibilities involving water resources, transportation, and emergency preparedness, the MRC advisor group membership must also include the DOT, FEMA, USDA, and EPA. Current and expanded river commission function and structure are suggested in Appendix I.

COORDINATION OF LEVEE ACTIVITY

At the same time that the Administration is considering long-term floodplain management objectives, the federal government has appropriated funds for the repair of many levees damaged by the 1993 flood. The actions proposed subsequently in this chapter and elsewhere in the report are not directed at stopping ongoing authorized activities but are presented to provide necessary integration among federal programs. Federal and state oversight over non-federally constructed levees is diffuse. Several states regulate construction in floodplains, but many do not. The situation is further exacerbated by the potential for future flow increases that could occur if development continues upstream and the uncertainty about changes that may occur in long term weather patterns. Without a systematic approach, a variety of levee problems will continue.

Action 10.3: *Assign responsibility for development of an Upper Mississippi River and Tributaries (UMR&T) system plan and for a major maintenance and rehabilitation program for federally related levees to an expanded Mississippi River Commission, operating under the USACE.*

The objective of developing the UMR&T system plan is to determine how best to integrate existing facilities in the upper Mississippi River Basin into an efficiently functioning flood damage reduction system that is compatible with floodplain ecosystem function. A component of the plan would incorporate all eligible levees in the upper Mississippi River basin into a program to ensure their long-term functional integrity for flood damage reduction and to improve ecosystem function. The functional integrity objective would be accomplished through a federal-state-local cost-shared program of systematic major maintenance and major rehabilitation. Routine maintenance and repair would continue to be a state-local responsibility. The ecosystem function restoration objective would be met by such measures as installation of water control structures in the levees to allow connection of the river with floodplain wetlands and former channels during non-floodplain wetlands and former channels during non-flood periods. These facilities would also be used to control flooding of areas behind levees when overtopping is imminent to avoid a levee breach and the consequence of catastrophic flooding. Involvement in the program by levee sponsors would be voluntary.

Development of such a plan will require a survey to evaluate and identify all levees on the main stems of the Mississippi, Missouri, and the Illinois rivers, for program eligibility and/or design criteria. The survey will include tie-back or flank levees on tributaries and those tributary levees currently in the USACE PL 84-89 program. During this survey, information can be gathered to form a foundation for systematic analysis of each levee under the objectives of system floodplain management and flood damage reduction.

The USACE is currently engaged in completing repairs to hundreds of levees under its PL 84-89 program. In addition the Congress has charge the USACE with completion of a Floodplain Management Assessment of the upper Mississippi River Basin by the spring of 1995.[5] This ongoing activity could, with congressional approval, be redirected in scope to take advantage of information gathered during the post-flood recovery and reconstruction process.

Action 10.4: *Seek approval from the Congress to redirect the USACE Floodplain Management Assessment of the upper Mississippi River Basin to development of an UMR&T systems plan. Place this assessment under the Mississippi River Commission operating under USACE.*

The refocused study would assess the condition of presently existing levees and would develop a general plan for basin flood damage reduction, including structural and nonstructural measures. Development of a flood damage reduction strategy should be collaborative and conducted using the revised *P&G* and the NEPA process to ensure full participation of affected and interested parties in floodplain management. The systemic approach will necessarily involve consideration of the upper Mississippi River Basin and the basin of its principal tributary, the Missouri River, as individual and aggregate watersheds with both unique and common human uses and ecosystem functions. Representatives of the USDA, FEMA, DOI, and EPA should participate on the study team because of their agency missions in watershed management, floodplain regulation, natural resources stewardship, and water quality protection.

Action 10.5: *Following completion of the survey, seek authorization from the Congress to establish the UMR&T project.*

Authorization of the UMR&T project is needed to assign responsibility to the USACE to develop and execute the federal program of major maintenance and major rehabilitation (MM&MR) of those levees found to be eligible for inclusion. The UMR&T project would be identified as a separate line item in the USACE budget and would be funded by annual appropriation.[6] Under the MM&MR program, the USACE would be responsible for major maintenance and major rehabilitation of levees that are

determined by the USACE to be eligible for the federal program. Major maintenance includes such activities as levee survey and setbacks; repair of levee slides, culverts and floodwalls; slope paving; and major erosion protection. The FY 94 MRC budget for repair of 1,600 miles of main stem levees in the MR&T projects is $4.9 million. Although by comparison the total length of levees in the UMR&T project would be greater, they are smaller in size and the river depths and velocities are lower. Thus the annual cost of major maintenance for the proposed UMR&T project is expected to be the same order of magnitude as for the MR&T project. The cost of major rehabilitation is one of either pay now or pay later; money not spent in a systematic way to rehabilitate aging levee drainage pumping facilities, culverts, gate structures and like facilities will be spent making emergency repairs during and after floods. The federal cost of repairing levees in the upper Mississippi River Basin that were damaged during the 1993 flood is expected to amount to $300 million.

To be eligible for inclusion in the MM&MR program, levees would have to be of such construction as to meet the USACE engineering standards for structural integrity and for proper siting, and they would have to be in good standing in the current USACE PL 84-99 program (or be working toward that end under the 1993 flood-recovery effort). Local levee sponsors would include the states as co-sponsors, and would have to be a part of a community enrolled in the NFIP, agree to obtain structure and crop insurance (in the amended program), limit floodfighting, and participate in environmental enhancement activities. For details of the MM&MR program, see Appendix H.

Role of the States

Levees not currently eligible for emergency repair under the PL 84-99 program, and thus not eligible for the UMR&T project, should be regulated by the states when changes are made for either repair, rehabilitation, realignment, or improvement. Future inclusion of a levee in the PL 84-89 program would require, in addition to meeting current USACE eligibility criteria, acknowledgement by the state that the levee is publicly sponsored, does not cause adverse river hydraulic conditions elsewhere, and provides an appropriate level of protection. A levee that subsequently becomes eligible for the PL 84-89 program would require congressional authorization to become eligible for inclusion in the UMR&T project. Levee sponsors and owners who choose not to participate in the PL 84-89 program and those ineligible for participation will not receive federal assistance for repair of damaged levees. This may not preclude assistance under the USDA Emergency Watershed Program.

As discussed elsewhere in this report, not all states in the upper Mississippi River Basin have a permit program whereby either proposed or existing levees are reviewed for compliance with state-established standards for design, construction, maintenance, and repair. Few if any control either the decision about where levees are placed relative to the river channel or whether a particular levee should be protected from overtopping (floodfought) during a flood, although such actions can have hydraulic and environmental consequence elsewhere. The Review Committee found that some states have little or no involvement in the processes associated with federal levee programs since federal agencies generally deal directly with levee districts. Given these circumstances and the number of levees damaged in the flood of 1993, it is clear that there is need for greater involvement of the states in the design, construction, maintenance, and repair of levees.

Recommendation 10.1: *Where they do not already do so, states should assume responsibility for regulating levee-related activities such as levee location, alignment, design, construction, upgrade, maintenance, repair, and floodfighting.*

This is not a call for levee construction but for state oversight of levees to assure their structural integrity and that actions in one location along the river do not create adverse impacts elsewhere.

Using current technology, the states have the capability to assure that existing levees are properly located and aligned to avoid or minimize hydraulic impacts and to avoid high energy, damage-prone locations on rivers. Using a levee permit program, states could also assure that the

embankment and foundation conditions meet engineering and environmental standards, that the level of protection afforded is commensurate with land use, that maintenance and repair are performed to assure structural integrity, and that floodfighting is limited to areas deemed critical by the state.

ECOSYSTEMS NEEDS

Although federal and state agencies recently have articulated general policies regarding pursuit of ecosystem management, they need a coordinated, multi-agency, ecosystem-based plan upon which to base water resource and floodplain management decisions. Pursuit of watershed planning requires a single hydrologic/hydraulic model. It also requires development of a natural resource baseline against which agencies can develop and implement appropriate maintenance or restoration plans within their areas of jurisdiction or expertise.

Ecosystem planning strives to protect or restore the function, structure, and species composition of an ecosystem, recognizing that all components are interrelated. The Review Committee recognizes that agriculture is the dominant land use in the upper Mississippi River Basin. Ecosystem planning, therefore, will necessarily include agriculture and forestry as vital contributing elements to ecosystem function and values. The FWS recognizes that the initial step to ecosystem planning is the identification of natural resource needs.[7] Information on the distribution, abundance, and ecological relationships of species and a comprehensive inventory and classification of ecosystems are fundamental nationwide needs.[8] Such information is largely incomplete for the upper Mississippi River Basin[9], and the Review Committee found that funding and support for the effort have been lacking. Ecosystem information is critical for setting resource objectives, examining alternatives within multiple-use planning, and implementing solutions. Additional uses of this information include scientifically sound input to ongoing flood damage reduction, navigation, private lands, water quality, and watershed programs of other agencies.

Action 10.6: *DOI should complete an ecological needs investigation of the upper Mississippi River Basin and provide a report to the Administration within 30 months.*

The ecological needs investigation would be collaborative between government agencies and private groups. It would incorporate information from the NBS, under the Long Term Resource Monitoring Program, the USACE, the USDA National Resource Inventory, and the Review Committee's Scientific Assessment and Strategy Team. An interim report will be necessary to assist activities described subsequently for Action 10.9. This interim report should be completed prior to August 1995. The final report would provide the necessary focal point from which government agencies could develop coordinated management strategies that reflect true resource needs, measure response to those strategies, and refine further research needs.

Ecosystems components have value for national trust resources such as migratory birds, wetlands, and interjurisdictional fisheries. It is anticipated that the investigation will identify missing components and contribute to understanding the mechanisms that move organisms toward endangered species candidacy. It also will assist avoidance of development conflicts resulting from endangered species listing.

Action 10.7: *Provide an early report in the USACE Upper Mississippi River - Illinois Waterway Navigation Study of environmental enhancement opportunities in the upper Mississippi River.*

COMMERCIAL NAVIGATION AND RECREATIONAL USE OF THE UPPER MISSISSIPPI RIVER

The upper Mississippi River 9-foot depth navigation project provides a wide range of recreational uses (from hunting, fishing, boating, and swimming, to sightseeing). Such recreational use supported over $1.2 billion in national economic benefits in 1990 (1990 price levels) and over 18,000 jobs. Boating (33.2%), fishing (28.8%), and sightseeing (15.8%) were the most popular activities. Visits included 62.7% to developed areas, 26.3% to marina slips, 7.0% to sightseeing areas, and 4.0% to permitted docks. Management of the project for commercial navigation produces some impacts on their natural and recreational resources, including conflicts between recreational and commercial use of the locks.

Using information generated during the DOI ecological need investigation, the USACE should develop a report detailing the relationship of its ongoing operation and maintenance activities as well as those of new navigation construction alternatives to ecological needs identified by the DOI. Because the Review Committee recognizes the value of identifying and acting on environmental enhancement opportunities as soon as possible, it is imperative that the USACE establish this report as a milestone in the overall schedule for the Navigation Study. The milestone will be based on the DOI investigation. The Review Committee recognises that the DOI investigation will be collaborative with the USACE and that establishment of the milestone will not affect the overall schedule for the Navigation Study.

A potential opportunity to enhance upper Mississippi River resources exists through alteration of dam-regulation operations (at-dam vs. mid-pool hinge control points) on some headwater pools at the USACE navigation dams.[10] With little or no impact to navigation, habitat benefits may be gained by alternately drying and inundating areas adjacent to the main channel between a navigation pool midpoint and the dam.

Action 10.8: *Provide a report on the ecological effects of relocating navigation pool control points under the USACE Navigation Study.*

A complete evaluation of navigation dam operations should be conducted under the ongoing USACE Navigation Study to determine if moving navigation pool control points from mid-pool to the dam is feasible and would produce significant benefits. Currently a similar interagency investigation is underway for Lock and Dam 25 on the upper Mississippi River. The Review Committee endorses this effort and would support expansion of the investigation, as necessary, to other facilities. If feasible from the standpoints of navigation and the acquisition of needed lands, and if benefits are significant, modification of water control plans should be implemented.

The Environmental Management Program (EMP) on the upper Mississippi River includes a major habitat rehabilitation component. Land acquisition, however, has not been utilized in alternative development, as a point of Administration policy. This has hampered habitat

rehabilitation efforts along the Illinois and middle Mississippi rivers, where few federal lands occur, even though these are the reaches in most need of rehabilitation.

Recommendation 10.2: *The USACE should consider land acquisition as an alternative during planning and design of habitat rehabilitation and enhancement projects under the Upper Mississippi River Environmental Management Program.*

This change would improve the effectiveness of the program, and could help to meet both environmental and flood flow attenuation needs. The Review Committee supports the efforts of state and federal EMP partner agencies in their pursuit of additional appropriations to support EMP land acquisition.

The upper Mississipps River Basin should be used as a demonstration ecosystem study area under the current National Performance Review's (NPR) "Reinventing Environmental Management" action item (Env 02 Develop Cross-Agency Ecosystem Planning and Management).[11] The study should be undertaken by the FWS to take advantage of other ongoing initatives in the Missouri and Mississippi river basins, as well as the information obtained through Action 10.6.

Action 10.9: *The Administration Interagency Ecosystem Management Task Force should select an Ecosystem Management Demonstration Project within the upper Mississippi River Basin, and establish a cross-agency ecosystem management team under DOI to develop plans and budgets for the project.*

Cross-agency partnerships have already been forged on the upper Mississippi and Missouri rivers through a variety of coordination mechanisms. Given the existence of these coordination groups, attainment of the NPR goal of August 1995 for completion of initial ecosystem management plans is possible. Expanding existing partnerships to develop measurable objectives for protection of existing resources and restoration of missing system components will require selection of one federal agency to serve in a lead capacity. While agency priority and budget adjustments will be necessary, this action is seen largely as a focused coordination effort and is not intended to represent a significant impact to the federal budget. Over time this coordination should result in elimination of duplicative efforts and their costs. DOI representation on the MRC will assure integration of the Demonstration Project with other MRC activities.

Part IV

INTO THE 21ST CENTURY

Chapter 11

USING SCIENCE AND TECHNOLOGY TO GATHER AND DISSEMINATE CRITICAL WATER RESOURCE INFORMATION

Policy decisions are being made in a data vacuum. Yet we are now in an era when the ability to collect and use field data has been greatly augmented by satellite and computer based technologies. There is an immediate need to provide a comprehensive inventory of damaged buildings, damaged infrastructure, impacted lands, and natural areas for conservation and restoration.

Association of State Floodplain Managers
Testimony before Congress, October 27, 1993

Science and technology can be utilized to improve the gathering and dissemination of information critical to water resources management. Floodplain managers need easy access to information about natural and manmade physical features, cultural resources, living resources, climatology, and hydrology of the basins in which they operate. In some flood-related areas, however, the social and physical sciences have knowledge gaps that require research.

Recommendations to improve basic knowledge and provide technical services required for floodplain management were made in 1966 in House Document 465, *A Unified National Program for Managing Flood Losses.*[1] At that time, some of the recommendations were unrealistic. In 1994, however, advances in science and technology now make many of them possible.

A COMMON DATABASE

Vice President Gore's National Performance Review (NPR) contains recommendations regarding the use of information technology to create a government that works better and costs less. The NPR advocates creation of a national spatial data infrastructure that would establish standards for data collection and cataloging and create a clearinghouse for finding, accessing, and sharing spatial data, in addition to addressing related issues.

As indicated in the NPR report, "Data collection is duplicated at the federal, state; local, and private levels for different purposes. Moreover, different entities are often unaware that much-needed data have already been acquired by another party. Even when specific spatial data are knownto exist, non-standardized collection procedures and lack of easy access often restrict their use."[2]

The most difficult task for the Review Committee was compiling useful data regarding the upper Mississippi River Basin. Basic information such as the amount of damages from the 1993 floods and the amount of expenditures related to disaster response and recovery

were not readily available, nor easily obtainable. Data assembled from a variety of sources were difficult to use because they were neither spatially referenced nor were they in compatible formats or structures. Precise answers to many questions were difficult, if not impossible, to obtain. For example: How many structures are in 100-year floodplains along the Mississippi and Missouri rivers? How many structures were affected by the flood? Where were levees located and what level of protection did they provide? How many people applied for assistance in a given county or community? Where is critical infrastructure located with respect to the floodplains? What is the expected flood crest, given a certain flow in the river? During a floodfight, the availability of such information is key to decisionmaking. Other data, such as the boundaries of the 100-year floodplain, were not in digital format and had to be digitized. Neither the public nor the nonprofit sectors uniformly apply Federal Information Processing Standards (FIPS) in collecting pre-disaster, response, or recovery data.

The SAST gathered information and geographically referenced data regarding the physical and environmental characteristics of the basin. The team collected several hundred gigabytes of information with the help of states, local communities, and federal agencies. The nation needs to continue maintaining and sharing the results of this effort with all entities having an interest in the upper Mississippi River Basin and to develop this database as a prototype for other future regional efforts. The USGS would be an appropriate lead agency to achieve this.

Action 11.1: *The USGS should establish a federal clearinghouse for data gathered during preparation of the Review Committee report.*

To manage floodplains, mitigate flood damages, and respond to and recover from a disaster, analysts and decisionmakers require easy access to basic data to audit disaster expenditures, identify loss concentrations, and formulate new preparedness and mitigation strategies. The USGS, in coordination with the Federal Geographic Data Committee, should take the lead in establishing a federal clearinghouse consistent with that outlined in the NPR for accessing and updating data acquired and developed for the flood-affected 9-state region in the Midwest. The SAST effort demonstrates the benefits of leveraging science and technology. The nation should share its findings with states, communities, and all interests in the upper Mississippi River Basin. Consideration should be given to the establishment of a multiagency committee to assist present and future users of the data.

BUILDING ON THE DATABASE

Advances in science and technology enable improvements to be made in data acquisition, hydrologic and hydraulic analysis, flood forecasting, and mapping.

National Inventory of Structures

The Review Committee was unable to obtain definitive numbers on how many structures were impacted in the Midwest Flood of 1993. Estimates ranged from 55,000 to 100,000 structures. It was also difficult to estimate the level of NFIP market penetration without time- and labor-intensive studies. These are two tasks that could easily be accomplished if a national inventory of structures existed. Nationwide, there is no authoritative estimate of the number of structures exposed to floods and other natural hazards. As a result, floodplain and emergency management decisions are often made based on inadequate information. This results in inappropriate allocation of resources.

Action 11.2: *FEMA should investigate the costs and feasibility of completing a national inventory of floodprone structures.*

A national inventory of floodprone structures should be performed by FEMA through the states and tribes to determine the number, location, building type, and functional uses of structures in floodplains. Technology

certainly makes such an inventory feasible. These data and the risk analysis that would become possible for the first time could allow the nation to focus mitigation and pre-disaster planning at specific areas of high risk. At the same time, funding for these activities could be targeted and adjusted in relation to the degree of exposure to the relative risk. In the event of a disaster, an immediate assessment of response needs would be available in summary format. This information would also enable targeting specific addresses to inform residents of the flood risk and the availability of insurance. Other potential users of such a database are communities, lenders, planners, citizen groups, and underwriters. This database would serve as a cornerstone in the national spatial data infrastructure recommended in the NPR.

Hydrologic, Hydraulic, and Hydrometeorologic Analysis

The Review Committee originally wanted to answer some questions about flow characteristics for the entire reach of the Mississippi River from Cairo to St. Paul and for the Missouri River from its mouth to Gavins Point. A model to accomplish this task, however, does not exist. Five USACE districts are involved in managing these river reaches, and the models used by each differ. Additionally, the availability of topographic data is limited to only certain river reaches.

Current one-dimensional models are unable to satisfactorily model the complex condition of flow in large rivers where water moves into large storage areas in the overbank floodplain and where land cover varies both in the cross section and along the length of the river. The most widely used model for flood elevation determination is HEC-2, a steady-state, one-dimensional, rigid-boundary model that cannot simulate levee breaches or take storage effects into account. UNET, a one-dimensional unsteady-flow model used by the Review Committee to model a portion of the basin, has the capability to assess impacts of levee breaches and associated storage effects. A system-wide, unsteady-flow model of the main stem rivers in the upper Mississippi River Basin would help evaluate the impacts of proposed structures and floodfighting, and could be used for coordinated ecosystem modeling, and for floodplain management decisions. Further, advanced hydrologic and hydraulic models can be combined with meteorologic observations and forecasts to provide information to enable better floodplain and water resources management.

Action 11.3: *The USACE, NWS, and USGS, with other collaborators, should continue development of basin-wide hydrologic, hydraulic, and hydrometeorologic models for the upper Mississippi River system.*

Federal, state, tribal, and local agencies should develop coordinated estimates of floodflow frequency curves, flood elevation profiles, and floodplain maps. Overall improvement in the modeling of complex river systems will lead to advances in hydrologic prediction capabilities for both real-time forecasts of flood events and for water-resources planning. Floodplain managers should consider one- and two-dimensional models for modeling complex areas.

Flood Risk Assessment

Models used for determining flood heights require current estimates of flood discharges. Maintaining up-to-date estimates of discharge-frequency curves requires that they be reviewed as the period of hydrologic record increases and whenever new peak flowrates are recorded. By doing so, the representative sample of the parent population of hydrologic event data is enlarged and the estimate of the frequency of occurrence associated with a given discharge is improved. The 1993 flood established new peak discharges on many tributaries and on major reaches of the main stem rivers. Discharge-frequency curves should be reevaluated to reflect the new data.

In addition, the adequacy of the existing streamgaging network for defining regional flood risk should be evaluated and the network enhanced if necessary. Enhancements coud include reactivation of discontinued streamflow gages or establishment of new gages at critical locations where flood risk is not reliably defined.

Recommendation 11.1: ***Federal water agencies, in collaboration with state, tribal, and local entities, should review and update, as necessary, discharge-frequency relationships for streamflow gages in the upper Mississippi River Basin to reflect the 1993 flood data. The adequacy of the existing streamgaging network should also be reviewed.***

In 1979 the USACE estimated flood discharges for the upper Mississippi River corresponding to the 5-, 10-, 50-, 100-, and 500-year frequency floods. Water surface profiles for the Mississippi River developed from these discharge frequency curves form the basis for FEMA's flood insurance rate maps for the areas along the Mississippi River. This is an example of the use of discharge-frequency curves and indicates the importance of keeping them representative of present conditions.

Federal Standards for Determining Flood Risk

Currently, the method of computing the relationship between annual flood peak discharge and frequency of occurrence is standardized among federal agencies.[3] Though this method was reviewed less than ten years ago, the magnitude of the 1993 flood and its possible effects on discharge-frequency curves for stations in the upper Mississippi River Basin provide the opportunity to ascertain the adequacy of the recommended method to reflect the probability distribution of annual peak discharges.

Action 11.4: ***The Hydrology Subcommittee of the Federal Interagency Advisory Committee on Water Data should review the current standards for computing discharge-frequency relationships in light of observations from the 1993 flood and other recent large floods in the upper Mississippi River Basin.***

Frequency curves are generally developed using the current federal standard distribution function (log-Pearson Type III) for annual peak discharges. This methodology should be reviewed. The bases for concluding which method produces the most representative relationships should include, in addition to probability theory itself, the end uses of the curves such as selecting the heights of flood protection facilities, evaluating the degree of risk of a site or a structure, determining regulatory floodplain limits, and establishing flood insurance rates.

Flood Forecasting

State and local authorities need river stage and discharge information for emergency situations, for local flood relief efforts, and for floodplain management. During the Midwest flood, conflicting estimates of flood crests created difficulties for local emergency response efforts. Especially important for floodwarning and forecasting are the presence of streamflow gages at location critical for providing flood alert for downstream populations center, and capabilities for remote sensing of gages, data transmission, and communications with other agencies. The NWS, USGS, and USACE should collaborate on a study of the effectiveness of the existing flood monitoring and information distribution system.

Recommendation 11.2: ***Federal agencies, coordinated by NWS and USGS, should collaborate on an assessment of the effectiveness of the streamgaging network and flood forecasting during the 1993 Midwest floods.***

This assessment should include an evaluation of the ability of the present streamgaging network to monitor the Mississippi River system and provide the public with timely and reliable flood warnings. The assessment should identify gaps, inconsistencies and areas of duplication in the present system and make recommendations on improvements. NOAA's *Natural Disaster Survey Report*[4] identifies the need for improvements to real-time hydrologic forecasting and provides 106 findings and recommendations resulting from an interagency evaluation of the 1993 Midwest flood.

Mapping

Critical to the development of any computer model used to estimate flood elevations is detailed topographic information. Engineers can use topographic information in a digital format more efficiently in computer models. Topographic information of the appropriate resolution or accuracy does not exist in a digital format for many locations in the flood-affected 9-state region of the Midwest, or in the nation, at a scale useful for floodplain management or for use in engineering models. Floodplain managers generally prefer contour intervals of two feet or less. Technologies are beginning to emerge that will produce accurate, high resolution digital elevation models at reasonable costs. Such models soon will be generally available.

Action 11.5: ***The Administration should support the USGS in development and acquisition of detailed digital topographic data and other land characteristics for use in floodplain management and other water resources management activities. Existing DOD technologies should be leveraged to assist in the acquisition of these data.***

Floodplain managers use detailed topographic data and other land characteristics in floodplain areas for many applications, such as floodplain boundary delineation, habitat and land cover/land-use mapping, and restoration projects.

MAPPING TECHNOLOGY TRANSFER INIATIVES

NASA has developed a scanning laser device (LIDAR) that operates from a commercial aircraft and collects fine- resolution, digital terrain data used in hydraulic models. The Houston Advanced Research Center, in coordination with NASA, developed an aircraft-mounted prototype suitable for a wide range of commercial applications. Concurrent with the LIDAR data, the prototype acquires high resolution color video imagery that can be digitally draped over the terrain data to visualize land use. NASA will conduct a system demonstration for an area downstream of Gavins Point Dam in June 1994.

The DOD Advanced Research Projects Agency (ARPA), working in conjunction with the USACE Topographic Engineering Center, is sponsoring the use of IFSARE (InterFerometric Synthetic Aperture Radar for Elevation), a radar technology employing a Lear Jet data-collection platform. Fine-resolution digital terrain elevations, as well as synthetic aperture radar (SAR) imaging will be generated by this system. The Environmental Research Institute of Michigan and the Jet Propulsion Laboratory are principal contributors to this program. Data have been acquired in the vicinity of Iowa City, Iowa, to provide sample data for applying this technology to the development of hydraulic models.

NASA, the USGS, and the USACE have agreed to participate in a test of these technologies along a reach of the Missouri River in the vicinity of Glasgow, Missouri.

ANALYSIS AND RESEARCH NEEDS

The Review Committee investigated some of the benefits and costs of floodplain occupancy, agriculture uses, and associated floodplain management measures. This investigation considered national productivity, the impacts on natural functions, and the equitable distribution of benefits, costs, incentives, and disincentives. Federal programs provide for transfer of funds that support several types of private floodplain activities; for example, navigation, agriculture, flood control, and transportation. The National Science Foundation should consider funding research to examine fully the flood-related impacts on these areas.

Although the Review Committee devoted a good deal of its time to floodplain hazards associated with levees, other flood hazards warrant study. These include alluvial stream channels and storm drainage overflow and backup. The National Science Foundation and interested federal agencies should establish a cooperative, jointly funded program to develop methods for mapping, regulating and identifying natural functions in these areas. SAST data would form the basis for further investigation.

Studies on the epidemiological factors and mental health impacts of floods are few in number. Research regarding the social impacts of floods needs federal support. Other items warranting further investigation are the funding of disaster relief and support of floodplain agriculture. With regard to the NFIP, the reasons for limited flood insurance market penetration should be studied.

Many questions posed by the Review Committee remain unanswered because of time or resource constraints or a lack of information. Even where available, information often led to new questions and new areas to be explored. Listed below are several topics that merit additional study.

Quantifying and Assessing Environmental Impacts

Environmental quality and species diversity remain as social services not sold in conventional markets. Evaluation methods that do not depend on market prices are needed to estimate the benefits of such services. The non-market value to be estimated is the amount of income an affected person would be willing to give up for an environmental service. Where environmental outputs can be identified and effects can be monetized, these monetized environmental effects should be included in benefit-cost analyses.

Significant research exists on non-market evaluation techniques. Most of this research estimates recreation benefits rather than benefits of passive services such as ecosystem health. Economists use two primary approaches to estimate the value of non-market goods: an indirect approach and a direct one.[5] Indirect approaches, such as the travel cost method or hedonic analyses, are based on the premise that the value people place on services is revealed by the choices they make in consuming them. These techniques depend on the observation of human behavior in a particular circumstance and cannot be used for hypothetical situations such as wetland restoration.

The direct approach uses survey techniques to directly elicit a person's value or willingness to pay. The most widely used approach is the contingent valuation method, where respondents are presented with information about the proposed environmental service (either an improvement or degradation) and asked what the change would be worth to them. The direct approach can also be used to evaluate existence values (the satisfaction an individual receives from simply knowing an environmental amenity exists or will continue to exist, even though the individual will never use it) and non-existing or hypothetical situations that indirect methods cannot handle. The reliability of estimates from surveys in these situations is often questionable. Experience with the contingent valuation method indicates it can be successful in estimating values associated with recreation outputs for which the potential user is familiar, for which the product can be clearly defined, and for which a plausible market can be defined. Applications become less successful when the respondent lacks familiarity with the product or when

the amount, quality, or other attributes of the product cannot be clearly defined. This especially true in trying to measure changes in the quality of environmental amenities or other management actions.

Action 11.6: *The Administration should direct that scientific research be conducted to identify state-of-the-art techniques or applications for estimating and assessing environmental and social impacts.*

Research should identify practical methods and improved techniques to allow greater consideration of impacts, both positive and negative, for which no market system exists. Such research would assist in evaluating the economic value of an environmental output or the willingness to pay to avoid an impact. Research is needed to improve techniques for measuring social or environmental outputs and for establishing criteria to assess the significance of such outputs from a regional and national perspective.[6] Many federal agencies, universities, and private consulting firms are focusing on research in these areas. An organization such as the National Research Council of the National Science Foundation could foster this type of research, with federal oversight provided by the Office of Environmental Policy. The Administration should require that research and case studies be completed and recommendations made concerning appropriate state-of-the-art techniques within three years of initiation.

Geomorphology

Satellite imagery and data analyses provide evidence that some levee failures along the Missouri River coincided with historic river channels (see Figure 2.6). Evidence indicates that levees that were largely responsible for raising flood water to levels that generated the high energies necessary to overpower and blow the levees, creating the scour holes and generating the sands that damaged the very farmlands the levees were designed to protect. In many areas riparian forests had minimal flood erosion or deposition damage. These areas commonly coincided with levees that did not fail, indicating some protection was given to levees by riverward forested areas. Evidence also indicated that levees placed in high energy zones would not hold, even if it were possible to excavate all the sand from the old channel and place the levees on a clay core. This suggests that levees should not be reconstructed in such high energy erosion zones, but should be set back to allow high energy zones to remain within a designated, functioning floodway. A mix of compatible land uses, such as dry-year farming, open space, recreation, fish and wildlife habitat, could occur within high energy floodways. Any such use, however, should not be eligible for future emergency federal disaster assistance. A study is needed immediately to better define, ducument, and map such high energy zones, at least along the Missouri River.

Recommendation 11.3: *The USACE and USGS should investigate and better define relationships between high energy erosion zones, other zones in floodprone areas, and levee failure.*

Hydologic and Hydraulic Benefits of Natural Floodplain Functions

The federal government establisheds the Minnesota Valley National Wildlife Refuge in the lower Minnesota River valley near the Minneapolis/St. Paul metropolitan area, in part, to maintain the floodplain as part of a naturally functioning ecosystem and floodwater storage/conveyance mechanism. Although the government did not establish the upper Mississippi River National Wildlife and Fish Refuge as a mechanism for flood damage reduction and control, it may have played a significant role in reducing local flood damages in the upper Mississippi River valley. Nonstructural flood damage reduction and control capabilities of floodplain land uses such as green spaces and wildlife refuges have not received adequate evaluation.[7]

Environmental groups have identified upland wetland water-storage capabilities lost to drainage over the past century as contributing factors in the heights of the 1993 floods in the upper Mississippi River Basin.[8] At the same time, agricultural interests have indicated that drainage tiles (underground drains) installed to dry out wetlands and wet soils provided a positive benefit in reducing flood heights by voiding the soils of water and creating a capacity in the soils for water storage. Once rains exceed a threshold level,

however, and soil surfaces are sealed, the ability of rainwater to infiltrate soil is lost and the water runs off.[9] Drainage tiles may have contributed to flood heights rather than lessening them.

Floodplain and upland areas functioning as temporary storage areas can have impacts on flood peaks. The quantification of these impacts has not been well documented. Use of natural storage areas (wetlands) for temporary storage of floodwater to decrease downstream flood heights has not been utilized in modern flood control policy. The mathematical models exist to analyze these impacts, although additional field data may be necessary. The Administration should request completion of these investigations as soon as possible. The functions of wetlands and their drainage for agricultural purposes need better evaluation.

The current USACE project in Marshall, Minnesota, offers the opportunity to further explore the effectiveness of upland treatment in flood damage reduction. Consideration should be given to the use of the watershed component of this project as a demonstration of the capabilities of upland treatment in reducing flood damages. A joint USACE-USDA evaluation of the results would add to the information available of this subject.

Action 11.7: ***The USACE and USDA, in collaboration with the DOI, should evaluate the effect of natural upland storage and floodplain storage in such areas as wetlands and forested wetlands on main stem flooding.***

Biotechnical Engineering

State, local, and private engineers and planners rely heavily on federal design manuals. Currently these manuals do not address biotechnical engineering -- channel or bank modification techniques that use vegetation in innovative ways in contrast to traditional bank sloping and riprap protection. Traditional approaches typically focus on maximizing flood conveyance only. Biotechnical engineering techniques can be employed in engineering designs and contribute to the natural functions of floodplains. These practices have not been incorporated into federal government standards. Federal agencies responsible for establishing guidelines should test and incorporate these methods into their design manuals.

Recommendation 11.4: ***Federal agencies should conduct research on biotechnical engineering techniques and incorporate them into design manuals.***

Disaster Relief Funding

Natural disasters in the United States are costly events in terms of both human lives lost and property damaged. Since FY 1989, over $27.6 billion has been spent on federal disaster assistance programs.[10] The Review Committee heard concerns expressed about the current system of funding disaster relief through emergency supplemental appropriations and the subsequent effects on the federal deficit.

Recommendation 11.5: ***OMB should review the current system of funding disaster relief; consideration should be given to encouraging the National Science Foundation to support a review.***

Floodplain Agriculture

The role of the federal farm programs in influencing sound floodplain management continues to receive great attention. Other federal policies, however, also affect land-use decisions. Data currently exist to support research on the effects of federal incentives and disincentives on agricultural production in the floodplain.

Recommendation 11.6: ***USDA should evaluate the impact of federal farm programs on agricultural land use decisions in and out of the floodplain.***

Flood Insurance Market Penetration

The Review Committee was not able to obtain definitive information on NFIP market penetration or on who buys flood insurance and who does not and why. Much of the information that is currently available is based on inadequate information, personal observation, or speculation. This knowledge is critical to developing strategies to increase compliance with the mandatory purchase requirements and to increase voluntary purchase of flood insurance.

Recommendation 11.7: ***FEMA should conduct research on the issue of NFIP market penetration to determine who buys flood insurance and who does not and why.***

Other Research and Analysis Needs

The Review Committee's investigation revealed several other areas in which research is needed, as described in the following recommendation.

Recommendation 11.8: ***The National Science Foundation should consider funding research on the following subjects:***

- ***Full accounting of all public and private benefits and costs of floodplain occupancy and associated floodplain management measures, including both monetary and non-monetary methods of accounting,***
- ***Mapping and regulating areas with movable stream channels and storm drainage overflow and backup,***
- ***Special impacts of floods, including epidemiological and mental health factors, and***
- ***The feasibility and effectiveness of the use of meteorologic data and geomorphic and botanical evidence in conjunction with hydrologic and hydraulic models to estimate flood frequency.***

5. Smith, V. Kerry, "Nonmarket Valuation of Environmental Resources: An Interpretive Appraisal," Land Economics, 69(1): 1-26 (February 1993); Ribando, Marc O., and Daniel Hellerstein, *Estimating Water Quality Benefits: Theoretical and Methodological Issues*, Technical Bulletin 1808, (Washington, DC: USDA Economic Research Service, September 1992).

6. The interagency Economics Advisory Group pointed out that although methods exist for qualifying and monetizing environmental benefits in terms of both direct and indirect uses, these methods have not been applied to all areas for which monetized values are desired. Any application, however, requires a clear definition of the ecological effects that result from alternative actions. This is usually obtainable for impacts of national significance. It becomes difficult for lesser effects and smaller projects where the biological increments of change are small. Without a clear definition, survey responses about the value of hypothetical environmental changes will be unreliable.

Chapter 12

A FLOODPLAIN ACTION PLAN

Any great disaster or problem usually produces a by-product called "opportunity". This is no less true today as we review the Great Flood of 1993 and our policies for managing floodplains.

Jim Edgar
Governor of Illinois, June 1994

The Review Committee advocates a new approach to managing the floodplains and related watersheds of the nation. This approach involves a shared challenge. The situation that exists on floodplains today is the result of past federal policy decisions that were successful in achieving past national goals changed. In evaluating ongoing and future floodplain management, the nation must recognize not only that these shifts and changes have occurred but that no action taken today should reduce the opportunity for future adjustments in national goals and purposes. The Review Committee presents a vision for floodplain management that meets these goals.

Achieving this vision of floodplain management will require cooperative action by the Congress, the Executive branch, and the states. The vision and supporting action plan formulated by the Review Committee are interrelated and interactive. Partial success is possible with piecemeal application, but attaining the vision requires complete implementation by all parties in a timely fashion.

The theme developed by the Review Committee is that government at all levels and individuals must share the responsibility of appropriately managing land and water resources to reduce the nation's vulnerability to flood disasters. Coordination of environmental, social, and economic planning is essential to maximize efficiency, equitably share burdens, and distribute responsibility.

The Review Committee calls upon Congress to act on a legislative agenda designed to maximize the efficiency and effectiveness of existing programs, respond to identified gaps with new programs, and provide funding to enable existing programs to function as designed. Major legislative actions requested include:

- Enactment of a Floodplain Management Act to coordinate federal-state actions, and
- Amendments to the NFIP to reduce moral hazard problems and to decrease federal disaster expenditures.

The Review Committee recognizes that these requests require analysis and deliberation by the Congress. Although action is desirable sooner rather than later on these actions, which are indispensable components of the new direction in floodplain management, delay in enactment will not prevent commencement of the policy shift proposed by the Review Committee.

The Review Committee also asks the Executive branch of the government to make changes. The Executive Office of the President can have an immediate impact on floodplain management by promptly implementing the following changes:

- Revitalizing the Water Resources Council to Coordinate and direct federal plans for water management;
- Reestablishing basin commissions;
- Reissuing an expanded EO 11988; and
- Establishing new objectives for *Principles and Guidelines.*

Concurrent with these actions by the President, the Review Committee asks federal agencies involved with water resource and floodplain issues to convene interagency task forces to coordinate activities presently conducted independently. In addition, suggested changes in federal regulations will further the goals of floodplain management programs.

The need for reform in floodplain management is great and the number of proposed actions considerable. Timing, an essential element, is critical. The first step is to get moving and begin the needed changes.

ACTION OUTLINE

CONGRESSIONAL ACTIONS

Legislative Actions

Floodplain Vision/Resource Planning:

- Enact a national Floodplain Management Act (Action 5.1);
- Continue and expand conservation and voluntary land acquistion programs in the Farm Bill, focusing on critical lands (Action 6.3); and
- Support insurance coverage for mitigation actions necessary to comply with local floodplain management regulations (Action 8.9).

Operations:

- Revise Section 1134 of the Water Resource Development Act of 1986 to provide for phase-out of federal leases in the floodplain (Action 5.6);
- For communities not in the NFIP, limit public assistance grants (Action 5.7);
- Provide authority for loans for the upgrade of infrastructure and other public facilities (Action 5.9);
- Enact legislation allowing cost share participation and eligibility requirements under Sections 1135 and 906 of the WRDA of 1986 to include federal, state, and non-governmental contributions (Action 7.7);
- Provide states the option of receiving FEMA Section 404 Hazard Mitigation Grants as a block grant (Action 8.5);
- Provide funds in major disasters where supplemental appropriations are made for buyouts and hazard mitigation, through FEMA's Section 404 Hazard Mitigation Grant Program (Action 8.6);
- Provide authority to reduce the amount of post-disaster support to those who could have bought flood insurance but did not, to that level needed to provide for immediate health, safety, and welfare; provide a safety net for low-income flood victims (Action 9.5);
- Continue to support reform of Federal Crop Insurance that limits crop disaster assistance payments, increases participation, and makes the program more actuarially sound (Action 9.8); and
- Establish the UMR&T project (Action 10.5).

Floodplain Management Funding:

- Provide authority for flexibility in use of programmed funds in emergency situations (Action 7.4).

Planning, Coordination, and Hazard Mitigation:

- Establish a programmatic buyout and hazard mitigation program with funding authorities independent of disaster declarations (Action 8.7);
- Increase the NFIP market penetration through improved lender compliance with the mandatory purchase requirement (Action 9.2); and
- Provide for the escrow of flood insurance premiums or payment plans to help make flood insurance affordable (Action 9.3).

EXECUTIVE BRANCH ACTIONS

Administrative Actions

Leadership, Policy, Planning and Coordination:

- Revitalize the Water Resources Council (Action 5.2);
- Reestablish the basin commissions in a revised form reflecting current needs (Action 5.3);
- Issue a new Executive Order to reaffirm the federal government's commitment to floodplain management with an expanded scope (Action 5.4);
- Direct all federal agencies to conduct an assessment of the vulnerability of flooding using a scientific sample of federal facilities and those state and local facilities constructed wholly or in part with federal aid (Action 5.5);
- Establish new co-equal objectives for planning water resources projects under the Principles and Guidelines document to enhance national economic development and enhance the quality of the environment (Action 5.10);
- Establish a lead agency for coordinating acquisition of title and easements to lands acquired for environmental purposes (Action 7.1);
- Allocate funds for mitigation lands in concert with and at same pace as project construction (Action 7.8);
- Establish the USACE as the principal federal levee construction agency (Action 8.1);
- Establish upper Mississippi and Missouri basin commissions (Action 10.1);
- Expand the mission of the Mississippi River Commission to include the upper Mississippi and Missouri Rivers. Expand Commission membership to include the DOI (Action 10.2);
- Assign responsibility for development of an upper Mississippi River and tributary system plan for a major maintenance and major rehabilitation program for federally related levees to an expanded Mississippi River Commission, operating under the USACE (Action 10.3); and

- Seek approval from the Congress to redirect the USACE Floodplain Management Assessment of the upper Mississippi River Basin to development of the UMR&T system plan. Place this assessment under the expanded Mississippi River Commission (Action 10.4).

Operations

- Propose supplementing, with appropriated funds, funds obtained for floodplain mapping from NFIP policyholders (Action 6.7);
- Develop emergency implementation procedures to organize federal agencies for environmental land acquisitions (Action 7.2);
- Require agencies to co-fund ecosystem management using Operation and Maintenance funds (Action 7.6);
- Support the USGS in development and acquisition of detailed digital topographic data and other land characteristics for use in floodplain management and other water resources management activities (Action 11.5); and
- Direct that scientific research be conducted to identify state-of-the-art techniques or applications for estimating and assessing environmental and social impacts (Action 11.6).

Disaster Relief/Recovery:

- Provide funding for the development of state and community floodplain management and hazard mitigation plans (Action 6.5);
- Reaffirm support for the USACE criteria under the PL 84-99 levee repair program and send a clear message that future exceptions will not be made (Action 8.2); and
- Hold an interagency strategic planning meeting for those Presidentially declared disasters that require a multi-agency recovery effort (Action 9.1).

Interagency Activities

Policy, Planning, and Coordination:

- Establish interdisciplinary interagency review of the *P&G* document by affected agency representatives with regard to the potential structural vs. nonstructural project bias, inclusion of a system of accounts, inclusion of collaborative planning, and expansion of *P&G* application to water and related land programs, projects, and activities (Action 5.11);
- Establish an interagency task force, jointly chaired by the USDA and EPA, to formulate a coordinated, comprehensive approach to multiple objective watershed management (Action 6.1);
- Coordinate and support federal riverine and riparian restoration (Action 6.2);
- Formalize environmental considerations in multi-agency restoration activity through a coordinated Memorandum of Agreement (Action 7.3);
- Restrict support of floodfighting to those levees that have been approved for floodfighting by the USACE (Action 8.3);
- Establish a task force to develop common procedures for federal buyouts and mitigation programs (Action 8.4);
- Select an ecosystem management demonstration project within the upper Mississippi River Basin and establish a cross-agency ecosystem

management team under the DOI to develop plans and budgets for the project (Action 10.9);

- Continue development of basin-wide hydrologic, hydraulic, and hydrometerologic models for the upper Mississippi River system (Action 11.3);
- Review the current standards for computing discharge-frequency relationships in light of observations from the 1993 flood and other recent large floods in the upper Mississippi River Basin (Action 11.4); and
- Evaluate the effect of natural upstream storage and floodplain storage in such areas as wetlands and forested wetlands on main stem flooding (Action 11.7).

Individual Agencies

Federal Emergency Management Agency:

- Encourage communities to obtain affordable private insurance for infrastructure as a prerequisite to receiving public assistance (Action 5.8);
- Promote the NFIP Community Rating System as a means of encouraging communities to develop floodplain management and hazard-mitigation plans and incorporate floodplain management concerns into their ongoing community planning and decisionmaking (Action 6.4);
- Map all communities with flood hazard areas that are developed or could be developed (Action 6.6);
- Utilize technology to improve floodplain mapping (Action 6.8);
- Continue to enforce substantial damage requirements, but decide on a definition of substantial damage and stick to that definition (Action 8.8);
- Develop a program to reduce losses to repetitively damaged insured properties through insurance surcharges, increased deductibles, mitigation insurance, and/or mitigation actions (Action 8.10);
- Develop improved marketing techniques for NFIP (Action 9.4);
- Require actuarially based flood insurance behind all levees that provide protection less than the standard project flood (Action 9.6);
- Increase the 5-day waiting period for flood insurance coverage to at least 15 days (Action 9.7); and
- Investigate the costs and feasibility of completing a national inventory of floodprone structures (Action 11.2).

U.S. Army Corps of Engineers:

- Provide an early report in the Upper Mississippi-Illinois Waterway Navigation Study of environmental enhancement opportunities in the upper Mississippi River (Action 10.7); and
- Provide a report on the ecological effects of relocating navigation pool control points under the Navigation Rehabilitation Study (Action 10.8).

U.S. Department of the Interior:

- Focus land acquisition efforts on river reaches and areas with significant habitat values or resource impacts (Action 7.5); and
- Complete an ecological needs investigation of the upper Mississippi River Basin and provide a report to the Administration within 30 months (Action 10.6).

U.S. Geological Survey (DOI):

- Establish a federal clearinghouse for data gathered during preparation of the Review Committee report (Action 11.1).

Chapter 13

COST ANALYSIS

Some of the recommended actions may result in increased costs to the federal government as well as to states, non-federal sponsors, and individual floodplain occupants. Many of the costs will be incurred over the next few years but will ultimately result in savings to the same parties for many years in the future. Many also reflect the cost of normal business or operations. Costs have been estimated for certain significant actions such as the enactment of a national Floodplain Management Act (Action 5.1), revitalizing the Water Resources Council (Action 5.2), and reestablishing basin commissions (Action 5.3). The cost details for Action 5.1 are found in Appendix D and for Actions 5.2 and 5.3 in Appendix I. The Review Committee did not have the time or resources to develop specific costs for all of the proposed actions. The details of specific action implementation should be analyzed and the costs estimated by those who will administer these actions.

Table 13.1 attempts to identify where additional costs to the federal government are likely and where potential savings, to whomever they may accrue, may occur. This additional cost commitment may take the form of a shift in priorities for human resources or a cost of normal Washington level attention and coordination. These items are annotated with the abbreviations "SIP" for shift in priorities and "CNB" for cost of normal business. For some actions, however, increased federal government costs are required and are identified in the table by the abbreviation "IC" for increased cost.

Potential savings for each recommended action are handled similar to the cost column and abbreviations for the areas of savings are as follows: environmental enhancements (EE); improved customer assistance (ICA); increased efficiencies (IE); reduced claims payments (RCP); reduced disaster assistance (RDA); reduced environmental impact (REI); and reduced flood damages (RDA).

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee

ACTIONS	ADDITIONAL COSTS TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 5.1: Enact a national Floodplain Management Act to define governmental responsibilities, strengthen federal-state coordination and assure accountability.	IC	ICA, IE, RDA, REI, RFD
Action 5.2: Revitalize the Water Resources Council.	IC	ICA, IE, REI
Action 5.3: Reestablish Basin Commissions in a revised form reflecting current needs.	CNB, IC, SIP	ICA, IE, REI
Action 5.4: Issue a new Executive Order to reaffirm the federal government's commitment to floodplain management with an expanded scope	CNB, SIP	RDA, REI, RFD
Action 5.5: OMB should direct all federal agencies to conduct an assessment of the vulnerability of flooding using a scientific sample of federal facilities and those state and local facilities constructed wholly or in part with federal aid.	CNB, SIP	RFD
Action 5.6: Seek revision of Section 1134 of the Water Resources Development Act of 1986 to provide for phase-out of federal leases in the floodplain.	CNB	RDA, REI, RFD
Action 5.7: For communities not participating in the NFIP, limit public assistance grants.	CNB	RDA
Action 5.8: Encourage communities to obtain affordable private insurance for infrastructure as a prerequisite to receiving public assistance.	CBE	RDA
Action 5.9: Provide loans for the upgrade of infrastructure and other public facilities.	CBE	RDA

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee (continued)

ACTIONS	ADDITIONAL COSTS TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 5.10: Establish as the new, co-equal objectives for planning water resources projects under Principles and Guidelines: (1) To enhance national economic development by increasing the value of the Nation's output of goods and services and improving national economic efficiency, and (2) To enhance the quality of the environment by the management, conservation, preservation, creation, restoration, or improvement of the quality of natural and cultural resources and ecological systems.	CNB, SIP	EE, ICA, REI
Action 5.11: Establish interdisciplinary, interagency review of the *P&G* by affected agency representatives to address: (1) Structural versus non-structural project bias; (2) Inclusion of system of accounts or a similar mechanism for displaying impacts; (3) Inclusion of collaborative planning in an ecosystems context for major studies; and (4) Expansion of the application of the revised *P&G* to water and land programs, projects, and activities to include: (a) All federally constructed watershed and water and land programs; (b) National parks and recreation areas; (c) Wild, scenic, recreational rivers and wilderness areas; (d) Wetland and estuary projects and coastal zones; and (e) National refuges.	CNB, SIP	EE, ICA, IE, REI
Action 6.1: The Administration should establish an interagency task force, jointly chaired by the USDA and EPA, to formulate a coordinated, comprehensive approach to multiple objective watershed management.	CNB	ICA, IE

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee (continued)

ACTIONS	ADDITIONAL COSTS TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 6.2: The DOI, USDA, and EPA should coordinate and support federal urban and suburban stream and riparian area restoration.	CNB	EE
Action 6.3: The Administration's legislative proposals for the 1995 Farm Bill should support continuation and expansion of conservation and voluntary acquisition programs focused on critical lands within watersheds.	IC	EE, REI, RFD
Action 6.5: Provide funding for the development of state and community floodplain management and hazard mitigation plans.	IC	ICA, IE, REI, RDA, RFD
Action 6.6: Map all communities with flood hazard areas that are developed or could be developed.	IC	ICA, IE, RDA, REI, RFD
Action 6.7: To improve and accelerate delivery of NFIP map products, the Administration should propose supplementing those funds obtained for floodplain mapping from NFIP policyholders with appropriated funds.	IC	ICA, IE, RDA, REI, RFD
Action 6.8: Utilize technology to improve floodplain mapping.	IC	ICA, IE, RDA, REI, RFD
Action 7.1: The Administration should establish a lead agency coordinating acquisition of title and easements to lands acquired for environmental purposes.	CNB	EE, ICA, IE, RCP, RDA, REI, RFD
Action 7.2: The Administration should develop emergency implementation procedures to organize federal agencies for environmental land acquisitions.	CNB	IE
Action 7.3: The DOI should formalize environmental considerations in multi-agency disaster recovery land restoration activity through a coordinated Memorandum of Agreement.	CNB	EE, IE, REI

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee (continued)

ACTIONS	ADDITIONAL COST TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 7.4: Seek legislative authority for flexibility in use of programmed funds in emergency situations.	CNB	EE, ICA, REI
Action 7.5: The DOI should focus land acquisition efforts on river reaches and areas with significant habitat values or resource impacts.	CNB	EE, REI
Action 7.7: Enact legislation allowing cost-share participation and eligibility requirements under Sections 906 and 1135 of the 1986 WRDA to include federal, state, and non-governmental contributions as well as work in-kind.	CNB, SIP	EE, ICA, REI
Action 8.2: The Administration should reaffirm its support for the USACE criteria under the PL 84-99 levee repair program and send a clear message that future exceptions will not be made.	CNB	IE, RDA
Action 8.3: Federal and state officials should restrict support of floodfighting to those levees that have been approved for floodfighting by the USACE.	CNB	IE
Action 8.4: Establish a task force to develop common procedures for federal buyouts and mitigation programs.	CNB, SIP	ICA, IE
Action 8.5: Provide states the option of receiving Section 404 Hazard Mitigation Grants as a block grant.	CNB	ICA, IE
Action 8.6: Provide funds in major disasters where supplemental appropriations are made for buyouts and hazard mitigation, through FEMA's Section 404 Hazard Mitigation Grant Program.	CNB	ICA, IE
Action 8.7: Establish a programmatic buyout and hazard mitigation program with funding authorities independent of disaster declarations.	CNB, SIP	IE, RCP, RDA, REI
Action 8.8: The FEMA should continue to enforce substantial damage requirements, but decide on a definition of substantial damage and stick to that definition.	CNB	RCP, RDA

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee (continued)

ACTIONS	ADDITIONAL COSTS TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 8.9: The Administration should support insurance coverage for mitigation actions necessary to comply with local floodplain management regulations.	CNB	IE, RCP, RDA, RFD
Action 8.10: Develop a program to reduce losses to repetitively damaged insured properties through insurance surcharges, increased deductibles, mitigation insurance, and/or mitigation actions.	CNB, SIP	RCP, RDA, REI
Action 9.3: Provide for the escrow of flood insurance premiums or payment plans to help make flood insurance affordable.	CNB	ICA, IE, RDA
Action 9.4: Develop improved marketing techniques.	CNB	ICA, RDA
Action 9.5: Reduce the amount of post-disaster support to those who could have bought flood insurance but did not to that level needed to provide for immediate health, safety, and welfare; provide a safety net for low-income flood victims.	CNB	IE, RDA
Action 9.6: Require actuarial-based flood insurance behind all levees that provide protection less than the standard project flood.	IC	ICA, RDA
Action 9.7: Increase the 5-day waiting period for flood insurance coverage to at least 15 days.	CNB	IE, RCP
Action 9.8: Administration should continue to support reform of Federal Crop Insurance that limits crop disaster assistance payments, increases participation, and makes the program more actuarially sound.	IC	ICA, IE
Action 10.1: Establish upper Mississippi and Missouri basin commissions with a charge to coordinate development and maintenance of comprehensive water resources management plans to include, among other purposes, ecosystem management, flood damage reduction, and navigation.	IC	ICA, IE, REI

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee (continued)

ACTIONS	ADDITIONAL COSTS TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 10.2: The Administration should expand the mission of the Mississippi River Commission to include the upper Mississippi and Missouri rivers. Further, to recognize ecosystem management as a co-equal federal interest with flood damage reduction and navigation, the Administration should request legislative change to expand commission membership to include the DOI.	IC, SIP	ICA, IE, REI
Action 10.3: Assign responsibility for development of an Upper Mississippi River and Tributaries (UMR&T) system plan and for a major maintenance and major rehabilitation program for federally related levees to an expanded Mississippi River Commission, operating under the USACE.	IC, SIP	EE, ICA, IE, RDA, REI, RFD
Action 10.4: Seek approval from the Congress to redirect the USACE Floodplain Management Assessment of the upper Mississippi River Basin to development of an UMR&T systems plan. Place this assessment under the Mississippi River Commission, operating the USACE.	CNB, SIP	ICA, IE
Action 10.5: Following completion of the survey, seek authorization from the Congress to establish the UMR&T project.	CNB	ICA,IE, RDA, REI, RFD
Action 10.6: DOI should complete an ecological needs investigation of the upper Mississippi River Basin and provide a report to the Administration within 30 months.	CNB, SIP	ICA, REI
Action 10.7: Provide an early report in the USACE Upper Mississippi River - Illinois Waterway Navigation Study of environmental enhancement opportunities in the upper Mississippi River.	CNB	EE, REI
Action 10.8: Provide a report on the ecological effects of relocating navigation pool control points under the USACE Navigation Rehabilitation Study.	CNB	EE, REI

Table 13.1 Fiscal Impact of Actions Recommended by the Review Committee (continued)

ACTIONS	ADDITIONAL COSTS TO FEDERAL GOVERNMENT	POTENTIAL SAVINGS
Action 10.9: The Administration Interagency Ecosystem Management Task Force should select an Ecosystem Management Demonstration Project within the upper Mississippi River Basin and establish a cross-agency ecosystem management team under the DOI to develop plans and budgets for the project.	CNB, SIP	EE, ICA
Action 11.1: The USGS should establish a federal clearinghouse for data gathered during preparation of the Review Committee report.	IC	ICA, IE, REI
Action 11.2: FEMA should investigate the costs and feasibility of completing a national inventory of floodprone structures.	CNB	ICA, IE, RDA, RFD
Action 11.6: The Administration should direct that scientific research be conducted to identify state-of-the-art techniques or applications for estimating and assessing environmental and social impacts.	CNB, SIP	EE, ICA, IE, REI
Action 11.7: The USACE and USDA, in collaboration with the DOI, should evaluate the effect of natural upstream storage and floodplain storage in such areas as wetlands and forested wetland on mainstem flooding.	CNB, SIP	EE, ICA, RDA, REI, RFD

LEGEND:

COSTS

CBE: Cannot Be Estimated
CNB: Cost of Normal Business
IC: Increased Cost
SIP: Shift in Priorities

SAVINGS

EE: Environmental Enhancement
ICA: Improved Customer Assistance
IE: Increased Efficiency
RCP: Reduced Claims Payment
RDA: Reduced Disaster Assistance
REI: Reduced Environmental Impact
RFD: Reduced Flood Damages

Chapter 14

PERCEPTIONS, IDEAS, AND PROPOSALS

From the outset of this review, the Floodplain Management Review Committee has benefited from the support of hundreds of individuals and groups, many of which had strong opinions on what should be done to solve the problems of the floodplain. With less than five months to complete its review, the Review Committee was unable to address each and every issue raised. Some concerns clearly merited further study, and Chapter 11 describes needed analysis and research.

Other issues were deemed beyond the scope of the Review Committee's charge, but nonetheless deserve consideration in the on-going debate about the management of the nation's resources. Should steps be taken to reduce or eliminate federal subsidies of floodplain activities? Have government programs induced inappropriate floodplain usage by shifting the consequences of certain actions from individuals to the federal government? Should the contribution of local interests to construction and repair of flood control structures be increased? Should disaster funding policies and procedures within the federal budget process be changed?

FEDERAL FARM PROGRAMS

Throughout the review, some federal economists and many non-federal groups have proposed phasing out federal subsidies in general and federal farm program payments in particular to floodplain activities, because they represent intrusions into the free market by distorting incentives and thus may encourage floodplain activity. The Review Committee did examine the role of federal farm programs as they influence individual farmers' decisions to farm in bottomlands. The study looked at both program payments and the support provided to farmers by federal levee repairs.

Each agricultural producer in the floodplain makes farming decisions based on a collection of factors, many of which differ from location to location. Input prices tend to be the same at all locations, but production practices and potential yields depend on the characteristics of the land. Cash receipts will depend on whether the farmer participates in a crop price support program. In addition, the level of flood protection will determine whether a given year's yield will be realized and what the expected flood damages will be. From a farmer's perspective, the viability of farming a particular area depends on the net income that can be earned. Government programs for price and income support, levees, drainage, technical assistance, subsidized crop insurance premiums, and crop disaster assistance all serve to lower the cost of farming on the floodplain.

Many agricultural levees were constructed and maintained by local districts with no use of federal or state funds prior to 1993, so those flood control structures cannot be considered as part of a past subsidy to floodplain agriculture. If these levees are repaired with federal funds, the added benefit would reduce future production costs for the farmer. Farm programs offer a producer higher profits for growing certain crops, so the type of bottomland agriculture is also influenced by government policies. Farmers with lower levels of flood protection may switch to alternative crops such as growing biomass fuel. The economic viability of such choices is currently being studied. Site characteristics and government policies will determine a farmer's choices. Programs offering easements, levee set-backs, or "green" payments will have to take factors affecting farmer decisions into account.

Preliminary results from a study funded by EPA and being conducted by the Center for Agricultural and Rural Development at Iowa State University and the Center for National Food and Agricultural Policy at University of Missouri - Columbia indicate that in some areas participation in federal farm programs and the existence of levees will determine whether a crop is grown and which crop is chosen. In other areas of the floodplain, agriculture would be profitable even without participation in any farm or levee program.

Elimination of federal farm programs for floodplain farmers might make operations less viable and might influence some to leave the floodplain. It appeared to the Review Committee that it would be difficult to determine which floodplain farmers should not receive program payments. A substantial portion of American farming is in the floodplain. Much of the agricultural base of Missouri, Arkansas, Mississippi, and Louisiana exists in the floodplain. If the intent of removing payments or subsidies is to alter behavior that is believed to contribute to environmental problems, then it might be more productive to remove payments or offer "green payments" in areas where agriculture operates under less than optimal conditions, e.g., highly erodible land, drylands, etc.

While the issue of the merits of federal farm programs is important, it merits airing in a context lager than the floodplain and with a greater recognition of the difficulties of selective application of any such policy.[1]

MORAL HAZARD

In providing support for a range of floodplain activities, does government create a "moral hazard?" This phrase is used in the insurance industry describe the situation when an insured party has lower incentive to avoid risk because an enhanced level of protection is provided.

If an individual or government entity does not bear the financial consequences of an action there is little reason to mitigate the danger; therefore, the insured party is more likely to be at risk (or will expend too little effort to avoid risk) than one who has to bear all consequences. The insurance provider usually has few ways of observing whether proper care or precautions are taken. Private insurance companies deal with the moral-hazard problem by offering less than full coverage and requiring payments (deductibles) which increase the policyholder's incentive to take protective measures. Another way that insurance providers cope with moral hazard is to base each period's premiums on claims from previous periods. This method increases the policy holder's level or risk avoidance. Some federal provision of hazard insurance is subsidized through reduced premiums and administrative fees which lowers an individual's stake in avoiding harm. The availability of supplementary compensation diminishes the efficiency of insurance to encourage risk sharing. The Review Committee recognizes that through provision of disaster assistance and, in some cases, enhanced flood protection, the government may in fact be reducing incentives for local governments and individuals to be more prudent in their actions. The subject was discussed frequently in the field and with many of the Review Committee's advisors but without resolution. Some older studies have indicated that the presence of federal support does not create a disincentive to buy flood insurance. The Review Committee has sought to reduce the moral hazard through recommendations that limit disaster assistance and propose loans rather than grants for infrastructure upgrades. The Review Committee notes the potential for moral hazards to develop and cautions agencies involved in floodplain management to be aware of this potential.

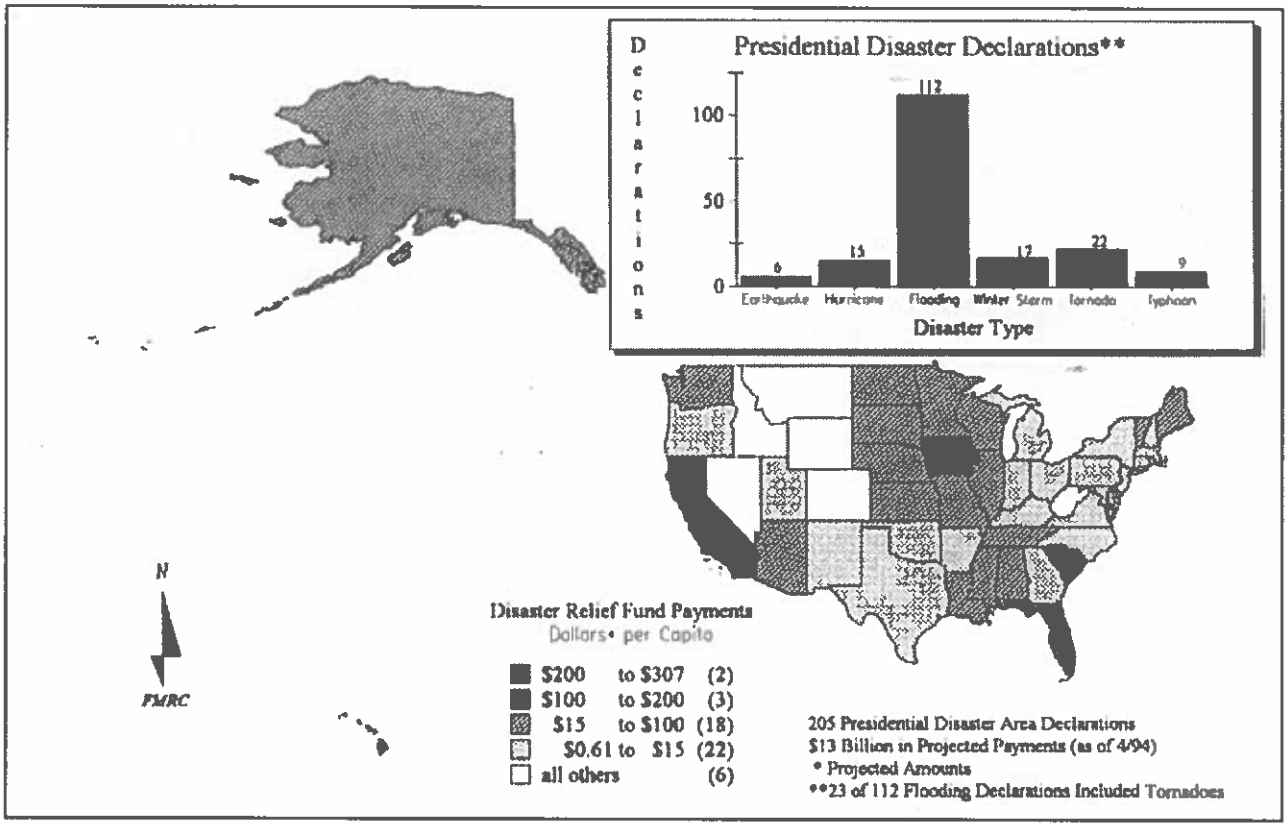
FEDERAL FISCAL ROLE IN FLOOD CONTROL

Some people state that the federal government's role in funding flood control projects should be limited to paying costs related to federal benefits, with responsibility for costs associated with regional and local benefits falling to the local sponsor.[2] At present, under the provisions of the Water Resources Development Act of 1986, cost-sharing

for flood control projects is set at a local contribution of not less than 25 percent and not more than 50 percent, depending on the circumstances. Levee repairs, carried out under the provisions of PL 84-99 by the USACE, require a 20 percent local contribution, although the requirement for cost-sharing was determined by the Administration, not the Congress.

The federal interest in flood control was stated most clearly by the Flood Control Act of 1936, "...the Federal Government should improve or participate in the improvement of navigable waters or their tributaries...for flood control purposes if the benefits to whomsoever they may accrue are in excess of the estimated costs..." The rationale for this federal involvement was based in part on the magnitude of the physical threat and potential damages to the nation from flooding, and in part on recognition that navigable waters are interstate and activities in one area can have major effects on other areas.

The Congress, working with The Administration, has set cost-sharing rules based on congressional and Administration determinations as to the nature of the threat and the ability of state and local governments to bear the costs of projects rather than on the allocation of net benefits. The Review Committee recognizes that shifts in cost-sharing formulas would alter floodplain behavior but had neither the time to analyze nor the resources to develop any rationale for changing the existing cost-share arrangements.



FUNDING DISASTERS

Natural disasters in the United States are costly events in terms of both human lives lost and property damaged. From FY 1989 through FY 1993, over $27.6 billion has been spent on federal disaster assistance programs. Figure 14.1 shows the number of Presidential declarations over the past five years by disaster type and the dollars per capita that went to disaster relief payments for each state under the FEMA program. Although flood declarations comprised the majority of Presidential disasters declarations, earthquakes (California) and hurricanes (South Carolina, Florida) have caused greater per capita damage. All but six states experienced disasters severe enough to warrant Presidential declarations. States in the northeast battled coastal flooding while the south recovered from hurricanes and the midwest from floods.

The rising frequency and costs of natural disasters have prompted a variety of concerns. Some have questioned the federal government's role in funding disaster recovery, citing the potential for rising expenditures in an era of budgetary restraint, the possible incentives that federal relief creates for people to locate in disaster-prone areas, and the potential for elements of federal, state, and local government to rely on disaster relief for infrastructure repair. Others, assuming that a federal obligation to fund recovery exists, point to hazard mitigation as a cost-effective alternative to providing disaster assistance. Funding preventive measures such as relocating structures out of the floodplain can decrease the demand for disaster relief.

Although congressional budgetary reform policies are outside the scope of this report, the Review Committee frequently heard concerns expressed about the current system of funding disaster relief through emergency supplemental appropriations, exempting disaster relief from the scrutiny received by other spending, while permitting it to add to the federal deficit. This situation also may create an incentive for federal agencies to accept backlogs in maintenance for activities in disaster prone areas, recognizing that an emergency spending opportunity for catching up may occur. The OMB should support study of and attention to the long-term implications of the 'above-cap' funding process.

Figure 14.1 Presidential Disaster Declarations, 1989-1993

Source: Federal Emergency Management Agency. April 1994.

PEOPLE, THE MEDIA, AND THE FEDERAL FLOOD RESPONSE

Compassion plays a major role in the way people respond to disasters and rush to provide disaster relief. The speed with which the entire nation learns of disasters is almost immediate. For example, because of the television coverage of the 1989 World Series, those watching had the experience of actually being present during a major earthquake. As for the 1993 floods, the nation can remember pictures carried by CNN of the house being swept away when a levee was breached. Viewers were left wondering how this could happen rather than why the house was there in the first place.

The best media flood-relief stories became those of suffering people and those complaining about the lack of quick government assistance. Politicians and decision-makers were bombarded with calls and they responded by declaring additional counties part of the disaster area and by promising quick relief. FEMA Disaster Field Offices, set up in many cities and towns, were themselves flooded with applications for disaster relief. The media attention helped agencies get needed information to citizens, but also may have increased expectations about the level of assistance that was available or the speed at which help could be provided.

Human compassion and the way news is reported influences how Congress and the nation respond to disasters. A great push arose to replace levees along the Missouri River, many of which should not be replaced without careful design and engineering considerations. If federal response to disaster relief is driven by the immediacy of an event, rather than by rational

decisionmaking, the effort to put everything back to the way it was may increase future risk rather than promote long-term solutions to risk reduction. In the haste of some disaster relief and under the pressure of the media effect, the nation may have subsidized some bad decisions and penalized some good ones, foregoing opportunities for change. A caring, supportive approach for disaster victims must never be lost; but there must be, in tandem, an effort to ensure decisionmaking that reflects long-term as well as short-term goals.

NON-URBAN LEVEES

Congressional and Administration support of the 1993 supplemental appropriations for PL 84-99 clearly indicates strong support for that program. Several groups in and outside the federal government, however, proposed eliminating all federal support of levee repairs under PL 84-99. Lack of federal post-disaster support probably would result in eventual economic failure for some previously protected land and a gradual conversion of formerly protected land from agriculture to natural areas, which in turn could provide additional flood storage and reduce future agricultural flood damages.

Before a levee can be repaired, on a cost-shared basis, under PL 84-99, the USACE or SCS must conduct an economic analysis indicating that the benefits of the repair outweigh the costs. This requirement mirrors the requirements for new construction, but looks only at the costs and benefits associated with the emergency repairs. Sponsors of levees that do not meet the benefit-cost test for repairs may not find it profitable to continue to farm, but the action that forced this decision was one based on accepted analysis practices rather than one based on a desire to reallocate the land. Provisions are available under current laws to obtain interest in such land from willing sellers (see Chapter 7).

MISSOURI RIVER BANK STABILIZATION AND NAVIGATION

Clearly, there is a relationship between the Missouri River Bank Stabilization and Navigation Project and the decline of habitat and ecosystems along that river. In recent years the USACE has made efforts to adjust operation of the system to better accommodate environmental concerns. Nevertheless, during the course of its review, the Review Committee encountered many individuals and several conservation agencies that believe the economic and social benefits derived from the project do not outweigh the environmental costs associated with it. The Review Committee reviewed benefit-cost calculations for the navigation component of the project prepared by the USACE Institute for Water Resources using the current *Principles and Guidelines* procedures for the reach of the river between Sioux City, Iowa, and Kansas City. This analysis indicated that, using the existing procedures, there is a favorable ratio, even when navigation tonnage involving river operations and bank stabilization benefits is excluded. The Review Committee recognizes that the USACE is in the process of completing its multi-year study of the water control operations of the Missouri River main stem reservoir system and is about to release a draft Environmental Impact Statement (EIS) covering the program of releases from the reservoirs and their relationship to the ecology of the river, navigation, hydropower, flood control, water supply, and recreation. Discussions with the USACE indicate that the draft EIS will address many environmental concerns. The 'Master Manual' review study is being conducted under a full public involvement process in accordance with the NEPA. The Review Committee believes it would be appropriate for the USACE, after completion of the action on the 'Master Manual,' to conduct an analysis of potential modifications to the structural components of the navigation system to determine what benefits can be obtained through these actions. The USACE should also, under the recommended procedures for project review (Chapter 5), conduct an analysis, by reach, of the total benefits and costs of navigation operations on the Missouri River.

PROPERTY RIGHTS

Two senior members of Congress expressed to the Review Committee a concern felt by many individuals who also corresponded with the Review Committee.

> The respect and adherence to the rights of property owners as drafted in our Constitution are of central importance to the federal government's role in floodplain management. Any acquisition of lands, expansion of wetlands, and the purchase of easements and rights-of-way should be done with adequate compensation to the landowner. Likewise, the federal government should refrain from the use of condemnation when attempting to move residents out of the floodplain. Any expansion of buyout and relocation initiatives must be carried out on a willing-seller basis.

There has been no suggestion in this report that either land or property be condemned by the federal government. Sound floodplain management will result from a strong partnership among federal, state/tribal and local governments and the private citizens of the nation. Decisions on land acquisitions should result from consultations within this partnership. The recommendations of this report tie all federal acquisitions of land or property for environmental or relocation purposes to a willing-seller scenario.

The report recognizes that the federal government should not support fiscally the rebuilding of some flood damaged structures, to include levees and homes, when it does not make economic or engineering sense. To some, this failure to support rebuilding is seen as an abridgement of the rights of the owners of the property. The Review Committee does not see this to be the case. Some individuals have stated that the federal government's failure to repair their flood-damaged levees, even though they were ineligible for participation in one of the emergency programs, constitutes an abridgement of their entitlement to these repairs and thus a violation of their property rights. The Administration has determined the eligibility criteria for each existing levee repair program. The Review Committee has endorsed the criteria being used by the USACE to determine eligibility for participation in levee repair programs (Action 8.2) and does not see the denial of repairs to be either an entitlement or a property rights issue.

Similarly, some individuals have complained that any restrictions on an individual's or a group's 'right' to floodfight constitutes another possible abridgement of property rights. The Review Committee recognizes the rights of individuals and groups to protect their own property from destruction provided that their actions do not increase flood damages to other groups or individuals. The law concerning protection against a common enemy is complex and the rights and responsibilities of individuals and groups involved in such actions vary widely by state and locality. The Review Committee has recommended that before federal and state governments provide fiscal or in-kind support to floodfights, they ensure that the actions being taken will not have adverse impacts on other groups or individuals. Individuals and groups retain the ability to 'go it on their own' subject to state and community floodplain management regulations (including floodway regulations adopted by communities to participate in the NFIP). These individuals and groups are subject to whatever liability they generate as a result of their actions. Land use controls developed by a community as a result of participation in the NFIP represent community decisions.

Several individuals discussed with the Review Committee their concern that national environmental programs have resulted in a shifting of property from private ownership and that these shifts constituted a taking of sorts. Wherever possible, the Review Committee investigated the comment and could only identify programs in which there had been willing sellers.

ENDNOTES

1. A federal economist notes, in proposing an end to farm program payments, that major institutional changes can be very disruptive and transitions are important in order to minimize disruptions. "People make major investments based on market distortions introduced by subsidies. Eliminating existing subsidies is disruptive and equity requires that beneficiaries be given an opportunity to adjust to the correction of these distortions. However, not eliminating subsidies imposes an unfair burden on the rest of society. Living, working and investing in a floodplain is inherently risky. If people are not confronted with the full cost of such behavior, resources are misallocated and costly inefficiencies result. It is inequitable to ask Federal taxpayers to subsidize and finance such activities."

2. One economist notes, "The Federal Government should not be in the business of financing projects which produce local and/or regional benefits. The Federal Government should establish standards for management of the floodplain. Subject to budgetary constraints, if a proposed project has a benefit-cost ratio greater than one for Federal benefits, the Federal Government should pay for the provision of Federal benefits and locals should pay all other costs."

Chapter 15

INTO THE 21ST CENTURY

The Midwest Flood of 1993 was a significant hydrometeorological event. In some areas it represented an unusual event; in most others, however, it was just another of the many that have been seen before and will be seen again. Flood flows similar to those experienced by most of the Midwest will continue to occur.

Excessive rainfall, which produced standing water, saturated soils, and overland flow, caused major damages to upland agriculture and some communities. In turn, runoff from this rainfall created, throughout the basin, flood events that became a part of the nation's 1993 TV experience. Damages overall were extensive; $12-$16 billion that can be counted and a large amount in the unquantifiable impacts on the health and wellbeing of the population of the Midwest.

Human activities in the floodplains of the Midwest over the last three centuries placed people and property at risk. Loca and federal flood damage-reduction and floodplain management programs reduced the annual risk and, during the 1993 flood, prevented nearly $20 billion in potential damages. Some of these programs, however, have drawn the population to high-risk areas and created greater exposure for future damages. In addition, flood damage-reduction, navigation and agricultural activities have severely reduced available floodplain habitat and have compromised natural functions on which fish and wildlife rely.

Over the last 30 years the nation has learned that effective floodplain management can reduce vulnerability to damages and create a balance among natural and human uses of floodplains and their related watersheds to meet the social and environmental goals of the nation. The nation, however, has not taken advantage of this capability.

The Interagency Floodplain Management Review Committee proposes a better way to manage the nation's floodplains. The report begins with establishing that all levels of government, all businesses, and all citizens interested in the floodplain should have a stake in properly managing this resource. All of those who support the risk, either directly or indirectly, must share in the management and the costs of reducing the risk. The federal government must lead by example; state and local governments must manage the floodplains; and individual citizens must adjust their actions to the risk they face.

The Review Committee supports an approach to floodplain management that replaces a focus on structural solutions with a sequential strategy of avoidance, minimization and mitigation. In many cases, by controlling runoff, managing ecosystems for all their benefits, planning the use of the land, and identifying those areas at risk, the hazard can be avoided. Where the risk cannot be avoided, damage minimization approaches, such as elevation and relocation of buildings, and construction of reservoirs or flood protection structures, are carried out only when they can be integrated into an overall systems approach to flood damage reduction in the basin.

When floods occur, damages to individuals and communities can be mitigated with a flood insurance program that obtains its support from those who are protected. Full disaster support for those in the floodplain is contingent on participation in these self-help mitigation programs. By internalizing these risks, the moral hazard associated with full government support is reduced.

To ensure a long-term, nationwide approach to floodplain management, the Review Committee proposes legislation to develop and fund a national floodplain management

program with principal responsibility and accountability at the state level. It also proposes revitalization of the federal Water Resources Council to better coordinate federal activities, limited restoration of some basin commissions for basin-wide planning, and reissuance of a Presidential Executive Order requiring adherence to floodplain management principles by federal agencies and their programs.

Recognizing that the existing developed condition of the upper Mississippi River Basin includes individually authorized federal flood control projects and levees built by local groups and individuals, the Review Committee also proposes a plan to identify and evaluate the needs of the basin, to ensure the integrity of a flood damage reduction system that meets the needs of the basin, and to restore natural floodplain functions on appropriate lands.

THE 21ST CENTURY FLOODPLAIN

The vision of the 21st Century floodplain described in Chapter 4 can become a reality.

Human activity in the floodplain will continue, but with the clear understanding that any activity is subject to the residual risk of flooding and that the costs of this risk are to be borne by the sponsors of the activity. All new activity will be evaluated for its economic, social, and environmental impacts and its effects on other activities in the floodplain.

The threat to urban centers whose existence depends on the river for commerce or whose locational advantage is tied historically to the floodplain will be reduced by a combination of upstream land treatment, floodways, and floodproofing. In some cases, levees and floodwalls will continue to provide part of the vulnerability reduction. Many sections of these communities, where frequent flooding had been a way of life for the residents, will become river-focused parks and recreation areas as former occupants relocate to safer areas on higher ground. Adherence to strict land-use regulations by the community will stop unwise development.

Those whose homes were at risk in low lying areas outside the urban centers will have moved to higher ground. Outside of the urban areas, industry will protect its own facilities against major floods. The water and wastewater treatment plants, power plants, and major highways and bridges that serve these centers will be elevated out of the flood's reach or protected against it. Much of this infrastructure, as well as the homes, businesses, and agricultural activities located behind most levees, will be insured against flooding through full participation in commercial or federally supported insurance programs.

The floodplain of the 21st Century will be rich in both agriculture and natural systems. At the upstream end of well-maintained levees, federally built water-control structures will permit controlled passage of river waters to keep sloughs wet throughout the year, maintaining and restoring aquatic habitat with resultant benefits for fisheries, waterfowl, and other wildlife. Levees will be modified to provide for controlled overtopping in the event of high water, eliminating the catastrophic failures that occurred in the past. Participation in a federal crop insurance program will protect the agricultural investments.

Some of the lower land will be converted from row crops to alternative crops or silviculture or returned to a natural state under federal or state easements. Many levees that were frequently destroyed in the past by flood waters will be removed or relocated to ensure their integrity or provide for a floodway.

Upland of the floodplain, programs to improve the treatment of lands, control new runoff, and restore wetlands will reduce the flows during frequent floods and shave the peaks off larger events, improving conditions in the floodplain. Both commercial and recreational vessels will continue to ply the river's waters, operating in a navigation system that enhances riverine ecosystems through water-level adjustments and control.

The floodplain will meet the needs of both human and natural systems.

SHARING THE CHALLENGE

The Review Committee has suggested a bold yet realistic and straightforward approach to improving floodplain management:

- Share responsibility and accountability for accomplishing floodplain management among all levels of government and with the citizens of the nation. The federal government can not go it alone, nor should it take a dominant role in the process.

- Establish, as goals for the future, the reduction of the vulnerability of the nation to the dangers and damages that result from floods and the concurrent and integrated preservation and enhancement of the natural resources and functions of floodplains. These goals seek to avoid unwise use of the floodplain, mitigate vulnerability when floodplains must be used, and mitigate those damages that do occur.

- Organize the federal government and its programs to provide the support and the tools necessary for all levels to carry out and participate in effective floodplain management.

The tools, authorities and programs are available at the federal, state, tribal, and local level to move toward accomplishment of these goals. Many of the nation's past activities in the floodplain make sense, produce desirable results, and should be continued. Others do not and should be stopped. While many aspects of current programs are in need of modification, the problem is not one of lack of understanding of how to manage floodplains and their associated watersheds, it is a problem of will and organization. There are no silver bullets in the floodplain management business, no single actions that will suddenly reduce the vulnerability of those who are currently at risk or stave off placing others in the same position.

If the nation is to move ahead, it must do so in a manner that recognizes the many stakeholders in the floodplain management effort and appropriately divides the responsibilities among them. Many state and local governments have done a great job at floodplain management and the nation can build on that success; others need encouragement; all need support. Operating together with common goals, governments, businesses, and private citizens can make sound floodplain management a reality throughout the nation.

By giving the states and local governments more responsibilities and supporting their efforts, by improving the efficiency of federal efforts, and by ensuring that individuals recognize and assume their personal responsibilities for floodplain activities, the federal government can share the challenge of floodplain management and see to its accomplishment.

WHAT'S NEXT?

The Review Committee has proposed 60 actions and made recommendations concerning 28 other issues. These proposals represent a package whose interrelationship will continue to exist even if one or more of the components fails to be implemented. The Review Committee would caution that the strong linkages among the actions and recommendations require that, as any one is considered, it needs to be addressed in the context of those to which it relates.

Chapter 12 provided a road map for further action, assigning responsibilities to appropriate agencies for specific actions. Unless these actions are tracked by the Administration, the cohesion of the disparate actions could be lost.

The United States has a rare opportunity to make a change in floodplain management. It should not be missed.

GLOSSARY

100-year flood: A term commonly used to refer to the one percent annual chance flood. The 100-year flood is the flood that is equaled or exceeded once in 100 years on the average, but the term should not be taken literally as there is no guarantee that the 100-year flood will occur at all within a 100-year period or that it will not recur several times.

Acre-foot: A unit measure of volume equal to one acre covered to a depth of one foot; often used to describe reservoir capacity or the amount of water flowing past a point in a river over a specified time period. One acre-foot equal 43,560 cubic feet, or 326,700 gallons.

Actuarial rates: Insurance rates determined on the basis of a statistical calculation of the probability that a certain event will occur. Actuarial rates, also called risk premium rates, are established by the Federal Insurance Administration pursuant to individual community Flood Insurance Studies and investigations undertaken to provide flood insurance in accordance with the National Flood Insurance Act and with accepted actuarial principles, including provisions for operating costs and allowances.

Aggradation: The process of filling and raising the level of a streambed by deposition of sediment.

Agricultural levee: A levee for which the majority of benefits are derived from protection of agricultural lands.

Backwater lake: A lake connected to a river at its downstream end that fills principally from the rise of the river rather than from inflow from the lake's drainage area.

Backwater: a) A rise in upstream water level caused by an increase in flow downstream. b) An upstream water level rise caused by obstructions downstream, such as ice jams or debris.

Bank stabilization: Use of structural measures such as rock, concrete, or other material to stabilize channel banks against movement and erosion.

Bankfull stage: At a given location, the maximum elevation to which a river can rise without overflowing its banks. (*see* **Flood stage**)

Base flood: A flood of specific frequency and used for regulatory purposes. The NFIP has adopted the "100-year" flood as the base flood to indicate the minimum level of flooding to be used by a community in its floodplain management regulations.

Basin: A region or area drained by a river system. Also, the total land area that contributes runoff to any given point on a river or stream. Often called a watershed.

Biotechnical engineering: Channel or bank modification techniques that use vegetation in innovative ways, in contrast to traditional bank sloping and riprap protection.

Bluff line: A steep headland or cliff which in some topographical settings defines the edge of a floodplain.

Bottomland hardwoods: Tree species that occur on water-saturated or regularly inundated soils. Classified as wetlands, these areas contain both trees and woody shrubs.

GLOSSARY

cfs: The rate of flow (*see* **Discharge**) past a given point, measured in cubic feet per second. One cubic foot of water equals about 7 1/2 gallons.

Collaborative approach: A commitment to working collectively to solve complex, inter-related concerns. A collaborative effort requires more than consultation, coordination, and seeking public input.

Community Assistance Program (CAP): The program established by the Federal Emergency Management Agency and intended to assure that communities participating in the NFIP are carrying out the flood loss reduction objectives of the program. The CAP provides needed technical assistance to NFIP communities and attempts to identify and resolve floodplain management issues before they develop into problems requiring enforcement action.

Community Rating System (CRS): A program developed by the Federal Emergency Management Agency and intended to encourage -- by use of flood insurance premium reductions -- community and state activities that go beyond the basic NFIP requirements; the CRS gives communities credit for certain activities to reduce flood losses, facilitate accurate insurance rating, and promote the awareness of flood insurance.

Conservation tillage: Practices that reduce cultivation of soil, leave a protective vegetative layer on the surface, and thereby serve to reduce or minimize soil erosion.

Crest: The highest water level at a given location during a flood event.

Crop rotation: Growing crops in a cropping sequence designed to provide adequate residue for maintaining or improving soil condition.

Cumulative impacts: The impacts on the environment that result from the incremental impact of an action when added to other past, present and reasonably foreseeable actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

Dam: A structure built across a waterway to impound water. Dams are used to control water depths for navigation or to create space to store water for flood control, irrigation, water supply, hydropower or other purposes.

Debris: Objects such as logs, trees and other vegetation, building wreckage, vehicles, shipping carts or dead animals carried by water in a flood (or by wind, as in a hurricane or tornado).

Degradation: A process of lowering the level of a streambed by scour and erosion.

Design flood: The maximum amount of water for which a flood control project will offer protection. Selection is based on engineering, economic and environmental considerations.

Dike: In most areas of the U.S., an earthen or rock structure built partway across a river for the purpose of maintaining the depth and location of a navigation channel. In others areas the term is used synonymously with levee.

Discharge: Rate of flow in a river or stream measured in volume of water per unit of time. (*See* **cfs**)

Drainage tiles: Short lengths of perforated pipe made of clay, concrete, or plastic installed in soil to remove free water for the purpose of crop production.

GLOSSARY

Drainage area: Total land area from which water drains to a point on a river. The upper Mississippi River *drainage area* comprises 23% of the land area of the 48 contiguous United States.

Ecosystem: Biological communities (including humans) and their environment (or watershed) treated together as a functional system of complementary relationships, including transfer and circulation of energy and matter.

Ecosystem integrity: Maintenance of the structural and functional attributes characteristic of a particular locale or watershed, including normal variability.

Ecosystem management: Management of the biological and physical resources of an ecosystem or watershed in an attempt to maintain the stability of its structural, functional, and economic attributes, including its normal variability.

Emergency spillway: *See* **Spillway.**

Emergency: Any instance for which, in the determination of the President, federal assistance is needed to supplement state and local efforts and capabilities to save lives and protect property and public health and safety or to lessen or avert the threat of a disaster in any part of the United Sates.

Encroachments: Activities or construction within the floodway, including fill, new construction, substantial improvements, and other development, that may result in an increase in flood levels.

Environmental assessment: An examination of the beneficial and adverse impacts on the environment of a proposed action, such as a water resources project, and alternative solutions.

Executive Order 11988: The floodplain Management Executive Order, issued in 1977, specifying the responsibilities of the federal agencies in floodplain management. EO 11988 directed federal agencies to evaluate and reflect the potential effects of their actions on floodplains and to include the evaluation consideration of flood hazards in agency permitting and licensing procedures.

Federal Interagency Floodplain Management Task Force: The Task Force established in 1975 to carry out the responsibility of the President to prepare for the Congress a Unified National Program for Floodplain Management; member agencies are the Department of Agriculture, Department of the Army, Environmental Protection Agency, Federal Emergency Management Agency, Department of the Interior, and the Tennessee Valley Authority.

Federal trust resources: As applied in this report, these resources include migratory birds, federally listed threatened and endangered species and species that are candidates for listing, interjurisdictional fisheries and wetlands. Such resources are protected by international treaty, and/or federal law in recognition of their ecological and/or commercial significance.

Field borders: A strip of perennial vegetation established on the edge of a field. It involves plantings of herbaceous vegetation or shrubs.

Flash flood: Flood with a very rapid rate of rise that is caused by intense rainfall. During flash floods the time between peak rate of rainfall and peak flow is very short.

Flood/flooding: A general and temporary condition of partial or complete inundation of normally dry land areas from the overflow of river and/or tidal waters and/or the unusual accumulation of waters from any source.

GLOSSARY

Flood control structures: Structures such as dams, dikes, levees, drainage canals, and other structures built to modify flooding and protect areas from flood waters.

Flood discharge: The quantity of water flowing in a stream and adjoining overflow areas during times of flood. It is measured by the amount of water passing a point along a stream within a specified period of time and is usually measured in cubic feet of water per second (**cfs**).

Flood frequency: The frequency with which a flood of a given discharge has the probability of recurring. For example, a 100-year frequency flood refers to a flood discharge of a magnitude likely to occur on the average of once every 100 years or, more properly, of a magnitude that has a one-percent chance of being equaled or exceeded in any year. Although calculation of possible recurrence is often based on historical records, there is no guarantee that a 100-year flood will occur at all or that it will not recur several times within any 100-year period.

Flood hazard: The potential for inundation that involves risk to life, health, property, and natural floodplain values.

Flood Hazard Mitigation Teams: Teams consisting of representatives of the 12 federal agencies that signed an interagency agreement to provide technical assistance to states and communities for nonstructural flood damage reduction measures. The teams are typically employed after each major flood disaster declared by the President to provide technical assistance and guidelines to communities and states affected by the disaster.

Flood Insurance Rate Map (FIRM): An official map of a community on which the Federal Emergency Management Agency has delineated both the special hazard areas and the risk premium zones applicable to the community. FIRMs typically identify the elevation of the one-percent annual chance flood and the areas that would be inundated by that level of flooding; they are used to determine flood insurance rates and for floodplain management.

Flood insurance: The insurance coverage provided through the National Flood Insurance Program.

Flood of record: The highest flood historically recorded at a given location.

Flood-pulse advantage: The amount by which fish yield is increased by a natural predictable flood pulse.

Floodplain management regulations: Zoning ordinances, subdivision regulations, building codes, health regulations, and special purpose ordinances that cover, for example, floodplains, grading, and erosion control and other regulations to control future development in floodplains and to correct inappropriate development already in floodplains.

Floodplain management: A decision-making process whose goal is to achieve appropriate use of the nation's floodplains. Appropriate use is any activity or set of activities that is compatible with the risk to natural resources and human resources. The operation of an overall program of corrective and preventive measures for reducing flood damage, including but not limited to watershed management, emergency preparedness plans, flood control works, and floodplain management regulations.

Floodplain resources: Natural and cultural resources including wetlands, surface water, groundwater, soils, historic sites, and other resources that may be found in the floodplain and that provide important water resources, living resources (habitat), and cultural/historic values.

GLOSSARY

Floodplain: Low lands adjoining the channel of a river, stream, watercourse, lake, or ocean, that have been or may be inundated by floodwater and other areas subject to flooding.

Floodproofing: The modification of individual structures and facilities, their sites, and their contents to protect against structural failure, to keep water out, or to reduce the damaging effects of water entry.

Flood stage: A site-specific river level at which flood damage may start to occur; usually at or above the top of the riverbank. Flood heights are often measured relative to the flood stage elevation. (*See* **Stage**).

Flood storage pool: A volume of space in a reservoir reserved for storage of flood water.

Floodwall: Reinforced concrete walls that act as barriers against floodwaters thereby helping to protect floodprone areas. Floodwalls are usually built in lieu of levees where the space between developed land and the floodway is limited.

Floodway: The channel of a river or other watercourse and the adjacent land areas that must be reserved to discharge the flood without cumulatively increasing the water surface elevation more than a designated amount. The floodway is intended to carry deep and fast-moving water.

Flowrate: Rate of flow (discharge) at a specific location in a river or floodplain.

Freeboard: A factor of safety usually expressed in feet above a flood level for purposes of designing flood protection facilities and floor floodplain management. Freeboard tens to compensate for the many uncertain factors that could contribute to flood heights greater than the height calculated for a selected size flood and floodway conditions, such as wave action, bridge obstructions, and the hydrological effect of urbanization of the watershed.

Gated outlets: Conduits, such as pipes or box culverts, in which mechanical gates are placed for the purpose of controlling the discharge.

Geographic Information System (GIS): A computerized system designed to collect, manage, and analyze large volumes of spatially referenced and associated attribute data.

Greenway: A protected linear open-space area that is either landscaped or left in its natural condition. It may follow a natural feature of the landscape, such as a river or stream, or it may occur along an unused railway line or some other right of way.

High energy erosion zones: Areas on the floodplain, such as the location of a former channel, that are subject to extensive scour and sediment transport during overbank flows.

Hinge-control points: Points in slackwater navigation pools where the water level is used as an index to establish gate settings at navigation dams for maintaining navigable depths.

Hydraulics: The science dealing with the mechanical properties of liquids that describes the specific pattern and rate of water movement in the environment.

Hydrology: The science dealing with the properties, distribution, and circulation of water on and below the surface of the land and in the atmosphere.

GLOSSARY

Interjurisdictional Fisheries: Fish and shellfish resources whose habitat includes waters shared by two or more states.

Land treatment measures: Measures used to reduce runoff of water to streams or other areas; techniques include maintenance of trees, shrubbery, and vegetative cover; terracing; slope stabilization; grass waterways; contour plowing; and strip farming.

Levee: A linear earth embankment used to protect low-lying lands from flooding. A levee extends from high ground adjacent to a floodprone area along one side of a river to another point of high ground on the same side of the river.

Lock: A structure adjacent to a dam or in a canal to allow passage of vessels from one water level to another. The lock consist of a chamber with gates at either end, in which water is raised or lowered. Navigation lock and dams normally do not store flood water.

Lower Mississippi River Basin: The portion of the Mississippi River Basin that drains into the Mississippi River from its confluence with the Ohio River to the Gulf of Mexico.

Lower Mississippi River: The reach of the Mississippi River from the confluence of the Ohio River at Cairo, Illinois, to the Gulf of Mexico.

Major disaster: Any natural catastrophe or, regardless of cause, any fire, flood, or explosion in any part of the United States which, in the determination of the President causes damage of sufficient severity and magnitude to warrant major disaster assistance under the Robert T. Stafford Disaster Relief and Emergency Assistance Act.

Middle Mississippi River: The reach of the Mississippi River between its confluence with the Missouri River at St. Louis, Missouri, and its confluence with the Ohio River at Cairo, Illinois.

Mitigation: Any action taken to permanently eliminate or reduce the long-term risk to human life and property and the negative impacts on natural and cultural resources that can be caused by natural and technological hazards.

Mitigation lands: Lands acquired to offset adverse impacts of water resource (or other) projects

National Wetlands Inventory Project: Wetlands mapping on a national basis performed by the U.S. Fish and Wildlife Service to provide scientific information on the extent and characteristics of the nation's wetlands and consisting of detailed maps and status and trends reports.

Natural resources and functions of floodplains: Include, but are not limited to, the following: natural flood and sediment storage and conveyance, water quality maintenance, groundwater recharge, biological productivity, fish and wildlife habitat, harvest of natural and agricultural products, recreation opportunities, and areas for scientific study and outdoor education.

Navigation channel: The channel maintained in a body of water for the purpose of assuring a depth adequate for commercial vessels.

Nonstructural measures: A term originally devised to distinguish techniques that modify susceptibility to flooding (such as watershed management, land use planning, regulation, floodplain acquisition, floodproofing techniques and other construction practices, and flood warning) from the more traditional structural methods (such as dams, levees, and channels) used to control flooding.

GLOSSARY

One-percent annual chance flood: A flood of a magnitude that has a one-percent chance of being equaled or exceeded in any given year. Often referred to as the 100-year flood or base flood, the one-percent annual chance flood is the standard most commonly used for floodplain management and regulatory purposes in the United States.

Permanent vegetation: Perennial vegetation such as grasses, shrubs, and trees which provides cover to soil and prevent erosion.

Principles and Standards/Principles and Guidelines: "The Principles and Standards for Planning of Water and Related Land Resources" is a presidential policy statement issued in September 1973 that established a framework for improved planning for the use of water and related land resources based on the objectives of national economic development and environmental quality. the "Principles and Standards" were revised and issued in 1983 as the "Economic and Environmental Principles and Guidelines for Water and Related Land Resources for Implementation Studies."

Quad Cities: The metropolitan area comprised of Davenport, Iowa; Bettendorf, Iowa; Rock Island, Illinois; and Moline, Illinois.

Recurrence interval: The average interval in which a flood of a given size is equaled or exceeded as an annual maximum.

Regulatory floodplain: The area adjoining a river, stream, lake, or ocean that is inundated by a regulatory flood. In riverine areas the floodplain usually consists of a regulatory floodway and regulatory flood fringe (also referred to as a floodway fringe). In coastal areas the floodplain may consist of a single regulatory floodplain area or a regulatory high-hazard area and a regulatory low-hazard area.

Regulatory floodway: The area regulated by federal, state, or local requirements to provide for the discharge of the base flood so the cumulative increase in water surface elevation is no more than a designated amount (not to exceed one foot as the minimum standard set by the National Flood Insurance Program).

Repetitive loss: A flood-caused loss of more than $1,000 to a repetitive loss structure.

Repetitive loss structure: A structure for which two or more losses of more than $1,000 (building and contents combined) have been paid since 1978.

Riparian ecosystems: Distinct associations of soil, flora, and fauna occurring along a river, stream, or other body of water and dependent for survival on high water tables and occasional flooding.

Riparian vegetation: Hydrophytic vegetation growing in the immediate vicinity of a lake or river.

Riparian zone: The border or banks of a stream. Although this term is sometimes used interchangeably with floodplain, the riparian zone is generally regarded as relatively narrow compared to a floodplain. The area is typically subject to frequent, short duration flooding.

Risk: The probability of being flooded.

Rock closing dams: In reaches of rivers where multiple channels are formed by islands, rock dikes that span the side channel, generally where it departs from the main channel, are called rock closing dams. They serve to direct flow to the main channel.

GLOSSARY

Scour hole: Erosional holes developed as a result of breached levees. Locally called blow, blew, or blue holes.

Scour: Process of eroding surface soil by flowing water which results in gullies in the landscape.

Section 409 Hazard Mitigation Plan: A plan prepared as required by Section 409 of the Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 by any jurisdiction that receives federal disaster assistance.

Sediment and debris basin: Retention structure constructed on or adjacent to a watercourse to store sediment and debris.

Side channel: A stream or channel to the side of the major channel or stream.

Slackwater navigation dam: A dam placed across a river for the purpose of creating water depth sufficient for navigation. The term slackwater refers to the relatively low velocity in the navigation pool compared to an open river.

Slough: A swamp, march, bog or pond as part of a bayou, inlet or backwater.

Spillway: A feature of a dam allowing excess water to pass without overtopping the dam. Usually a spillway functions only in a large flood.

Stage: The height of the water surface in a river or other body of water measured above an arbitrary datum, usually at or near the river bottom.

Standard project flood: A very large (low frequency) design flood standard applied to the design of major flood control structures and representing the most severe recombination of meteorological and hydrological conditions considered reasonably characteristic of a particular region.

Strip cropping: Growing crops in a systematic arrangement of strips or bands along a contour.

Structural measures: Measures such as dams, reservoirs, dikes, levees, floodwalls, channel alterations, high-flow diversions, spillways, and land-treatment measures designed to modify floods.

Substantial improvement: Any repair, reconstruction, or improvements of a structure, the cost of which equals or exceeds 50 percent of the market value of the structure either before the improvement or repair is started or if the structure has been damaged and is being restored, before the damage occurred.

Substantial damage: The amount of damage to a structure caused by flooding that may be sustained before certain regulatory and flood insurance requirements are triggered. As defined in NFIP regulations, a building is considered substantially damaged when the cost of restoring the building would exceed 50 percent of the market value of the structure.

Tailwater: The reach of stream or river located immediately below a water control structure such as a dam. In contrast, headwater is the term applied to the pool immediately above a dam.

Terrace: A raised bank of earth having vertical or sloping sides and a flat top used to control surface runoff.

GLOSSARY

Upper Mississippi River Basin: The portion of the Mississippi River basin that is above the confluence of the Ohio River. It includes the Missouri River Basin.

Upper Mississippi River: The reach of the Mississippi River from its confluence with the Missouri River at St. Louis, Missouri, upstream to its headwaters at outlet of Lake Itasca in Minnesota.

Watershed: A region or area contributing ultimately to the water supply of a particular watercourse or water body.

Wetlands: Those areas that are inundated by surface or groundwater with a frequency sufficient to support and, under normal circumstances, does or would support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction. Wetlands generally include bottomland hardwoods, swamps, marshes, bogs, and similar areas such as sloughs, potholes, wet meadows, river overflow, mud flats, and natural ponds.

Wing dikes: Rock wing dikes or dams, closing dams, wood pile dikes, and bendway weirs are types of channel training structures used to divert river flows toward a single main channel used for navigation. Generally constructed perpendicular to flow, and constructed to various submergent of emergent elevations, these structures usually function most effectively at lower flows.

APPENDIX A

CHARTER OF THE FLOODPLAIN MANAGEMENT REVIEW COMMITTEE

THE WHITE HOUSE

WASHINGTON

TO: BG Gerald E. Galloway, Jr.

FROM: Administration Floodplain Management Task Force --
T.J. Glauthier, Associate Director, Office of Management and Budget
Kathleen McGinty, Director, White House Office of Environmental Policy
James R. Lyons, Assistant Secretary of Agriculture for Natural Resources

SUBJECT: Directive on the Establishment of an Interagency Floodplain Management Review Committee

The purpose of this directive is to establish an Interagency Floodplain Management Review Committee and to designate you as Executive Director of the Committee. The Committee will undertake an intensive review to: Determine the major causes and consequences of the Great Flood of '93; evaluate the performance of existing floodplain management and related watershed management programs; and make recommendations as to what changes in current policies, programs, and activities would most effectively achieve risk reduction, economic efficiency, and environmental enhancement in the floodplain and related watersheds. As appropriate, the Committee should identify legislative initiatives that might be proposed by the Administration.

Because floodplain management involves a complex intergovernmental system of Federal, State, tribal, and local responsibilities, you will ensure outreach to and consultation with other levels of government and the public. You should conduct your activities and deliberations in an open environment.

The Review Committee will include a multi-disciplinary and interagency group of experts in fields relevant to floodplain management. The individuals listed at Attachment 1 have been assigned by their agencies to the Committee. As necessary, you are authorized to request additional assistance, on an ad-hoc basis, from those agencies and from activities not currently represented on the Committee. The Council of Economic Advisors staff will assist in coordination of economic analysis support. The Justice Department will provide legal assistance. FEMA will coordinate public affairs and Congressional and intergovernmental relations for the Committee. The Scientific Assessment and Strategy Team, which was established by a White House directive dated November 24, 1993, (Attachment 2), is further assigned to the Review Committee and will operate under the Committee's direction.

Resources to support the salaries of individuals assigned to the Committee will be provided by parent agencies. You will be provided an appropriate budget to support the travel and other activities of the committee. As coordinated by OEP and OMB, you will be provided a three-person administrative support staff, office space, and supporting equipment.

For the period of this study, you will be assigned to the White House and will report directly to us. You will serve as the primary representative of the Committee for purposes of public outreach and communications and will have executive responsibility for organizing and executing the work of the Committee.

Not later than February 1, 1994, you will submit to us for approval a detailed mission statement for the Committee and a time-phased work plan. The mission statement should reflect coordination with as broad a segment of interested activities as possible. Not later than May 1, 1994, you will provide a preliminary report to us on the results of the review. A final report will be issued to the public by June 1, assuming expeditious review by the Administration. Every 3 weeks, or more frequently if required, you will provide us with in-process-reviews of the effort.

APPENDIX B

FLOODPLAIN MANAGEMENT REVIEW COMMITTEE MEMBERSHIP AND ACTIVITIES

COMMITTEE MEMBERS AND ACTIVITIES

Washington, DC-based Members

U.S. Military Academy
BG Gerald E. Galloway -- Executive Director

U.S. Department of Agriculture
Dr. Margriet Caswell, Economic Research Service, Washington, DC
Thomas Wehri, Soil Conservation Service, Washington, DC

U.S. Department of Army (Army Corps of Engineers)
Richard DiBuono, Washington, DC
Arnold Robbins, Vicksburg, MS
Harry Shoudy, Washington DC

U.S. Department of the Interior
Robert Clevenstine, Fish and Wildlife Service, Rock Island, IL
Jerry Rasmussen, Fish and Wildlife Service, Columbia, MO

Environmental Protection Agency
Shannon Cunniff, Washington, DC
Joseph Ferrante, Washington, DC
Lewis Rosenbluth, Washington, DC

Federal Emergency Management Agency
Mary Jean Pajak, Washington, DC
Michael Robinson, Washington, DC

Sioux Falls, SD-based Members Scientific Assessment and Strategy Team

U.S. Geological Survey
Dr. John Kelmelis, Reston, VA, Team Leader

U.S. Department of Agriculture
David Buland, Soil Conservation Service, Huron, SD
Dr. Maurice Mausback, Soil Conservation Service, Lincoln, NE
James Reel, Soil Conservation Service, Des Moines, IA

U.S. Department of Army (Corps of Engineers)
Dr. Gary Freeman, Vicksburg, MS
S.K. Nanda, Rock Island, IL
Tim Peterson, Omaha, NE

U.S. Department of the Interior
Dr. John Dohrenwend, U.S. Geological Survey, Menlo Park, CA
Ron Erikson, Fish and Wildlife Service, Twin Cities, MN
John Evans, U.S. Geological Survey, Reston, VA
Dr. David Galat, National Biological Survey Columbia, MO
Dr. William Kirby, U.S. Geological Survey, Reston, VA
Mark Laustrup, National Biological Survey, Onalaska, WI
Tim Liebermann, U.S. Geological Survey, Carson City, NV

Thomas Owens, National Biological Survey, Onalaska, WI
Wayne Rohde, U.S. Geological Survey, Sioux Falls, SD

Environmental Protection Agency
Milo Anderson, Chicago, IL
Cathy Tortorici, Kansas City, KS

Federal Emergency Management Agency
Mark Whitney, Washington, DC

Additional Support Provided to the FMRC by:

Council on Environmental Quality
Kathleen Gallagher
Patty Leppert-Slack

U.S. Department of Agriculture
Valerie Parich
Tammy Short

U.S. Department of Commerce
Alma Ripps

US Department of the Interior
Yvette Pryor

U.S. Department of Justice
Ted Bolling

Environmental Protection Agency
Charlynne Boddie

Federal Emergency Management Agency
Daniel Cotter
Paige Darden
Mary Jo Vrem
Mark Whitney

Tennessee Valley Authority
Curt Goff

Additional Support Provided to the SAST by:

Federal Emergency Management Agency
Daniel Cotter, Washington, DC

U.S. Geological Survey
Byron Stone, Reston, VA
Charles Trautwein, Sioux Falls, SD

Hughes STX Corporation
Norman Bliss, Sioux Falls, SD
Ron Risty, Sioux Falls, SD

INFORMATION GATHERING ACTIVITIES

Meetings with Federal Agencies

Department of Agriculture – Agricultural Stabilization and Conservation Service
Department of Agriculture – Farmers Home Administration
Department of Agriculture – Federal Crop Insurance Corporation
Department of Agriculture – Rural Development Administration
Department of Agriculture – Soil Conservation Service
Department of the Army – Corps of Engineers
Department of the Army – Institute for Water Resources
Department of Commerce – Economic Development Administration
Department of Commerce – National Weather Service
Department of Health and Human Services
Department of Housing and Urban Development
Department of the Interior – Bureau of Indian Affairs
Department of the Interior – Bureau of Reclamation
Department of the Interior – Fish and Wildlife Service
Department of the Interior – U.S. Geological Survey
Department of the Interior – National Biological Survey
Department of the Interior –National Park Service
Department of Transportation
Environmental Protection Agency
Federal Emergency Management Agency
General Accounting Office
Office of Management and Budget
Small Business Administration

APPENDIX B

Meetings with National and Regional Organizations

Advisory Council on Historic Preservation
American Farm Bureau Federation
American Rivers
American Society of Civil Engineers
Association of American State Geologists
Association of State Flood and Stormwater Managers
Association of State Floodplain Managers
Association of State Wetland Managers
Coalition to Restore Aquatic Ecosystems
Coalition to Restore Urban Waterfronts
Environmental Defense Fund
Interstate Council on Water Policy
National Association of Conservation Districts
National Association of Home Builders
National Association of Realtors
National Corn Growers Association
National Fish and Wildlife Foundation
National Governors Association
National Trust for Historic Preservation
National Wildlife Federation
Natural Disaster Coalition
MARC 2000
Sierra Club
The Nature Conservancy
Upper Mississippi River Basin Association
Working Group on Sustainable Redevelopment
World Wildlife Fund

OUTREACH ACTIVITIES

Attendance at Conferences, Meetings and Workshops

Association of State Floodplain Managers Conference – Tulsa, OK
Fish and Wildlife Interagency Committee Meeting – Rock Island, IL
Governor's State Floodplain Workshop – Springfield, IL
Governor's Task Force on Floodplain Management – Jefferson City, MO
Illinois Association for Floodplain and Stormwater Management Conference – Lisle, IL
Iowa Flood Recovery Workshop – Davenport, IA
Lower Mississippi River Conservation Committee – Little Rock, AR
Mississippi Interstate Cooperative Resource Association – Overland, KS
Minnesota Water '94 Conference – Minneapolis, MN
SCS State Conservationist Meeting – Kansas City, MO
State Floodplain Task Force Meeting – Madison, WI
State Floodplain Task Force Meeting – Minneapolis, MN
State Flood Task Force Meeting – Des Moines, IA
State Task Force Meeting – Lincoln, NE
State Task Force Meeting – Pierre, SD
Technical Workshop – St. Louis, MO
Upper Mississippi River Basin Association Meeting – St. Louis, MO
Upper Mississippi River Conservation Committee – LaCrosse, WI
USACE Floodplain Management Assessment Public Meeting – St. Paul, MN
USACE Floodplain Managers Meeting – Reno, NV
USACE Floodplain River Flood Control Association – Quincy, IL
World Wildlife Fund Conference – Jefferson City, MO
World Wildlife Fund Conference – Rock Island, IL
World Wildlife Fund Conference – Winona, MN

Representative Mineata (D – CA)
Representative Minge (D – MN)
Representative Nussle (R – IA)
Representative Regula (R – OH)
Representative Skeen (R – NM)
Representative Skelton (D – MO)
Representative Smith (D – IA)
Representative Talent (R – MO)
Representative Volkmer (D – MO)
Representative Weldon (R – PA)

US House of Representatives Members Represented by Staff

Ken Kopocis, Scott Slesinger/Representative Applegate (D – OH)
Committee on Public Works and Transportation, Subcommittee on Water Resources and Environment

Bob Schmidt/Representative Bevill (D – AL)
Committee on Appropriations, Subcommittee on Energy and Water Development

Darby Becker/Representative Costello (D – IL)

Beth Phillips/Representative Danner (D – MO)

Dan O'Grady/Representative Durbin (D – IL)

Roxanne Smith/Representative Evans (D – IL)

Tom Meluis/Representative Fields (R – TX)
Committee on Merchant Marine and Fisheries, Subcommittee on Environment and Natural Resources

Miguel Gonzalez/Representative Glickman (D – KS)

Sarah Dahlin/Representative Johnson (D – SD)

Barry Scanlon, Brian Doherty/Representative Kennedy (D – MA)
Committee on Banking, Finance, and Urban Affairs, Subcommittee on Consumer Credit and Insurance

Frank Purcell/Representative Lightfoot (R – IA)

Ann Swartz/Representative Marzullo (R – IL)

Bill Warfield/Representative McDade (R – PA)
Committee on Appropriations, Subcommittee on Interior

Lara Battles/Representative Skelton (D – MO)

Dan Ashe, Barbara Polo/Representative Studds (D – MA)
Committee on Merchant Marine and Fisheries, Subcommittee on Environment and Natural Resources

APPENDIX C

U.S. FARM PROGRAM

PRODUCTION ADJUSTMENT/PRICE SUPPORT

The Food, Agriculture, Conservation, and Trade Act of 1990 (The 1990 Farm Bill) continued the market orientation of its predecessor, the Food Security Act of 1985. The stated goals of the 1990 Farm Bill were to ease financial stress for farmers, reduce government costs, reduce crop surpluses, maintain export competitiveness, and enhance environmental quality. The most widely known features of farm policy are the Production Adjustment/Price Support Programs administered by the Agricultural Stabilization and Conservation Service of the USDA. These programs are aimed at supporting farm income and keeping agricultural production in line with anticipated needs. In general, farmers enrolled in the program are given a price support for growing specified commodities. Not all agricultural crops are included. If an acreage reduction program is in effect, farms are required to place a specified proportion (set-aside) of their acreage based on previous cropping history (base acres) in conservation uses (acreage conservation reserve - ACR). Two major floodplain crops, wheat and corn, are in the acreage reduction program, but soybeans are not.

Price support programs were first authorized in 1933. Support can be through loans, purchases, payments, or a combination of these methods. A deficiency payment rate is calculated as the difference between the "target" price which is currently set by the Secretary of Agriculture at the statutory minimum level, and the higher of the actual market price per crop unit or the loan rate. The total payment to the farmer is the payment rate multiplied by the eligible production. The eligible production is calculated as the payment acres (base acres minus set-aside/ACR acreage minus 15 percent normal flex acres) times the program yield which is a fixed amount based on past production averages.

Even in its most simplified form, the program is complex. There are other important factors that determine profitability for an individual farmer. For example, there may be a cost associated with maintaining a cover crop on the set-aside acres. A farmer can grow a crop other than corn on the normal flex acres (15 percent) which would change the per-acre calculations. If land quality and productivity vary on the farm then the average yield per acre may differ when the farmer participates in the program. Such consideration are important to individuals, but make discussions of federal farm programs unnecessarily confusing. Therefore, the following example is presented to illustrate the importance of farm productivity, market prices, and farm program parameters such as the set-aside rate, target price, and program yield in determining whether a farmer will participate and the level of government payments. Table C.1 shows a simplified example of how a corn farmer would compare his/her income with and without participation in the USDA Commodity Program.

APPENDIX C

Table C.1 Example of Accounting Method for Evaluating Participation in the Federal Farm Program for Corn.

		Not Participating in Program	Participating in Program
Production Calculations			
Base acres	acres	100	100
Set-aside/ACR	acres	NA	10
Permitted acres	acres	NA	90
Maximum pay. acres	acres	NA	75
Planted acres	acres	100	90
Actual yield	bu/acre	135	135
Total production	bushels	13,500	12,150
Market price	$/bu	2.10	2.10
Revenue from sale	$	28,350	25,515
Total production cost	$175/acre	17,500	15,750
Payment Calculations			
Program yield	bu/ac	NA	115
Program production	bushels	NA	8,625
Deficiency pay. rate	$/bu	NA	.65
Program payment	$	NA	5,606.25
Farmer Income			
Total net income	$	10,850.00	15,371.25

Notes: "NA" means not applicable for farmer not enrolled in Commodity Program. Calculations were made using parameters similar to those used in the 1993 Corn Program: Set-Aside rate = 10%; Program Yield = 115 bushels per acre based on a national average; and Target Price = $2.75 per bushel. Program production is [(100*0.85) – (100*0.10)]*115. The deficiency payment rate is the target price minus the market price (2.75-2.10 = 0.65). For simplicity, the loan rate is not included in the analysis. Planted acres are equal to the base acres less the set-aside acres.

APPENDIX D

FLOODPLAIN MANAGEMENT ACT

FUNDAMENTAL COMPONENTS OF PROPOSED LEGISLATION

The Interagency Floodplain Management Review Committee recommends that the Administration propose enactment of a law with the following components:

1) A national policy on floodplains and floodplain management which:

a) Encourages actions to avoid or minimize vulnerability to floods, and to mitigate flood losses;

b) Recognizes that fundamentally, floodplain management must be implemented from the bottom up;

c) Promotes comprehensive systems approaches to floodplain management;

d) Encourages participation in the National Flood Insurance Program;

e) Encourages linkage between state emergency floodplain, natural resource, and coastal zone managers;

f) Recognizes and encourages the link between management of watersheds, ecosystems, and floodplains;

g) Establishes that all federal agencies will address the new vision of floodplain management in undertaking their activities; and

h) Recognizes and encourages the link between pre-disaster planning and hazard mitigation in floodplain management.

2) Incentives for states to develop a capacity for and commitment to floodplain management including:

a) Multi-hazard mitigation grants to states for planning and implementation activities. States could pass grants along to communities.

b) Research and technical assistance grants for floodplain management to assist states in carrying out research, including mapping, and training required with respect to floodplain management. States could pass grants along to communities.

c) Federal projects would have to be consistent, to the maximum extent practicable, with state floodplain management plans.

d) Participation in on-going, non-disaster flood damage reduction and mitigation activities could be withheld from those states that do not undertake floodplain management planning.

3) Guidelines for states as to what essential elements are required for a state floodplain management plan to receive federal approval (establishes a 5-year period to complete a floodplain management plan). Essential elements for federal approval of state floodplain management plans include:

a) Use of the standard project flood and one percent per annum floodplain to set priorities for planning and decisionmaking;

b) Consistency with NFIP requirements;

c) Mechanisms to achieve greater participation in NFIP by individuals;

d) Definition of what constitutes appropriate land and water uses within the floodplain that have a direct, significant impact on flood stage (level of significance to be defined by states but not less than NFIP floodway requirements);

e) An inventory and designation of areas of particular concern within the floodplain and watersheds (inclusive of aquatic areas) affecting flooding;

f) Identification of the means by which states propose to exert control over the land and water uses referred to above (such as a state permit program);

g) Broad guidelines on priorities of land uses in particular areas, including those uses of lowest priority; and,

h) Watershed management plans.

4) Cost-sharing. Establishes the amount of any grant made pursuant to this Act as initially not exceeding 80 percent of the state's cost of undertaking the activity of the grant and will decrease over ten years to a 50 percent share. Establishes greater funding priority given to states with documented individual participation in NFIP in excess of a minimum percentage, e.g., 50 percent.

ESTIMATED RESOURCE REQUIREMENTS

It is estimated that implementations of the Act would require an increase of the FEMA staff by 15 individuals nationwide to distribute grants and oversee the program. The total annual federal cost of the program, for staffing and grants, is estimated as $70 million. Grants would be used to supplement state efforts and would therefore represent a sharing of the costs of building and implementing floodplain management programs meeting federal standards.

APPENDIX E

FEDERAL POLICIES AND PROGRAMS FOR FLOODPLAIN MANAGEMENT

ADMINISTRATIVE GUIDELINES

Floodplain Management

Executive Order 11988, 24 May 1977, requires federal agencies to provide leadership and take action to: (1) avoid development in the base (100-year) floodplain unless it is the only practicable alternative; (2) reduce the hazards and risk associated with floods; (3) minimize the impact of floods on human safety, health and welfare; and (4) restore and preserve the natural and beneficial values of the floodplain.

Protection of Wetlands

Executive Order 11990, 24 May 1977, directs federal agencies to provide leadership in minimizing the destruction, loss, or degradation of wetlands. Section 2 of this order states that, in furtherance of the National Environmental Policy Act of 1969, agencies shall avoid undertaking or assisting in new construction located in wetlands unless there is no practicable alternative.

Principles and Guidelines

The Principles and Guidelines established by the Water Resources Council and approved by the President on February 3, 1983, prescribe a single federal objective, national economic development (NED), and do not specifically characterize other plans that must be in the array of alternatives considered by federal agencies in planning water resources development projects. They do, however, allow for display of potential impacts in four accounts: NED, environmental quality (EQ), regional economic development (RED) and other social effects (OSE). Alternative plans formulated must include a plan that reasonably maximizes net national economic development benefits, consistent with the federal objective. This plan is identified as the NED plan and is the one to be recommended for federal action, unless the Secretary of a department or head of an independent agency grants an exception to this rule. Exceptions may be made when there are overriding reasons for recommending another plan, based on other federal, state, local and international concerns. The Principles and Guidelines are applicable to USACE implementation studies for civil works water project plans and to similar plans of the SCE, TVA, and BOR. They have no standing as Administrative Rules.

U.S. DEPARTMENT OF AGRICULTURE

Agricultural Stabilization and Conservative Service

Agricultural Conservation Program: The Soil Conservation and Domestic Allotment Act of 1936 provides cost sharing to farmers and ranchers to encourage them to carry out conservation and environmental practices on agricultural land that result in long-term public benefits. Practices eligible for cost sharing include: establishment or improvement of permanent vegetative cover, contour or strip-cropping systems, and terrace systems; development

of springs, seeps and wells; installation of pipelines, storage facilities, and other measures intended to provide erosion control on range or pasture land; installation of water impoundment reservoirs for erosion control, conservation, and environmental and wildlife enhancement; planting trees and shrubs and improving timber stands for protection against wind and water erosion and for timber production; and development of new or rehabilitation of existing shallow water areas to support Food, habitat, and cover for wildlife. Practices that are primarily production-oriented are not eligible for cost-sharing.

Agricultural Water Quality Protection Program: The Food Security Act of 1990 authorizes USDA to enter into 3- to 5-year agreements with farm owners and operators to develop and implement plans to protect water quality. These agreements do not preclude crop production on the enrolled acreage. Eligible lands include wellhead protection areas within 1,000 feet of public wells, areas of karst topography where sinkholes convey runoff water directly into groundwater, critical areas having priority problems resulting from agricultural non-point sources of pollution, areas where agricultural non-point source pollution is adversely affecting threatened or endangered species habitats, and other environmentally sensitive areas identified by the USDA, the EPA, DOI, or state agencies.

Conservation Reserve Program: The Food Security Act of 1985, as amended, encourages farmers through 10- to 15-year contracts with USDA, to stop growing crops on cropland subject to excessive erosion or that contributes to a significant water quality problem and plant it to a protective cover of grass or trees. A conservation plan describing the conservation measures and maintenance requirements to be carried out by the owner or operator during the term of the contract must be agreed to by the participant and the district conservationist.

Disaster Payments: The Agriculture Consumer Protection Act of 1973 authorized disaster payments to compensate farmers for prevented plantings and unusually low yields due to natural disasters, adverse weather, and other conditions beyond a producer's control. The program covered wheat, barley, corn, sorghum, rice and cotton. Prior to enactment of the Federal Crop Insurance Act of 1980, the disaster payments program compensated eligible farmers for losses due to natural disasters. The Act ended the disaster assistance program for those counties in which Federal Crop Insurance was available. However, the Secretary of Agriculture has the discretion to issue disaster type payments to counties if he thinks the situation warrants it. Disaster payments to an individual under the wheat, feed grains, upland cotton, and rice programs combined cannot exceed $100,000.

Emergency Conservation Program: The Agricultural Credit Act of 1978 provides emergency funds for sharing with farmers and ranchers the cost of rehabilitating farmland damaged by wind erosion, floods, hurricanes, or other natural disasters, and for carrying out emergency water conservation measures during periods of severe drought. The natural disaster must create new conservation problems, which, if not treated, would (1) impair or endanger the land; (2) materially affect the productive capacity of the land; (3) represent unusual damage which, except for wind erosion, is not the type likely to recur frequently in the same area; and (4) be so costly to repair that federal assistance is or will be required to return the land to productive agricultural use. Conservation problems existing prior to the disaster involved are not eligible for cost-sharing assistance. Cost-share agreements are required, and federal assistance cannot exceed 65 percent of the actual, average, or estimated cost of performing the emergency induced work.

Forestry Incentives Program: The Cooperative Forestry Assistance Act of 1978 encourages landowners to plant trees on suitable open lands or cut over areas and to perform timber stand improvement work for production of timber and other related forest resources. Cost-share agreements between the landowner and the Secretary of Agriculture are based on forest management plans developed by the landowner in cooperation with and approved by the State forestry agency. Cost-sharing assistance cannot exceed 65 percent of the cost of work under approved plans.

APPENDIX E

Price and Income Support Programs: Commodity Credit Corporation (CCC) programs support and stabilize farm prices and income and maintain stable levels of supply. These goals are accomplished through CCC payments, purchases, and acreage reduction programs. Price and income support programs began with the Agricultural Adjustment Act of 1933 which introduced a number of new policies including payments to farmers for voluntary acreage reductions, on-farm storage, and marketing agreements. All subsequent farm legislation has continued to emphasize price and income supports for major crops.

a) *Nonrecourse Commodity Loans:* Congressionally-established loan rates provide minimum crop prices through nonrecourse loans to farmers. A nonrecourse loan is one which farmers are not obligated to repay; they can simply forfeit the collateral (the crop). A farmer can place the crop in storage and receive a loan from the government based on the established loan rate. If the market price rises above the loan rate, the farmer can sell the crop on the market and repay the loan, interest, and storage costs. If the market price does not rise above the loan rate, the farmer can default on the loan (without penalty) and turn the crop over to the government. Consequently the loan rate places a floor under the commodity price for a participant.

b) *Deficiency Payments:* Congressionally established target prices for certain crops enable participating farmers to receive "deficiency payments" from the CCC for eligible program commodities when commodity prices fall below the target price for specified periods of time. The legislative deficiency payment rate is the target price for specified periods of time. The legislative deficiency payment rate is the target price minus the higher of: (1) the loan rate, or (2) the national average market price for the first five months of the marketing year. Deficiency payments are based on "program yields" rather than actual yields. Program yields are established by the Agricultural Stabilization and Conservation Service (ASCS) county committees and are a function of the farm's historical yields. Deficiency payments are multiplied by a program allocation factor. In years when program expenditures are high, the Secretary of Agriculture can invoke the program allocation factor in order to reduce expenditures. The program allocation factor is legislated to be between 0.8 and 1.0, but its actual value is not known by farmers at sign-up time.

Sodbuster Provision: The Food Security Act of 1985, as amended, discourages the conversion of highly erodible land to agricultural production. If highly erodible grassland or woodland is used for cropland production, producers may lose eligibility for: price and income supports, crop insurance, FmHA loans, CCC storage payments, farm storage facility loans, and other programs under which USDA makes payments. Sodbuster applies to highly erodible land which was not planted to annually tilled crops from 1981-85. To maintain eligibility for USDA program benefits, producers must have a conservation plan approved by their local conservation district for any highly erodible land broken out for crop production after that date.

Supply Restriction Programs: Acreage reductions, set-asides, paid land diversions, and payment-in-kind programs have been the primary means of restricting supply. The general goal of these policies is to reduce the number of acres planted and thus reduce crop production. If an acreage reduction or set-aside is in effect, producers must reduce their plantings by a specified percentage of the acreage base for each enrolled commodity to be eligible for CCC loans, purchases, and payments.

Swampbuster Provision: The Food Security Act of 1985, as amended, discourages the conversion of natural wetlands to cropland use. With certain exceptions, if producers converted a wetland area to cropland after December 23, 1985, they lose eligibility for several USDA program benefits (see list above under sodbuster provision).

Wetlands Reserve Program: The Food Security Act of 1990 provides financial incentives for restoration and protection of wetlands if farmers agree to long-term (30-year or permanent) easements. Farmed or converted

wetlands (must have been converted prior to December 23, 1985), adjacent functionally related lands, and riparian areas that link wetlands are eligible for enrollment. In addition, farmed wetlands and adjoining lands enrolled in the conservation reserve may be permitted to be enrolled if they have high wetland functions and values, were not planted to trees under a Conservation Reserve Program (CRP) contract, and are likely to return to production after they leave the CRP. The federal government will provide not less than 75 percent cost-share for restoration, plus lump sum payment for easement.

Water Bank Program: The Water Bank Act of 1970, as amended, provides for preservation and improvement of major wetlands as habitat for migratory waterfowl and other wildlife; conservation of surface waters; reduction of runoff, soil and wind erosion; flood control; improved water quality; improved subsurface moisture; and enhancement of the natural beauty of the landscape. Under this program, wetland owners enter an agreement with the ASCS promising not to drain, burn, fill, level, or use the wetland for a 10-year period. The Water Bank Program agreements extend protection to and require conservation measures on adjacent upland habitat. In exchange, the landowner receives an annual payment designed to reflect local real estate values. If the land is also under FWS agreement, the annual payment is reduced by 20 percent. When accepting an area into the program, ASCS tries to maintain a 3:1 or 4:1 ratio of uplands to wetlands. The term "wetlands," for purposes of carrying out the program, includes: seasonally flooded basins or flats, fresh meadows, shallow fresh marshes, deep fresh marshes, open fresh water, shrub swamps, and wooded swamps. Participants in the program enter in to 10-year agreements, with provisions for renewal, and receive payments for approved conservation work.

Soil Conservation Service

Cooperative River Basin Program: Section 6, PL 83-566, provides for technical assistance to Federal, State, regional, and local governments in formulating and carrying out plans for conservation use treatment measures, nonstructural measures, and development. Plans may include management and structural measures, or combinations thereof. There are no cost sharing requirements.

Emergency Watershed Protection Program: Section 216, PL 81-516 and Section 404, Title IV, PL 95-331 provided the Soil Conservation Service with authorization for disaster relief funding in repairing damages to waterways and watersheds. Work includes debris removal and erosion control for waterways, levee repair and relocations.

Emergency Wetland Reserve Program: The same authority as Emergency Watershed Protection Program provides for the purchase of easements from persons owning cropland who voluntarily agree to restore farmed, converted, or potential wetlands. The combined cost of restoring the land and levees must exceed the fair market value of the affected cropland to be eligible for the program. The easements are purchased to promote wetland values such as hydrology and vegetation, and protect the functions and values of wetlands or wildlife habitat, water quality improvement, flood water retention, floodway enhancement, environmental education, and other values determined appropriate by SCS. Use of the easement lands for cropland is prohibited.

Watershed Protection: Section 3, Watershed Protection and Flood Prevention Act of 1954; PL 83-566 provides for technical assistance to state and local governments in planning and carrying out works of improvement to protect, develop, and utilize the land and water resources in small watersheds under 250,000 acres in size. Conservation land treatment, structural, and nonstructural measures are used to address problems related to watershed protection, flood prevention, and agricultural and nonagricultural water management. Nonstructural measures are preferred. Projects must be sponsored by entities legally organized under state law, or any Indian tribe or tribal organization, having authority to carry out, operate, and maintain works of improvement. Cost-sharing requirements are variable, depending on the nature of the project.

Farmers Home Administration

Debt Cancellation Conservation Easements: FmHA can forgive debt in exchange for conservation easements on environmentally sensitive portions of a borrower's property. A conservation easement may be obtained for a period of not less than 50 years. A perpetual easement will usually be recommended. Both current and delinquent FmHA borrowers are eligible to participate in the dept restructuring conservation easement program. The borrowers must have loans secured by real estate. The easements can be established for conservation, recreational, and wildlife purposes on farm property that is wetland, wildlife habitat, upland, or highly erodible land. Non-program borrowers are not eligible to participate. There is no cost sharing.

Loans: Below market rate ownership and operating loans are available directly to farmers through FmHA. The relatively low rates reduce the cost of capital and may encourage farmers to expand the size of their operations. The loans are made primarily to family farmers who cannot obtain private credit to finance operations or make farm improvements. In addition the FmHA increasingly has been providing disaster emergency loans that can reduce the risk of farming in floodprone areas. The FmHA issued regulations in 1983 (7 CFR Part 1940.301) stating that FmHA loans are not to be allowed for activities that would directly or indirectly affect wetlands, unless there is "no practical alternative." In addition, FmHA will soon publish regulations implementing the farm debt restructure and conservation set-aside provisions of the Food Security Act of 1985 (section 1318). This program will allow a farmer who is unable to repay his loan to have a portion of his FmHA loan cancelled in exchange for a conservation easement of at least 50 years. The percentage of the debt forgiven will be equal to the percentage of the farm acreage (secured by the loan) which is placed under easement.

Transfers of Inventory Farm Properties to Federal and State Agencies for Conservation Purposes: Under the Consolidated Farm and Rural Development Act, FmHA can transfer certain inventory farm properties to Federal and State agencies. The transfer must be for conservation purposes. The property must have marginal value for agricultural production, be classified as environmentally sensitive, or be of special management importance. Properties containing important resources such as wetlands, floodplains, riparian zones, historical sites or endangered species may qualify. Inventory farm properties that are inholding, lie adjacent to, or occur in proximity to, federally- or state-owned lands may qualify. There is no cost share involved.

DEPARTMENT OF THE ARMY, U.S. ARMY CORPS OF ENGINEERS (USACE)

Fish and Wildlife Enhancement: Section 906, Water Resource Development Act of 1986, PL 99-662 provides that for any project measures recommended to enhance fish and wildlife, costs will be entirely federal when the benefits have a national character and, where they do not, non-federal interests shall reimburse 25 percent of the costs. The non-federal share of operations, maintenance and rehabilitation costs will, in all cases, be 25 percent.

Flood Emergency Operations and Disaster Assistance: PL 84-99 covers emergency activities pursuant to PL 99-84, as amended by the Flood Control the Flood Control Act of 1962 and further amended by PL 93-252 and PL 99-51. It provides for floodfighting and rescue operations; post-flood response; emergency repair and restoration of flood-damaged or destroyed flood-control works such as levees; emergency protection of federally authorized hurricane and shore protection works being threatened; the repair or restoration of federal hurricane- or shore-protection structures damaged or destroyed by wind, wave, or water action of other than an ordinary nature; emergency supplies of clean water to any locality confronted with a source of contaminated water causing or likely to cause a substantial threat to the public health and

welfare of the inhabitants of the locality; and emergency water supplied for human and livestock use in areas determined to be drought distressed. Provision of advance flood damage-reduction measures by the USACE is supplemental to individual and local community efforts, rather than a replacement for them. USACE protective and preventive measures are generally of a temporary nature designed to meet an imminent flood threat. Permanent rehabilitation work to protect against the threat of future disasters is considered separately from advance measures. A declaration of a state of emergency or written request by the governor of a state is a prerequisite to furnishing advance measures under PL 84-99. Local interests are required to remove temporary works provided as advanced measures.

It is USACE policy to obtain local assurances for assistance. Local cooperation for accomplishment of advance measures and rehabilitation works require local assurances to: (1) provide without cost to the United States all lands, easements, and rights-of-way necessary for the authorized emergency work; (2) hold and save the United States free from damage due to the authorized emergency work; and (3) maintain and operate all the rehabilitation work after its completion. Under PL 84-99, emergency funds may be expended directly by the USACE for authorized purposes. PL 84-99 does not authorize reimbursement of local interests for any of their costs for emergency operations accomplished on their behalf. Also, PL 84-99 authority and funds are not used in lieu of other USACE authorities. The Corps may perform emergency work on public and private lands and waters for a period of ten days following a governor's request for assistance. This work must be essential for the preservation of life and property, including, but not limited to, channel clearance, emergency shore protection, clearance and removal of debris and wreckage endangering health and safety, and temporary restoration of essential public facilities and services. In the event of a Presidential declaration of a major disaster or emergency declared by the Director of the Federal Emergency Management Agency, the USACE can provide assistance to state and local governments in essential recovery operations when and as directed by the President through FEMA under provisions of PL 93-288. The Corps fully responds to all requests from the FEMA director or regional director.

Flood Plain Management Services Program: Section 206, Flood Control Act of 1960, as amended, provides for the USACE to furnish floodplain information and technical assistance to states, counties, and cities for prudent use of land subject to flooding from streams, lakes, and oceans. Services include: developing and interpreting flood and floodplain data such as flood hazard mapping; providing a broad assessment of the impact of structural and nonstructural flood damage-reduction measures; providing technical assistance on floodproofing systems and techniques; and assessing the possible impacts of land-use changes on the physical, socio-economic, and environmental conditions of the floodplain.

Planning Assistance to States: Section 22, Water Resources Development Act of 1974, PL 93-251 authorizes cooperation with states and federally recognized Indian Tribes in the preparation of comprehensive plans for the development, utilization, and conservation of the water and related resources of drainage basins located within the boundaries of the state and submitting to Congress reports and recommendations with respect to appropriate federal participation in carrying out the plan. Typical activities studied under this program are flood damage reduction, water supply, water conservation, water quality, hydropower, erosion, navigation, and methodologies to evaluate wetlands or other resources. Expenditures in any one state cannot exceed $300,000 in any one year, as amended by Section 921 of the Water Resources Development Act of 1986. Federal input to the state planning program is on an effort- or service-sharing basis in lieu of an outright grant. The non-federal share of costs in 50 percent; in-kind services are not accepted.

Project Modifications to Improve Environment: Section 1135, Water Resources Development Act of 1986; PL 99-662 provides for modifications of the operation of completed USACE projects for the purpose of improving environmental quality. The program can be used to protect, restore or create wetlands, provided the work involves modification of water resources projects for the purpose of improving environmental quality. The program can be used to protect, restore, or create wetlands, provided the work involves modification of a water resources project constructed by the USACE. Type of projects that could be considered include: installation of gaged culverts in USACE levees; opening oxbows cut off by USACE levees or navigation features; or realignment of a levee to allow areas between the levee and the channel to

revert to historic floodplain habitat. The non-federal sponsor is responsible for 25 percent of the cost of study and implementation, which includes any necessary lands, easements, rights-of-way, relocations, and disposal areas. No work-in-kind is creditable. The non-federal sponsor is also responsible for 100 percent of incremental operation and maintenance costs.

Regulation of Dredged or Fill Material into U.S. Waters: Section 404, Clean Water Act of 1977 requires a USACE permit for discharges of dredged or fill materials into the waters of the United States. Such discharges, to qualify for a permit, must be in compliance with the guidelines published by the Environmental Protection Agency to implement Section 404(b)(1) of the Clean Water Act. Section 404(c) of the Act authorizes the Administrator of EPA to prohibit or restrict the use of a disposal site whenever it is determined that the discharge of such materials will have an unacceptable adverse effect on municipal water supplies, shellfish beds and fishery areas, wildlife, or recreational areas.

Regulation of Navigable Waters: Section 10, River and Harbor Act of 3 March 1899 prohibits the unauthorized obstruction or alteration of any navigable water of the United States. A USACE permit is required for the construction of any structure in or over any navigable water of the United States or the accomplishment of any other work affecting the course, location, condition, or physical capacity of such waters.

Water Resources Development Projects: The USACE is the principal Federal agency with responsibility for flood control and navigation projects, which in some cases include other purposes such as water supply, recreation, hydroelectric power, and fish and wildlife enhancement. Such projects, with certain exceptions, require specific authorization by Congress. Examples of exceptions include small, single-purpose projects for flood control or navigation which can be carried out under several continuing authorities such as Section 205 of the Flood Control Act of 1948, as amended, and Section 107 of the Rivers and Harbors Act of 1960, as amended. For flood control projects, the minimum local cost-share is 25 percent. The value of any lands, easements, and rights-of-way count as part of the 25 percent, but a minimum cash contribution must be made for structural flood control projects and must be equal to five percent of the construction cost. Since all lands, easements, and rights-of-way necessary for the construction of a project are the on-federal sponsor's responsibility, it is possible for the non-federal share of a structural flood control project to exceed 25 percent; however, the non-federal share cannot exceed 50 percent. The non-federal cost-share for navigation projects varies, depending upon project depth. The Water Resources Development Act of 1986 (PL 99-662), which established current cost sharing for Federal water resources development projects, also requires 50-50 sharing of costs of feasibility studies conducted by the USACE which lead to the development of water projects, and makes the non-federal sponsor responsible for all operations and maintenance costs of flood control projects authorized in and after the 1986 Act. Reconnaissance studies leading to feasibility studies are conducted at full federal expense. Under the Pick-Sloan Missouri River Basin Program (authorized by the Flood Control Act of 1944), the USACE constructed five large dams and reservoirs along the main stem Missouri River during the 1950s and 1960s. Four of these are in South Dakota, while Garrison is in North Dakota. The USACE operates these main stem dams and reservoirs for multiple purposes: flood control, irrigation, navigation, recreation, wildlife, municipal and industrial water supplies, and hydroelectric power. Tributary projects are constructed and operated by both the USACE and the Bureau of Reclamation.

U.S. DEPARTMENT OF COMMERCE, ECONOMIC DEVELOPMENT ADMINISTRATION (EDA)

The EDA flood relief program provides for grant awards to assist communities, industries, and firms adversely impacted by the flood of 1993 and other disasters to assist in the long-term economic recovery of the affected area.

Grant awards can be used to respond to emergency infrastructure needs as well as unmet needs for public infrastructure improvements that are not adequately addressed by FEMA or other federal agencies. The 1993 Supplemental Appropriation provided $200 million to EDA through September 30, 1995, to carry out this effort. Non-federal cost sharing requirements are 25 percent for economic adjustment and technical assistance grants, and 20 percent for public works direct grants.

ENVIRONMENTAL PROTECTION AGENCY (EPA)

Control of Non-point Pollution: Section 319, Clean Water Act provides for grants to state agencies to implement restoration activities that control non-point pollution. There is a 40 percent state match.

Wastewater Treatment Plants: Capitalization grants for state revolving funds provide for loans to local municipalities to repair, replace, or relocate wastewater treatment plants damaged by the floods of 1993. There are no cost sharing requirements. The municipalities receive loans against state revolving funds and repay 100 percent plus interest.

Wetland Protection: State development grants provide for grants to states and federally recognized Indian tribes to develop new or refine existing state and tribal wetlands protection programs. Only state agencies and federally recognized Indian tribes are eligible. Some funds can be passed through by state and other entities, but the state must have a major role in the project. Funds cannot be used for relocation of farm or urban structures or to support construction activities. The project sponsor must provide 25 percent of total cost.

FEDERAL CROP INSURANCE CORPORATION (FCIC)

Federal crop insurance was established by the Federal Crop Insurance Act of 1938, but essentially operated as a pilot program for four decades. The Federal Crop Insurance Corporation Act of 1980 greatly expanded the program to make it the major policy for protection from crop failure. The federal government subsidizes the premiums and administrative costs of the insurance program. A variety of coverage levels are available. The higher the yield guarantee level and the higher the price election, the higher will be the premium the farmer will pay. If at harvest time, farm yields are below the yield guarantee level, an insurance adjuster will visit the farm and determine the indemnity which the farmer is entitled to receive. Crop insurance reduces the risks involved in agricultural production, protecting farmers against yield losses from a variety of natural causes, including flooding, which is likely to occur on cleared bottom land areas. Under Swampbuster farmers who plant on newly converted wetlands are ineligible for crop insurance coverage on all planted acreage.

FEDERAL EMERGENCY MANAGEMNT AGENCY (FEMA)

Hazard Mitigation Grant Program: Section 404, Robert T. Stafford Disaster Relief and Emergency Assistance Act, as amended, provides for grants to state and local governments, certain private non-profit organizations or institutions, and Indian tribes for hazard mitigation actions after a Presidentially declared disaster. Funds can be used for projects to protect either public or private property. Examples of projects include: structural hazard control, such as debris basins; retro-fitting, such as elevation or flood proofing to protect structures from future damage; acquisition and relocation of structures from hazard-prone areas; and development of state or local standards to protect new and substantially improved structures from disaster damage. The non-federal sponsor is required to pay 25 percent of the project's total eligible costs.

National Flood Insurance Program (NFIP): The National Flood Insurance Act of 1968, as amended, makes flood insurance available to protect the individual in participating communities from financial loss in the event of a flood. Under the NFIP insurance is subsidized, up to an amount specified, for existing buildings in areas designated as flood hazard areas by FEMA. New buildings pay the full actuarial cost of flood insurance. The land-use control measures required of communities to gain and maintain eligibility for flood insurance are complementary to other floodplain management efforts. Section 202 of PL 93-234 states that no federal officer or agency shall approve any financial assistance for acquisition or construction purposes after July 1, 1975, for use in any area identified by FEMA as an area having special flood hazards unless the community in which such area is situated is then participating in the National Flood Insurance Program. Section 402 of WRDA 1986 expands the prohibition against federal participation in flood hazard areas by including federal participation in construction of local flood control projects.

Purchase of Floodplain Property: Section 1362 of the National Flood Insurance Act of 1968 provides for federal acquisition of previously flood-damaged property owners the opportunity to relocate to non-flood-prone areas. To be eligible, the property owner must have a flood insurance policy in force when the damage occurs, and at least one of the following criteria must be met: (1) the currently damaged structure must have been damaged by at least three previous floods over a 5-year period, with an average damage of 25 percent or more of the value of the structure; (2) a single flood has damaged the structure 50 percent or more of its value or beyond repair to its pre-flood condition; and (3) any single event has left the structure damaged and irreparable, either due to local ordinance limitations or significantly increased building costs. Communities participating in the program must agree to accept title to purchased property and manage it for open space or other non-development purposes. The property owner may retain ownership of buildings by moving them to another location.

U.S. DEPARTMENT OF HOUSING AND URBAN DEVELOPMENT (HUD)

Community Development Block Grant Program: This program provides for formula grants to metropolitan cities and urban counties and to States for use in non-entitlement areas which do not receive entitlement grants. All funded activities must meet one of three broad national objectives: to benefit low and moderate income persons, to eliminate slums and blight, or to meet urgent community development needs.

HOME Program: This program provides for formula grants to states and larger cities and urban counties for permanent housing for low-income persons. Funds can be used for acquisition, new construction, rehabilitation, and tenant-based rental assistance.

Section 108 Loan Guarantee Program: This program provides for loan guarantee assistance to states to finance: acquisition of real property; relocation of property, homes, and businesses; rehabilitation of publicly owned real property, including repair and reconstruction of public utilities, such as water and sewer systems; housing rehabilitation, including elevation of properties; and economic development.

U.S. DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Established by the Reclamation Act of 1902, the Bureau constructs, operates, and maintains multipurpose water projects in the 17 western States, primarily for irrigation, hydroelectric power generation, and municipal and industrial water supply. Projects also provide flood control and recreational benefits, but these are generally not primary project purposes. The Bureau also manages any

water distribution facilities associated with the USACE projects constructed under the Pick-Sloan Missouri River Basin Program. As with the USACE projects, the non-federal cost burden has increased recently for Bureau projects. On new projects the Bureau requires the non-federal sponsors to contribute 50 percent of feasibility study costs and finance up-front a portion of the construction costs for the project (as opposed to delaying reimbursement until after construction is completed and the project is operating, as was the historical practice). Further, the Bureau's approach to any new hydroelectric projects has been tightened significantly: the entire construction cost must be paid by the non-federal sponsor during the construction period.

Fish & Wildlife Service (FWS)

North American Wetlands Conservation Fund: Provides for Federal cost-share funding on a 50-50 basis to states, local governments, businesses, and individuals to protect, restore, and manage a diversity of wetland habitat for migratory birds and other wildlife.

Partners for Wildlife: This program provides for grants and technical assistance to private landowners interested in restoring wetlands and riparian habitats on their land. Landowners enter into a binding agreement with the FWS to restore and protect the site. Agreements are for a minimum 10-year period, but landowners are given a higher priority for funding if they intend to protect the area perpetually. Cost sharing is negotiated. The FWS can cost share with the Agricultural Stabilization and Conservation Service, State agencies, conservation organizations, and others.

Small Wetlands Acquisition Program (SWAP): Under this program the FWS can either purchase wetlands and surrounding upland areas outright or enter into a perpetual easement agreement which places restrictions on the wetlands. In the case of an outright fee purchase, the FWS buys the land at the current market value. This valuation is performed by examining recent land sales where land sold contained wetlands. When purchasing a wetlands area, the FWS seeks to obtain a ratio of 2:1 upland to wetland. In the case of an easement purchase, the landowner gives up rights and responsibilities to drain, fill, burn, or level the wetlands. All other ownership rights and responsibilities remain. Uplands are not restricted with a FWS lease as in the purchase. Easement payments are made on a one-time, lump sum basis, with the payment varying according to land values in the immediate area and the development potential of the wetlands.

National Park Service (NPS)

Federal Land Transfer, Federal Land-to-Parks Program: This program provides for technical assistance and transfer of available surplus federal real property to states and local governments for the purpose of establishing state and local parks for recreation and open space. Properties must be made available by the General Services Administration.

Rivers and Trails Conservation Program: This program provides for NPS staff assistance to communities for river and trail corridor planning and open space preservation efforts. Cost-sharing is variable, usually in the form of in-kind services.

SMALL BUSINESS ADMINISTRATION (SBA)

SBA makes disaster loans to non-farm, private sector owners of disaster damaged property for uninsured losses, including homeowners and renters, businesses of all sizes, and nonprofit organizations. Loans can be used by a property owner to restore any property, including wetlands damaged by flooding. Owners of non-farm, flood damaged properties may use loan funds to help fund acquisition of a replacement property at a different site. In cases of forced relocation of substantial damage (as defined by the National Flood Insurance Program administered by the Federal Emergency Management Agency) in a special flood hazard area, the damaged property may be treated as a total loss, making the property owner eligible for full replacement value. Loans generally have an

interest rate of 4 percent and terms up to 30 years, depending on borrowers' ability to repay. Borrowers, such as businesses, able to use their own resources to meet disaster needs without hardship pay a higher interest rate (generally 8 percent) and their loans are limited to a three-year term. Business loans and those to nonprofit organizations are limited to a statutory maximum or $1.5 million, except that SBA has authority to grant a waiver for businesses that are major sources of employment. Loans to homeowners are limited to $100,000 for real estate, $20,000 for personal property, $100,000 for refinancing of prior liens, and $24,000 for additional mitigation devices not required by code.

RURAL DEVELOPMENT ADMINISTRATION

Water and Water Disposal Loans and Grants: This program provides for loans and grants (75 percent of project costs) to public entities such as municipalities, counties, special-purpose districts, Indian tribes, and non-profit corporations to develop water and waste disposal systems in rural areas and towns with a population less than 10,000. It also provides for technical assistance and training grants, solid waste management grants, and emergency community water assistance grants. The emergency community water assistance grants can be made in rural areas and cities or towns with a population not in excess of 5,000 and a median household income not in excess of 100 percent of a state's non-metropolitan median household income. Additional funds are available through June 30, 1994, to assist rural areas and cities and towns, with a population not in excess of 15,000, to cover costs that are a consequence of the Midwest floods or other Presidential declared disasters that occurred in 1993.

Business and Industrial Guaranteed Loans: Business and industrial guaranteed loans may be made in any area outside the boundary of a city of 50,000 or more and its immediate adjacent urbanized areas with population density of no more than 100 persons per square mile. Priority is given to applications for projects in open country, rural communities, and towns of 25,000 and smaller. Any legal entity, including individuals, public and private organizations and federally recognized indian tribal groups, may borrow. Additional funds are available to guarantee loans made by private lenders to cover costs arising from the consequences of Presidential declared disasters. The maximum loan amount that can be guaranteed is $10 million.

Community Facility Loans: This program provides for loans to public entities such as municipalities, counties, special purpose districts, nonprofit corporations, and Indian Tribes to construct, enlarge, or improve community facilities for health care, public safety and public services.

TENNESSEE VALLEY AUTHORITY (TVA)

Among other objectives, the 1933 TVA Act charged the agency with controlling destructive floodwaters along the Tennessee River and its tributaries. TVA has a unique dual approach to flood risk reduction that combines a system of dams and reservoirs with proactive floodplain management. TVA's Flood Risk Reduction Program reduces flood damage potential in a manner which reduces property damage and the threat to loss of life, supports appropriate economic development, preserves natural floodplain values, and enhances effective multipurpose reservoir operations. TVA develops and provides flood risk data which includes flood flows, flood elevations, and flood risk mapping. It conducts engineering analyses to determine impacts of proposed floodplain development and evaluate the effectiveness of proposed flood damage reduction alternatives. Where appropriate, TVA designs and implements flood damage reduction projects. It supports state and local floodplain management efforts through educational and technology transfer activities.

APPENDIX F

STATE FLOODPLAIN MANAGEMENT PROGRAMS

The text and table in this appendix are taken from a special report by the Association of State Floodplain Managers, Inc., entitled *Floodplain Management, 1992, State and Local Programs,* and were reprinted by permission.

The Nature of State Floodplain Management

State governments derive their authority to plan and implement floodplain management actions from the police power that is vested in them by the U. S. Constitution. The principal roles played by states in floodplain management today include coordination of the National Flood Insurance Program (NFIP) for the activities within their jurisdictions; planning and implementing programs and projects for managing their own floodplains, including state-level regulations; providing technical expertise of all kinds to individuals and to other levels of governments, especially localities; coordinating local and regional programs within their jurisdictions; entering into agreements with other states to cope with multi-jurisdictional flood problems; and acting as liaisons with the federal government. Sometimes states compensate for the inability or unwillingness of local governments to take certain actions to reduce their flood risk or preserve the natural functions of their floodplains. Direct state regulation of some aspects of land use, of selected types of lands, and of certain kinds of activities is becoming more typical.

Most states have floodplain management programs that are a composite of varied activities undertaken by different agencies and other entities within the state. The central office is usually the one that coordinates the NFIP for that state. In 33 states that function is housed in a department for natural resources, water resources, or environmental protection. In nine states it is within an emergency preparedness agency, in six with a department of community affairs, and in two states with a state planning office. Two states manage their floodplains principally out of a transportation department. Sometimes, most or all of the activities related to floodplain management are organized into one office or department, and sometimes they are scattered throughout state government, necessitating careful coordination.

The myriad of programs that affect floodplain management -- emergency preparedness and response, natural resources protection, environmental quality, structural control measures, planning, and economic development -- along with the wide variety in local and regional efforts, makes the floodplain management picture of each state unique.

APPENDIX F

Table F.1: Summaries of State Floodplain Management Activities, 1991 (Source: Adapted from Association of State Floodplain Managers, 1992)

	Budget: State Contribution/Total (in $1000)	Programs for Mapping Floodplain Areas	Riverine Regulatory Standards Exceeding NFIP Minimums	Regulations for Areas Behind Levees	Programs for Acquisition & Relocation Program Funding	Cooperative Projects to Protect Floodplain Resources

APPENDIX G

EXECUTIVE ORDER ON FLOODPLAIN MANAGEMENT

Executive Order 11988, issued in 1977, represented an effort by the executive branch to coordinate federal activities to reduce the impact which federal activities have on the nation's floodplains. In the course of its work, the Review Committee determined that the Executive Order brought about a significant and beneficial change in federal floodplain activities. It also determined that certain weaknesses had become apparent which require a revised order to be issued. A new Executive Order would reaffirm the basic principles of the former order and address newly uncovered issues.

Content of the Revised Executive Order

The floodplains which adjoin the nation's inland and coastal waters have long been recognized as having special values to U.S. citizens. They have provided wildlife habitat, agricultural and forest products, vital ecosystem functions, and park and recreation areas. Unwise use and development of our riverine, coastal, and other floodplains, however, not only destroys many of the special qualities of these areas but can post a severe threat to human life, health and safety.

Since the adoption of a national flood control policy in 1936, the federal government has invested billions of dollars in structural protection from floods. The vulnerability of floodplain inhabitants and their property persist, federal expenditures for disaster relief and recovery do not diminish, river dependent ecosystems decline, and environmental deterioration continues.

The problem arises mainly from unwise land use practices. The federal government must acknowledge its influence over floodplain development and set the example for floodplain management. Federally funded or assisted construction and improvements, property management, financial and technical assistance, and permits and licenses for federally regulated activities must be consistent with the goals of floodplain management: reducing the vulnerability to damage and protecting and enhancing the environment.

In addition to minimizing danger to humans in floodplains and maintaining and enhancing natural resources, sound floodplain management protects the federal investment and represents responsible business practice. It seeks to avoid the potential loss of human and other natural resources and reduce the risk of flood damage to properties benefiting from federal assistance.

Because unwise floodplain development can lead to the loss of human and natural resources, it is simply a bad federal policy and should be avoided. In order to avoid, to the greatest extent possible, the adverse impacts associated with the occupancy and modification of floodplains, and to avoid direct or indirect support of floodplain development wherever there is a practicable alternative, a revised Executive Order on floodplain management is necessary. The Review Committee recommends that the Administration should direct that:

Each agency provide leadership and take action to reduce the risk of flood loss; to minimize the impact of floods on human safety, health, and welfare; and to restore and preserve the natural and beneficial functions of floodplains in carrying out, in a manner which furthers national economic and environmental goals, its responsibilities for:

> (1) acquiring, managing, and disposing of federal lands and facilities;
>
> (2) providing federally undertaken, financed, or assisted construction and improvements;

(3) conducting federal activities and programs affecting land use and water resources planning; and

(4) permitting and licensing federally regulated activities.

Each agency would have a responsibility to prescribe procedures to implement the policies and requirements of the revised Order. These policies and procedures should evaluate the potential economic, social and environmental effects of any actions the agency may take in a floodplain and ensure that its planning programs and budget requests reflect consideration of flood hazards and the principles of sound floodplain management.

Each agency should determine whether a proposed action will occur in a floodplain. This determination should be made according to floodplain maps issued by the Federal Emergency Management Agency, or a more detailed map of an area, if available. If such maps are not available, the agency should develop the appropriate information to make the determination of the location of the floodplain and obtain FEMA's concurrence. For major federal actions significantly affecting the quality of the human environment, the evaluation will be included in any statement prepared under Section 102(2)(C) of the National Environmental Policy Act (NEPA).

Prior to undertaking or assisting in the repair, maintenance, improvement, or rehabilitation of any structure or facility in the floodplain, the agency should conduct an assessment of the vulnerability of that structure to flooding and the feasibility of lessening such impact through mitigation techniques.

The agency should consider all alternatives to avoid development in the floodplain for any activity the agency has determined to, or proposes to, conduct, support, or allow in a floodplain. If the head of the agency finds that the only practicable alternative consistent with the law and the Executive Order requires development in a floodplain, the agency should, prior to taking action, design or modify the action to reduce to the maximum extent practicable, the potential harm to or within the floodplain consistent with regulations issued in response to a revised Executive Order.

Each agency should send a notice, not to exceed three pages in length including a location map, to the state and appropriate area-wide clearinghouses for the geographic areas affected. The notice should include: (i) the reasons why the action is proposed to be located in a floodplain; (ii) a statement indicating whether the action conforms to applicable state or local floodplain protection standards; and (iii) a list of the alternatives considered. Agencies should endeavor to allow a brief comment period prior to taking any action.

Agencies should provide FEMA with a notice that includes: (i) the reasons why the action is proposed to be located in a floodplain; (ii) a statement indicating whether the action conforms to applicable state or local floodplain protection standards; and (iii) a list of the alternatives considered. Whenever practicable, agencies should provide this notice concurrent with a brief comment period prior to taking any action. If FEMA determines that the proposed action is inconsistent with the revised Executive Order, then FEMA can refer the issue to the Water Resources Council.

Each agency should also provide opportunity for early public review of any plans or proposals for actions in the floodplain in accordance with Section 2(b) of Executive Order No. 11514, as amended, including the development of procedures to accomplish this objective for federal actions whose impact is not significant enough to require the preparation of an environmental impact statement under Section 102(2)(C) of the NEPA of 1969, as amended.

Any requests for new authorizations or appropriations transmitted to the Office of Management and Budget should indicate, if the action proposed is located in a floodplain, that the proposed action has been reviewed for alternatives and minimization of adverse impact in accord with the revised Executive Order.

Each agency should require that: (1) all of its water and land use plans comply with the terms of this order; (2) its regulations and operating procedures require an evaluation and consideration of potential flood hazard prior to the issuance of licenses, permits, loans, or grants-in-aid for programs that they administer; and (3) its regulations provide appropriate guidance so that applicants for federal licenses, permits, loans, or grants can incorporate, in their applications, the evaluation required above.

APPENDIX G

Each agency should issue or amend existing regulations and procedures within one year to comply with the revised Executive Order. These procedures should explain the means that the agency will employ to pursue risk reduction and environmental enhancement in connection with its activities in the floodplain. To the extent possible, existing processes, such as NEPA, should be utilized to fulfill the requirements of the revised Executive Order. Agencies should prepare their procedures in consultation with the Water Resources Council, FEMA, and Office of Environmental Policy and should update such procedures as necessary.

All federal agencies with responsibilities for construction or operation of federal real property and facilities, or licensing or permitting of federally regulated facilities, should take the following measures:

The regulations and procedures established by the Executive Order should, at a minimum, require the construction of federal structures and facilities be in accordance with the standards and criteria of the National Flood Insurance Program, except that all facilities or infrastructure which can be reasonably considered as critical to the health and safety of the public and the environment should be required to have protection capable of withstanding the standard project flood. They should deviate only to the extent that the standards of the National Flood Insurance Program are demonstrably inappropriate for a given type of structure or facility, or its location.

If, after compliance with requirements of the Executive Order, it is determined that there is no practicable alternative to placing new construction or rehabilitating structures of facilities in a floodplain, at a minimum the requirements of the National Flood Insurance Program should be applied. To achieve flood protection, agencies should, wherever practicable, elevate structures above the base flood level rather than filling in land.

If property used by the general public has suffered flood damage or is located in an identified flood hazard area, the responsible agency should provide on such structures, and other places where appropriate, conspicuous delineation of past and probable future flood height in order to enhance public awareness of and knowledge about flood hazards.

When property in the floodplain is proposed for lease, easement, right-of-way, or disposal to non-federal public or private parties, the agency should (1) reference in the conveyance those uses that are restricted under identified federal, state, tribal, or local floodplain regulations; and (2) attach other appropriate restrictions to the uses of properties by the grantee or purchaser and any successors, except where prohibited by law; or (3) withhold such properties from conveyance.

Comply to the maximum extent practicable with state, tribal, or local rules or regulations for development in floodplains of each jurisdiction within which a federal facility is located or proposed to be located if such rules or regulations provide for more stringent levels of flood protection or require mitigation measures more extensive than those required by the National Flood Insurance Program.

Agencies which guarantee, approve, regulate, or insure any financial transaction which is related to an area located in a floodplain should, prior to completing action on such transaction, inform any private parties participating in the transaction of the hazards of locating structures in the floodplain.

The Water Resources Council should develop guidance for implementing the provisions of the revised Executive Order within six months of its being signed. The head of each agency should submit a report to the Office of Environmental Policy and the Water Resources Council regarding the status of their procedures and the impact of the Executive Order on the agency's operations. Thereafter, the Water Resources Council should periodically evaluate agency procedures and their effectiveness.

The proposed Executive Order should not apply to assistance provided for emergency work essential to save lives and protect property and public health and safety, performed pursuant to Sections 402 and 403 of the Robert T. Stafford Disaster Relief and Emergency Assistance Act, as amended (PL 93-288). To the extent the provisions of the Executive Order would be applicable to projects covered by Section 104(h) of the Housing and Community Development Act of 1974, as amended (88 Stat. 640, 42 USC 5304(h)), the responsibilities under those provisions may be assumed by the appropriate applicant, if the applicant has also assumed, with respect to such projects, all of the responsibilities, for environmental review, decisionmaking, and action pursuant to the NEPA of 1969, as amended.

The executive order should apply to all federal agencies and federally owned corporations.

APPENDIX H

PROPOSED FEDERAL PROGRAM FOR MAJOR MAINTENANCE AND MAJOR REHABILITATION OF LEVEES

The concept of and the actions necessary for establishing a federal program to ensure the integrity of levees in the upper Mississippi River Basin are presented in Chapter 10 and in the Action Plan. Specific elements of the proposed program as it pertains to both federally built/locally maintained levees and locally built/locally maintained levees are presented here.

DETAILS OF THE PROGRAM

Levee districts/owners desiring to participate in the USACE major maintenance and major rehabilitation (MM&MR) program would submit requests, through their state, to the USACE within a three-month period following initiation of the program by the Administration. The USACE would then group these requests into a project that would be submitted to the Congress for authorization. Levees would be placed in an Upper Mississippi River and Tributaries (UMR&T) project, which includes the Missouri River Basin, to be established as a line item in the USACE program.

Federally Built, Locally Maintained Levees Currently in the USACE PL 84-99 Emergency Repair Program

Eligibility. On approval by the Congress. the USACE would become responsible for major maintenance and major rehabilitation (MM&MR) of levees. To become eligible for participation in these programs, states and local sponsors would agree to:

a. Participate in the National Flood Insurance Program (NFIP).
b. Continue responsibility for routine maintenance and control of the levees.
c. If the levee affords less than one percent annual chance (100-year) flood protection, require all development behind the levee to comply with provisions of the NFIP.
d. If levee provides less than standard project flood (SPF) level protection, require all structures and crops behind the levees be insured.
e. Not raise the height of the levee during floods without the agreement of the USACE.
f. In the event of any required repair, renewal, or realignment, pay 25 percent of the cost and provide the necessary borrow material and any required lands, easements, and rights-of-way. The non-federal share shall not exceed 50 percent of the total project cost.
g. In coordination with the appropriate federal and state agencies, assist in developing, at minimal cost to the land owners or the local sponsors, appropriate environmental enhancements to the land behind the levees.

Major Rehabilitation Survey. The USACE would conduct a review of all levees in the program to determine long-term rehabilitation requirements and potential for upgrade. The primary determinant of eligibility for major rehabilitation and/or upgrade would be the results of an expanded benefit-cost analysis under revised *Principles and Guidelines* which includes, in addition to economic factors, the social and environmental benefits and costs. The review would also include an assessment of the impacts of any rehabilitation on the hydraulics of the river. State and local sponsors would agree to:

a. Pay 25 percent of the expense of any major rehabilitation, renewal, or upgrade.
b. Include appropriate environmental enhancements or operating measures in any major rehabilitation or renewal projects. The costs of these enhancements would be shared by the non-federal sponsor only in so far as the benefits could be assessed as local. For enhancements that are of regional or national significance, the non-federal share would be provided by the state, private organizations, or other authorized federal agency.

Locally Built, Locally Maintained Levees Currently in the USACE PL 84-99 Emergency Repair Program or Designated by Either the SCS or the EDA for Inclusion

Initial Eligibility. Since locally built levees may not have been constructed in accordance with sound engineering practices and at hydraulically appropriate locations, the USACE initially would screen all levees proposed for inclusion in the MM&MR program to determine any potential problems. Levee sponsors whose levees failed to meet the USACE engineering standards would be required to bring those structures up to standards at sponsor expense prior to inclusion in the federal MM&MR program. Those located at hydraulically inappropriate locations would not be eligible. To become eligible, states and local sponsors would agree to:

a. Participate in the NFIP.
b. Continue responsibility for routine maintenance and control of the levees.
c. If the levee is determined by the USACE to provide protection against less than the one percent annual chance (100-year) flood, require all development to comply with the NFIP.
d. Require that all structures and crops behind the levees be insured.
e. Not raise the height of the levee during floods without the agreement of the USACE.
f. In the event of any required repair, renewal, or realignment, pay 25 percent of the cost and provide the necessary borrow material and any required lands, easements, and rights-of-way. The non-federal share shall not exceed 50 percent of the total project cost.
g. In the event of levee failure, share the cost (25 percent) and provide the lands, easements, and rights-of-way necessary to ensure the future stability of the levee.
h. In coordination with the appropriate federal and state agencies, assist in developing, at minimal cost to the land owners or the local sponsors, appropriate environmental enhancements to the land behind the levee.

Major Maintenance and Major Rehabilitation: On approval by the Congress, the USACE would become responsible for future major maintenance and major rehabilitation of those levees accepted into the federal MM&MR program.

Major Rehabilitation Survey. The USACE would conduct a review of all levees accepted into the program to determine long term rehabilitation requirements and potential for renewal. The primary determinant of eligibility for major rehabilitation would be the results of an expanded benefit-cost analysis under revised *Principles and Guidelines* which include, in

addition to economic factors, the social and environmental benefits and costs. The review would also include an assessment of the impacts of any rehabilitation on the hydraulics of the river. State and local sponsors would agree to:

a. Pay 25 percent of the expenses of any major rehabilitation, renewal, or upgrade.
b. Include appropriate environmental enhancements or operating measures in any upgrade or renewal projects. The costs of these enhancements would be shared by the non-federal sponsor only in so far as the benefits could be assessed as local. For enhancements that are of regional or national significance, the non-federal share should be provided by the state, private organization, or other authorized federal agency.

APPENDIX I

COORDINATION MECHANISMS

WATER RESOURCES COUNCIL

Purpose

The revitalized Water Resources Council should launch and promote cooperation among the federal agencies and the states. It should exist as a mechanism to bring together appropriate policymakers to address key water resources issues. The WRC should align federal floodplain management goals with other broad national goals; provide a single point of focus to assist coordination and resolution of interstate water resource management issues; serve as an innovative planning and technology center (including intergovernmental data gathering and dissemination activities); and resolve federal agency disputes. The WRC should operate under a clarified set of responsibilities compatible with Title I of the 1965 Act and capitalize on the experience of the previous Council. Should the WRC prove an ineffective organization for accomplishing these activities, it should be abandoned.

Membership

Participation in the Council, currently chaired by the Secretary of the Interior, needs to be broadened to include the Administrator of the EPA and the Director of FEMA -- two agencies that did not exist at the time the WRC was first conceived. The participation of these agencies is critical for addressing floodplain management issues. Because EPA's program responsibilities include restoration and enhancement of the nation's water quality, and FEMA's responsibilities include administration of the NFIP and flood recovery, they both merit a role in the Council. Therefore, the Secretary of the Interior should request that the Administrator of EPA and the Director of FEMA become full-time participants on the Council. In addition to the Secretary of the Interior, EPA and FEMA, membership of the Council should be the Secretaries of Army; Agriculture; Commerce; Housing and Urban Development; Health and Human Services and the Chair of the Federal Energy Regulatory Commission. Other agency heads may be called upon by the Chair when matters affecting their responsibilities are considered by the Council.

Staffing

The Secretary of the Interior, as Chair of the Water Resources Council, should restaff the Council. A small staff to support the Council's mandate is suggested. A Director, five professionals and one administrative support/secretary is suggested as the minimum desirable staffing level. Two professionals are envisioned for a Floodplain Management Division.

Budgeting

As authorized in the Act, the Council shall request a budget for professional and support staff and necessary office space, equipment, travel, and contract fund. A budget of $950,000 is envisioned for this purpose.

APPENDIX I

BASIN COMMISSIONS

Designation

The President should establish basin commissions as a forum for coordinated federal and state planning across basin(s) and within sub-basins (as determined appropriate). The WRC should, in coordination with states, define the geographic reach of the commissions. Section 201 of the Water Resources Planning Act of 1965 (PL 89-80) describes how basin commissions can be requested by either the Water Resources Council or states and then declared by the President.

Purpose

Each basin commission should serve as the principal agency for the coordination of federal, state, interstate, local, and non-governmental plans for their designated areas and operate under a clarified set of responsibilities compatible with Title II of PL 89-80, but building upon the lessons learned from the previous commissions. The basin commissions will actively lead collaborative efforts that focus beyond traditional water management challenges to undertake integrated examination of ecosystem management, biodiversity conservation, flood control, water supply, navigation, water quality, and sustainable development issues. The focus of these commissions is on action not on oversight.

Membership

The basin commissions would be co-chaired by a representative of a federal agency and a representative of a state governor. To clearly advance state leadership in floodplain management, the voting role of federal agencies should be limited. The Governor of each basin state shall appoint a member that serves at the pleasure of the Governor.

Staffing and Budgeting

Organization of the basin commissions using existing federal and state programs and budgets to accomplish tasks will increase coordination, cooperation and leveraging of limited funding and achieve a comprehensive approach to issue resolution. The basin commission would create an environment where agencies' activities are orchestrated to achieve multiple benefits for the basin. One means of ensuring this approach is to keep actual basin commission staffing to a minimum. A director and a staff of 3 to 4 full-time professionals is suggested; these would not be federal employees. Where appropriate, the current basin association staffs could assume this responsibility. Average annual budgets of $400,000 are estimated for the Upper Mississippi River Basin Commission and the Missouri River Basin Commission and would be cost-shared by the federal government. As special projects require additional funding to the federal and state agencies, the river basin commission may request appropriations from Congress and/or the state legislatures.

APPENDIX I

EXPANDED MISSISSIPPI RIVER COMMISSION

Purpose

The current Mississippi River Commission (MRC) provides a necessary connection between the public, a construction, operations and maintenance agency, and the executive branch of U. S. government, as well as implementation oversight of a range of water resources activities. The MRC has established a record of expertise and accomplishment, has a clear charter in the basin, and has established processes to make recommendations to the Administration and Congress, and to have funds appropriated for implementation. The purpose for the expansion is to link the entire Mississippi River Basin together to provide a system-wide approach. The composition of the Commission should be expanded to include the additional responsibility of program integration between the construction and environmental missions of the USACE and the ecosystem stewardship missions of the DOI.

Membership

The current Commission has, by Presidential appointment, seven members. There are 3 USACE and 3 civilian members and one member from the NOAA Coast and Geodetic Survey. The President should seek approval from Congress to add a member from DOI and should nominate a membership which ensures appropriate distribution of decision-making authority among action agencies, as well as ensuring representative authority to follow through on plans and projects approved by the Commission and authorized by Congress. A possible membership is provided on the next page.

APPENDIX I

EXPANDED MISSISSIPPI RIVER COMMISSION

Current MRC	Expanded MRC
Authorities from headwaters to Head-of-Passes, La., including all tributaries.	In consultation with Congress, include tributaries in the upper basin.
Current focus is MR&T project.	Include UMR&T.
Seven Presidentially appointed members – 3 USACE, 3 Civilians, 1 NOAA (C&GS).	Add DOI from Assistant Secretary level. NOAA should be at-large.
Advisory to the Chief of Engineers.	Advisory to both Chief of Engineers and the Secretary of the Interior.
President is a Corps officer who is responsible for MR&T and reports to the Chief of Engineers.	Add UMR&T responsibility.
USDA advises.	USDA and EPA advise.
Duties include: -Recommend policy and work program of MR&T. -Study and report on project modifications. -Comment on matters authorized by law. -Conduct inspection trips and hold public hearings.	Additional duties: -Integrate ecosystem and watershed management strategies into currently authorized projects for flood control and navigation. -Study and report on natural resource conditions and improvements realized by integrated river management.
Has established processes to recommend administrative approval and/or Congressional authorization of specific proposals, and to have funds budgeted and appropriated for implementation.	Include DOI proposals and programs.
Uses MRC/LMVD and District staffs to develop plans and implement actions.	Include Corps Divisions and Districts in the upper Mississippi River Basin. Also include FWS Regions III, IV, and VI; NBS; GS; BOR; and BLM staff to collaborate and integrate natural resource management plans. Develop recommendations for state application.
Activities include general investigations, design, construction, and operations and maintenance.	Add oversight of refuge operations, inter-jurisdictional fisheries, Migratory Bird Program, and research.

Appendix J

SUMMARY OF COMMENTS

The Review Committee provided a draft copy of its report to federal agencies, members of Congress from the flood-affected area and leading key committees and subcommittees involved with subjects addressed by the report, the governors of the nine Midwest states, and a number of non-governmental organizations that had worked with the Review Committee during its fact finding and outreach phases. This review was intended to seek feedback from the above parties and was not intended as a substitute for a broad-based public comment period. Considerable interest, however, was expressed in the draft document and over 650 copies were distributed. Despite the very brief comment period, nearly 100 comments were received via facsimile, mail, and telephone by June 16, 1994. Five of the nine Midwest governors commented to the Review Committee; other Midwest governors assigned a lead agency to provide state comments.

The nature of comment letters ranged from full endorsement to opposition. Many of those who commented endorsed the report, or a subset of the actions and recommendations, or requested clarification. Conversely, some of those who commented opposed the report or a subset of the actions and recommendations. Others provided their thoughts regarding certain general issues and asked that their concerns be considered by the Review Committee. Some comments indicated that the reviewer had misinterpreted the Review Committee's intended message. Many of those who commented provided additional data, technical corrections, or pointed out typographical errors. Some noted that their comments were limited to the Executive Summary or only sections of the report due to the short review period. Some comments were general in nature and not reflective of the themes and specific proposals contained in the draft report; the Review Committee is, therefore, led to believe that the comments are reflective of perceptions of the report based on inaccurate summaries of the report by the media or some group.

The Review Committee reviewed all comments and made corrections, clarifications, and additions where warranted. The comments led to development of a better report and the efforts made by those who provided comments were appreciated. Where appropriate the Review Committee responses to comments appear below, in italics, to guide readers to particular clarifications or changes made in the final document.

Many individuals and organizations endorsed the report's themes and vision for what needs to be done to implement floodplain management. Many more organizations and individuals endorsed large numbers of the recommendations and actions while raising questions, concerns and/or objections to others. Summarizing the nature of the comments is difficult because the absence of opinion expressed on particular proposals may indicate support.

There was nearly universal comment that the Review Committee developed, within a short time frame, a comprehensive report addressing a wide variety of improvements needed to enhance the nation's approach to floodplain management. Nearly all commented that additional time to review the draft report would have been appreciated. Several indicated a desire to comment on the final document.

Nearly all made comments on areas where they believed the report could be strengthened or where they perceived omissions. Many raised concerns regarding the costs associated with the report as a whole and with specific recommendations -- many indicating that their support was dependent, at least in part, on the cost trade-offs.

MAJOR THEMES OF COMMENTS

Several areas of the report generated the majority of the comments; however, not all comments reflected the same opinion.

Support for change

There was nearly universal support for a need to change the nation's approach to floodplain management; not surprisingly, there was a divergence of opinion regarding the means to achieve flood damage reduction. There was hesitation on the part of some reviewers to endorse the direction and approach made by the Review Committee. Nearly all agreed that a systems approach to floodplain management was needed to replace uncoordinated ad hoc efforts.

Treatment of watersheds

Many made comments regarding the draft report's treatment of watersheds. Some found that the report unduly emphasized the role, value, and significance of watershed and ecosystem planning with respect to achievement of floodplain management and flood damage reduction goals. Several of those who commented reflected concerns that the draft report did not adequately tie together preservation and restoration of aquatic ecosystems and watersheds with floodplain management. Several indicated that watershed management was not sufficiently integrated into floodplain management and that nonstructural alternatives to flood damage reduction were not given enough support.

Structural approaches

Many of those commenting felt that the existing structural approach to flood damage reduction had proven its value and not enough credit was given to the predominantly structural approach the nation has, in the past, taken to reduce flood damages. Many felt that nonstructural approaches were experimental and their merit uncertain. However, others were concerned that the report overemphasized structural solutions; some feared that the report might further broad interest in a widespread construction program consisting of large levees.

Administrative and organizational structures

Many comments reflected concern about the number of organizations proposed, the designation of leadership responsibilities, and the interaction and relationships among these organizations. These concerns reflected uncertainties about the costs of such proposals (which were not characterized in the draft) in comparison to the added value of these organizations. Other concerns reflected hesitation to endorse some or all of these proposals until a dialogue had been opened and charters proposed to further specify responsibilities, functions, and working relationships. While these concerns were expressed, many also recognized the need for better coordination at the federal and interstate levels.

Streamlining disaster relief and improvement of the NFIP

While not everyone commenting agreed with all of the proposals, support for streamlining disaster relief and the actions and recommendations aimed at improving the NFIP was widespread.

Infringement of property rights

Some of those who commented raised concerns that proposals in the Review Committee draft report would infringe on property rights.

> *[To clarify its intent and to address these concerns, the Review Committee added additional text in the report emphasizing the voluntary nature of buyouts and clarifying that limits to floodfighting would not prevent floodfights consistent with state and local floodplain management regulations.]*

APPENDIX J

COMMENTS ON ACTIONS AND RECOMMENDATIONS

Many of the comment letters reflected specific objections or concerns with proposed actions and recommendations; others focused on proposals that they supported. Summarized, below, are those actions and recommendations for which at least six of those commenting provided definitive statements of either support, concern or objection.

Basin Commissions, Upper Mississippi and Missouri River Basin Commissions (Actions 5.3 and 10.2)

No other proposal in the report generated so many specific comments as the basin commissions. Many of the comments expressed a desire not to create basin commissions in the same form as those that existed in the late 1960s and the 1970s.

> *[The Review Committee concurs that new basin commissions should take on a different function and approach and both learn from and build upon the lessons of the previous basin commissions. This was the basis for the proposed changes to the previous basin commissions' function and structure. The Committee has also altered Figures 5.1 and 10.1 to clarify the relationships among the Water Resources Council, the basin commissions, and the Mississippi River Commission.]*

Many of those who commented expressed confusion regarding the relationships between the Mississippi River Commission and the Upper Mississippi River Basin Commission. Some comments reflect further confusion in that they were considered the same organization.

> *[The Review Committee has made changes to further clarify the relationships between these organizations. Figure 10.1 has been changed to distinguish between lines of "command" or oversight and lines of coordination. It is unfortunate that the names of these organizations are so similar – to try to further distinguish them, the final document refers to basin commissions as opposed to river basin commissions.]*

Many of those who commented reserved endorsement of basin commissions until further dialogue on their purpose, functions, and methods of operation was pursued.

Increase the state role in all floodplain management activities (Recommendation 5.2)

This recommendation generated a large number of specific comments, with half supporting the recommendation and half against. The general reason for not supporting the recommendation reflected a concern that interjecting the states between levee districts or local communities would increase bureaucracy and slow response. Supporters generally expressed that states' need to exercise their responsibilities and their involvement would add value to efforts to achieve floodplain management goals.

Mississippi River Commission (Action 10.2)

Many comments were also received regarding the Mississippi River Commission. Overall, most comments expressed reservations about this proposal, but for a variety of reasons. Some comments arose from concerns about the nature of activities of the Commission in the past (prior to the last decade) and the Commission's ability or interest in taking on a broader nonstructural approach to floodplain management. Others arose from not wanting to broaden the Commission's membership and charter to address related ecological resource issues or not trusting the Commission's interest in pursing these issues. Others objected to extending the geographical extent of the Mississippi River Commission's authority.

> *[The Review Committee added new text to clarify the legislative authority of the Mississippi River Commission which already assigns the Commission's authorities to extend from the river's mouth near the Head of Passes to its headwaters. The Review*

Committee feels that further dialogue on the relationship between basin commissions and the Mississippi River Commission and the functions and duties of the Mississippi River Commission could allay some concerns and develop support for this action.]

Water Resources Council (Action 5.2)

The proposal to revitalize the Water Resources Council generated numerous comments. Generally there was broad support for the WRC or a similar entity to provide a mechanism for interagency, policy level coordination. Several were hesitant to support the proposal until further operational and administrative issues had been developed. Some questioned the political desire to renew the Council.

Floodplain Management Act (Action 5.1)

Several comments specifically indicated support for a floodplain management act to define governmental responsibilities, strengthen federal-state coordination and assure accountability and fund state floodplain management programs.

New Executive Order on Floodplain Management (Action 5.4)

Overall comments supported this action. Several comments, however, indicated that the executive order was an inappropriate Administration action circumventing Congress. Some comments indicated that FEMA oversight of compliance with the EO was unnecessary.

[The Review Committee notes that the existing Executive Order on Floodplain Management has been in place since 1977 without objection from Congress. The Review Committee's proposal is intended to reaffirm Administration support for floodplain management and to clarify certain federal responsibilities to undertake a sequence of avoiding floodplain development, minimizing the adverse effects from flooding and to the floodplain, and finally mitigating potential flood damages. It does not represent a departure from congressional policy on floodplain management. The Review Committee agreed with comments indicating that FEMA's role should include resolution of disagreements over EO compliance and that FEMA should only refer to the Water Resources Council those issues were significant attempts to reach resolution had failed.]

Principals and Guidelines (Actions 5.10 and 5.11)

Many of those specifically commenting on Actions 5.10 and 5.11 reflected support for establishing co-equal objectives for the *P&G*. A few expressed concern regarding the mechanism used to evaluate environmental quality and compare alternative courses of action. Several noted the difficulties inherent in both quantifying and monetizing attributes contributing to environmental quality. The establishment of an interdisciplinary, interagency review of other aspects (including application of the *P&G*) raised objections regarding the application of the *P&G* to specific types of actions, including those to which the current *P&G* now apply.

[The purpose of the interdisciplinary, interagency review is to discuss and address whether the revised P&G could and should be applied to a broader array of federal decisions and to develop guidelines for application of the principles.]

Develop common procedures for buyouts (Action 8.4)

Most comments registered support for this concept. Some expressed concerns regarding whether there could be common procedures for programs with different purposes.

Hazard Mitigation Grants as block grants (Action 8.5)

Most comments regarding this Action reflected support. Concern was raised regarding means to ensure that states used the funds appropriately.

Establishing the USACE as the principal levee construction agency (Action 8.1)

Of those commenting on this Action, nearly all supported it. Concern was raised regarding the continued role of the USDA with respect to agricultural levees.

> *[The Review Committee has added clarifying language to better reflect the relationship of the USACE to USDA and other federal agencies considering levee projects.]*

Extend 5-day waiting period for flood insurance coverage (Action 9.7)

All those commenting on this action supported the extension of the time period. Several supported further lengthening the time period beyond the 15 days recommended by the Review Committee to account for the potential for flood crests moving further downstream on the Mississippi. Concern was noted that the waiting period should not apply when a home is being purchased.

> *[Text was added to clarify that there would be no waiting period associated with purchase of flood insurance at closing after purchase of a home].*

Expansion of conservation and voluntary acquisition programs in 1995 Farm Bill (Action 6.3)

There was broad support for continuing these programs.

DOI coordinating environmental acquisition (Action 7.1)

Some concerns were raised regarding whether DOI had the in-house capability to perform this function. Others raised concerns regarding the extent of DOI responsibilities and applicability of this proposal to dual purpose acquisitions. Some pondered the federal interest in additional land management responsibilities.

> *[The Review Committee reviewed the language of this and related actions to ensure that DOI's function was one of coordination of acquisition. Agreements between agencies would be developed to determine specific procedures and applicability of those procedures. The text already indicates that lands acquired in fee will not necessarily be held or managed by the DOI or the federal government.]*

Limiting public assistance grants for communities not participating in the NFIP (Action 5.7)

Most all of those who commented on this Action indicated support.

Integration of flood response and recovery under FEMA (Recommendation 9.1)

Of those commenting, most supported the proposal. One suggested that FEMA needed Presidential support to achieve cooperation from cabinet-level agencies.

> *[The Review Committee believes that response and recovery require leadership from a single knowledgeable agency, just as land acquisition for environmental purposes and levee construction requires leadership and coordination by knowledgeable agencies. The Review Committee sees these delineations of clear responsibility as critical to providing a streamlined, responsive, and efficient program for response, recovery, and overall floodplain management.]*

Multi-objective watershed management task force (Action 6.1)

There was general support for this proposal although a few thought it was unnecessary.

ANALYSIS OF COMMENTS BY ORIGINATORS

Congress

Congressional reaction to the report was mixed. While all felt the report to be balanced, concern was raised by some members regarding the impact of the recommendations on their constituents. Some members indicated interest in sponsoring legislation to implement some of the proposals in the draft report.

Federal Agencies

Federal agencies provided comments ranging from full support to specific technical comments that indicated neither specific support nor opposition to the proposals in the draft report. A few comments reflected hesitation to alter current policies, approaches, and responsibilities without further dialogue with or guidance from Administration leadership.

States

Comments were received from all but one Midwest state and were generally supportive of the report and its vision. One state from outside the Midwest noted general support for the proposals. Several states indicated their readiness and willingness to take on the challenges and responsibilities articulated in the draft report. Some concerns were raised about organizational and administrative mechanisms. A few raised concerns about the level of funding and technical assistance that would be provided to states. A few comments were received from state legislators. These letters reflected that the report was recommending cessation of levee repair work in their jurisdiction and were concerned that the proposals in the report would adversely impact navigation and farming along the rivers.

Levee and drainage districts and individual farmers

Several reflected concerns that the Review Committee draft report was calling for a unilateral buyout of bottomland agriculture to restore wetlands. Many reflected a concern that the report emphasized environmental protection over flood hazard protection to bottomland activities. However, many also expressed support for recommendations and actions contained in the report. Some were deeply concerned with what they perceived in the report to be a prohibition against all floodfighting. Some noted that property rights of farmers and others needed to be more carefully considered. Several noted concerns about the impact of buyout and acquisition on the local and regional economy and the impact on tax roles.

Environmental non-governmental organizations

Strong support for reestablishment of the Water Resources Council was noted in all comments made by these organizations. While some environmental organizations supported the report, many expressed serious concernsthat the report did not sufficiently emphasize restoration of aquatic ecosystems, watershed management and nonstructural approaches to floodplain management. Many comments also reflected concerns about issues that the report failed to address including the role of federal programs influencing bottomland farming and navigation issues on the Missouri River. Concerns were raised about the efficacy of the Mississippi River Commission to pursue new mandates. Concerns were raised that the report appeared to support a new levee construction program on the Upper Mississippi and Missouri rivers.

Other non-governmental organizations

A number of non-governmental organizations, including several professional affiliation, and regional planning and coordination organizations commented on the draft. As might be expected, there was considerable divergence of opinion on specific proposals. The opinions summarized on the draft report reflect the differences of the many non-governmental organizations. Several indicated long-standing support for several of the recommendations in the report. Some commented that the report was "anti-agriculture" and one commented that the report was "anti-city".

Others

Comments were received from a wide variety of other organizational entities consisting of state agencies, cities, and individuals, including public school teachers; academics from across the nation in the fields of water resources, natural hazards, and hydrology; land-owners in the Midwest; and other interested parties. As with comments from other sectors, their were a variety of viewpoints expressed which ranged from endorsement of the report to objections to specific recommendations.

RE: Noise Pollution

Dear Mr. Christopher Cline,

We are righting this letter to inform you of the action we are taking in regards to the lack of concern of the Mach Mining Company in Johnston City, Illinois. I (Patricia) have been to see the land agent at Mach Mining (Gary Schmitz) a number of times to try and resolve the enclosed problems and at one point Mr. Schmitz offered to purchase ear plugs to remedy the noise problem we are facing, however cute that was it does not solve the problem. We have got the run around from the mine staff, hurry up and wait or sorry about your luck. I'm not sure they understand how bad this problem is to us who have to live here on a regular basis'.

The Grant family has lived in this rural area (property and roads) for the past 68 + years. This area is primarily rural farm homes and family. Normal traffic on our roads (Liberty School Rd and Dean Rd) were local's a proximally 15 - 20 cars per day, we were able to let our children walk, ride bikes and ride horses up and down these rural roads. I (Patricia) moved in this area about 10 years ago. The reason I moved here is because it was peaceful, quiet, safe and I could ride my horses up and down the roads and not worry.

All of these things changes when "Cline Resource and Development Company" purchased the old Zeigler property on Liberty School Road. Once ground was broke and the mining process was started back in spring of "2005" everything changed in our once quiet farming community. We no longer feel safe to ride our horses, or let our children ride there bikes or walk back and forth to each others homes because of the increase of traffic and heavy equipment using Liberty School Rd . Sitting outside to listen to nature is impossible because of the traffic, noise, dirt and dust created by Cline Resource and Development project adjunct to our property. In short this once quiet place is now riddled with, large buildings, massive coal and dirt piles, cranes, drilling rigs, hoist towers, coal towers, and the

noise from the mine vent fan, and a rail road track. Traffic increased due to employees, concrete trucks (some times running 24 hours a day), delivery trucks, heavy equipment (running at all hours using back up beepers), semi trucks using jake-breaks, and most every one speeding.

Mr. Cline, my primary concern is with the noise from the mine vent fan running 24/7 adjunct to our property, the location of said fan is North/East approximately 1/8 mile from the front door of Randy Grant and Patricia Wallace, the location to Donald Grant 's residents is South/East approximately 1/8 to ¼ mile. I believe the noise pollution generated by the operations at Mach Mining Coal Company on Liberty School Road in Williamson County, Johnston City, Illinois, may be over the limits set by Illinois Pollution Control Board.

We do not wish to move from our homes. We are hoping that you will consider our concerns and we can come up with an solution to satisfy all of us. We would rather work this problem out amicably, but if forced to we will pursue this matter through the legal system to obtain the relief we are seeking. I have enclosed all regulations pertaining to my formal complaint that I will be filing, if we do not resolve this problem with in the next (15) days, I will be filing a Formal Complaint with the Illinois Pollution Control Board, complaint enclosed.

Your prompt attention in this matter will be greatly appreciated.

Sincerely,

Donald Grant

6. ***Describe the type of pollution that you allege (e.g., air, odor, noise, water, sewer back-ups, hazardous waste) and the location of the alleged pollution. Be as specific as you reasonably can in describing the alleged pollution.***

Low rumble, echoing whirl noise coming from an air shaft exhaust fan (temporary fan) located on Dean Road in Williamson County Illinois, approximately 1/8 mile N.E. of Randy Grant and Patricia Wallace's home and farm property on Liberty School Rd, the proximity to Donald Grant is S.E. about 1/8 to less than ¼ mile from his home and farm property on Dean Road. Additional noise at the same location are as follows back-up beepers from heavy equipment, coal droppping from the raw coal tower, train cars banging together and the train whistle, Additional traffic noise at all hours of the day and night from employees of the coal company, delivery trucks to the coal company, semi trucks hauling material, rock and miscellaneous material, and concrete trucks. The lights from the coal company property shine in our house all night long.

7. ***Describe the duration and frequency of the alleged pollution. Be as specific as you reasonably can about when you first noticed the alleged pollution, how frequently it occurs, and weather it is still continuing (include seasons of the year, dates, and times of day if known).***

The noise from the coal company started in the summer of 2005. This includes, at least a 75% increase of traffic (semi's, concrete trucks, on a few occasions the concrete trucks were 24 hours a day, heavy equipment, back-up beepers, dirt, dust). The fan noise started on 9-16-06, this is the temporary fan, according to the land agent for Mach Mining (Gary Schmitz). It is the sole source of air for their long wall operation belonging to the Respondent at this time, Mr Schmitz did inform us that the permanent fan will be in operation by the end of Janurary 2007. The temporary fan noise started on 9-16-06 and runs 24/7 unless there is a power failure or shut-down. There is not one place on our property adjunct to this coal company that the fan can not be heard.

8. ***Describe any bad effects that you believe the alleged pollution has or has had on human health, on plant or animal life, on the environment, on the enjoyment of life or property, or on any lawful business or activity.***

The effect on the complainants personal health has been numerous, lack of restful sleep, headaches, unable to relax in our own homes, irritability and fatigue, At time's I (Patricia) have the uncontrollable urge to just cry because the noise is never ending. We can not enjoy sitting outside any more because of the fan noise. Donald has gone to the expence of adding a room on the other side of his home to try to get away from the noise from the fan. All this is due to the noise from the Respondent's property.

9. ***Describe the relief you seek from the Board (e.g., an order that the respondent stop polluting, take pollution abatement measures, perform a cleanup, reimburse cleanup cost, change its operation, or pay a civil penalty (note that the Board cannot order the respondent to pay your attorney fees or ant out-of-pocket expenses that you incur by pursuing an enforcement action))***

Complainants request that the Board order the Resopndents to cease and desist from further violations of applicable statutes and regulations and, more specially, order the Respondents to permanently reduce the noise level to a point that it no longer causes a disturbance to the Complainants personal and emotional health and or their property. We feel that a silencer installed on the fans will greatly reduce the noise levels.

10. ***Identify any identical or substantially similar case you know of that is already pending before the Board or in another fourm against this respondent for the same alleged pollution (note that you need not include and complaints made to the Environmental Protection Agency or any of local government).***

A suit has been filed in Williamson County Court by, Attorney Jay Schafer of 111 West Main Street, Marion, Illinois 618-997-5611 he is under retainer for the family's of Phil Anderson, Shirley Davies, and Roland Rogers all located on Liberty School Road in Williamson County, Marion, Illinois. This Suite was filed in the early 2006.

11. ***State weather you are representing (a) yourself as an individual or (b) your unincorporated sole proprietorship. Also, state whether you are an attorney and, if so, whether you are licensed and registered to practice law in Illinois. (Under Illinois law, an association, citizens group, unit of local government, or coporation must be represented before the Board by an attorney. Also, an individual who is not an attorney cannot represent another individual or other individuals before the Board. However, an individual who is not an attorney is allowed to represent (a) himself of herself as an individual or (b) his or her unincorporated sole proprietorship, though the individual may prefer having attorney representation.)***

The complaintants all representing themselves.

12.

(Complainant's signature)

CERTIFICATION

I, Randy Grant , Donald Grant, Patricia Wallace, on oath or affirmation, state that I have read the foregoing and that it is accurate to the best of my knowledge.

NOTICE TO RESPONDENT

NOTE: THIS STATEMENT MUST BE INCLUDED IN THE SERVICE OF THE FORMAL COMPLAINT ON THE RESPONDENT

INFORMATION FOR RESPONDENT RECEIVING FORMAL COMPLAINT

Please take notice that today I filed with the Clerk of the Illinois Pollution Control Board (Board) a formal complaint, a copy of which is served on you along with this notice. You may be required to attend a hearing on a date set by the Board.

Information about the formal complaint process before the Board is found in the Environmental Protection Act (Act) (415 ILCS 5/1 *et seq.*) and the Board's procedural rules (35 Ill. Adm. Code 101 and 103). These can be accessed at the Board's Web site (www.ipcb.state.il.us). The following is a summary of some of the most important points in the Act and the Board's procedural rules. It is provided for general informational purposes only and does not constitute legal advice or substitute for the provisions of any statute, rule, or regulation:

Board Accepting Formal Complaint for Hearing; Motions

The Board will not accept this formal complaint for hearing if the Board finds that it is either "duplicative" or "frivolous" within the meaning of Section 31(d) of the Act (415 ILCS 5/31(d)) and Section 101.202 of the Board's procedural rules (35 Ill. Adm. Code 101.202). "Duplicative" means that an identical or substantially similar case is already pending before the Board or in court. *See* 35 Ill. Adm. Code 103.212(a) and item 10 of the formal complaint.

"Frivolous" means that the formal complaint seeks relief that the Board does not have the authority to grant, or fails to state a cause of action upon which the Board can grant relief. For example, the Board has the authority to order a respondent to stop polluting and pay a civil penalty, to implement pollution abatement measures, or to perform a cleanup or reimburse cleanup costs. The Board does not have the authority, however, to award attorney fees to a citizen complainant. *See* 35 Ill. Adm. Code 103.212(a) and items 5 and 9 of the formal complaint.

If you believe that this formal complaint is duplicative or frivolous, you may file a motion with the Board, within 30 days after the date you were served with the complaint, requesting that the Board not accept the complaint for hearing. The motion must state the facts supporting your belief that the complaint is duplicative or frivolous. Memoranda, affidavits, and any other relevant documents may accompany the motion. If you need more time than 30 days to file a motion alleging that the complaint is duplicative or frivolous, you must file a motion for an extension of time within 30 days after service of the complaint. A motion for an extension of time must state why you need more time and the amount of additional time you need. Timely filing a motion

alleging that the complaint is duplicative or frivolous will stay the 60-day period for filing an answer to the complaint. *See* 35 Ill. Adm. Code 103.204, 103.212(b).

All motions filed with the Board's Clerk must include an original, nine copies, and proof of service on the other parties. Service may be made in person, by U.S. mail, or by messenger service. Mail service is presumed complete four days after mailing. *See* 35 Ill. Adm. Code 101.300(c), 101.302, 101.304.

If you do not respond to the Board within 30 days after the date on which the complaint was served on you, the Board may find that the complaint is not duplicative or frivolous and accept the case for hearing. The Board will then assign a hearing officer who will contact you to schedule times for telephone status conferences and for hearing. *See* 35 Ill. Adm. Code 103.212(a).

Answer to Complaint

You have the right to file an answer to this formal complaint within 60 days after you receive the complaint. If you timely file a motion alleging that the complaint is duplicative or frivolous, or a motion to strike, dismiss, or challenge the sufficiency of the complaint, then you may file an answer within 60 days after the Board rules on your motion. *See* 35 Ill. Adm. Code 101.506, 103.204(d), (e), 103.212(b).

The Board's procedural rules require the complainant to tell you as respondent that:

> **Failure to file an answer to this complaint within 60 days may have severe consequences. Failure to answer will mean that all allegations in the complaint will be taken as if admitted for purposes of this proceeding. If you have any questions about this procedure, you should contact the hearing officer assigned to this proceeding, the Clerk's Office or an attorney. 35 Ill. Adm. Code 103.204(f).**

Necessity of an Attorney

Under Illinois law, an association, citizens group, unit of local government, or corporation must be represented before the Board by an attorney. In addition, an individual who is not an attorney cannot represent another individual or other individuals before the Board. However, even if an individual is not an attorney, he or she is allowed to represent (1) himself or herself as an individual or (2) his or her unincorporated sole proprietorship. *See* 35 Ill. Adm. Code 101.400(a). Such an individual may nevertheless wish to have an attorney prepare an answer and any motions or briefs, and present a defense at hearing.

Costs

In defending against this formal complaint, you are responsible for your attorney fees, duplicating charges, travel expenses, witness fees, and any other costs that you or

your attorney may incur. The Board requires no filing fee to file your answer or any other document with the Board. The Board will pay any hearing costs (*e.g.*, hearing room rental, court reporting fees, hearing officer expenses).

If you have any questions, please contact the Clerk's Office at (312) 814-3629.

ORIGINAL

ILLINOIS POLLUTION CONTROL BOARD
CASE # PCB 2007-135
GEORGE R. STRUNK vs. WILLIAMSON ENERGY LLC.s POND CREEK MINE #1
.BOARD MEMBER; MOORE,A.S. HEARING OFFICER; WEBB C.

.DECEMBER 3, 2007

. RESPONSE TO WILLIAMSON ENERGY LLC,s SECOND MOTION TO DISMISS;
BY AND FOR GEORGE R. STRUNK, A PRIVATE CITIZEN OF THE STATE OF ILLINOIS-HAVING TO LIVE NEXT DOOR TO THIS NIGHTMARE CALLED A COAL MINE.

. I HAVE HONESTLY AND IN GOOD FAITH SENT IN EVIDENCE AND RECORDS OF PERSONAL LOGS AND NOTES OF WILLIAMSON ENERGY`S CONTINUED VIOLATION OF ILLINOIS POLLUTION LAWS. I CONTINUE TO SEE AND HEAR THE VIOLATIONS OF MY RIGHT TO A CLEAN ENVIRONMENT.

. THEIR ATTORNEYS CONTINUE TO SEEK DISMISSAL OF MY COMPLAINT. BUT THEY HAVE OFFERED NO EVIDENCE CONTRARY TO MY COMPLAINTS. JUST THEIR RETORICAL LEGAL MUMBO-JUMBO OF HOW I HAVE WRITTEN AND TRIED TO PRESENT MY COMPLAINTS. THE FACTS SHOULD CLEARLY SPEAK FOR THEMSEVES!

1. THEY CONTINUE TO POLLUTE THE AIR WE BREATHE BY ALLOWING DUST TO BE BLOWN FROM THEIR MINE SITE.
2. THEY CONTINUE TO POLLUTE THE QUIETNESS OF OUR RURAL RESIDENCE WITH NOISE OF THEIR EQUIPMENT{FANS-CONVEYORS-PREP PLANT-MOBILE EQUIPMENT-COAL TRUCKS-TRAINS}, OFTEN WAKING US IN THE NIGHT. ALWAYS DISTURBING OUR ATMOSPHERE. I ONLY WISH YOU WOULD WITNESS THIS FIRSTHAND.
3. THEY CONTINUE TO LIGHT UP OUR NIGHT SKY WITH ADDING EVEN MORE "SECURITY LIGHTS". SEEMINGLY DIRECTED AWAY FROM THE MINE AND TOWARD MY HOME. WE HAVE TO KEEP THE CURTAINS CLOSED TO GET SOME SLEEP.
4. AS FOR WATER POLLUTION; I AM STILL WAITING FOR THE I.E.P.A. TO PROVIDE ME WITH RECORDS I REQUESTED THROUGH THE F.O.I.A. I AM SURE YOU COULD ACCESS THEM A LOT QUICKER.
5. THIS IS AND SHOULD BE A VERY SIMPLE CASE; POND CREEK MINE #1 IS IN VIOLATION OF THE IEPA LAWS OR THEY ARE NOT. LET THE HARD EVIDENCE SPEAK FOR ITSELF. NO AMOUNT OF LEGAL RETORIC SHOULD BE ALLOWED TO INTERFERE WITH JUSTICE OR CHANGE THE TRUE FACTS. IS IT O.K. FOR THE MINE TO DESTROY THE ENVIRONMENT WE SO DEARLY LOVE AND NOT BE HELD RESPONSIBLE? THIS IS WHERE YOU THAT SIT ON THE ILLINOIS POLLUTION CONTROL BOARD COME INTO PLAY. I URGE YOU TO SEE THE TRUE FACTS AND HARD EVIDENCE AND COME TO A QUICK DECISION. WILLIAMSON ENERGY LLC,s POND CREEK MINE #1 IS VIOLATING OUR ENVIRONMENTAL LAWS.

. THANK YOU FOR YOUR TIME,
. GEORGE R. STRUNK

RE: Annual pH and Settleable Solids Tests for Ponds 001-008

To whom it may concern:

In accordance with NPDES Permit No. IL0077666 please find reported below results of annual pH and settleable solids tests for ponds 001 through 008.

Pond 001 pH 7.2 Settleable Solids <0.25 mg/L
Pond 002 pH 7.8 Settleable Solids <0.25 mg/L
Pond 003 pH 7.4 Settleable Solids <0.25 mg/L
Pond 004 pH 7.8 Settleable Solids <0.25 mg/L
Pond 005 pH 7.4 Settleable Solids <0.25 mg/L
Pond 006 pH 8.2 Settleable Solids <0.25 mg/L
Pond 007 pH 8.1 Settleable Solids <0.25 mg/L
Pond 008 pH 8.1 Settleable Solids <0.25 mg/L

Please contact me if you need any further information.

Sincerely,

Brenton Mumford

Search | Export Data

This web application allows users the ability to search for historical Discharge Monitoring Report (DMR) data. Please select whether you want to search by permittee name or Id. You will also be required to select a monitoring year. Please note this searches millions of records and returns a large dataset. Response time may be several seconds between searches. Records can be sorted by clicking on any of the column headings.

Field Inspection Report

Company:	Williamson Energy, LLC
Mine:	Pond Creek Mine #1
County:	Williamson
Location:	Johnston City
NPDES #:	IL0077666
BOW ID:	W1998590001
Inspection Date:	August 29, 2019
Inspected by:	Brian Rodely
Type of Inspection:	Compliance Sampling
Contact Person(s):	Clayton Cross, Chris Skelton, Gary Vancil
Arrival Time:	9:15 AM
Departure Time	12:50 PM
Weather:	Sunny, 89°F.

Compliance Sampling Inspection

August 29, 2019 Compliance Sampling: A compliance sampling inspection was conducted at the above-referenced 540-acre NPDES permitted underground mine. The mine site includes drainage control structures, eight sediment basins, slope, preparation plant, coal stockpile, refuse disposal area, railroad loop, roads, ventilation shafts, parking areas, coal conveyors, and office/maintenance buildings.

Permitting: NPDES permit IL0077666 was issued/effective June 28, 2005 with an expiration date of July 1, 2010 has been administratively continued through timely renewal submissions and contains the discharge limitations for permitted outfalls at the site. The permit was modified February 7, 2013 reflect a name change to Williamson Energy, L.L.C., Pond Creek Mine No. 1.

Discharge Monitoring Reports: Quarterly DMR's are to be received by the Agency's DWPC, Compliance Assurance Section, by the 15th day of April, July, October, and January for the preceding three months. An annual storm water monitoring and sampling plan is due by November 1st of each year.

Drainage Control & Water Treatment: There are 8 NPDES permitted outfalls at this site each associated with a sedimentation basin. Outfalls 001, 002, 003, 004, and 005 are classified as Alkaline Mine Drainage. Outfalls 006, 007, and 008 are classified as Acid Mine Drainage. Sedimentation basins control runoff from three refuse disposal areas (RDA), coal stock piles, and approximately 2.7 million gallons per day of groundwater infiltration into the mine. All outfalls report to unnamed tributaries to Pond Creek.

Findings: The attached 7 photo pages, site plan, and water flow diagram should be consulted to clarify the following activities. I arrived at the unnamed tributary to Pond Creek crossing Dean Road about ½ mile east of the intersection of Dean Road and Liberty School Road at approximately 9:15 am. The stream appeared to have a small flow (approximately 100 gpm) of clear water. A nearby

property owner was working along Dean Road near the unnamed tributary bridge across Dean Road. The owner told me that I need to take samples on Saturday or Sunday when the ditch is rolling "dark gob water" released when the mine knows it will not be caught. I told the land owner that he could file a complaint. The land owner said that when he complained the last time the mine "gave him a hard time". Sample PCDR was taken in the unnamed tributary upstream (south) of Dean Road as documented in photo 1. I proceeded to pond 009 along Dean Road and turned into an actively used entrance to assess the emergency spillway at pond 009. I noted that the emergency spillway had over 2 feet of freeboard before discharge as shown in photo 2. Water was running into pond 009 from the direction of RDA3 and pumps appeared operational in the western end of the pond as shown in photo 3. I called Clayton Cross and was unable to make contact. Next, I called Gary Vancil and explained that I was at the Pond Creek Mine where I needed to conduct an NPDES inspection of the site. Vancil told me that Cross was with him but on another call. Vancil said that he would attempt to contact Brenton Mumford the Pond Creek Mine Engineer or someone to meet me at the Mine Gate. Vancil called back and told me that he was coming with Chris Skelton to meet me at the mine and take me where I needed to go. Cross then returned my call and said that he may be down to the mine later to meet with me.

Vancil and Skelton arrived at the mine and I explained that I needed to observe the mine's water collection and management system including collection ditches, sedimentation basins, and outfalls. We proceeded to outfall 002 that was observed to be non-discharging at the time of inspection as shown in photo 4. Pond 002 collects runoff from the raw coal pile and water is pumped to the freshwater for use in the prep plant. Photo 5 shows the non-discharging culvert outfall 006. It was noted that water has recently discharged from 006 due to water remaining in the corrugated pipe as indicated by the yellow arrow in photo 5. Sample PC006DS shown in the foreground of photo 5 was taken of standing water in the receiving stream of 006 as indicated by the white arrow. The receiving stream appeared to have slight staining on the stream bank vegetation that was recently lodged due to significant water flow with no recent precipitation. I then observed outfalls 008 and 007 that were not discharging as shown in photos 6 and 7. Clayton Cross met with us at outfalls 007 and 008 where we discussed the operations at Pond Creek Mine. Cross left the group and we proceeded to non-discharging outfalls 005, 003, 004, and 001 as shown in photos 8 through 11. I noted that newly constructed water holding cells located north of the mine office along Liberty School Road appeared to only contain storm water with no piping to receive or discharge mine process water. Finally, we walked the collection ditch south of RDA 3 progressing east from Dwina Road. The southern collection ditch is shown in photo 12 where water is actively pumped to the ditch from the southern cell of RDA 3. We walked east then approximately ¼ mile north to a retention dam with a large elevation change resulting in an approximate 15-foot waterfall as shown in photo 13. Vancil and Skelton advised me that specific information about the collection system and sedimentation ponds could be provided by Pond Creek Mine Engineer Brenton Mumford. I left the mine at approximately 12:50 pm.

Subsequent Information: 9/3/19: IDNR inspector Will Gillespie called and told me he heard there was a "leak" at the Pond Creek Mine. I told Gillespie that I conducted an inspection at the mine and found a wet culvert at 006 with standing water in the receiving stream that I sampled. I also discussed the possibility of mine discharges occurring during off hours as reported by a

nearby land owner. Gillespie indicated that he has received similar information about off-hour discharges from multiple sources. Gillespie also told me that he has been attempting to have the mine dredge some sedimentation ponds with limited results at this time.

09/19/19: Sample results were received at the Marion Regional Office for Sample PCDR taken at Dean Road and PC006DS taken downstream from outfall 006.

35 IAC Subtitle C Part 302 Subpart B General Use Water Quality Standards calculated or provided Acute Standard Water Quality Standard (ASWQS) are shown below with the reported sample results.

Sample results for PCDR are attached and provided below:

Parameter	Fe	Sulfates	Chlorides	Mn	Hardness
ASWQS (mg/L)	1.0	1391	500	9.24	N/A
PCDR (mg/L)	0.069	1790	1150	0.03	289

Sample results for PC006DS are attached and provided below:

Parameter	Fe	Sulfates	Chlorides	Mn	Hardness
ASWQS (mg/L)	1.0	1180	500	7.79	N/A
PC006DS (mg/L)	ND	1780	1140	0.04	230

General Use Water Quality Standards are exceeded for Sulfates and Chlorides as shown above. Sulfates are calculated using the maximum value of 500 for Chlorides.

Discharge Monitoring Report Submittal: Discharge monitoring reports have been evaluated for all outfalls from January 2018 through March 2019. DMR's appear to have been submitted with no discharge reported during non-precipitation events despite the daily influent of approximately 2.7 million gallons of underground mine water. The water mass balance of influent water and discharged water does not appear consistent.

Apparent Violations: The following apparent monitoring and effluent violations were noted during the CSI Inspection at Pond Creek Mine #1.

General Use Water Quality Standards are exceeded for 35 IAC Subtitle C Part 302 Subpart B Sections 302.203 (staining downstream) and 302.208 (numerical ASWQS).

Monitoring Violations: Analysis not conducted of discharges, inadequate frequency of sampling, and invalid/unrepresentative sample as required by permit.

Summary: All affected areas of the mine appear to drain to sedimentation ponds and the collection system appears adequate with no unpermitted discharges noted. Samples were taken in the unnamed tributary to Pond Creek downstream from the mine immediately south of Dean Road. A local land owner indicated that the unnamed tributary to Pond Creek has heavy dark flow during non-business hours due to mine water release. A sample was also taken of the unnamed tributary immediately downstream from outfall 006 that appeared to recently discharge due to water in the corrugated tile, staining on receiving stream vegetation, and remaining pools of water in the stream bed. No discharges have been reported from January 2018 through March 2019 during non-precipitation events despite the estimated 2.7 million gallons of daily mine water pumped to the surface collection system. Sample Results PCDR and PC006DS show excursions of General Use Water Quality Standards for Sulfates and Chlorides.

NOTICE OF FILING

TO: See attached service list (VIA ELECTRONIC FILING)

PLEASE TAKE NOTICE that I have today filed with the Office of the Clerk of the Illinois Pollution Control Board by electronic filing the following Notice of Filing and Complaint, copies of which are attached and hereby served upon you. You may be required to answer the charges of the Complaint at a hearing before the Board, at a date set by the Board.

Failure to file an answer to this complaint within 60 days may have severe consequences. Failure to answer will mean that all allegations in the complaint will be taken as if admitted for purposes of this proceeding. If you have any questions about this procedure, you should contact the hearing officer assigned to this proceeding, the clerk's office, or an attorney.

NOTIFICATION - YOU ARE HEREBY NOTIFIED that financing may be available through the Illinois Environmental Facilities Financing Act [20 ILCS 3515/1, et seq.] to correct the alleged violations.

Respectfully submitted,

PEOPLE OF THE STATE OF ILLINOIS,
KWAME RAOUL, Attorney General of the State of Illinois

COMPLAINT

Complainant, PEOPLE OF THE STATE OF ILLINOIS, by KWAME RAOUL, Attorney General of the State of Illinois, complains of Respondent, WILLIAMSON ENERGY, LLC, a Delaware limited liability company, as follows:

COUNT I
WATER POLLUTION

1. This Count is brought on behalf of the People of the State of Illinois, by Kwame Raoul, Attorney General of the State of Illinois, on his own motion and at the request of the Illinois Environmental Protection Agency ("Illinois EPA"), pursuant to the terms and provisions of Section 31 of the Illinois Environmental Protection Act ("Act"), 415 ILCS 5/31 (2016).

2. Illinois EPA is an administrative agency of the State of Illinois, created pursuant to Section 4 of the Act, 415 ILCS 5/4 (2016), and is charged, *inter alia,* with the duty of enforcing the Act. Illinois EPA is further charged with the duty to abate violations of the National Pollutant Discharge Elimination System ("NPDES") Permit Program under the Federal Clean Water Act ("CWA"), 33 U.S.C. §1342(b)(7).

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

3. The Illinois Pollution Control Board ("Board") is an independent board created by the Illinois General Assembly in Section 5 of the Act, 415 ILCS 5/5 (2016), and charged, *inter alia*, with the duty of promulgating standards and regulations under the Act.

4. Respondent, WILLIAMSON ENERGY, LLC, is a Delaware limited liability company in good standing and authorized to do business in the State of Illinois by the Illinois Secretary of State.

5. At all times relevant to this Complaint, Respondent has owned and operated Pond Creek Mine No. 1, a coal mine and coal preparation plant located at 18000 Dean Road, approximately 4 miles east-northeast of Johnston City, Williamson County, Illinois ("Facility").

6. The Facility consists of drainage control structures, eight sediment basins, slope preparation plant, coal stockpile, refuse disposal area, railroad loop, roads, ventilation shafts, parking areas, coal conveyors, and office and maintenance buildings.

7. On June 28, 2005, Illinois EPA issued NPDES Coal Mine Permit No. IL0077666 (the "Permit") to Steelhead Development Company, LLC, setting forth the terms and conditions for discharges from the Facility. On September 24, 2006, Steelhead Development Company, LLC, transferred the Permit to Respondent. On February 7, 2013, Illinois EPA reissued the Permit to Respondent. The Facility is currently authorized for discharges as specified in the Permit.

8. The Permit authorizes Respondent's discharges into an unnamed tributary of Pond Creek as follows:

Outfall	**Classification**
001, 002, 003, 004, 005	Alkaline Mine Drainage
006, 007, 008	Acid Mine Drainage

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

9. On April 21, 2016, Illinois EPA conducted an inspection of the Facility in response to a complaint received by the Illinois EPA Emergency Response Unit, citing the existence of black tar-like material in an unnamed tributary of Pond Creek ("Unnamed Tributary") crossing Dean Road, located approximately half of a mile to the east of the intersection of Dean Road and Liberty School Road, downstream from the Facility ("Sample Location 1").

10. At the time of the April 21, 2016 inspection and at times better known to Respondent, the Unnamed Tributary had a substantial flow of approximately 3,000 gallons per minute of light gray-colored, turbid liquid containing slurry solids with dark staining on the stream bank and stream bed at Sample Location 1. Illinois EPA collected a sample ("Sample 1") from the Unnamed Tributary at Sample Location 1.

11. During the April 21, 2016 inspection, representatives of Respondent informed Illinois EPA that an unpermitted discharge had occurred at the Facility earlier that day during an inspection by the Illinois Department of Natural Resources ("DNR").

12. Respondent's facility maintains several sedimentation ponds as part of the Facility's water management operations. Pond 007/008 utilized a diesel pump to reroute acid mine drainage supernatant within the Facility as part of stormwater management and water recycling operations. The pump's suction line was held by a float and supernatant was pumped from near the surface of Pond 007/008.

13. At a time better known to Respondent, Respondent placed the Pond 007/008 diesel pump's discharging outlet end in Outfall 002. Outfall 002 is permitted to discharge alkaline mine drainage from Pond 002 into the Unnamed Tributary.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

14. During the inspection by DNR, a float failed on the suction line of the pump in Pond 007/008. The float failure caused the pump's intake to drop into slurry solids at the bottom of Pond 007/008. In addition to the slurry solids, Pond 007/008 contained and contains acid mine drainage liquids. Consequently, Respondent pumped slurry solids and acid mine drainage liquids out of Pond 007/008 and discharged them onto Outfall 002. As a result of the discharge, slurry solids and acid mine drainage liquids drainage liquids were discharged from Outfall 002 into the Unnamed Tributary and flowed in a generally northeastern direction, eventually reaching and flowing past Sample Location 1.

15. Upon information and belief, the float failure and pumping of slurry solids and acid mine drainage liquids from Pond 007/008 onto Outfall 002 lasted at least 30 minutes, at or before 11:00 a.m. on April 21, 2016, until approximately 11:30 a.m on April 21, 2016.

16. At dates and times better known to Respondent, Respondent pumped acid mine drainage liquid from Pond 007/008, through the suction pump, and discharged onto Outfall 002.

17. At the time of the April 21, 2016 inspection and at times better known to Respondent, dark staining and a thin, dark layer of solids were noted at and immediately downstream of Outfall 002, progressing down the Unnamed Tributary.

18. Section 12(a) of the Act, 415 ILCS 5/12(a) (2016), provides as follows:

> No person shall:
>
> (a) Cause or threaten or allow the discharge of any contaminants into the environment in any State so as to cause or tend to cause water pollution in Illinois, either alone or in combination with matter from other sources, or so as to violate regulations or standards adopted by the Pollution Control Board under this Act.

19. Section 3.315 of the Act, 415 ILCS 5/3.315 (2016), provides as follows:

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

> "Person" is any individual, partnership, co-partnership, firm, company, limited liability company, corporation, association, joint stock company, trust, estate, political subdivision, state agency or any other legal entity, or their legal representative, agent or assigns.

20. Respondent, a limited liability company, is a "person" as that term is defined in Section 3.315 of the Act, 415 ILCS 5/3.315 (2016).

21. Section 3.165 of the Act, 415 ILCS 5/3.165 (2016), provides as follows:

> "Contaminant" is any solid, liquid, or gaseous matter, any odor, or any form of energy, from whatever source.

22. Acid mine drainage and slurry solids are "contaminants" as that term is defined in Section 3.165 of the Act, 415 ILCS 5/3.165 (2016).

23. Section 3.545 of the Act, 415 ILCS 5/3.545 (2016), provides as follows:

> "Water pollution" is such alteration of the physical, thermal, chemical, biological or radioactive properties of any waters of the State, or such discharge of any contaminant into any waters of the State, as will or is likely to create a nuisance or render such waters harmful or detrimental or injurious to public health, safety or welfare, or to domestic, commercial, industrial, agricultural, recreational, or other legitimate uses, or to livestock, wild animals, birds, fish, or other aquatic life.

24. Section 3.550 of the Act, 415 ILCS 5/3.550 (2016), provides as follows:

> "Waters" means all accumulations of water, surface and underground, natural, and artificial, public and private, or parts thereof, which are wholly or partially .within, flow through, or border upon this State.

25. Pond Creek and the Unnamed Tributary are "waters" of the State as that term is defined in Section 3.550 of the Act, 415 ILCS 5/3.550 (2016).

26. At or before 11:00 a.m. on April 21, 2016, until approximately 11:30 a.m. on April 21, 2016, Respondent discharged acid mine drainage and slurry solids from Pond 007/008 onto Outfall 002, causing the discharge of acid mine drainage and slurry solids into the Unnamed

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

Tributary, and thereby altering the physical, chemical, or biological properties of waters of the State in such manner likely to create a nuisance or to render the water harmful or detrimental to public health, safety, or welfare, or to other legitimate uses or users of the waters. Respondent's release of acid mine drainage and slurry solids into waters of the State caused or tended to cause "water pollution," as that term is defined by Section 3.545 of the Act, 415 ILCS 5/3.545 (2016).

27. On dates and at times better known to Respondent, Respondent discharged acid mine drainage from Pond 007/008 onto Outfall 002, causing the discharge of acid mine drainage into the Unnamed Tributary, and thereby altering the physical, chemical, or biological properties of waters of the State in such manner likely to create a nuisance or to render the water harmful or detrimental to public health, safety, or welfare, or to other legitimate uses or users of the waters. Respondent's release of acid mine drainage into waters of the State caused or tended to cause "water pollution," as that term is defined by Section 3.545 of the Act, 415 ILCS 5/3.545 (2016).

28. By causing, threatening, or allowing the discharge of contaminants into waters of the State so as to cause or tend to cause water pollution in Illinois, Respondent violated Section 12(a) of the Act, 415 ILCS 5/12(a) (2016).

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count I:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Section 12(a) of the Act, 415 ILCS 5/12(a) (2016);

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against Respondent a civil penalty of $50,000.00 for each violation of Section 12(a) of the Act, 415 ILCS 5/12(a) (2016), and an additional civil penalty of $10,000.00 for each day such violations continued, pursuant to Section 42(a) of the Act, 415 ILCS 5/42(a) (2016);

E. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

F. Ordering such other and further relief as the Board deems appropriate and just.

COUNT II
WATER POLLUTION HAZARD

1-27. Complainant realleges and incorporates by reference herein paragraphs 1 through 17 and 19 through 28 of Count I as paragraphs 1 through 27 of this Count II.

28. Section 12(d) of the Act, 415 ILCS 5/12(d) (2016), provides as follows:

No person shall:

* * *

(d) Deposit any contaminants upon the land in such place and manner so as to create a water pollution hazard.

29. On April 21, 2016, at times better known to Respondent, Respondent's discharge of acid mine drainage and slurry solids onto Outfall 002 caused dark staining and left a thin, dark layer of solids in and around Outfall 002.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

30. On April 21, 2016, at times better known to Respondent, the dark staining and dark layer of solids progressed downstream from where Outfall 002 discharges into the Unnamed Tributary and caused staining and solids deposition along its stream banks.

31. The dark staining and dark layer of solids deposited on and around Outfall 002 and along the stream banks of the Unnamed Tributary constituted a water pollution hazard.

32. By depositing contaminants upon the land at and near the Facility in a place and manner so as to create a water pollution hazard, Respondent violated Section 12(d) of the Act, 415 ILCS 5/12(d) (2016).

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count II:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Section 12(d) of the Act, 415 ILCS 5/12(d) (2016);

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against Respondent a civil penalty of $50,000.00 for each violation of Section 12(d) of the Act, 415 ILCS 5/12(d) (2016), and an additional civil penalty of $10,000.00 for each day such violations continued, pursuant to Section 42(a) of the Act, 415 ILCS 5/42(a) (2016);

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

E. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

F. Ordering such other and further relief as the Board deems appropriate and just.

COUNT III
VIOLATION OF WATER QUALITY STANDARDS

1-24. Complainant realleges and incorporates by reference herein paragraphs 1 through 22, 24, and 25 of Count I as paragraphs 1 through 24 of this Count III.

25. Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), provides, in pertinent part, as follows:

> No person shall:
>
> * * *
>
> (f) Cause, threaten or allow the discharge of any contaminant into the waters of the State, as defined herein . . . without an NPDES permit for point source discharges issued by the Agency under Section 39(b) of this Act, or in violation of any term or condition imposed by such permit. . . .

26. Section 3.105 of the Act, 415 ILCS 5/3.105 (2016), provides the following definition:

> "Agency" is the Environmental Protection Agency established by this Act.

27. Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), provides as follows:

> (a) Except as in compliance with the provisions of the Act, Board regulations, and the CWA, and the provisions and conditions of the NPDES permit issued to the discharger, the discharge of any contaminant or pollutant by any person in the waters of the State from a point source or into a well shall be unlawful.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

28. Section 301.240 of the Board's regulations, 35 Ill. Adm. Code 301.240, provides the following definition:

> "CWA" means the Federal Water Pollution Control Act, as amended, (33 U.S.C. 1251 et seq., Public Law 92-500 enacted by Congress October 18, 1972 as amended by the "Clean Water Act", Public Law 95-217, enacted December 12, 1977, as amended.)

29. Section 502(14) of the CWA, 33 U.S.C. § 1362(14), provides the following definition:

> 14) The term "point source" means any discernible, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged. This term does not include agricultural stormwater discharges and return flows from irrigated agriculture.

30. Outfall 002 and Outfall 007/008 were and are "point sources," as that term is defined in Section 502(14) of the CWA, 33 U.S.C. § 1362(14).

31. Special Condition 1 of the Permit provides as follows:

> No effluent from any mine related facility area under this permit shall, alone or in combination with other sources, cause a violation of any applicable water quality standard as set out in the Illinois Pollution Control Board Rules and Regulations, Subtitle C: Water Pollution.

32. Illinois EPA analyzed Sample 1, collected from Sample Location 1 during the April 21, 2016 inspection, and testing provided the following results:

Constituent	Unit	Sample 1
Chloride	mg/L	752
Iron	mg/L	1.9

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

33. Section 302.201 of the Board regulations, 35 Ill. Adm. Code 302.201, provides as follows:

> Subpart B contains general use water quality standards which must be met in waters of the State for which there is no specific designation (Section 303.201).

34. The Unnamed Tributary and Pond Creek are waters of the State for which there is no specific designation.

35. Section 302.208(d) of the Board's regulations, 35 Ill. Adm. Code 302.208(d), provides, in pertinent part, as follows:

> The standard for the chemical constituents of subsection[] (g) . . . shall not be exceeded at any time except for those waters in which the Agency has approved a mixing zone or in which mixing is allowed pursuant to Section 302.102.

36. Illinois EPA has not approved a mixing zone for Facility discharges, and the Permit does not authorize a mixing zone in which mixing is allowed pursuant to Section 302.102 of the Board's regulations, 35 Ill. Adm. Code 302.102.

37. Section 302.208(g) of the Board's regulations, 35 Ill. Adm. Code 302.208(g), provides, in pertinent part, as follows:

> g) Single-value standards apply at the following concentrations for these substances:

Constituent	Unit	Standard
Chloride (total)	mg/L	500
Iron (dissolved)	mg/L	1.0

38. Sample 1 contains concentrations exceeding the applicable water quality standards of 500 mg/L for Chloride and 1.0 mg/L for Iron.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

39. Upon information and belief, Respondent's discharge of acid mine drainage liquids and slurry solids from Outfall 002 into the Unnamed Tributary caused an exceedance of the applicable water quality standards for Chloride and Iron, 35 Ill. Adm. Code 302.208(d), (g).

40. By causing an exceedance of applicable water quality standards set out in Section 302.208(g) of the Board's regulations, 35 Ill. Adm. Code 302.208(g), Respondent violated Section 302.208(d) of the Board's regulations, 35 Ill. Adm. Code 302.208(d).

41. By violating Section 302.208(d) of the Board's regulations, 35 Ill. Adm. Code 302.208(d), Respondent caused or threatened or allowed the discharge of contaminants into the environment so as to violate regulations or standards adopted by the Board under the Act, and thereby violated Section 12(a) of the Act, 415 ILCS 5/12(a) (2016).

42. By causing an exceedance of applicable water quality standards set out in Subtitle C of the Board's Regulations, Respondent violated Special Condition 1 of the Permit.

43. By violating Special Condition 1 of the Permit, Respondent discharged contaminants or pollutants in the waters of the State from a point source in violation of the provisions and conditions of the Permit, and thereby violated Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a).

44. By violating Special Condition 1 of the Permit, Respondent caused, threatened, or allowed the discharge of a contaminant into the waters of the State in violation of the terms or conditions imposed by the Permit, and thereby violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016).

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count III:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Sections 12(a) and (f) of the Act, 415 ILCS 5/12(a), (f) (2016), Sections 302.208(d) and 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 302.208(d) and 309.102(a), and Special Condition 1 of the Permit;

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against Respondent a civil penalty of $50,000.00 for each violation of Section 12(a) of the Act, 415 ILCS 5/12(a) (2016), and Section 302.208(d) of the Board's regulations, 35 Ill. Adm. Code 302.208(d), and an additional civil penalty of $10,000.00 for each day such violations continued, pursuant to Section 42(a) of the Act, 415 ILCS 5/42(a) (2016);

E. Assessing against the Respondent a civil penalty of $10,000.00 for each day of violation of Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), and NPDES Permit No. IL0077666, pursuant to Section 42(b)(1) of the Act, 415 ILCS 5/42(b)(1) (2016);

F. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

G. Ordering such other and further relief as the Board deems appropriate and just.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

COUNT IV
OFFENSIVE CONDITIONS

1-31. Complainant realleges and incorporates by reference herein paragraphs 1 through 22, 24, and 25 of Count I and paragraphs 25 through 31 of Count III as paragraphs 1 through 31 of this Count IV.

32. Section 302.203 of the Board's regulations, 35 Ill. Adm. Code 302.203, provides, in pertinent part, as follows:

> Waters of the State shall be free from sludge or bottom deposits, floating debris, visible oil, odor, plant or algal growth, color or turbidity of other than natural origin. . . .

33. Section 406.202 of the Board's regulations, 35 Ill. Adm. Code 406.202, provides, in pertinent part, as follows:

> In addition to the other requirements of this Part, no mine discharge or non-point source mine discharge shall, alone or in combination with other sources, cause a violation of any water quality standards of 35 Ill. Adm. Code 302 or 303. . . .

34. Section 402.101 of the Board's regulations, 35 Ill. Adm. Code 402.101, provides, in pertinent part:

* * *

> "Mine Discharge": any point source discharge, whether natural or man-made, from a mine related facility. . . . The term mine discharge includes surface runoff discharged from a sedimentation pond. . . .

35. Respondent's discharge of acid mine drainage liquids and slurry solids from Outfall 002 constituted a "mine discharge" as that term is defined in Section 402.101 of the Board's regulations, 35 Ill. Adm. Code 402.101.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

36. At times better known to Respondent, Respondent discharged acid mine drainage liquids and slurry solids from Outfall 002, causing dark staining, sludge, bottom deposits, and color and turbidity of other than natural origin to accrue in the Unnamed Tributary, a water of the State, and thereby caused an "offensive condition" prohibited by Section 302.203 of the Board's regulations, 35 Ill. Adm. Code 302.203.

37. By discharging a "mine discharge" that caused a violation of water quality standards codified at 35 Ill. Adm. Code Part 302, Respondent violated Section 406.202 of the Board's regulations, 35 Ill. Adm. Code 406.202.

38. By violating Section 406.202 of the Board's regulations, 35 Ill. Adm. Code 406.202, Respondent caused or threatened or allowed the discharge of contaminants into the environment so as to violate regulations or standards adopted by the Board under the Act, and thereby violated Section 12(a) of the Act, 415 ILCS 5/12(a) (2016).

39. By causing an "offensive condition" prohibited by an applicable water quality standard set out in Subtitle C of the Board's Regulations, Respondent violated Special Condition 1 of the Permit.

40. By violating Special Condition 1 of the Permit, Respondent discharged contaminants or pollutants in the waters of the State from a point source in violation of the provisions and conditions of the Permit, and thereby violated Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a).

41. By violating Special Condition 1 of the Permit, Respondent caused, threatened, or allowed the discharge of a contaminant into the waters of the State in violation of the terms or conditions imposed by the Permit, and thereby violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016).

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count IV:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Sections 12(a) and (f) of the Act, 415 ILCS 5/12(a), (f) (2016), Sections 309.102(a) and 406.202 of the Board's regulations, 35 Ill. Adm. Code 309.102(a) and 406.202, and Special Condition 1 of the Permit;

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against Respondent a civil penalty of $50,000.00 for each violation of Section 12(a) of the Act, 415 ILCS 5/12(a) (2016), and Section 406.202 of the Board's regulations, 35 Ill. Adm. Code 406.202, and an additional civil penalty of $10,000.00 for each day such violations continued, pursuant to Section 42(a) of the Act, 415 ILCS 5/42(a) (2016);

E. Assessing against the Respondent a civil penalty of $10,000.00 for each day of violation of Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), and NPDES Permit No. IL0077666, pursuant to Section 42(b)(1) of the Act, 415 ILCS 5/42(b)(1) (2016);

F. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

G. Ordering such other and further relief as the Board deems appropriate and just.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

COUNT V
OFFENSIVE DISCHARGES

1-28. Complainant realleges and incorporates by reference herein paragraphs 1 through 22, 24, and 25 of Count I, paragraphs 29 and 30 of Count III, and paragraphs 34 and 35 of Count IV as paragraphs 1 through 28 of this Count V.

29. Section 406.107 of the Board's regulations, 35 Ill. Adm. Code 406.107, provides as follows:

> In addition to the other requirements of this Chapter, no mine discharge effluent shall contain settleable solids, floating debris, visible oil, grease, scum or sludge solids. Color, odor and turbidity shall be reduced to below obvious levels.

30. Respondent's mine discharge contained settleable solids, sludge solids, and color and turbidity above obvious levels, which caused dark staining, sludge, bottom deposits, and color and turbidity alterations in the Unnamed Tributary, and therefore constituted an "offensive discharge" in violation of Section 406.107 of the Board's regulations, 35 Ill. Adm. Code 406.107.

31. By violating Section 406.107 of the Board's regulations, 35 Ill. Adm. Code 406.107, Respondent caused or threatened or allowed the discharge of contaminants into the environment so as to violate regulations or standards adopted by the Board under the Act, and thereby violated Section 12(a) of the Act, 415 ILCS 5/12(a) (2016).

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count V:

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Section 12(a) of the Act, 415 ILCS 5/12(a) (2016), and Section 406.107 of the Board's regulations, 35 Ill. Adm. Code 406.107;

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against Respondent a civil penalty of $50,000.00 for each violation of Section 12(a) of the Act, 415 ILCS 5/12(a) (2016), and Section 406.107 of the Board's regulations, 35 Ill. Adm. Code 406.107, and an additional civil penalty of $10,000.00 for each day such violations continued, pursuant to Section 42(a) of the Act, 415 ILCS 5/42(a) (2016);

E. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

F. Ordering such other and further relief as the Board deems appropriate and just.

COUNT VI
NPDES PERMIT VIOLATIONS

1-30. Complainant realleges and incorporates by reference herein paragraphs 1 through 17 and 19 through 25 of Count I and paragraphs 25-30 of Count III as paragraphs 1 through 30 of this Count VI.

31. Standard Condition 5 of the Permit provides, in pertinent part, as follows:

> Proper operation and maintenance. The permittee shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) which are installed or used by the permittee to achieve compliance with conditions of this permit. . . .

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

32. The Permit authorizes Outfall 007 and Outfall 008 to discharge acid mine drainage. Section 402.101 of the Board's regulations, 35 Ill. Adm. Code 402.101, defines "Acid or Ferruginous Mine Drainage" as "mine drainage which, before any treatment, has a pH of less than 6.0 or a total iron concentration greater than 10 mg/L." *See also* 40 C.F.R. §§ 434.30-.35.

33. The Permit authorizes Outfall 002 to discharge alkaline mine drainage ("Alkaline Mine Drainage Effluent Limitations"). Section 402.101 of the Board's regulations, 35 Ill. Adm. Code 402.101, defines "Alkaline Mine Drainage" as "mine drainage which, prior to treatment, has a pH equal to or greater than 6.0 and a total iron concentration of less than 10 mg/L." *See also* 40 C.F.R. §§ 434.40-.45.

34. The discharge of slurry solids from the bottom of a sedimentation pond onto and through Outfall 002 constituted improper operation and maintenance of facilities and systems of treatment and control, and is therefore a violation of Standard Condition 5 of the Permit.

35. Respondent was and is not authorized to discharge slurry solids or acid mine drainage liquids through Outfall 002, which is permitted to discharge alkaline mine drainage liquids under the terms and conditions of the Permit.

36. By discharging slurry solids and acid mine drainage liquids through Outfall 002, Respondent violated the Alkaline Mine Drainage Effluent Limitations of the Permit.

37. By violating Standard Condition 5 and the Alkaline Mine Drainage Effluent Limitations of the Permit, Respondent discharged contaminants or pollutants in the waters of the State from a point source in violation of the provisions and conditions of the Permit, and thereby violated Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a).

38. By violating Standard Condition 5 and the Alkaline Mine Drainage Effluent Limitations of the Permit, Respondent caused, threatened, or allowed the discharge of a

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

contaminant into the waters of the State in violation of the terms or conditions imposed by the Permit, and thereby violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016).

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count VI:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), Standard Condition 5 of the Permit, and the Alkaline Mine Drainage Effluent Limitations of the Permit;

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against the Respondent a civil penalty of $10,000.00 for each day of violation of Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Section 309.102(a) of the Board's regulations, and NPDES Permit No. IL0077666, pursuant to Section 42(b)(1) of the Act, 415 ILCS 5/42(b)(1) (2016);

E. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

F. Ordering such other and further relief as the Board deems appropriate and just.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

COUNT VII
NPDES BYPASS VIOLATIONS

1-31. Complainant realleges and incorporates by reference herein paragraphs 1 through 17, 19 through 22, 24, and 25 of Count I and paragraphs 25 through 30 of Count III and paragraphs 32 and 33 of Count VI as paragraphs 1 through 31 of this Count VII.

32. Acid mine drainage discharges and alkaline drainage discharges are authorized under separate provisions of the Permit and have distinct effluent standards and limitations.

33. Section 305.102 of the Board's regulations, 35 Ill. Adm. Code 305.102, provides, in pertinent part, as follows:

> (a) Every person within this State operating a . . . wastewater source shall submit operating reports to the Agency at a frequency to be determined by the Agency. "Agency" means the Illinois Environmental Protection Agency. Such reports shall contain information regarding the quantity of influent and of effluent discharged, of wastes bypassed and of combined sewer overflows. . . .
>
> (b) Every holder of an NPDES (National Pollutant Discharge Elimination System) permit is required to comply with the monitoring, sampling, recording and reporting requirements set forth in the permit and this Chapter.

34. Standard Condition 12(b) of the Permit provides as follows:

> (b) Anticipated noncompliance. The permittee shall give advance notice to the Agency of any planned changes in the permitted facility or activity which may result in noncompliance with permit requirements.

35. Standard Condition 13(a)(1) of the Permit provides as follows:

> (a) Definitions.
>
> (1) Bypass means the intentional diversion of waste streams from any portion of a treatment facility.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

36. Pond 007/008 is a "treatment facility" as that term is used in Standard Condition 13(a)(1) of the Permit.

37. Respondent's intentional diversion of waste streams from Pond 007/008 to Outfall 002 constituted a "bypass" as that term is used in Standard Condition 13(a)(1).

38. Standard Condition 13(c)(1) of the Permit provides as follows:

> (c) Notice.
>
> (1) Anticipated bypass. If the permittee knows in advance of the need for a bypass, it shall submit prior notice, if possible at least ten days before the date of the bypass.

39. Standard Condition 13(d) of the Permit provides as follows:

> (d) Prohibition of bypass.
>
> (1) Bypass is prohibited, and the Agency may take enforcement action against a permittee for bypass, unless:
>
> (i) Bypass was unavoidable to prevent loss of life, personal injury, or severe property damage;
>
> (ii) There were no feasible alternatives to bypass, such as the use of auxiliary treatment facilities, retention of untreated wastes, or maintenance during normal periods of equipment downtime. This condition is not satisfied if adequate back-up equipment should have been installed in the exercise of a reasonable engineering judgment to prevent a bypass which occurred during normal periods of equipment downtime or preventative maintenance; and
>
> (iii) The permittee submitted notices as required under paragraph 13(c).

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

> (2) The Agency may approve an anticipated bypass, after considering its adverse effects, if the Agency determines that it will meet the three conditions listed above in paragraph 13(d)(1).

40. By failing to submit prior notice of the anticipated bypass, Respondent violated Standard Condition 13(c)(1) of the Permit.

41. Respondent's bypass was not approved by Illinois EPA or otherwise unavoidable, lacking in feasible alternatives, or properly noticed to Illinois EPA. Respondent's bypass was therefore prohibited and a violation of Standard Condition 13(d) of the Permit.

42. By failing to give advance notice of planned changes to the permitted facility or activity which resulted in noncompliance with permit requirements, Respondent violated Standard Condition 12(b) of the Permit.

43. By violating Standard Conditions 12(b) and 13(c)(1), (d) of the Permit, Respondent discharged contaminants or pollutants in the waters of the State from a point source in violation of the provisions and conditions of the Permit, and thereby violated Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a).

44. By failing to submit operating reports to Illinois EPA containing information regarding the quantity of wastes bypassed, Respondent violated Section 305.102(a) of the Board's regulations, 35 Ill. Adm. Code 305.102(a).

45. By failing to comply with the reporting requirements of the Permit, Respondent violated Section 305.102(b) of the Board's regulations, 35 Ill. Adm. Code 305.102(b).

46. By violating Section 305.102 of the Board's regulations, 35 Ill. Adm. Code 305.102, and Standard Conditions 12(b) and 13(c)(1), (d) of the Permit, Respondent caused, threatened, or allowed the discharge of a contaminant into the waters of the State in violation of regulations adopted by the Board with respect to the NPDES program and the terms or

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

conditions imposed by the Permit, and thereby violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016).

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count VII:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Sections 305.102(a) and (b) of the Board's regulations, 35 Ill. Adm. Code 305.102(a), (b), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), and Standard Conditions 12(b), 13(c)(1), and 13(d) of the Permit;

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against the Respondent a civil penalty of $10,000.00 for each day of violation of Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Sections 305.102(a) and (b) of the Board's regulations, 35 Ill. Adm. Code 305.102(a), (b), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), and NPDES Permit No. IL0077666, pursuant to Section 42(b)(1) of the Act, 415 ILCS 5/42(b)(1) (2016);

E. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

F. Ordering such other and further relief as the Board deems appropriate and just.

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

COUNT VIII
FAILURE TO COMPLY WITH GOOD MINING PRACTICES

1-29. Complainant realleges and incorporates by reference herein paragraphs 1 through 17, 19 through 22, 24, and 25 of Count I and paragraphs 25 through 30 of Count III as paragraphs 1 through 29 of this Count VIII.

30. Section 406.204(b) of the Board's regulations, 35 Ill. Adm. Code 406.204(b), provides, in pertinent part, as follows:

> In determining whether an operator is utilizing good mining practices designed to minimize discharge of total dissolved solids, chloride, sulfate, iron and manganese, the Agency shall consider whether the operator is utilizing the following good mining practices, further defined in the Sections indicated:
>
> * * *
>
> (b) Retention and control within the site of waters exposed to disturbed materials (Section 406.206). . . .

31. Standard Condition 27 of the Permit provides, in pertinent part, as follows:

> The permittee shall comply with, in addition to the requirements of the permit, all applicable provisions of 35 Ill. Adm. Code, Subtitle C, Subtitle D, Subtitle E. . . .

32. Respondent failed to adequately retain and control on-site waters exposed to disturbed materials, resulting in the unpermitted discharge.

33. Because Respondent failed to comply with the Good Mining Practices of Section 406.204(b) of the Board's regulations, 35 Ill. Adm. Code 406.204(b), Respondent failed to comply with an applicable provision of 35 Ill. Adm. Code Subtitle D, and thereby violated Standard Condition 27 of the Permit.

34. By violating Standard Condition 27 of the Permit, Respondent discharged contaminants or pollutants in the waters of the State from a point source in violation of the

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

provisions and conditions of the Permit, and thereby violated Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a).

35. By violating Standard Condition 27 of the Permit, Respondent caused, threatened, or allowed the discharge of a contaminant into the waters of the State in violation of the terms or conditions imposed by the Permit, and thereby violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016).

PRAYER FOR RELIEF

WHEREFORE, Complainant, PEOPLE OF THE STATE OF ILLINOIS, respectfully requests that the Board enter an order in favor of the Complainant and against the Respondent, WILLIAMSON ENERGY, LLC, on Count VIII:

A. Authorizing a hearing in this matter at which time Respondent will be required to answer the allegations herein;

B. Finding that Respondent violated Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), and Standard Condition 27 of the Permit;

C. Ordering Respondent to cease and desist from any further violations of the Act and associated regulations;

D. Assessing against the Respondent a civil penalty of $10,000.00 for each day of violation of Section 12(f) of the Act, 415 ILCS 5/12(f) (2016), Section 309.102(a) of the Board's regulations, 35 Ill. Adm. Code 309.102(a), and NPDES Permit No. IL0077666, pursuant to Section 42(b)(1) of the Act, 415 ILCS 5/42(b)(1) (2016);

Electronic Filing: Received, Clerk's Office 2/4/2019 **PCB 2019-085**

E. Awarding to Complainant its costs, including expert witness, consultant, and attorney fees, expended in pursuit of this action, pursuant to Section 42(f) of the Act, 415 ILCS 5/42(f) (2016); and

F. Ordering such other and further relief as the Board deems appropriate and just.

Respectfully submitted,

PEOPLE OF THE STATE OF ILLINOIS,
ex rel. KWAME RAOUL, Attorney General
of the State of Illinois

Demographic Profile

EJSCREEN EJ Indexes

Eleven primary environmental justice (EJ) indexes of EJSCREEN, EPA's screening tool for EJ concerns. EPA uses these indexes to identify geographic areas that may warrant further consideration or analysis for potential EJ concerns. Note that use of these indexes does not designate an area as an "EJ community" or "EJ facility." EJSCREEN provides screening level indicators, not a determination of the existence or absence of EJ concerns. For more information, see the EJSCREEN home page.

Demographic Profile of Surrounding Area (3 Miles)

This section provides demographic information regarding the community surrounding the facility. ECHO compliance data alone are not sufficient to determine whether violations at a particular facility had negative impacts on public health or the environment. Statistics are based upon the 2010 US Census and American Community Survey data, and are accurate to the

extent that the facility latitude and longitude listed below are correct. The latitude and longitude are obtained from the EPA Locational Reference Table (LRT) when available.

REND LAKE WATER SUPPLY WITHDRAWAL AGREEMENT

between the

STATE OF ILLINOIS,
ADENA RESOURCES, LLC
and AKIN WATER DISTRICT

EXHIBIT A

Attached are the following documents:

1. Water Supply Agreement between the State of Illinois and Adena Resources, LLC effective September 21, 2007.

2. Amendment Number One to the September 21, 2007 Agreement between the State of Illinois and Adena Resources, LLC effective August 14, 2009.

WATER SUPPLY AGREEMENT

This agreement ("Agreement") is made and entered into as of the [21st] day of [September], 2007, by and between the **STATE OF ILLINOIS**, acting through and represented by the Illinois Department of Natural Resources (hereinafter referred to as "State of Illinois"), and **ADENA RESOURCES, LLC** (hereinafter referred to as "Adena"), (the State of Illinois and Adena Resources, LLC are also referred to herein individually as a "party" and collectively as the "parties").

RECITALS

WHEREAS, the Flood Control Act of 23 October 1962 (Public Law 874, 87th Congress), authorized the construction, operation, and maintenance of the Rend Lake Dam and Reservoir on the Big Muddy River in the vicinity of the city of Benton, Illinois (hereinafter referred to as "Rend Lake"); and

WHEREAS, the State of Illinois has entered into a written contract dated September 23, 1988 with the United States of America known as "Contract Between the United States of America and the State of Illinois for Water Storage Space in Rend Lake Reservoir" and designated as "Contract No. DACW43-88-C-0088" (such contract is hereinafter referred to as the "Rend Lake Contract"), a copy of which is attached hereto as Exhibit A; and

WHEREAS, pursuant to the Rend Lake Contract, the State of Illinois has rights to certain storage space for water impounded in Rend Lake and rights to distribute or otherwise assign rights to such water to be withdrawn from Rend Lake to be used for municipal and industrial water supply; and

WHEREAS, Adena has been authorized by Williamson Energy, LLC to serve as business agent in entering into an agreement for water supply for the Pond Creek #1 coal mine; and

WHEREAS, Adena has been authorized by Sugarcamp Energy, LLC to serve as business agent in entering into an agreement for water supply for the Sugarcamp coal mine; and

WHEREAS, Adena, as business agent for the coal mines, has requested an agreement from the State of Illinois to withdraw water directly from Rend Lake, for the purpose of supplying water for the Pond Creek #1 and Sugarcamp coal mines; and

WHEREAS, Adena is willing to make payments, as provided for in this Agreement, for the right to withdraw Rend Lake water under this Agreement; and

WHEREAS, Adena and the State of Illinois desire to enter into an agreement setting forth the terms and conditions under which Adena may withdraw water from Rend Lake.

STATEMENT OF AGREEMENT

NOW, THEREFORE, in consideration of the premises and the covenants and agreements herein contained, and intending to be legally bound, the State of Illinois and Adena agree as follows:

1. Incorporation of Recitals.

The foregoing Recitals are hereby incorporated by reference as if set forth fully herein.

2. **Water Withdrawal.**

(a) During the term of this Agreement, and subject to the terms and conditions of this Agreement, Adena shall have the right to withdraw up to the Daily Quota of water directly from Rend Lake.

(b) *Daily Quota.* The term *"Daily Quota"* as used in this Agreement means the summation of the *Pond Creek Quota* and the *Sugarcamp Quota.* The *Daily Quota* shall initially be set at 6.5 million gallons per day ("mgd") pursuant to subsections (c) and (d) of this Section. The *Daily Quota* will not increase in the future but may be decreased or eliminated in the future pursuant to the terms of this Agreement.

(c) *Pond Creek Daily Quota.* The term *"Pond Creek Daily Quota"* as used in this Agreement means the amount of water necessary to construct and operate the Pond Creek #1 coal mine, located in Williamson County, including but not limited to, the coal slurrying plant, dust suppression, or any other water requirements for the coal mine or any immediately adjacent support facilities necessary for the operation of the coal mine. The *Pond Creek Daily Quota* shall initially be set at 2.2 mgd based upon a water requirement for an annual coal production rate of 7 million raw tons per year. The *Daily Quota* will not increase in the future but may be decreased or eliminated in the future pursuant to the terms of this Agreement.

(d) *Sugarcamp Daily Quota.* The term *"Sugarcamp Daily Quota"* as used in this Agreement means the amount of water necessary to construct and operate the Sugarcamp coal mine, located in Franklin County, including but not limited to, the coal slurrying plant, dust suppression, or any other water requirements for the coal mine or any immediately adjacent support facilities necessary for the operation of the coal mine. The *Sugarcamp Daily Quota* shall initially be set at 4.3 mgd based upon a water requirement for an annual coal production rate of 14 million raw tons per year. The *Daily Quota* will not increase in the future but may be decreased or eliminated in the future pursuant to the terms of this Agreement.

(e) *Initial Withdrawal Date.* The term "Initial Withdrawal Date" as used in this Agreement means the first date that water is withdrawn for the construction and/or operation of the Pond Creek # 1 and the Sugarcamp coal mines.

3. Basis and Conditions for *Daily Quota* and Water Withdrawal Right

(a) Adena certifies that surface coal mining and reclamation operations Permit No. 375 from the Illinois Department of Natural Resources, Office of Mines and Minerals has been issued to Williamson Energy LLC for the Pond Creek #1 coal mine. Adena certifies that an application for a surface coal mining and reclamation operations Permit No. 382 for the Sugarcamp coal mine has been submitted to the Illinois Department of Natural Resources, Office of Mines and Minerals. Adena certifies that it has been authorized by Williamson Energy LLC to serve as business agent in entering into an agreement for water supply for the Pond Creek #1 coal mine. Adena certifies that it has been authorized by Sugarcamp Energy, LLC to serve as business agent in entering into an agreement for water supply for the Sugarcamp coal mine. Failure to possess the proper authorizations by Williamson Energy LLC and Sugarcamp Energy, LLC for Adena to serve as their business agent in this behalf is a breach of this Agreement and shall result in the termination of this Agreement.

(b) By January 1, 2008, Adena shall submit to the State of Illinois, evidence of an Illinois Department of Natural Resources, Office of Mines and Minerals "administratively complete application" for the Sugarcamp mine. The definition of "administratively complete application" is the same as that used in 62 Ill. Administrative Code 1700 through 1850. Failure to possess such application by the date set forth in this subsection is a breach of this Agreement and shall result in Adena's loss of the 4.3 mgd *Daily Quota* and water withdrawal right established for the Sugarcamp coal mine hereunder.

(c) By July 1, 2008, Adena shall submit to the State of Illinois, evidence of an Illinois Department of Natural Resources, Office of Mines and Minerals surface coal mining and reclamation operations permit for the Sugarcamp mine. Failure to obtain such permit by the date set forth in this subsection is a breach of this Agreement and shall result in Adena's loss of the 4.3 mgd *Daily Quota* and water withdrawal right established for the Sugarcamp coal mine hereunder.

(d) By July 1, 2010, Adena shall have completed construction activities for the Sugarcamp coal mine and have begun coal production. Failure to complete such construction activities and to begin coal production by the date set forth in this subsection is a breach of this Agreement and shall result in Adena's loss of the 4.3 mgd *Daily Quota* and water withdrawal right established for the Sugarcamp coal mine hereunder.

(e) By July 1, 2012, and by July 1 of each subsequent five-year period, Adena shall furnish to the State of Illinois an official annual coal production summary report for the Pond Creek #1 mine, identifying the annual raw coal production in tons for each of the previous five years. If for any such five-year period the highest annual raw coal production for one of the previous years is not at least 4 million tons, a reduction to the *Pond Creek Daily Quota* shall occur using the following *Pond Creek Daily Quota* adjustment formula:

Pond Creek Daily Quota = [highest annual raw coal production tonnage in last five-year period] divided by [4 million tons] multiplied by [2.2 mgd]

The *Pond Creek Daily Quota* may be reduced multiple times under the terms of this subsection. If use of the *Pond Creek Daily Quota* adjustment formula pursuant to the process set forth above does not result in a reduction of the current *Pond Creek Daily Quota*, the current *Pond Creek Daily Quota* shall remain unadjusted. Any reduction(s) under this subsection is permanent and cannot be subsequently reacquired. No increase to the *Pond Creek Daily Quota* is allowed. If a reduction to the *Pond Creek Daily Quota* is made under this subsection, the new *Pond Creek Daily Quota* shall become effective October 1 of that year.

(f) By July 1, 2015, and by July 1 of each subsequent five-year period, Adena shall furnish to the State of Illinois an official annual coal production summary report for the Sugarcamp mine, identifying the annual raw coal production in tons for each of the previous five years. If for any such five-year period the highest annual raw coal production for one of the previous years is not at least 8 million tons, a reduction to the *Sugarcamp Daily Quota* shall occur using the following *Sugarcamp Daily Quota* adjustment formula:

Sugarcamp Daily Quota = [highest annual raw coal production tonnage in last five-year period] divided by [8 million tons] multiplied by [4.3 mgd]

The *Sugarcamp Daily Quota* may be reduced multiple times under the terms of this subsection. If use of the *Sugarcamp Daily Quota* adjustment formula pursuant to the process set forth above does not result in a reduction of the current *Sugarcamp Daily Quota*, the current *Sugarcamp Daily Quota* shall remain unadjusted. Any reduction(s) under this subsection is permanent and cannot be subsequently reacquired. No increase to the *Sugarcamp Daily Quota* is allowed. If a reduction to the *Sugarcamp Daily Quota* is made under this subsection, the new *Sugarcamp Daily Quota* shall become effective October 1 of that year.

(g) At any time prior to or during the operation of the coal mines, Adena agrees to provide immediate notice to the State of Illinois of any changes in plans or circumstances which may result in a reduction in its Rend Lake water supply requirements. Notice of any changes in plans, request for *Daily Quota* reductions, or terminations in Adena's *Daily Quota*, shall be provided in accordance with Section 14.

(h) If Adena loses or the State of Illinois completely reduces the *Daily Quota* to zero pursuant to the terms of this Section, this Agreement shall terminate.

4. **Allocation of Available Water.**

(a) *No Over Allocations.* The parties acknowledge that the State of Illinois may, subsequent to the date of this Agreement, enter into agreements or other arrangements with, or may issue permits to, third parties relating to the allocation, extraction, withdrawal or use of water from Rend Lake. However, the State of Illinois expressly covenants that in no case and under no circumstances will the State of Illinois enter into such agreements or arrangements, issue such permits, or take any other actions which, when taken either individually or in aggregate, result in the actual or potential allocation, extraction, withdrawal or use of water in excess of the total amount of water under the control of the State of Illinois pursuant to the terms

and conditions of the Rend Lake Contract as of the date of this Agreement (any such action shall be referred to as an "Over Allocation").

(b) *Over Allocations.* In the event that the State of Illinois takes any action or fails to take any action resulting in, or which is likely to result in, an Over Allocation to any third party (each, an "Over Allocation Party"), the State of Illinois shall grant Adena priority rights to the storage, withdrawal and use of water over and against each and every Over Allocation Party for the term of this Agreement, and the State of Illinois will use its best efforts and legal authority to ensure that any Over Allocation does not materially affect Adena' rights under this Agreement. The State of Illinois acknowledges that Adena' right to withdraw its *Daily Quota* is critical to its industrial operations. Accordingly, the State of Illinois shall notify Adena of any Over Allocation, which notification shall include the name, address, and contact information of the Over Allocation Party.

(c) *Water Emergency.* The parties acknowledge that the State of Illinois may enter into agreements with other parties to allocate, secure or otherwise beneficially use water from Rend Lake for Domestic Water Use, as defined herein, and Non-Domestic Water Use, as defined herein, and that the State of Illinois is otherwise authorized and entitled to protect the health and safety of its citizens. Therefore, in the event of a declared water emergency, as declared by the Director of the Illinois Department of Natural Resources or other responsible state official, which results in an insufficient supply of water in Rend Lake to satisfy the water allocated and used for both Domestic Water Use, as defined herein, and Non-Domestic Water Use, as defined herein, and which deficiency of Rend Lake water would pose a direct threat to the public health or safety of communities relying upon water from Rend Lake (such an event is referred to as a "Water Emergency"), then the State of Illinois reserves its rights to prohibit or restrict, on an equal or pro-rata basis respectively, by volume of water used for Non-Domestic Water Use, the use of all Rend Lake water (except for the quantity of water which has been allocated to the Rend Lake Conservancy District under Contract RL-65-1, and existing and future amendments thereto) for all Non-Domestic Water Use until the Domestic Water Uses for which Rend Lake water has been allocated are otherwise satisfied. A "Water Emergency" shall also be deemed to exist, and the State of Illinois may proceed to exercise its rights to prohibit or restrict water use, if the Director of the Illinois Department of Natural Resources makes a reasoned determination in accordance with applicable law that such withdrawal of water from Rend Lake for Non-Domestic Use will result in imminent, substantial and irreparable damage to natural resources. If the Director of the Illinois Department of Natural Resources makes a Water Emergency determination, Adena may seek to alleviate the water shortage, seek approval of the Director to mitigate any damages to natural resources and continue water use, or seek reconsideration of the determination. Any prohibition or pro-rata reduction allocation, as more fully set forth in the following subsection, would apply on an equal percentage basis to the volume of all water used for Non-Domestic Use by each party receiving Rend Lake water; *provided, however,* that each and every Over Allocation Party shall reduce its Non-Domestic Use of water from Rend Lake to zero before any prohibition of pro-rata reduction shall be applicable to Adena.

(d) *Allocation of Mixed Use in Water Emergency.* Except for the water allocated to or may be allocated to the RLCD, if any party entitled to use water from Rend Lake has both Domestic Water Uses and Non-Domestic Water Uses (collectively "Total Water Use"), whether

supplied in whole or in part by Rend Lake water, then the pro-rata reduction allocation of Rend Lake water applicable to such party's Non-Domestic Water Use during a Water Emergency shall be determined based on the percentage of such party's Total Water Use that constitutes Non-Domestic Water Use. Thus, for example, if a party's Total Water Use is singularly supplied by 10 mgd of Rend Lake water and such party uses 50% of that water (*i.e.*, 5 mgd) for Domestic Water Use, then the remaining 50% of that water (*i.e.*, 5 mgd) used for Non-Domestic Water Use will be subject to the Rend Lake water pro-rata reduction. Likewise, if a party supplements its existing water usage with Rend Lake water, then the percentage of that party's total Non-Domestic Water Use will be used to determine that party's pro-rata Rend Lake water allocation reduction. For example, if such a party utilizes 30 mgd from a source other than Rend Lake and supplements that amount with 10 mgd from Rend Lake, for a total of 40 mgd, and 50% of that Total Water Use (*i.e.*, 20 mgd) is for Non-Domestic Water Use, then 50% of that party's Rend Lake water (*i.e.*, 5 mgd) would be subject to a water allocation reduction during a Water Emergency.

(e) *"Domestic" and "Non-Domestic" Water Use.* The term "Domestic Water Use" as used in this Agreement means use of water for household drinking, cooking, sanitary, health and similar purposes, as well as for medical facilities and fire protection; however, the parties agree that "Domestic Water Use" does not include use of water for any commercial or industrial uses, lawn sprinkling, commercial or non-commercial car washes, or recreation purposes (whether in a residential or other setting). The term "Non-Domestic Water Use" as used in this Agreement means any use other than Domestic Water Use. The term "Domestic Water Users" as used in this Agreement means those persons or entities using water solely for Domestic Water Use. The term "Non-Domestic Water Users" as used in this Agreement means those persons or entities using water for any use other than Domestic Water Use.

(f) *Notice of Water Emergencies.* The State of Illinois shall provide Adena notice of any anticipated or actual Water Emergency as soon as practicable, which notice shall include the dates and expected duration of any Water Emergency and whether or not the State of Illinois anticipates the prohibition or pro-rata reduction of any Non-Domestic Water Use in connection with the Water Emergency.

5. **Term of Agreement.**

This Agreement shall become effective upon execution by the parties and shall remain in full force and effect for a period of 40 years from the date first set forth above, unless otherwise terminated pursuant to the provisions of this Agreement.

6. **Payment and Metering.**

(a) Within 30 days of the parties' full execution of this Agreement, Adena shall pay to the State of Illinois the amount of $6,500, which represents a non-refundable payment to secure the water allocation set forth in this agreement.

(b) For purposes of maintaining an accurate record of the water withdrawn from Rend Lake by Adena, Adena agrees to furnish and install, prior to the Initial Withdrawal Date and at

Adena' sole cost, reasonably necessary meters or measuring devices satisfactory to the State of Illinois and the U.S. Army Corps of Engineers (USACE). Such meters or devices shall be available for inspection by the State of Illinois and the USACE, at their expense, at all reasonable times and upon reasonable notice to Adena.

(c) Following the Initial Withdrawal Date, Adena shall prepare monthly withdrawal statements and provide such statements to the State of Illinois and USACE in accordance with Article 4A of the Rend Lake Contract.

(d) Upon full execution of this Agreement, Adena shall be billed by the State of Illinois for Adena's proportionate share of the Water Supply Costs (as defined below) incurred by the State of Illinois pursuant to the Rend Lake Contract. Billing shall commence when the USACE bills the State and shall continue on an annual basis thereafter for the term of this Agreement, unless otherwise terminated. Adena' proportionate share of actual experienced Water Supply Costs shall be based on the amount of the *Daily Quota* allocated to Adena, relative to the available yield (currently 70 mgd) of water assigned to the State of Illinois' control under Article 1 of the Rend Lake Contract. For purposes of this Agreement, "Water Supply Costs" shall mean all charges to the State of Illinois calculated pursuant to the formulas set forth in Articles 5B, 5C, 5D and 5E of the Rend Lake Contract in the form attached hereto as Exhibit A.

(e) For charges pursuant to Article 5C of the Rend Lake Contract (*i.e.*, "Annual Operation and Maintenance Costs"), Adena shall make a check payable to the Finance & Accounting Office, USACE and submit this check to the State of Illinois within 30 calendar days of receipt of its annual bill. For charges pursuant to Articles 5B and 5D of the Rend Lake Contract (*i.e.*, "Major Replacement Cost" and "Major Rehabilitation Costs," respectively), Adena shall submit payment (check payable to the Finance & Accounting Office, USACE) to the State of Illinois in accordance to repayment arrangements established by the Contracting Officer pursuant to Article 7B of the Rend Lake Contract. If Adena shall fail to make any of the aforesaid payments when due, then Adena shall be responsible for all delinquent payments incurred pursuant to Article 5E of the Rend Lake Contract.

(f) The State of Illinois has identified potential operational and recreational impacts associated with water supply withdrawals from Rend Lake. The parties recognize the State of Illinois' interests in the protection of other lake resources as well as to supply water for industrial and other purposes. The State of Illinois may pursue a feasibility study in conjunction with a project cooperation agreement with the Corps of Engineers or other competent party. The study will address water supply impacts along with other impacts associated with the economic development, mining, and wildlife management. The study may specifically examine the costs, benefits and feasibility of installing a spillway control gate and fish barrier. Adena is willing to support the State of Illinois' efforts to implement these studies, mitigation activities or other improvements to Rend Lake which may be determined beneficial. Therefore, Adena agrees to pay $148,590 to the State of Illinois, or a designee of the State's choice, which shall be applied to pay the cost of these studies and/or construction measures which may be determined beneficial, or shall be applied to pay for habitat activities at Rend lake as the State of Illinois determines to be appropriate. Payment will be made as follows; (i) $74,295 on or before the first

anniversary of the parties full execution of this Agreement and (ii) $74,295 on or before the second anniversary of the parties full execution of this Agreement.

(g) The payment obligations set forth in this Section 6 include all payments required by Adena for the water storage, withdrawal and use rights set forth under this Agreement. Adena shall not be required to make any other payment(s) to any other party (including without limitation any other governmental entity or private party) in consideration for the rights set forth under this Agreement. Adena shall not be responsible for any outstanding or unpaid fees owed by the State of Illinois or any other party prior to the date of this Agreement.

7. Termination.

(a) Prior to the Initial Withdrawal Date, Adena may terminate this Agreement for any reason and in its sole discretion upon 30 days' written notice to the State of Illinois. Such termination shall release Adena from all obligations under this Agreement.

(b) If the Initial Withdrawal Date does not occur by December 31 of the third year after the year in which this Agreement is executed (which date shall be referred to as the "Pre-Operation Termination Date"), this Agreement shall terminate; provided, however, that Adena may extend the Pre-Operation Termination Date by one (1) year upon payment by Adena to the State of Illinois the amount of $6,500 and upon the agreement of the State of Illinois, which agreement shall not be unreasonably withheld. Thereafter, the parties may agree to further extensions of the Pre-Operation Termination Date upon such terms and conditions as the parties may mutually agree. Any termination under this subsection shall release Adena and the State of Illinois from any and all obligations under this Agreement.

(c) After the Initial Withdrawal Date, Adena may terminate Adena' obligations under this Agreement upon 30 days' written notice to the State of Illinois if, prior to such termination, Adena identifies a party: (i) that is willing to accept assignment of all of Adena' rights, duties, and obligations under this Agreement; and (ii) that meets with the approval of the State of Illinois, which approval shall not be unreasonably withheld. If Adena satisfies the conditions for termination of this Agreement as provided in this subsection (c), Adena shall be released from its obligations under this Agreement.

8. Changes in Law.

The parties acknowledge that statutory changes or judicial clarifications in applicable federal or state law after the date of this Agreement may affect the rights of the parties to this Agreement. In the event of such a change or clarification in applicable law, Adena or the State of Illinois may request amendment of this Agreement to conform to such a change, or to clarify the rights of the parties as a result of such a change.

9. Limitations.

The parties agree that the State of Illinois will act subject to the terms and provisions of the Rend Lake Dam and Reservoir on the Big Muddy River Act, and other applicable laws.

10. **Right to Transfer or Assign.**

Subject to pre-approval by the State of Illinois, which approval shall not be unreasonably withheld, conditioned or delayed, Adena may transfer or assign any or all of its rights and obligations under this Agreement at any time during the term of the Agreement, whether before or after the Initial Withdrawal Date, as herein defined, to any of the following parties:

(a) Any subsidiary, parent or other related corporate entity of Adena;

(b) Any lending institution providing financing in whole or in part to the construction and operation of the Pond Creek #1 and Sugarcamp coal mines.

11. **Successors and Assigns.**

Notwithstanding anything to the contrary, this Agreement shall be binding upon and inure to the benefit of the parties hereto and their respective successors and assigns.

12. **Water Quality.**

Adena recognizes that this Agreement provides for storage space for use of raw water only. The State of Illinois makes no representation with respect to the quality of water and assumes no responsibility therefore, or for treatment of the water.

13. **Force Majeure.**

Neither party shall be liable to the other for failure to perform its obligations hereunder if and to the extent that such failure to perform is caused by or results from causes beyond its control, including, without limitation, strikes, lockouts, or other industrial disturbances; civil disturbances; fires; floods; acts of God; acts of a public enemy; but excluding the financial inability of such party to perform its obligations under this Agreement and excluding the acts or omissions of such party's agents or subcontractors.

14. **Notices.**

Any notice required or permitted to be given to either party shall be deemed to be received by such party (i) three (3) days after deposit in the United States Registered or Certified Mail, Return Receipt Requested, or (ii) one (1) business day after deposit with a nationally recognized overnight delivery service for next day delivery, or (iii) upon personal delivery to the party to whom addressed provided that a receipt of such delivery is obtained, or (iv) upon successful transmission by telecopy, in any case addressed to the parties at the following addresses:

If to State of Illinois:	Illinois Department of Natural Resources Office of Water Resources One Natural Resources Way Springfield, Illinois 62702-1271 Attention: Director Telecopy No.: (217) 785-5014
If to Adena:	Adena Resources, LLC P.O. Box 1829 1107 W: DeYoung, Suite E Marion, Illinois 62959 Attention: Matt Fifield Telecopy No.: (618) 998-8012
	(with a copy not constituting notice to):
	Brian A. Glasser, Esq. Bailey & Glasser, LLP 227 Capitol Street Charleston, WV 25301 Telecopy No.: (304) 342-1110

or to the parties at such other addresses or telecopy numbers as they may designate by notice to the other party as herein provided.

15. **Governing Law.**

This Agreement and the legal relations of the parties shall be governed by the laws of the State of Illinois applicable to agreements negotiated, executed, delivered, and fully performed in such state.

16. **Captions.**

Headings of particular sections are inserted only for convenience and are in no way to be construed as part of this Agreement or as a limitation of the scope of the sections to which they refer.

17. **Severability.**

The various terms, provisions and covenants herein contained shall be deemed to be separate and severable, and the invalidity or unenforceability of any of them shall in no manner affect or impair the validity or enforceability of the remainder hereof.

18. **Waiver.**

(a) No waiver of the terms, conditions and covenants of this Agreement shall be binding and effective unless the same shall be in writing signed by the parties.

(b) A waiver of any breach of the terms, conditions and covenants of this Agreement shall be for the one time only and shall not apply to any subsequent breach.

19. **Authority to Execute.**

Each of the undersigned certifies, by his/her signature, that he/she is authorized to execute this Agreement on behalf of his/her respective party and that he/she possesses authority to bind his/her party to the terms and conditions set forth herein. Execution of this Agreement does not indicate and shall not be construed as a waiver by either party of any statutory, common law, or other rights which either party has or may have under applicable law.

[REMAINDER OF PAGE INTENTIONALLY BLANK]

IN WITNESS WHEREOF, the parties have caused this Agreement to be executed and to become binding and effective as of the day and year first set forth above.

EXHIBIT A

Contract Between the United States of America and the State of Illinois for Water Storage Space in Rend Lake Reservoir

("Rend Lake Contract")

Contract No. DACW43-88-C-0088 dated 23 September, 1988

AMENDMENT NUMBER ONE
to the
SEPTEMBER 21, 2007 AGREEMENT
between the
STATE OF ILLINOIS
and
ADENA RESOURCES, LLC

THIS AMENDMENT is made between the **STATE OF ILLINOIS**, acting through and represented by the State of Illinois, Department of Natural Resources (hereinafter referred to as "State of Illinois"), and **ADENA RESOURCES, LLC** (hereinafter referred to as "Adena"), (Adena and the State of Illinois are also referred to herein individually as a "party" and collectively as the "parties").

WITNESSETH:

WHEREAS, the State of Illinois and Adena entered into an agreement, (hereinafter referred to as **"AGREEMENT"**), effective September 21, 2007, which provides that Adena, pursuant to the terms and conditions of the AGREEMENT, may withdraw from Rend Lake; and,

WHEREAS, Adena failed to meet the July 1, 2008 deadline requirement to obtain a surface coal mining and reclamation operations permit for the Sugarcamp mine as cited under Section 3(c) of the AGREEMENT, and,

WHEREAS, Adena obtained a surface coal mining and reclamation operations permit for the Sugarcamp mine on August 19, 2008; and,

WHEREAS, Adena has requested waiver of the Section 3 (c) July 1, 2008 deadline requirement, citing the permit delay as an unforeseen circumstance; and

WHEREAS, the State of Illinois has determined that 1) the circumstances necessitating this AMENDMENT were not reasonably foreseeable at the time the AGREEMENT was executed, 2) this AMENDMENT is germane to the AGREEMENT as originally executed, and 3) this AMENDMENT to the AGREEMENT is in the best interest of the State of Illinois.

NOW, THEREFORE, the parties hereto, being the same parties as to the September 21, 2007 AGREEMENT, agree to the following amendments thereto:

1. Section 3(c) of the AGREEMENT is hereby removed.

2. All other covenants under terms of the September 21, 2007 AGREEMENT remain unchanged and in full force and effect.

AMENDMENT NUMBER TWO
TO THE
SEPTEMBER 21, 2007 AGREEMENT
between the
STATE OF ILLINOIS/ DEPARTMENT OF NATURAL RESOURCES,
and the
ADENA RESOURCES, LLC

THIS AMENDMENT is made between the **STATE OF ILLINOIS**, acting through and represented by the State of Illinois, Department of Natural Resources (hereinafter referred to as the "State of Illinois"), and ADENA RESOURCES, LLC (hereinafter referred to as "Adena"), (Adena and the State of Illinois are also referred to herein individually as a "party" and collectively as the "parties").

Witnesseth:

WHEREAS, the State of Illinois and Adena entered into an agreement, (hereinafter referred to as "AGREEMENT"), effective September 21, 2007, which provides that Adena, pursuant to the terms and conditions of the AGREEMENT, may withdraw from Rend Lake; and

WHEREAS, Section 3(c) of the said agreement was amended on August 14, 2009; and

WHEREAS, The United States Army Corp of Engineers has notified the State of Illinois on November 24, 2014 that payments from an entity that does not have an agreement or contract directly with the U.S. Army Corps of Engineers will not be accepted, and the DEPARTMENT has determined that this notification necessitates the amendment of Paragraph 6(e) to the AGREEMENT.

NOW THEREFORE, the parties hereto mutually agree that Paragraph 6(e) of said agreement be amended to read as follows:

(e) For charges pursuant to Article 5C of the Rend Lake Contract (i.e., "Annual Operation and Maintenance Costs"), Adena shall make a check payable to the State of Illinois, mailed directly to the Illinois Department of Natural Resources, Attn: OWR – Water Supply Engineer, One Natural Resources Way, Springfield, IL 62702-1271within 30 calendar days of receipt of its annual bill. For charges pursuant to Articles 5B and 5D of the Rend Lake Contract (i.e., "Major Replacement Cost" and "Major Rehabilitation Costs," respectively), Adena shall submit payment payable to the State of Illinois, mailed directly to the Illinois Department of Natural Resources, Attn: OWR – Water Supply Engineer, One Natural Resources Way, Springfield, IL 62702-1271 in accordance to repayment arrangements established by the Contracting Officer pursuant to Article 7B of the Rend Lake Contract. If Adena shall fail to make any of the

aforesaid payments when due, then Adena shall be responsible for all delinquent payments incurred pursuant to Article 5E of the Rend Lake Contract.

Case history on the reduction of chlorides from mine water

by Srikanth Muddasani, Kathleen Lagnese, Kashi Banerjee and Carla Robinson

Mine water generated from underground coal mining operations contains both dissolved and particulate solids. Dissolved solids primarily consist of sodium, calcium, magnesium, potassium, chlorides and sulfates. When discharged to a receiving stream without treatment, these constituents create a potentially toxic environment for aquatic life.

A case study is presented to discuss how a centralized treatment plant treats mine water from six locations to meet discharge limitations for chlorides. Located in West Virginia, this facility consistently achieves less than the National Pollutant Discharge Elemenation System (NPDES) permit limitation of 218 mg/L chlorides in the discharge while generating almost zero liquid waste. The dissolved solids concentration in the influent ranges between 5,000 and 10,000 mg/L, with chloride concentrations of 1,000 to 2,000 mg/L and sulfate concentrations of 2,000 to 6,000 mg/L.

The mine water is treated using advanced treatment technology to produce clean water for discharge or reuse. The treatment process comprises aeration, softening, filtration, reverse osmosis (RO) reject softening, evaporation, crystallization, final effluent remineralization and sludge dewatering. The solid waste generated in the treatment process is landfilled on site. The leachate is sent back to the facility's thermal treatment process. Because no liquid waste leaves the property, this plant is termed a zero liquid waste (ZLW) facility.

The advanced water treatment system was built to meet a new 218 mg/L regulatory limitation imposed by the West Virginia Department of Environmental Protection for chlorides discharged to surface waters. The system is designed to treat a maximum flow of approximately 795 m^3/h (5 million gpd) of mine water. The treatment process utilizes RO membrane treatment to achieve the effluent criteria, and evaporation and crystallization technology to manage the RO concentrate from the water treatment process. As a result, the system produces clean water for discharge while generating zero liquid waste. The effluent water can be used for industrial purposes or discharged to a receiving stream. A water impact index (WIIx) study indicated that discharge of this high-quality water into the

Mine-SORB™ by FloLogix

A Breakthrough in Water Treatment Chemistry!

Mine-SORB by FloLogix is a next generation chemistry platform developed to solve many of today's most difficult water treatment challenges. Highly effective for problem contaminants including iron, aluminum, sulfates, TSS and selenium, Mine-SORB's dry blended formulation is non-hazardous and extremely cost effective.

Mine-SORB integrates easily with most existing water treatment equipment, helps reduce total water treatment costs, and insures discharge compliance.

Key Mine-SORB Advantages Include:

- **Excellent for removal of iron, aluminum, sulfates, TSS and certain forms of selenium in a single treatment step**
- **Improves water quality**
- **Reduces total treatment cost**
- **Lowers solids/sludge production**
- **Formulation can be customized for specific applications or requirements**

Visit us at **FloLogix.com** or call **1-877-674-0496** today to learn how Mine-SORB can help solve your water treatment challenges. We will exceed your expectations!

FloLogix

HAYWARD

WHY SETTLE FOR METAL?

FLV Series Bag and Cartridge Filters

Get the advantages of Hayward's industry-leading thermoplastic Flow Control products and solutions!

- Ability to handle harsh chemicals and environments
- Outstanding long-term performance in highly corrosive applications
- Materials of construction that prevent contamination of sensitive fluids
- Economical life cycle cost vs. metal and traditionally specified materials

Hayward Flow Control Products and Solutions are designed and suitable for use in key piping systems and applications such as:

- Electro-winning solutions
- Chemical handling, production and distribution
- Mineral extraction
- Water treatment, transmission and disposal

For more information on Hayward Flow Control products and solutions, call 1.888.429.4635 or visit us online at haywardflowcontrol.com

Monongahela River watershed may improve the water quality for downstream water users. The waste produced in the treatment process, including softening sludge and salt, is disposed of in an onsite landfill.

Currently, the plant is treating at an average flow of 490 m^3/h (3.1 million gpd) of mine water with an average influent chloride concentration of 1,530 mg/L and an average effluent chloride concentration of 11 mg/L.

Design basis versus current feed condition

Table 1 shows the design condition versus current average condition, while Table 2 shows the key effluent

Table 1

Design assumptions.

Parameter	Design condition	Current avg feed condition [3]
Design flow, GPM	3,500 Max (1750 Min, 2,300 Avg)	2142
pH, S.U.	5 – 10	7.54
Temperature, ° F	38 – 85	72
Calcium, mg/L as ion	300	226
Magnesium, mg/L as ion	200	102
Chlorides, mg/L as ion	1,500	1,530
Sulfates, mg/L as ion	5,500	2,700 [1]
Iron as $Fe+^2$, mg/L as ion	150	0.27 [2]
Parameter	**Design condition**	**Current average feed condition [3]**
Manganese, mg/L as ion	2	0.27 [2]
Aluminum, mg/L as ion	8	0.01 [2]
Alkalinity, mg/L as $CaCO_3$	700 - 1200	897
TDS (estimated), mg/L	10,000	7,900

Notes:

[1] Average value based on the data collected between Aug. 20 – Sept. 5, 2014.

[2] Average value based on the data collected during startup (March 19 – May 31, 2013).

[3] Other average values were based on the data collected between Jan. 21 – May 31, 2014.

water quality requirements.

The differences between the design basis and the current average feed water concentrations of iron, manganese, aluminum, sulfate and total desolved solids (TDS) are related to the fact that pretreatment is performed at some of the six mine locations prior to discharging to the centralized water treatment plant. The design basis was developed assuming no pretreatment at the upstream sources. The existing pretreatment systems, however, do not significantly impact the feed water chloride concentration. As a result, it is very close to the original design value.

The treatment process consists of the treatment steps described in this article.

Effluent water quality requirements.

Parameters	Maximum effluent concentration
Chlorides, mg/L	<218 [1]
TDS, mg/L	<150 [2]
pH	6 - 9
Minimum hardness, mg/L as $CaCO_3$	≥50

Note:
[1] NPDES permit requirement for outfall discharge.
[2] Consent decree requirement applied to product water prior to remineralization.

Raw water pretreatment

Equalization. The influent to the treatment system is water from three mines collected at six different sites. As noted previously, pretreatment for metals removal is performed at some of these sites prior to conveyance to the water treatment plant. Two separate pipelines convey the water to the 11,360 m^3 (3 million gal) raw water feed tank shown in the upper right corner of Fig. 1. Backwash water from the multimedia filters is also directed to the raw water tank, along with discharges from various collection sumps at the site. Residence time in the tank is approximately 12.5 hours at maximum design flow conditions. Jet mixing accomplished by a grid at the bottom of the tank prevents total suspended solids (TSS) from settling out in the tank and promotes equalization of the influent to the treatment process.

Aeration. From the raw water tank, the water is pumped to an aeration tank, where the air oxidizes dissolved iron to form a ferric hydroxide precipitate. Effluent from this aeration tank overflows into a second aeration tank where the pH can be increased with caustic soda (NaOH) to promote the precipitation of dissolved manganese, if needed (this is not the case currently).

Softening. The second aeration tank overflows into an adjacent full flow softening tank (Fig. 2), where water is lime soda ash softened. Based on the design condition, softening is required prior to RO to reduce calcium hardness and to avoid potential calcium sulfate precipitation at high recovery. The softening tank is equipped with a draft tube reactor to ensure thorough solids contact with the recycled sludge and treatment chemicals. The softening tank effluent flows to a solids contact clarifier that removes the precipitated solids. A majority of the precipitated sludge is recycled back to the crystallization tank at a specified sludge recycle ratio to promote crystal growth kinetics and improved settling. The excess sludge is wasted from the system and pumped to the sludge holding tank.

Aluminum precipitation and filtration. The clarifier effluent flows into an aluminum precipitation tank where the pH is adjusted to 6.5 to 7.2 S.U. for removal of aluminum. Based on the design condition mentioned, aluminum removal is required to avoid potential downstream RO fouling. Sodium hypochlorite

is also added here to inhibit bacterial growth in the downstream filters.

The aluminum precipitation tank overflows into an adjacent concrete multimedia filter feed (MFF) tank. Based on economic considerations, an MMF system was selected instead of ultrafiltration. The MMF system consists of seven vertical multimedia filters operated in parallel (Fig. 3). Each filter vessel is 3.6 m (12 ft) in diameter and 2 m (6 ft) high. Filtration of suspended solids is provided by a 1-m (3-ft) deep bed comprised of layers of garnet, sand and anthracite with a gravel underdrain. A filter aid is used to enhance the removal of suspended and colloidal particles. The MMF system effluent is pumped to the RO feed tank, and filter backwash water is directed to raw water feed tank.

Reverse osmosis membrane system

The RO feed tank effluent is pumped through a 5-micron cartridge filtration system to remove any fine colloidal particles. Antiscalant and sodium bisulfite are added prior to RO to protect the membranes from scaling and from residual free chlorine that can damage the membranes. The single-pass, reverse-osmosis process is a three-stage system design with 18 x 9 x 4 – 7 M array. The main objective of the RO system is removal of chlorides and other dissolved solids present in the water. The RO system consists of five parallel skids, each sized for 25 percent of the design flow with one standby unit. The RO system is designed to operate at a flux rate of 10-12 GFD (17-20 LMH). The RO system is designed to operate at a high water recovery rate of 85 percent. The clean permeate produced by the RO system is sent to the product water tank where it combines with distillate from the evaporation/crystallization process prior to being remineralized.

Final effluent remineralization. The final effluent water is remineralized using carbon dioxide and lime water to meet the effluent requirement for total hardness (50 mg/L as $CaCO_3$), which protects the aquatic life in the receiving stream. The treated water flows into Hibbs Run, a tributary to Buffalo Creek that ultimately discharges to the Monongahela River. In addition, final effluent water can also be sent to onsite truck loading stations for reuse in other industrial operations.

RO reject softening. An evaporator feed tank collects the RO reject as well as leachate from the onsite landfill for subsequent processing through the facility's thermal

Figure 4

Reverse osmosis system.

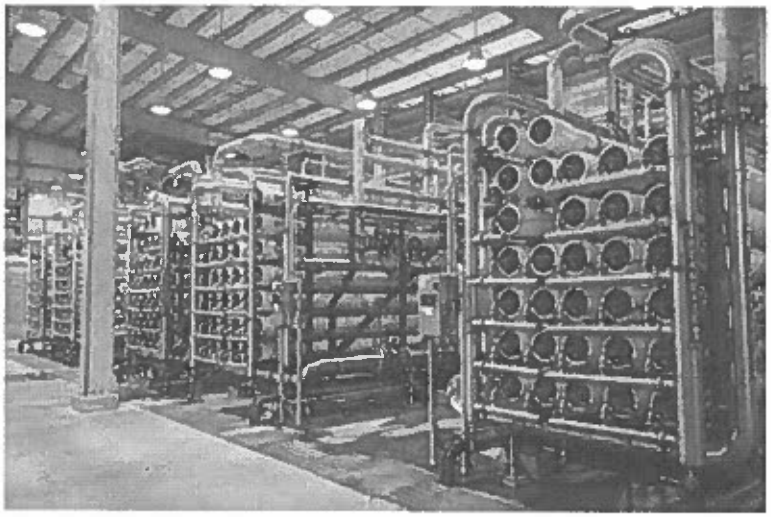

Figure 5

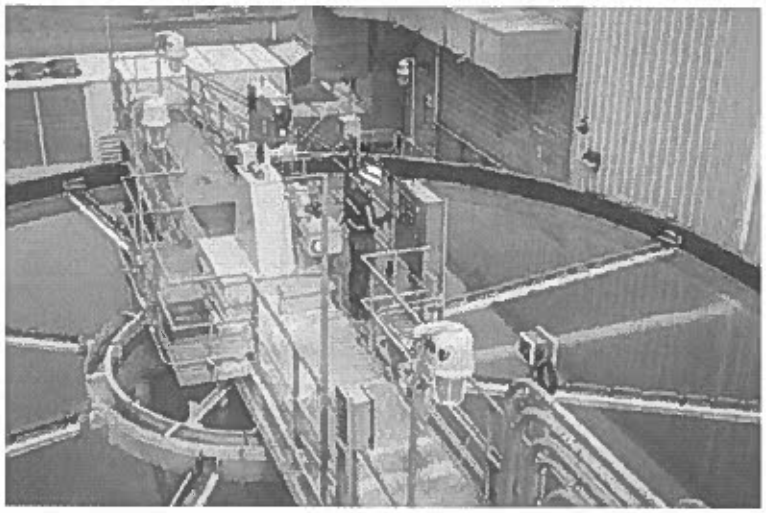
RO reject softening clarifier.



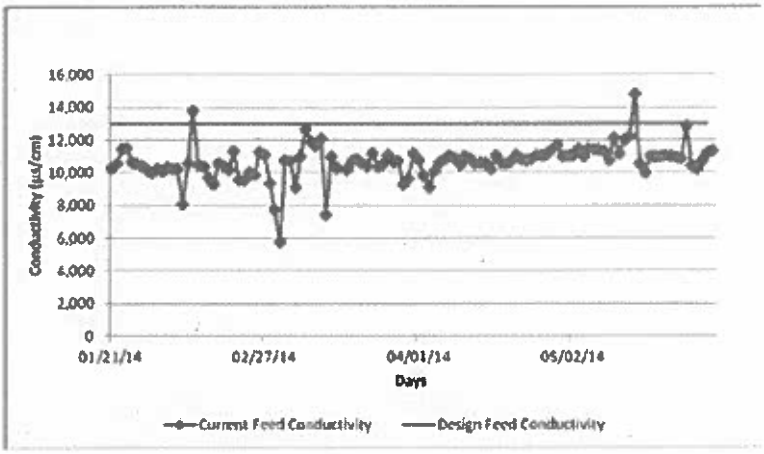


Figure 6

Evaporator and crystallizer.

Figure 7

Feed water conductivity.

treatment process. The evaporator/crystallizer system is designed to handle corrosive materials with high salt concentrations. However, it must first be treated to prevent fouling of the heat transfer surfaces within the evaporator. Treatment consists of chemical softening in a second RO reject softening tank followed by solids settling in a second flocculating clarifier, acidification, preheating and deaeration/ decarbonation. Sludge from the reject softening process is sent to the sludge holding tank.

Evaporator and crystallizer

The evaporator concentrates the RO reject by removing water in an energy-efficient, economical manner prior to the crystallization system. The evaporator is a concentric falling film unit divided into two sections, a low concentration side and a high concentration side. The split design reduces the overall power consumption of the system by allowing a portion of the evaporation to occur at a lower boiling point rise than the final concentration leaving the evaporator.

The evaporator operates as a mechanical vapor recompression system. Vapors created by concentrating the feed brine are recompressed by the evaporator fan to a higher pressure and, consequently, a higher temperature. These vapors are then recycled back into the heater shell to provide the heat source for concentrating the brine. This design eliminates constant steam use from auxiliary sources. The vapor that condenses on the outside of the evaporator heater tubes leaves the evaporator shell side and gravity drains to the distillate tank. The evaporator distillate combines with distillate from the crystallizer unit and is pumped through the feed preheater for heat transfer to incoming brine. This cools the distillate, which is then conveyed to the product water tank. The high-solids brine from the evaporator is sent to the crystallizer feed tank for further concentration in the crystallizer unit.

The crystallizer has a vapor body, a recirculation pump and a forced circulation heat exchanger. Similar to the evaporator, the vapors created by concentrating the slurry within the crystallizer are recompressed by fans. Heat from the mechanically recompressed vapors is transferred through the tubes of the heater to the brine. The concentrated brine collects in the vapor body and is recirculated through the heater. As the evaporation process continues, the concentration of the brine contained in the vapor body increases. As the concentration increases, the solution becomes supersaturated and salts precipitate from solution, resulting in a brine slurry.

A slipstream of the recirculating crystallizer slurry is sent to two centrifuges for dewatering. The two centrifuges are located in a dewatering building as are two filter presses dedicated to the softening sludge. The dewatered salt cake produced by the centrifuges is disposed in the on-site landfill together with the dewatered softening sludge filter cake. The liquid from the centrifuges is returned to the crystallizer feed tank.

Sludge dewatering. Wasted sludge from the full flow softening and RO reject softening process is combined and dewatered using two plate-and-frame filter presses housed in the dewatering building. The filter cake produced by the presses is collected in trucks for transport to the on-site landfill for disposal.

Operating results and discussion

The effluent water quality requirements for TDS and chlorides were provided in Table 2. Operating data for conductivity, as well as recent sampling results for chlorides and sulfates, were used to evaluate the treatment plant performance in achieving these treatment

Table 3

Estimated waste generation in treatment process based on current average and design condition.

Waste	Design condition	Current average condition
Softening sludge (on a 100% dry basis)	6,666 lb/hr	2,500 lb/hr
Salt (on a 100% dry basis)	17,500 lb/hr	8,460 lb/hr
Total waste generated (on 100% dry basis)	24,166 lb/hr	10,960 lb/hr

goals.

TDS removal

The consent decree limit for TDS is 150 mg/L. Figure 7 illustrates the variation of actual feed water conductivity measurements recorded from Jan. 21, 2014 to May 31, 2014, relative to the design influent concentration. The current average feed water conductivity is 10,270 µs/cm, compared to the design assumption of 13,000 µs/cm.

Figure 8 illustrates product water conductivity level measured prior to the remineralization process, as well as the current final discharge conductivity measured after the remineralization process. The required TDS concentration prior to remineralization is less than 150 mg/L. The average product water conductivity before remineralization is 67 µs/cm (approximately 42 mg/L TDS). The average final effluent conductivity after remineralization is 140 µs/cm (approximately 88 mg/L TDS). The remineralization process adds dissolved calcium and carbonate ions to the water that are responsible for the increase in conductivity.

Chloride removal

The principal driver for this project was to meet the NPDES effluent discharge chloride limit of less than 218 mg/L. Figure 9 shows the current feed chloride concentration versus current effluent concentration as measured in grab samples collected and analyzed in the facility's onsite lab from Aug. 20-Sept. 5, 2014. The current average feed water chloride concentration is 1,530 mg/L and average final effluent water chloride concentration is 11 mg/L.

Waste generated

The wastes generated in the treatment plant (softening sludge filter cake and salt cake) are disposed in an onsite landfill. Table 3 shows the estimated amount of softening sludge and salt produced based on the design feed condition and the current average feed condition (Table 1). The waste generated currently is less than designed, resulting in less frequent dewatering cycles and/or centrifuge use.

Conclusion

The centralized mine water treatment plant located in West Virginia was built to meet a new regulatory limit of <218 mg/L for chlorides. The advanced water treatment system utilizes state-of-the-art membrane technology to achieve the chloride limit and energy-efficient evaporation and crystallization technology for brine management. The plant performance consistently exceeds the design requirements. Solid waste generated in the treatment process is disposed in an onsite landfill and the leachate generated at the landfill is sent back to the facility's thermal treatment process. Because no liquid waste leaves the property, this facility is termed a ZLW facility. ■

REPORT TO THE UNITED STATES DISTRICT COURT FOR THE SOUTHERN DISTRICT OF WEST VIRGINIA ON THE CURRENT AND PROPOSED USE OF REVERSE OSMOSIS TREATMENT IN SURFACE AND UNDERGROUND COAL MINE SITES

EXECUTIVE SUMMARY

Pursuant to Federal Rule of Civil Procedure 53(a)(1)(C), Mr. James H. Kyles was appointed as Special Master of Engineering in CIVIL ACTION NO. 2:13-21588 (consolidated with 2:13-16044) by the Honorable Robert C Chambers. As part of the Memorandum Opinion and Order Regarding Injunctive Relief (Order), Mr. Kyles was directed to provide information on the current and proposed use of Reverse Osmosis (RO) treatment of water from surface and underground coal mine sites. The report presents a summary of available information related to the current and proposed use of RO to treat Mine Drainage (MD) water from surface and underground coal mine sites.

Reverse Osmosis (RO) has been successfully used to treat municipal and industrial wastewaters for several decades, and RO has been found to be an efficient process technology that can remove Total Dissolved Solids and reduce conductivity in streams well below the 300 µS/cm target as applied to MD water discharges in West Virginia under current court cases. However, the feasibility of applying RO in a technically efficient and cost effective manner is directly related to the target water quality and the selection of pretreatment unit operations upstream of the RO system.

Reported systems from literature were reviewed and evaluated with consideration applied to the specific quality of the Leatherwood Creek MD water. To validate the information available in literature, a review of current MD water RO plants was conducted. Interviews were conducted with the operation and engineering staff associated with these systems, and design, performance, operation, and maintenance items were discussed. As part of this evaluation, the total installed and operating cost as a function of system hydraulic capacity was considered and, again, validated against real world examples treating MD water. Total installed and operating costs for different flow rates have been identified and have been reported. It is expected that the total operating cost for a properly designed RO treatment system, including required pretreatment, would range from $10 to more than $18/1,000 gallons of MD water treated. Pretreatment accounts for approximately 20% of the operating costs, while the RO treatment accounts for 28%, with the balance (52%) being attributed to residual solids handling.

Discharge of RO water, with an absence of conductivity, may be as problematic as the current discharge of high conductivity water, as aquatic habitats cannot thrive in a system with low or no conductivity. As such, in order to meet effluent discharge requirements, a small portion of untreated raw MD water (<5%) may need be blended with the RO permeate in order to not negatively impact the receiving water quality.

It is concluded based on literature, actual operating data, and experience that RO treatment of MD water is technically and economically feasible. Key elements affecting feasibility are proper design and operation of RO pretreatment and reject management systems. In addition, novel RO applications, Ettringite/nanofiltration (NF) technology, and/or coupling of active treatment of concentrated and segregated valley fill underdrain flows should be explored further to minimize overall life cycle cost of the system.

REPORT TO THE UNITED STATES DISTRICT COURT FOR THE SOUTHERN DISTRICT OF WEST VIRGINIA ON THE CURRENT AND PROPOSED USE OF REVERSE OSMOSIS TREATMENT IN SURFACE AND UNDERGROUND COAL MINE SITES

1 INTRODUCTION

Pursuant to Federal Rule of Civil Procedure 53(a)(1)(C), Mr. James H. Kyles was appointed as Special Master of Engineering in CIVIL ACTION NO. 2:13-21588 (consolidated with 2:13-16044) by the Honorable Robert C Chambers. As part of the Memorandum Opinion and Order Regarding Injunctive Relief (Order), Mr. Kyles was directed to provide information on the current and proposed use of Reverse Osmosis (RO) treatment of water from surface and underground coal mine sites.

Specifically, the Leatherwood site Mine Drainage (MD) water requires treatment to reduce conductivity to below a target conductivity of 300 µS/cm. During trial, various approaches were proposed by the Parties, including Water Management (routing impacted water around sensitive receiving water bodies to larger, more robust waters) and RO. The Court directed the development of this report to become better acquainted with the "state of the industry" associated with the use of RO for the treatment of MD water.

This report presents a data summary of typical MD water quality, and provides a literature review of RO technology with specific application to MD water treatment. A literature review was conducted as part of this investigation. The literature search identified data from operating RO facilities and articles published in peer-reviewed academic journals. A discussion of RO pre-treatment, RO performance, and generation and treatment of residual RO reject is presented, along with RO applicability to MD water treatment and cost. Alternative treatment technologies are also identified.

2 DATA SUMMARY

Data from various operating RO facilities were analyzed and, while the resulting treated water quality meets the effluent quality requirements, the feasibility of the treatment is dependent on the volume of water treated, cost, and reliability of operation and maintenance. It is important to note that the influent quality of the mine discharge depends upon many factors, such as the mineral being mined, and geological and topographical characteristics such as catchment hydrology etc. (Miller, 2014)[1]. compares the influent water quality from Leatherwood Creek tributaries and Leatherwood Creek with those associated with the Buchannan Wastewater Treatment Plant (BWTP), the Northern West Virginia Water Treatment Plant (NWVTP), and MD observed at Boardtree and Stillhouse Branches. The data for these sites were supplied by FOLA. Additional data were obtained from Internet based research platform which was published by Veolia[2] and the Bingham Canyon Water Treatment Plant (BCWTP)[9] for studies conducted on high sulfate MD water.

Since NWVTP, Boardtree Branch, Stillhouse Branch, and South Africa sites have similar influent water characteristics, specifically elevated sulfate concentration and high sulfate/TDS ratio (i.e, >0.5), they are suitable for comparative treatability analysis with Leatherwood Creek due to high sulfate concentration.

Of specific interest to the feasibility of RO treatment are scale-forming compounds. The two major categories of scale forming compounds present in MD are sulfate-based and carbonate-based compounds. Metal-sulfate and metal-carbonate salts are sparingly soluble. Because an RO system concentrates the MD wastewater as a function of treatment, the solubility of these salts is exceeded and the formed precipitate scales the RO membrane surface, causing increased operation and maintenance.

Table 1: MD water influent Quality data for the entire treatment operation

Parameter	FOLA Site							Veolia	Utah
	Leatherwood Creek Tributaries		Leatherwood Creek	BWTP[3]	NWVTP[4], [11]	Boardtree Branch	Stillhouse Branch	South Africa Site[2]	BCWTP[9]

Single sulfate data point for Cogar Hollow with value greater than TDS was excluded

3 RO APPLICATIONS IN MINE DRAINAGE WASTEWATER TREATMENT

The RO membrane acts as a barrier to all dissolved salts and inorganic molecules, as well as organic molecules with a molecular weight greater than approximately 100 g/mol. Water molecules, on the other hand, pass freely through the membrane creating a purified product stream (permeate). Rejection of dissolved salts across the membrane into the permeate stream is typically 95% to >99%. The remaining concentrate (reject) is a concentrated brine solution of lower volume. Permeate salinity is proportional to the average feed salinity at the membrane surface. Therefore, an increase in feed salinity will result in a correspondingly higher permeate salinity.

Osmotic pressure is the pressure phenomena resulting from the difference of salt concentrations across an RO membrane. In order to transport water across the membrane, the osmotic pressure must be overcome through high pressure pumping. Osmotic pressure is a direct function of total dissolved solids (TDS) concentration. Hence, increased TDS levels result in increased osmotic pressure. Therefore, higher feed salinity will require higher feed pressure to produce a given permeate flow.

The recovery ratio (volume of permeate/volume of reject) is limited by the required permeate salinity and feed pressure limitations. Increasing system recovery ratio results in higher average salinity at the membrane surface with a proportional increase in the average feed osmotic pressure. Increasing the recovery ratio also increases the concentrate of salt in the reject stream.

The performance of membrane elements operating in a reverse osmosis system is affected by the feed water composition, feed temperature, feed pressure, and permeate recovery ratio. In practice, the recovery ratio is limited by the solubility of salts in the reject stream. As salts are concentrated, they exceed their solubility limit and precipitate from solution. When salts are present at high concentrations and/or have low solubility, recovery is lowered to minimize membrane scaling issues.

RO systems are designed to operate at a constant flux rate (i.e., to produce a constant permeate flow). Over operating time, the feed pressure is adjusted to compensate for fluctuation of feed water temperature, salinity and permeate flux decline due to fouling or compaction of the membrane (which is caused by increased feed pressure). When the flux has been reduced to less than the minimum required treatment flowrate, the RO membrane is cleaned in place with acid, caustic, or detergent, and then placed back in service. However, each time a membrane is cleaned, the resulting flux rate is decreased. Once the recovered flux rate is less than the required flux rate for treatment operations, the membrane element must be replaced. Membranes replacement can represent a significant operating cost for RO operation.

To minimize reject, systems can be configured as two stage. In a two stage system, the concentrate from the primary stage will re-pressurized and treated through an additional (second stage) RO system. The permeate from the second stage is returned to the influent of the primary stage and the concentrate from the second stage is the overall reject from the system. This arrangement can greatly reduce the reject volume to be treated or disposed.

3.1 RO TECHNOLOGY

Modern RO membranes are constructed of either cellulose acetate (CA) or polysulfone-based thin-film composite (TFC) membrane material. Table 2 below describes the material tolerance comparison and relative costs between CA and TFC membranes.

Table 2: Comparison between different membrane materials

Feature	CA	TFC	Reference
Flux	-	+	5
Salt rejection	-	+	
pH Tolerance	4-8	2-11	
Temperature Stability	<35 C	<45 C	
Chlorine tolerance	0.5mg/L⁺	0.1 mg/L*	5, 6
Operating pressure	600 psi	1000 psi	
Mechanical Strength	+	-	6
Resistance to hydrolysis	-	+	
Capital Cost	+	-	

There are differences in material formation and assembly within each category that can affect flux or operating pressure, and to a lesser extent, fouling potential due to surface smoothness treatment (specifically on TFC membranes). However, in general, one can consider RO membrane a commodity product with little difference in material or performance for similar membranes provided across the industry.

These elements are generally provided in two major configurations: spiral wound and tubular. Spiral wound elements have advantages of large surface area per membrane element, and thus are relevant to large flowrate systems. However, spiral windings have a small annular space for flow, so providing a solids-free feed is critical.

Tubular RO systems have large lumen space within the tubes, and can accommodate higher solids. However, due to the configuration, the surface area per element is much lower than the spiral wound units. Therefore, a much larger system is required, and becomes less cost effective for large flowrates.

The major difference in RO design to improve scaling resistance and/or reduce the potential pretreatment requirements is focused on improvements in the mechanical design of the RO unit. Three examples that may be relevant to MD wastewater are:

- Vibratory Shear Enhanced Processing (VSEP)
- ROChem Spacer Tube (ST) Technology

The VSEP technology utilizes reverse osmosis membrane leaf elements in a stacked-disk configuration that is configured as a single vertical element. The disk stack is oscillated in a motion similar to the agitator of a washing machine, but at a much faster speed. The oscillation produces a shear at the membrane surface of about 150,000 /s, which, according to the manufacturer, is approximately ten times the shear rate of the best conventional cross-flow systems. In a cross-flow membrane, the fluid velocity is greatest away from the membrane surface and a low shear region above the membrane surface exists. This low shear region promotes fouling and pore blockage along the membrane surface. In contrast, the shear in a VSEP System is focused at the membrane surface where it is most useful in preventing fouling, while the bulk fluid between the membrane disks moves very little.

The ROChem Spacer Tube (ST) technology is modification to the standard spiral wound (SW) membrane configuration. The ST module combines the open tube resilience with the efficiency and throughput of a conventional SW module to treat wastewater with high potential of fouling and scaling. Similar to the spiral wound module, the membrane envelopes are made of two flat membranes, between which an internal fabric collects permeate. However, the membrane envelopes are set apart by feed side spacers, creating open channels. The feed spacers used in the ST modules consist of two types of filaments with different diameters. The thick filaments (parallel to the channel axis) have direct contact with the membrane. The thin filaments (perpendicular to the channel axis) are of smaller diameter and have no contact with the membrane surface, allowing small particles to pass through on either side. According to the manufacturer, this allows the ST module to tolerate high dissolved solids and high turbidity, providing a greater resistance to scaling and fouling. This system allows for direct treatment of wastewater with minimal or no pre-filtration.

The spiral wound, tubular, VSEP, and ROChem units are all considered applicable to MD wastewater. Based on review of available literature, tubular RO, VSEP and ROChem do not appear to have applications (pilot or full-scale) operating on MD wastewater.

4 REPRESENTATIVE RO PRETREATMENT

The feasibility of RO operation in a technically efficient and cost effective manner is a related to the target water quality and the selection of pretreatment unit operations upstream of the RO system. If proper pretreatment is not implemented the RO may be prone to excessive scaling due to inorganic precipitate formation or fouling due to organic or biological growth on the membrane surface[7,14]. Both of these conditions decrease flux rates of water across the membrane, which increases operating pressure and lowers the throughput volume. This, in turn, requires increased membrane cleaning which reduces the membrane longevity. Scaling and fouling increase operation and maintenance of the system and causes more frequent membrane replacement. As such, a key aspect of efficient RO operation is proper pretreatment unit operation selection and operation[12].

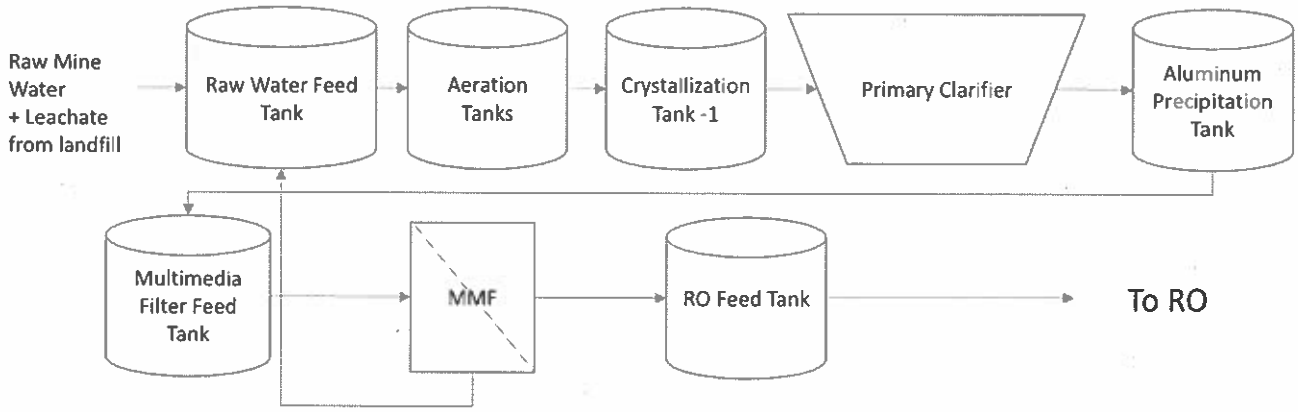
Based on experience and literature review there are several potential options for pretreatment to maximize efficiency of RO units treating MD wastewater. These pretreatment systems are each designed to remove

specific constituents from the influent waste stream, as described below. A pretreatment system usually consists of multi-unit processing trains designed to remove specific inorganic and organic constituents that present membrane scaling and fouling potential.

The quality of MD water and the pretreatment offered impacts the characteristics of the RO feedwater. Water quality can vary with different pretreatment process. Some sites like NWVTP have high sulfates, calcium, and carbonate alkalinity which require complex pretreatment chemistry to remove sulfate and carbonate scale-forming salts. Other sites like BWTP are mainly calcium and carbonate rich. A comparison of pretreatment effluent characteristic for NWVTP and BTWP is presented in Table 3

Table 3: Characteristics of the pretreatment effluent at different sites

Constituent	BWTP[3] mg/L	NWVTP[4] mg/L
pH, standard units @ 20°C	11.7	7
Conductivity, µS/cm	13,900	n/a
Turbidity, NTU	5	n/a
Total Dissolved Solids (105°C)	8,270	9765
Sodium	3,120	3217
Calcium	12.3	20
Total Sulfur	1.3	n/a
Sulfate	n/a	5071
Chloride	4,730	1379
t-Alkalinity (as CaCO3)	239	18
Notes: *** - pretreatment effluent was not available. Data is from clarifier effluent upstream of UF.**		



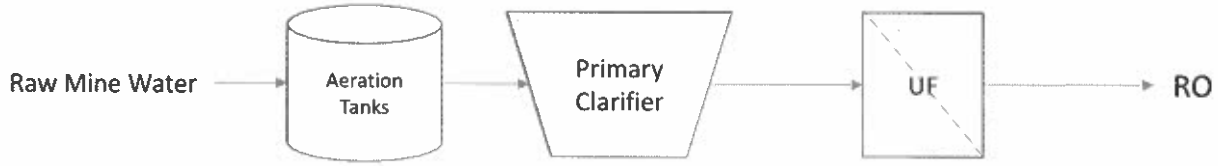
It is expected that the MD water from the Leatherwood site will have high concentration of sulfates and be most similar to NWVTP (see Table 1). A pretreatment system description for NWVTP is provided below. Additionally, descriptions of pretreatment systems for BWTP, BCWTP, and South Africa are provided for comparison.

4.1 NWVTP

The influent at NWVTP is characterized by high sulfate/TDS ratio which is what is observed at the tributaries to Leatherwood Creek. Figure 1 presents the NWVTP pretreatment process flow diagram. The NWVTP pre-treatment consists of aeration, chemical addition, chemical precipitation, gravity separation, and multimedia filtration (MMF) [10]. The MMF has a particle rejection of particles larger than 15µm[11].

The primary purpose of aeration is to oxidize dissolved ferrous iron to a more insoluble ferric iron thereby removing the dissolved iron from the influent water. During the aeration process, a portion of dissolved methane and carbon dioxide present in the feed water is also removed by the action of air stripping[10].

Figure 1: Pretreatment Process train at NWVTP



The effluent from the Aeration Tank overflows into a Crystallization Tank where dissolved manganese, along with remaining ferrous iron is oxidized and precipitated [as Manganese dioxide (MnO_2) and Iron hydroxide ($Fe(OH)_3$), respectively]. The effluent from the clarifier is transferred to secondary precipitation tank to remove dissolved aluminum. The effluent from this tank is sent to a MMF to remove residual aluminum solids[10,11].

Because of the effective pore size of the MMF, direct MMF to RO applications are not typically implemented in wastewater treatment applications.

4.2 BWTP

The influent at BWTP is characterized with high carbonate concentration. The process train as shown in Figure 2 consists of aeration tank, primary clarifier, and ultrafiltration (UF) unit. The UF has an effective pore size of 0.02µm, which provides excellent solids removal prior to the RO[3].

Figure 2: Pretreatment Process train at BWTP

4.3 SOUTH AFRICA

Veolia has conducted studies in South Africa wherein the pretreatment train consisted of iron coagulation, multimedia filters and Green Sand Filtration (dissolved iron and manganese removal). Several other pre-treatment steps were incorporated to extend membrane life: chlorination (to oxidize organic material), water softening (to remove dissolved calcium and magnesium hardness) and ion exchange (to reduce salt loading)[2]. As TFC membranes have a low tolerance to chlorine, a dechlorination step (either granular activated carbon, which provides a catalytic chlorination reduction on the carbon surface, or chemical dechlorination via sodium bisulfite injection) is required.

4.4 BCWTP

At BCWTP[9], the pretreatment system consists of bag and cartridge filters (particle rejection higher than 45 microns), ultraviolet system to prevent the biological fouling of the membranes from bacteria, and antiscalant system which injects a proprietary antiscalant compound used to prevent the scaling of gypsum (calcium sulfate) on the membranes.

4.5 PRETREATMENT USING ETTRINGITE FORMATION

Since the FOLA leatherwood Creek site is expected to contain high concentration of Sulfate, a potentially viable alternative is to precipitate sulfate via formation of Ettringite mineral. Ettringite is a mineral comprised of calcium oxide, calcium sulfate, aluminum oxide, and water ($3CaO{\cdot}3CaSO_4{\cdot}Al_2O_3{\cdot}31H_2O$). The mineral has very low water solubility and therefore can be precipitated out as solids readily. The advantage of forming Ettringite as a pretreatment step is that it removes both calcium and sulfate in a single process. Ettringite precipitation can be achieved in high-sulfate MD wastewater through addition of lime ($Ca(OH_2)$) and $Al(OH)_3$).

Currently FOLA has contracted Veolia to perform bench-scale testing to provide a proof-of-concept and establish the feasibility of the Ettringite precipitation process for removal of sulfate and TDS from the Stillhouse Branch[18], Boardtree Branch, or leatherwood Creek water. One of the goal of this study is to assess whether the Ettringite precipitation process may be applied as a cost-effective pre-treatment process to improve RO performance.

Additional discussion regarding this process are provided in Section 8.1.

5 EXAMPLE RO CASE STUDIES TREATING ACID MINE DRAINAGE WASTEWATER

Based on literature review (Juby, 2000)[7], most of the pilot trials have concluded that in order to improve membrane life, removal of turbidity from the raw mine water to less than 1 NTU and removal of oxidizing agents including chlorine to ensure a free residual of less than 0.1 mg/L is recommended. In addition to the other requirements of the membrane manufacturers, removal of strong acid, base, oxidants are required which can hydrolyze the RO cellulose acetate membrane. Moreover, as discussed in Section 4, selection of a proper pretreatment train is essential for sustainable operation of the RO unit.

The following subsections provide a description of RO system operations at NWVTP, BWTP, and BCWTP.

5.1 NWVTP

The ***NWVTP*** plant was designed to treat a flow of 3,500 gallons per minute. However, average operational flow during the first 6 months of operation was approximately 1,600 gallons per minute. The water recovery was reported to be 85% with 425 psi feeding the primary stage and 500 psi feeding the second stage. Reportedly, the reduced flow rate was due to the following reasons[8]:

1. High TOC levels in the influent feed.
2. Biological Fouling of the RO membranes resulting in lower recovery rates

These issues have been addressed over the past 2.5 years but several other problems including excessive maintenance of the thermal reject treatment (evaporator etc.) have occurred which have hampered daily operations. There have also been challenges in meeting the requirements of WET testing. It is possible that a TDS of 24 and pH of 5.7 may be contributing factors regarding the WET test. Blending effluent to maintain a reasonable ionic strength and neutral pH may be required. Further investigations need to be carried out as relevant information was not shared by personnel currently in charge of the operation.

The Table 4 below provides characteristics comparison for NWVTP at different sampling points. This data has been provided by FOLA. It should be noted that RO was effective in reducing the TDS at a flow of 3000 GPM

Table 4: Water quality at different sampling points across NWVTP[4]

Contaminant	Feed water	Permeate water	Reject water
Total Dissolved Solids (mg/L)	9765	24	62823
pH	7.1	5.7	7.54
Flow (GPM)	3500	2975	525

5.2 BWTP

Although the ***BWTP*** plant was designed to treat a flow of 1,600 gallons per minute, from 2011 – 2014, the facility treated an average flow of 484 gallons per minute. The system is configured as a two stage RO. The recovery of water was observed to be 80% with 400 psi feeding the first stage and 700 psi feeding the second stage. Reportedly, the decrease in actual operational flow was due to the following reasons[8]:

1. Persistent fouling of ultrafiltration (UF) membranes due to carryover of lime particulates from the clarifier, which suggests improper removal of the flocculated material. This also may be due to low cross-flow velocity within the UF membranes, which can lead to increased scale build-up due to a lack of mechanical scouring.
2. The secondary RO reject was returned to the mine pool, which increased the concentration of the dissolved solids and conductivity in the mine pool, leading to a buildup of pollutant load to the system.
3. Shutdown of RO units due to high operating second stage pressure.
4. Improper use of the diffuser discharge by blending in excessive amount of untreated wastewater
5. Inadequate materials of construction and sizing of the thermal treatment process.

5.3 BCWTP

BCWTP plant was designed to treat a flow of 3,500 gallons per minute. The plant has been in operation since 2011, first as a pilot-scale system (2011-2013) and then as a full-scale system (2013-current). The RO is a two stage system operating at 80% recovery. The learning notes from the operation include (Bacon, 2010)[9]

1. The RO unit treats water from shallow and deep wells which can also have high concentration of calcium and magnesium salts.
2. The membrane life was increased to 3-6 years (as compared to manufacturer specified 3 years) by optimizing cleaning schedule and reducing flux.

The following (Table 5) is a comparison of different streams within BCWTP. It may be observed that RO can be successfully used to improve MD water quality to meet treatment objectives.

Table 5: Water quality at different sampling points across BCWTP (Bacon, 2010)[9]

Contaminant	Feed Water	RO Permeate Water	RO Reject Water Quality
Specific Conductance (µS/cm)	2600	24	---
Total Dissolved Solids (mg/L)	2200	250	8,000
Sulfate (mg/L)	1500	250	3,800
pH	n/a	n/a	7.3
Flow (gpm)	3500	2800	700

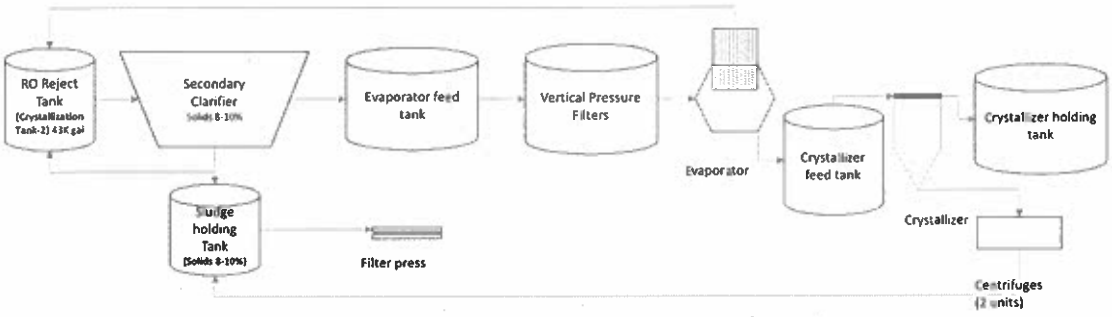
5.4 EFFLUENT BLENDING TO MAINTAIN TARGET EFFLUENT CONDUCTIVITY

According to the documents provided by FOLA (Document titled: Water & Waste Production by BWTP 160101) BWTP has blended the Raw water with Treated water in ratio of 2:1 to 5:1, resulting in water quality that did not meet the discharge permit criteria for conductivity. The conductivity of raw water was 13,900 while the conductivity of treated water is 80 µS/cm. Flow-weighted calculation indicates that a maximum of 1.5% untreated water may be blended with 98.5% of treated water to be able to meet target conductivity of 300 µS/cm. Per Section 5.1, blending may be required to maintain a reasonable ionic strength and neutral pH in the discharge stream.

6 REJECT HANDLING

Reject handling is the single most expensive part of RO system operation and includes treatment of water from RO reject and subsequent disposal of solids and/or liquid. In most cases the reject handling aspect makes the RO applicability financially unattractive.

Proper consideration for treatment & disposal of the concentrated solid waste is essential for overall feasibility of RO treatment and several alternate disposal methods need to be identified based on the local resources.



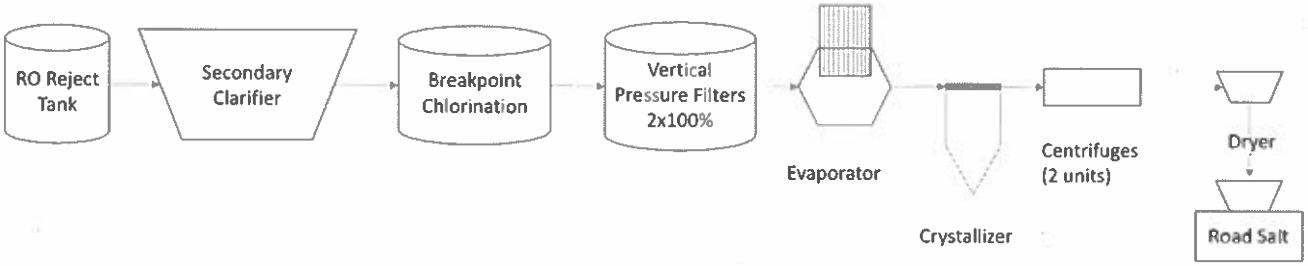
6.1 NWVTP

Figure 3 provides a process flow diagram of the RO concentrate management for NWVTP. The NWVTP is designed to be a zero liquid discharge system. The RO concentrate is primarily composed of sulfate salts. These salts are removed using a combination of chemical (cold lime softening) and thermal treatment. The supernatant from the softening process is directed to the facility's evaporator/crystallizer. Softening solids are dewatered in a plate-and-frame filter press. Crystallizer solids are dewatered in centrifuge[10].

The NWVTP facility produces approximately 110 tons of cold lime softening sludge and 240 ton of mixed salt per day[11]. This solid waste represents 0.121 lb / gal treated MD water. Considering the limited availability of landfills for disposal of sulfate sludge, NWVTP has invested in an on-site landfill to dispose the mixture of softener solids and crystallizer salts. The solids residuals have to meet end disposal requirements for a landfill.

The total capital cost of landfill was $12 Million with $800,000 specifically allocated towards leachate management and $4.6 million towards building the landfill. The balance of the cost was shared between various process units, construction of a building and equipment to address logistics of the solid waste handling at the landfill. The onsite disposal facility represents an operational cost of $4/ton in labor cost. It is important to note that the landfill capacity is about 288,000 tons and that this capacity is expected to be exhausted by December 2016[11, 16].

Figure 3: Downstream treatment of RO reject waste at NWVTP



6.2 BWTP

BWTP (Figure 4) had a comprehensive waste management system (similar to NWVTP). It is understood that this system also experienced problems of corrosion and lack of throughput capacity. The RO concentrate is primarily composed of carbonate salts.

The reject handling system consists of a RO reject tank followed by a Secondary Clarifier, Chlorination vessel, Vertical pressure filters, evaporators, crystallizers, centrifuges and a dryer to manufacture road salt. Salt produced from the RO reject could only be used for its intended application of road salt for 4 months per year, considering the demand for such product. During the balance of its operational period the sludge and salt was landfilled off-site at a cost of $480,000 (80 tons/day x $50/ton for 4 months) for off spec salt and $600,000 (12 months) for Solid waste (per year basis)[15].

Figure 4: Downstream treatment of RO reject waste at BWTP[10]

7 COST ANALYSIS

Table 6 below compares the operating costs between BWTP and NWVTP. Pretreatment accounts for approximately 20% of the operating costs while the RO treatment accounts for 28%, with the balance (52%) being attributed to residual solids handling. NWVTP has reported that the overall cost of treatment per gallon of MD water is approximately $7.70/1000 gal while the cost of RO treatment is approximately $2.20 /1000 gallon[11].

Studies (Sandy & DiSante)[12] have indicated that the Total Installed (TIC) and Operating and Maintenance cost of a RO treatment system (Class 5 costs[1]) are dependent on the operating capacity installed. These costs have been normalized to current indexes and are represented in Figure 5 and Figure 6, respectively. The TIC estimate does not include flow equalization and diversion infrastructure which may be required. Operating costs include maintenance, labor, energy, cleaning, chemical and (non-hazardous) residual disposal costs. The maintenance costs do not include membrane replacement costs.

By comparison, reportedly the overall capital cost (excluding the MD pretreatment and conveyance) of NWVTP, designed for capacity of 3,500 gpm, was approximately $95MM. This is consistent with the capital cost information presented in Figure 6 below.

Consistent with the costs, above, literature reports RO costs for treatment of MD water at a Gold mine in South Dakota were reported as $10 to $18 /1000 gallons (Butler, June 24, 2010)[13] (Sobolewski, 2006)[14]. The RO unit was operated at a pressure of 250 psi. At feed rate of 200 gpm, the RO unit operated at 50% recovery.

Table 6: Comparison of operating costs between BWTP and NWVTP

	BWTP operating costs[15]	NWVTP[16]
Flow rate	1600 GPM	3500 GPM
Labor	$1,383,000	$1,414, 000
Utilities	$3,069, 000	Included in other costs
Chemicals	$2,100,000	$4,173, 000
Pretreatment Utilities & Maintenance	$70,000*	$1,039,000
RO Utilities & Maintenance	Included in other costs	$2,144,000
Contract Services	$305, 000	---
Evaporator and Crystallizer Utilities & Maintenance	$171,000*	$ 3,095,000

[1] AACE estimated costs for concept screening (-20% to +100%).

	BWTP operating costs[15]	NWVTP[16]
Salt Handling Utilities & Maintenance	$250,000*	$255,400
Disposal of Byproducts	$1,100,000	$ 2,029,000
Total Annual Operations and Maintenance Expenses	$8,450,000	$14,151,00
Notes: *** - Includes maintenance only**

8 ALTERNATIVE TREATMENT CONSIDERATIONS

A literature review identified alternative pretreatment/membrane configurations applicable to MD wastewater. Each of these alternatives have been evaluated on a smaller scale, but neither have been implemented on the full-scale.

8.1 ETTRINGITE PRECIPITATION / NANOFILTRATION

Sulfate removal through the precipitation of Ettringite has been proposed as the SAVMIN process (Smit, 1999)[17]. Ettringite ($3CaO{\cdot}3CaSO_4{\cdot}Al_2O_3{\cdot}31H_2O$) has very low water solubility and therefore has the potential to remove both calcium and sulfate from MD wastewater. In addition to sulfate, metals can also be removed via co-precipitation with Ettringite. Figure 7 describes a potential treatment process train using the Ettringite process.

Figure 7: Potential SAVMIN treatment process chain for FOLA sites

The three stages of the process include:

1. Raising the pH with lime to range of 11.5-12
2. Addition of aluminum-based compound to remove residual calcium and sulfate as precipitated Ettringite sludge
3. pH-reduction of the treated water with CO_2 to meet effluent discharge criteria and precipitate residual $CaCO_3$

The Gypsum precipitation step of the SAVMIN process is valid for water that is super-saturated with sulfate.

According to the SAVMIN process Ettringite can either then be disposed of or dissolved in sulfuric acid to recover $Al(OH)_3$. Veolia[18] suggests that due to cost the aluminum coagulant needs to be regenerated to make the process feasible.

The resulting effluent can then be seeded with gypsum to produce more gypsum precipitate. Trials at a plant in South Africa successfully treated 500 m^3 of water with a sulfate concentration of 800 mg/L to <200 mg/L.

A variant on this process is the *Cost Effective Sulfate Removal* (CESR) process. CESR utilizes an alternate reagent in lieu of Aluminum hydroxide that does not require recovery[5].

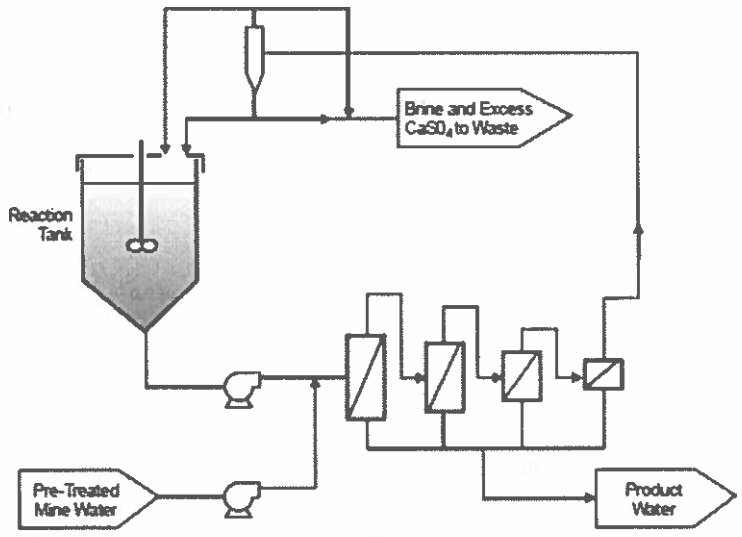
As mentioned in Section 4.5, Veolia is conducting bench-scale testing of the Ettringite process for removal of sulfate and TDS. Preliminary results from Veolia suggest that the gypsum precipitation step is unlikely to be

useful for water from the Leatherwood Creek site due to the sulfate concentration being near its saturation concentration[18].

If the Ettringite precipitation process effectively removes divalent ions and does not impart additional monovalent ions in the process, it is conceivable that this pretreatment process could be coupled with a downstream nanofilter (NF). This is because Leatherwood Creek TDS primarily comprises divalent salts. The passage of the small amount of monovalent TDS may be acceptable to meet the 300 µS/cm conductivity threshold.

NF units are considered a "loose" RO. They spiral wound membrane units that allow significant passage of monovalent ions, yet retain divalent ions and organic molecules with molecular weights >200 to 1000 g/mol, depending on the specific material selected.

The advantage of utilizing a NF is that it would require much lower operating pressure due to the passage of monovalent salts resulting in lower operating cost.



8.2 SEEDED REVERSE OSMOSIS (SRO):

A slurry of seed crystals from the downstream belt press (downstream from clarifier in the waste disposal system) can be recycled back to the primary clarifier. This seed can serve as a preferential growth sites for calcium sulfate, other calcium salts and silicates which begin to precipitate. The preferential growth of scale on the seed crystals prevents scale formation on the membrane surface. This technique is called the Seeded Reverse Osmosis (SRO) which actively promotes precipitation of $CaSO_4$ prior to RO membrane treatment, reducing the corrosion of the membrane walls and fouling by salt precipitation. The crystal slurry concentration is approximately 10% solids and a tubular reverse osmosis (TRO) membranes are required to mitigate fouling in this type of application (Bowell, 2004)[19].

SRO offers advantages in terms of high salt and water recovery and reduced costs. However, these benefits are usually offset by high energy consumption and poor control of $CaSO_4$ seed due to high slurry concentration and recycle.

A pilot plant for SRO has been operated in South Africa for 5000 hours and had a 96% water recovery reducing sulfate from approximately 6600 mg/L to 150 mg/L.

Figure 8: SRO/SPARRO process flow diagram[7]

8.3 SLURRY PRECIPITATION AND RECYCLE REVERSE OSMOSIS (SPARRO):

Redevelopment of the SRO process led to the patent of the Slurry Precipitation and Recycle Reverse Osmosis (SPARRO) process (Pulles, 1992)[20]. The novel features of this process are lower slurry concentration and recycle velocity, smaller reactor and a modified seed crystal and blow down system. SPARRO pilot plant test work has been conducted and includes the precipitation of metals by increasing effluent pH to 10 as a pretreatment step. This was followed by cooling, filtration and readjustment of pH 5 to 6 SU for protection of the membrane process[7].

9 SUMMARY AND CONCLUSIONS

Reverse Osmosis (RO) has been successfully used to treat municipal and industrial wastewaters for several decades, and RO has been found to be an efficient process technology that can remove Total Dissolved Solids and reduce conductivity in streams well below the 300 µS/cm target as applied to MD water discharges in West Virginia under current court cases. However, the feasibility of applying RO in a technically efficient and cost effective manner is directly related to the target water quality and the selection of pretreatment unit operations upstream of the RO system.

The influent composition, which is directly affected by the geographical topography and the type of product being mined, determines the process train to be selected. Data from various operating RO facilities treating MD water were analyzed and compared to the Leatherwood Creek MD water characteristics. Leatherwood Creek MD water contains elevated sulfates and carbonate hardness, which can make treatment challenging. The Leatherwood Creek MD water has a sulfate to total dissolved solids (TDS) ratio of that ranges between 0.56 and 0.97 with an average of 0.71, indicating that significant attention on pretreatment of influent MD water will be needed prior to any RO process. Other sites evaluated ranged from 0.51 to 0.73.

The key aspects of RO pretreatment on MD waters are to successfully reduce primary scale forming constituents, such as sulfate and carbonate hardness. Systems utilizing advanced membrane pre-filtration (i.e., ultrafiltration) are likely to provide acceptable RO feed water quality, if operated properly.

Reported systems from literature were reviewed and evaluated with consideration applied to the specific quality of the Leatherwood Creek MD water. To validate the information available in literature, a review of current MD water RO plants was conducted. Interviews were conducted with the operation and engineering staff associated with these systems, and design, performance, operation, and maintenance items were discussed. As part of this evaluation, the total installed and operating cost as a function of system hydraulic capacity was considered and, again, validated against real world examples treating MD water. Total installed and operating costs for different flow rates have been identified and have been reported. It is expected that the total operating cost for a properly designed RO treatment system, including required pretreatment, would range from $10 to more than $18/1,000 gallons of MD water treated. Pretreatment accounts for approximately 20% of the operating costs, while the RO treatment accounts for 28%, with the balance (52%) being attributed to residual solids handling.

Discharge of RO water, with an absence of conductivity, may be as problematic as the current discharge of high conductivity water, as aquatic habitats cannot thrive in a system with low or no conductivity. As such, in order to meet effluent discharge requirements, a small portion of untreated raw MD water (<5%) may need be blended with the RO permeate in order to not negatively impact the receiving water quality.

One of the more promising alternative approaches for Leatherwood Creek is Ettringite precipitation followed by nanofiltration (NF). Ettringite is a method of forming a crystalline calcium-aluminum-sulfate precipitate which can effectively remove the majority of divalent scale forming complexes and potentially reduce the overall TDS of the MD water. The resulting effluent may be acceptable to process through an NF membrane, which will reject all remaining divalent salts, but allow a certain passage of monovalent salts (i.e., sodium, chloride, etc.). This has the advantage of potentially meeting the effluent conductivity requirements at a lower operating pressure (and associated energy cost).

The coupling of technologies, including flow segregation of lower conductivity surface water and focusing treatment using RO or other technologies such as Ettringite precipitation followed by NF, may provide for a blended discharge of adequate quality. This approach may help minimize overall installation and operating costs by focusing treatment on the smaller, more impacted, portion of MD water, while utilizing the "water management" approach advocated by a number of mine owners (but avoiding long conveyance systems and potentially "moving the problem" from one receiving stream to another").

It is concluded based on literature, actual operating data, and experience that RO treatment of MD water is technically and economically feasible. Key elements affecting feasibility are proper design and operation of RO pretreatment and reject management systems. In addition, novel RO applications, Ettringite/NF technology, and/or coupling of active treatment of concentrated and segregated valley fill underdrain flows should be explored further to minimize overall life cycle cost of the system.

Treatment and disposal of saline wastewater from coal mines in Poland

by Bernt Ericsson and Bengt Hallmans

VBB VIAK-SWECO, Stockholm (Sweden)

SUMMARY

Some Polish coal mines are reviewed with respect to the disposal of saline wastewater into rivers and its environmental impact. The drainage water from mines has a daily contribution of, in the order of magnitude, 6,500 tons chlorides (Cl^-) and 0.5 tons sulphates (SO_4^{2-}) to the rivers Wisla and Odra. The river Wisla contributes to about 55 % of the water resources in Poland. This report is based on a part of a commission for the Ministry of Environmental Protection, National Resources and Forestry of Poland by COWI-VBB VIAK joint venture.

Different treatment and disposal schemes are described and compared from a technical-economical point of view, out of which methods for desalination with zero discharge as well as deep well injection are the most promising ones.

The desalination methods include reverse osmosis (RO) plant, thermal powered desalination and crystallization plant as well as facilities for dewatering and drying of sodium chloride (NaCl) to be sold in Poland and/or on the export market. The valuable main products are potable water, boiler feed water and sodium chloride. A special problem in this connection may be the radioactivity in the wastewater from some of the mines. Special treatment methods for radioactivity removal in the selected treatment and disposal scheme for the mine wastewater are discussed with respect to the effects of radioactivity on the saleability of the recovered salt.

SSDI 0011-9164(94)00148-0

In addition methods for recovery of the by-products magnesium hydroxide, iodine and bromine are considered from the point of view of economy and environmental protection.

Finally, the desalination project in Katowice for the coal mines Debiensko and Budryk is now in the end of the construction phase. Some modifications of the original design are shown.

INTRODUCTION

The drainage water from mines in Poland has a daily contribution of. in the order of magnitude, 6,500 tons chlorides and 0.5 ton sulphates to the rivers Vistula (Wisla) and Oder. The largest amounts of these salts, about 78%, derive from 18 mines located mainly in the Katowice mine district. It has been estimated that the river Vistula contributes to about 55% of the water resources in Poland. About 35% of the water demand (about 5 x 10^9 m^3/y) is withdrawn from the river Vistula itself.

The high salt content in the water from Vistula prevents at present its use within agriculture and causes tremendous economical losses due to corrosion attacks on pipes as well as machines and other equipment within the industry. At present only around 4% of the river water can be classified as drinking water. One of the most important task in order to protect the fresh water resources in Poland will accordingly be to protect the river Vistula against discharge of highly saline mine wastewater.

REVIEW OF SOME INDUSTRIAL WATER PROBLEMS IN POLAND

A commission, including investigation of industrial plants in Poland, for the Ministry of Environmental Protection, National Resources and Forestry of Poland, was performed by COWI-VBB VIAK joint venture. The industrial plants reviewed in this paper are 2 coal mines (Piast and Siersza) and 3 power plants (Siersza, Chorzow and Laziska), located in the industrial area of Katowice, with particular emphasis on water problems at the coal mines.

The water problems at the power plants are relatively small in comparison with e.g. Piast coal mine. At Siersza Power Plant different SO_4^{2-}-concentration limits have been set for different wastewater flows, none of which has not been exceeded according to the results of the analyses. The wastewater from the cooling system may have too high concentration of sulphate at a normal concentration factor. Nanofiltration should be the preferred membrane method for removal of 2-valent ions as

sulphate. Such a treatment makes it possible to increase the number of cycles for the cooling water in the cooling towers considerably.

At Chorzow Power Plant the total dissolved solids (TDS) in cooling water will increase from about 1,700 mg/l to about 5,200 mg/l depending on the recirculation ratio for the cooling. The river water for cooling contains high concentrations of chloride and sulphate as well as suspended solids (SS). In addition to SS and TDS it is essential to control hardness forming ions (primarily calcium), soluble organic matter, dissolved oxygen and gases, algal nutrients and slime producing organisms in cooling water. Treatment of the river water by reverse osmosis in order to prevent corrosion problems in the cooling towers and to increase the recirculation ratio should be desirable.

Three wastewater flows are collected in a pond at Chorsow power plant before discharge into the municipal sewerage. The salinity of the mixed wastewater is between 4,000–5,000 mg/l TDS. RO desalination of this wastewater should be considered. After sewage treatment the saline effluent is discharged into a river.

The water conditions at Laziska Power Plant are similar to those at Chorzow Power Plant. The raw water used for cooling water has relatively high concentrations of sulphate (SO_4^{2-}) and hardness with a salinity up to about 1,200 mg/l.

In the wastewater from the cooling system (9,000 m^3/d) the discharge limit concentrations of (SO_4^{2-}) and Cl^- are 200 mg/l and 300 mg/l, respectively. These limits are exceeded, particularly for SO_4^{2-} (about 900 mg/l). RO desalination should be preferred due to the high chloride concentration.

As exemplified above it would be desirable to treat some water and wastewater flows at the power plants by RO desalination or nanofiltration for removal of mainly 2-valent ions (SO_4^{2-} and hardness). An obstacle could be, however, the treatment and disposal of RO brine due to the increased costs.

The water and wastewater problems at Siersza coal mine are relatively small in comparison with Piast coal mine (see below). The sulphate concentrations in raw mine water and wastewater discharged into the river exceed the discharge limit 150 mg/l SO_4^{2-} by 250–300 mg/l. A possible desalination method would be nanofiltration.

At Piast coal mine the raw water qualities are acceptable. The mixed wastewater (21,000–25,000 m^3/d) contains a very high salinity (TDS = 93 g/l), however, which will cause the primary environmental problem. This has to be solved as soon as possible. The wastewater discharged to Gostynka river also contains radioactivity. The options for wastewater treatment will be discussed below.

OPTIONS FOR SALINE MINE WASTEWATER TREATMENT

Salinity and radioactivity problems (Piast/Czeczott)

The graph in Fig. 1 shows the logaritmic chloride (Cl^-) concentration at increasing depth at Piast coal mine. The groundwater from 200 m depth has approved quality as drinking water according to Polish Standards, but bacteriological problems may occur. The mixed very high salinity mine wastewater from Piast (av. = 22,000 m^3/d) is pumped to a pond, where mine wastewater of similar quality from a nearby coal mine Czeczott is admixed before discharge into the river Gostynka – a tributary of the Vistula river. The total waste water flow from this pond is about 33,000 m^3/d and the salt content about 129 g/l (discharge of about 4.3 tons salt per day) (see Table I). The limits of radioactivity are also exceeded. According to the results of analysis during 1990–91 the concentration of Ra-226 has varied between 4.72–5.64 Bq/l and of Ra-228 1.25–2.46 Bq/l. The discharge limit for the combined wastewater is 0.7 Bq/l. The removal of radioactivity is a pre-treatment stage in the thermal desalination and crystallization process, as the economics of such a process depends very much on the sale of the produced sodium chloride (NaCl). Radioactivity is not allowed in household salt, but this requirement is missing for salt in industrial use.

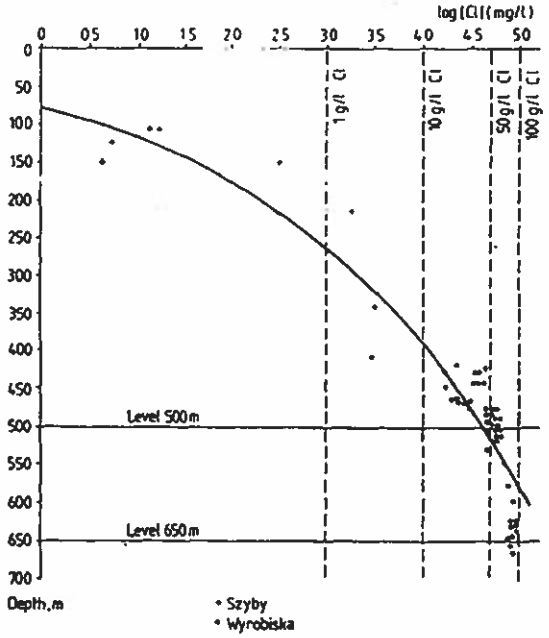

Fig. 1. Mine water salinity (as log (Cl^-) at different depth at Piast coal mine.

TABLE I

Average composition of combined wastewater from Piast/Czeczott coal mines.

	Average values
Temperature	18–20°C
pH	about 7
Suspended solids (SS)	200 mg/l
Total dissolved solids (TDS)	129 g/l
Alkalinity	2 meq./l
Total hardness	445 meq./l
Calcium	3,120 mg/l Ca^{2+}
Magnesium	3,400 mg/l Mg^{2+}
Sodium	40,930 mg/l Na^{+}
Potassium	670 mg/l K^{+}
Ammonium	17 mg/l NH_4^{+}
Manganese	12 mg/l Mn^{2+}
Total iron	2.2 mg/l Fe
Nitrate	12 mg/l NO_3^{-}
Chloride	75,600 mg/l Cl^{-}
Sulphate	3,350 mg/l SO_4^{2-}
Bromide	130 mg/l Br^{-}
Iodide	7.1 mg/l J^{-}
Wastewater flow	32,680 m^3/d (av.)

The following principal methods can be applied in order to eliminate the large salt discharge into the rivers:

- Zero discharge treatment with thermal desalination (vapour compression distillation according to the RCC method), crystallization for production of pure NaCl followed by heat drying of the crystals in e.g. rotary drums. The valuable products obtained from this treatment are mainly drinking water, distillate for boiler feed water and sodium chloride (NaCl).
- Deep well disposal for storage of the mine wastewater at a depth of 4,000–5,000 m.

- Pipeline transportation of salt water for discharge at a location of the receiving water, where the dilution is very high without any detrimental influence on the water quality.

The alternative with pipeline transportation to the Baltic Sea has not yet been evaluated but seems to be too expensive. This alternative will therefore not be discussed any further.

Thermal mine wastewater treatment for zero discharge

A pre-treatment plant for removal of radioactivity is required. Additional radioactivity may be removed more or less completely in the brine concentrators of the thermal powered desalination and crystallization plant and removed as a co-precipitate of calcium sulphate and radium sulphate (containing about 100 Bq/kg salt). This salt can be disposed in a mine hole.

Taking into account the very high salinity of the wastewater it will not be possible to apply reverse osmosis or ion exchange for removal of radioactivity. The remaining two methods are the following:

- Co-precipitation of radium and barium sulphate ($BaSO_4$).
- Lime or lime-soda softening.

The softening process implies the conversion of the hardness-forming and the radionuclide ions into insoluble compounds or precipitates. This method is, however, impractical due to the high hardness and consequently the large chemical demand.

The remaining method to be applied has been developed in Canada. The co-precipitation of barium and radium sulphate is accomplished by addition of barium chloride at an optimum pH-value of 7.0:

$$Ba^{2+} + Ra^{2+} + 2SO_4^{2-} \rightarrow BaSO_4 \cdot RaSO_4\ (S) \qquad (1)$$

The sludge separation stage is either sedimentation or filtration. The former includes dosage of ferric chloride and a polymer in separate flocculation tanks before the settling as well as recirculation of the radioactive chemical sludge from the settling tank to the first flocculation stage after dosage of ferric chloride. A part of this sludge is withdrawn and

disposed in e.g. a mine hole. If the other alternative is applied, a polymer is dosed before dual media filtration.

The main treatment stages in the thermal plant are the following (see Fig. 2):

- Thermal desalination and crystallization plant, including vapor compression distillation with seeded crystals technique (the RCC method), in order to concentrate the high-salinity wastewater to a maximum level without scaling in the condensor tubes. The crystallization of sodium chloride (NaCl), after separation of calcium sulphate (seed crystals), has probably to be performed as a 2-stage process. The crystallized salt is centrifuged and dried.
- Salt packaging and preparation plant (about 3,300 tons/day saleable NaCl salt).
- Potable water blending station for distillate (totally about 29,000 m^3/d) and well water. Some of the distillate will be used as boiler feed water.

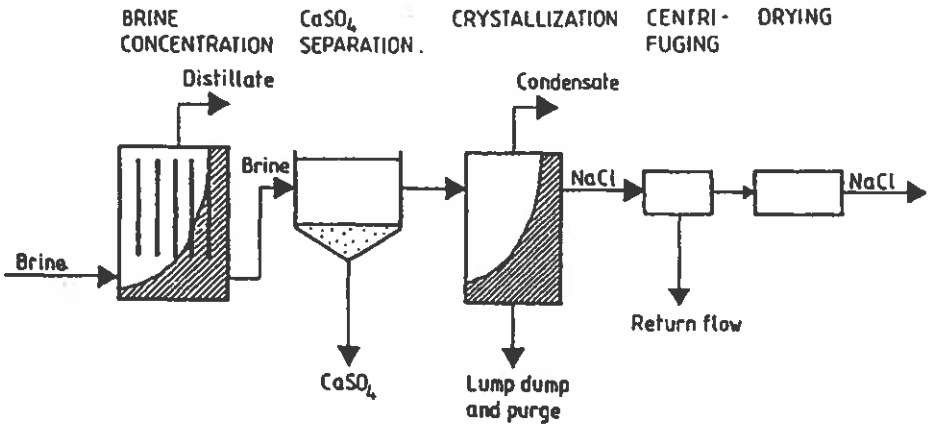

Fig. 2. Proposed flow scheme of the thermal plant for treatment of highly saline wastewater at Piast/Czeczott coal mines.

It is possible to recover some additional chemicals, viz. magnesium hydroxide (magnesium oxide), iodine and bromine, potassium chloride and calcium chloride. The recovery of magnesium oxide as well as of iodine and bromine by chlorine oxidation are strongly considered in Poland and may improve the economy. The yearly production of iodine and bromine is estimated to be 80 tons and 1,500 tons, respectively.

Magnesium oxide can be separated according to either the "dolomite process" or the "carnallite process". In the former process dolime (obtained by calcination of dolomite) is used for precipitation of magnesium hydroxide, in the latter process slaked lime (from limestone).

The dolomite process will produce about 128,000 tons MgO per year compared to about 60,000 tons/year for the carnallite process. The investment cost is higher for the dolomite process, but this process is evaluated to be more advantageous depending on the higher production rate of MgO for sale.

The thermal mine wastewater treatment method for zero discharge is realistic, if it is possible to sell the NaCl salt on the export market. This may be possible, as large salt dealers have paid in interest in the project. The reduced damage to the Vistula river has been estimated to save USD 860 million over the next 20 years. It should also be mentioned that waste coal from the two mines is planned to be used (fluid boilers) which improves the economy.

Deep well disposal

A pre-investigation for the Piast coal mine has been performed by Martech, USA. According to this report, based on current knowledge, deep well injection will be feasible if the wells are drilled to the approximate depth of 4,700 meters and the geological prerequisites are fulfilled. The judgment by geological and drilling experts is that this method is worth pursuing.

The proposal includes 10 wells in the Piast area, all located on safety piles to avoid subsidence. Subsidence could result in damage to the casings and tubings. The first well was planned to be drilled in 1992 near the existing mine water collection reservoir. The results are expected to be available a year later. Based on the findings and results of this test well and the tests on the existing shallow well, the total number of wells required to dispose the produced mine water as well as depth and configuration of future wells will be determined.

Centrifugal pumps will pump water from the mine wastewater pond through filters prior to being injected.

If the results will show the applicability of the deep well disposal method, it may be only a temporary solution and combined with the desalination method.

THE DESALINATION PROJECT IN KATOWICE

The desalination project in Katowice has been described by Masarczyk et al. [1].

This project in Katowice includes advanced treatment of wastewater for zero discharge from two adjacent coal mines, Debiensko and Budryk. The wastewater flow and salinity were designed for about 8 000 m^3/d and 22,600 mg/l, respectively, at Debiensko. The corresponding values of Budryk were about 3,500 m^3/d and 11,500 mg/l TDS. The complete treatment processes are divided into three main sections, viz.:

- Pre-treatment before reverse osmosis (RO)
- RO-plant including posttreatment of the RO permeate
- Thermal plant for brine concentration and separation of sodium chloride (NaCl) by crystallization.

As valuable main products drinking water, distillate and sodium chloride for household and industrial use are obtained.

This plant is now being taken into operation. The salinities of the two wastewater flows have been checked during the construction time in order to further investigate the yearly variation. The result turned out to be quite different from the values used for the design. The salinity of the wastewater from Debiensko has decreased considerably and that of Budryk wastewater increased. Therefore the intention is now to have a mixing station without need to change the original design of the two RO plants except for a pressure increase of the first stage permeate at Debiensko.

CONCLUSION

The most viable method at present for treatment and disposal of the highly saline mine wastewater seems to be the zero discharge desalination method for production of sodium chloride, potable water, boiler feed water, magnesium hydroxide (oxide), bromine and iodine as valuable products. The recent policy in Poland has been to increase the fines very much for such discharge into rivers.

The application of this method at Piast/Czeczott coal mines depends, however, on the possibilities to sell the very large amounts of NaCl produced (about 3,300 tons/d). If this problem is solved, preliminary cost calculations show that this method may be feasible. A similar plant is now being taken into operation in Katowice for zero discharge treatment of mine drainage water from Debiensko and Budryk coal mines.

An interesting alternative, if applicable, is the deep well disposal method, which also can be combined with the desalination method. An investigation at the Piast coal mine by drilling the first deep well to a depth

of about 4,700 meters is under progress. The results are expected to be available in a year.

An evaluation of the alternative with pipeline transportation to the Baltic Sea is expected to be presented in a feasibility study sponsored by the European Commission. At present it is considered to be too expensive.

From: Wendy VanDyk Evans
To: EPA.PublicHearingCom
Subject: [External] Pond Creek Mine comment
Date: Friday, January 17, 2020 4:19:52 PM

Dear EPA folks:

I would like to add my voice to the public outcry against Foresight Energy's proposal to add more mine effluent to local waterways. I found the untrue/misleading statement of the mine representative at the public hearing to be extremely worrying, especially when combined with the company's history of violations, which I was not previously aware of. In fact, I learned quite a lot in researching the matter, including the concept of the amount of time it takes for a particular concentration of pollutant to kill off half of a population of aquatic organisms. I am sure that as environmental scientists, you are very familiar with that type of metric and take it very seriously. Any possibility of such acute levels of poisoning must be avoided, and if the possibility is allowed, it must be for a very, very good reason. Increasing the profits or cutting the costs of an energy company, or even keeping such a company in business, does not qualify as a very good reason. We all know that coal is on its way out as an energy source. I would hate to consider that the EPA would allow any coal company to use its last throes to pollute the community's waterways on its way out.

I've seen what happened under the rule of declining but desperate coal companies over the last 20 years in central Appalachia. Approval for the coal companies there to pollute and degrade the landscape in the name of keeping jobs has resulted in ever-increasing poverty and hopelessness. The mountains are ruined and the people have nothing to show for it. Southern Illinois has a much better future, in my opinion, because we are not solely dependent on one industry. However, allowing coal to affect the waterways and the attendant fishing and recreation would be a serious mistake.

It would be helpful in situations like this for the EPA to issue a clearly written, easily understandable fact sheet with curated arguments for and against this type of proposal.

Thanks, and I look forward to hearing that the EPA has denied the permit.

Re: NPDES Permit No. IL0077666, Notice 7516c- Williamson Energy, LLC

Dear Ms. Lieberoff and other Illinois EPA officials;

These comments are submitted on behalf of Southern Illinoisans Against Fracturing Our Environment (SAFE) a volunteer, grassroots organization based in Southern Illinois. Our focus is upholding "the Law of the Land" Article XI of the Illinois Constitution, which provides that this and future generations have a right to a healthy environment. We oppose the issuance of the proposed permit to Williamson Energy, LLC.

Every pound of coal removed from IL and burned, adds carbon to the atmosphere, and that increases the instability of our climate, and our right to a safe and healthy environment for future generations. The impacts of this decision are cumulative and global. We plead to our state officials to consider the gravity of the matter of climate change and its severe implications to our health, our surrounding environment and the consequences of continuing to permit and concede to industries that undermine the transition to renewable energy by selling false hope and one sided economic benefits to rural, impoverished communities. The collective impacts on our community's health and the degradation to the surrounding environment were not taken into account when the mine purports their "value" of millions of dollars to Southern IL. Environmental justice starts with saying no to companies where stockholders and profits are the only priority of absentee business owners like this company.

We have many questions that were left unanswered or not adequately answered during the public hearing December 18, 2019.

General questions

Why would the IEPA issue a permit to a company when the company is going into bankruptcy and leave the burden of clean up on the backs of taxpayers? Please see the Institute for Energy Economics and Financial Analysis December 2019 at IEEFA.org (Exhibit A) We need only to look at the legacy of coal mines across Southern IL: Scarlet Mine in Stonefort, Saraha Woods and Rocky Branch outside of Harrisburg, and the mountains of overburden left

at Sugar Camp, Galatia, Ava, and impoundment ponds leaching into groundwater to see the burden of reclamation is quite the opposite of economic benefit.

Several documents state the pipeline is only for 10 years and then it will be removed. ***Is this the projected end of the date of the coal seam and mine closure?***

At the public hearing, a mine employee said the Company intends to operate at the site for another 50 years. (Transcript page 25, line 22) On page APP B-1 the IL DOA (Exhibit B) says the pipeline will be removed in 10 years. The citation "https" address given is grossly inaccurate as there are spelling errors within the link itself. With only a $500,000 bond as Foresight energy stocks are tanking, and on December 19, 2019 (the day of the public hearing) the company filed an 8-K Entry into a Material Definitive Agreement (Exhibit C) with "$1.25 billion in gross debt." (Exhibit D) ***Who is going to pay for the removal of this pipeline?***

EPA Enforcement concerns

We noticed on the IDNR permit application located here *https://www.dnr.illinois.gov/mines/LRD/Pages/PendingApplicationsDecisions.aspx* (Exhibit E) under Application Table 1.5.3 of document P456 ORIG PART1.pdf (page 54) A list of violations was submitted for the past 4 years, the IEPA was cited as giving one violation to Pond Creek and it was abated. There are several violations cited by IDNR.

- ***How many inspections has the IEPA completed since this mine has become operational? How many violations have been issued?***
- ***How many field inspectors does the Marion office currently have to call on for inspections?***
- ***Does IDNR Office of Mines and Minerals inspect or cover the same regulations the IEPA does?***

Monitoring

While researching the mining company on the EPA ECHO website, we noticed that the Pollutant loading report indicates:

- Loads for the current year are not based on a full reporting year because the data is not complete. The warning signs appear on all the reports since 2007. For the year 2014 the data is completely blank. ***Why is data incomplete? How does one know if the polluter has exceeded the allowable limits if the EPA is not requiring complete reporting data?*** *(Exhibit F)*

- In August of 2018 and 2019, EPA sampling (Exhibit G & H) showed minerals that exceed the reporting limit (Aluminum, Barium, Boron, Calcium, Magnesium, Nickel, Potassium, Sodium and Strontium) ***Please explain the excessive limits and lack of regulation of minerals that are cumulative and in large amounts, toxic to life.***

ECHO site issues:

- On Sunday, December 15, 2019, the ECHO site listed Williamson Energy LLC compliance status was yellow - "violation". On Wednesday, December 18- the day of the hearing-the Company's compliance status had changed to blue - "no violations identified". This was the case even though the Company's pollutant loading report lacked complete data, and even though the inspection report from 8.29.19 (Exhibit H) showed sulfates and chlorides greatly exceeding the permit limits. ***Please explain how, in a matter of days the Company's status on the ECHO site changed from yellow to blue?***

Citizen Monitoring

In a field inspection report for compliance sampling, dated 8.29.19, (Exhibit G) an EPA employee spoke to a nearby landowner who said "EPA should take sample on Saturday or Sunday when the stream is rolling dark gob water". This land owner was advised to make a formal complaint, to which he responded the mine gave him a hard time the last time he complained.

- ***What recourse should citizens take when they see a violation occurring and assume the risk of making a complaint, but yet the polluters are allowed to bully citizens into silence?***

- On 9/3/19, an IDNR inspector is cited in this report saying "he has received similar information from multiple sources about off hour discharges". ***Is this a recurring issue for the Company?***

- This same report states that despite the **daily** influent of approximately 2.7 million gallons of underground water seeping into the mine, there have been no discharge monitoring reports since March 2019, and the report goes on to say that the water mass balance of influent water and discharged water does not appear consistent.

- Sample results show the amounts of sulfates and chlorides greatly exceed the permit Water Quality standards. ***What measures of enforcement have been taken on this issue against the Company?***

- The report cites under Monitoring Violations: "Analysis not conducted of discharges, inadequate frequency of sampling, invalid/unrepresented sample as required by permit". ***How is it that a mine requesting a new permit to dump 2.9-3.5 million gallons per day of mining waste has no record of discharge for months at a time, no record of discharge release, and no water sampling data on public record? Where is the mining waste water going every day?***

Attorney General's office

Legislators can make all the rules in the world, but those rules are useless if there is no enforcement.Enforcement is pointless if the Attorney General's office does not prosecute civil or criminal cases. We expect Republican Governors to be lax on enforcement and prosecution, but we are dismayed by the few numbers of cases that Gov. Pritzker has sent to the AG's office- only 89, just a hair above Rauner's average. For comparison: Gov. Quinn's average was 144. (Exhibit I)

- ***If Pritzker cares about the environment, then why has the IEPA referred so few cases to the AG's office, even with all the consistent violations of this mine?***

Staff issues

Chicago Tribune article 12.05.19 (Exhibit I)

"Illinois also cut its environmental agency's workforce by 38% [in the past decade]—more than any other state."

"With a smaller staff and less money, the state agency has failed repeatedly to identify hazards to public health and hold polluters accountable, said Eric Schaeffer, a former top U.S. EPA enforcement official who directs the nonprofit Environmental Integrity Project and compiled one of the reports."

"We're jeopardizing the health and safety of Illinois citizens and the economic well-being of its businesses that rely on the Illinois EPA for timely permits and even-handed enforcement," said Mary Gade, who led the agency under former Republican Gov. Jim Edgar and later served as the regional U.S. EPA administrator under President George W. Bush."

"State inspections of air polluters have dropped 81% -"

- Has there been a drop in mining inspections since 2010? Of companies with NPDES permits? If so, by what percentage have the inspections dropped?

Conclusion

Based upon the evidence of multiple samples and reports of off hour discharge, in combination with less than ideal agency enforcement and oversight, SAFE's position is one of opposition to issuance of the NPDES permit as applied for, unless and until the company is willing to add real time data system (SCADA : Supervisory Control and Data Acquisition) that citizens may access 24 hours a day, 365 days a year and is overseen by an independent third party entity. If the company is willing to install a monitors for public access, we ask that the company provides a reclamation bond should any downstream pollution adversely impact the River, the residents and the environment. We ask the EPA to reduce the discharge to less than 500,000 gallons per day and that the state consider reducing the allowable amount to that of surrounding states to 500mg/l of sulfate and chlorides. We also ask that the state provide citizens with support and recourse when reporting illegal discharges from harassment. Unless and until these conditions are met, SAFE opposes the company's request to Discharge into the Big Muddy River, and ask the IL EPA stand with the citizens downstream and deny the permit.

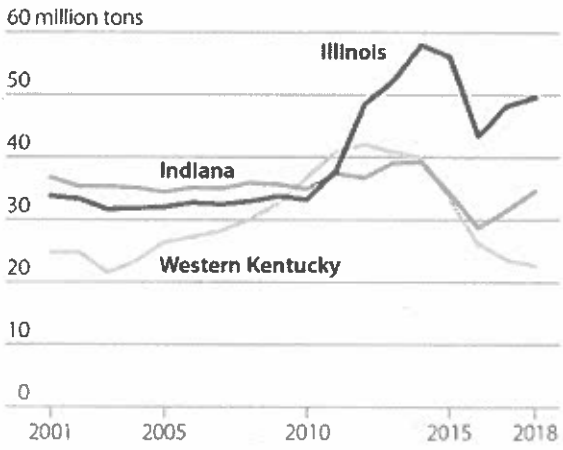
Dim Future for Illinois Basin Coal



Market Forces and Shifting Preferences Are Eroding Customer Base Domestically and Abroad

Executive Summary

Twenty years from now, most of the Illinois Basin coal industry will be gone. Currently one of the major U.S. producing regions of thermal coal for domestic and foreign electricity generation, by 2040 it will have largely faded away as utilities shift to cleaner, cheaper generation resources.

In 2018, the Illinois Basin produced 106.8 million tons of thermal coal, about 14 percent of the total mined nationwide. Most of that total was used domestically, the remainder was exported. The Basin, which straddles the Ohio River in parts of three states—southern Illinois, southwest Indiana and western Kentucky—does not produce any of the metallurgical coal used in steelmaking, meaning it cannot escape the rapid transition now under way in the electric generation sector, both domestically and abroad.

Illinois Basin Coal Production by State

Source: Energy Information Administration

Domestic utilities, which bought nearly 80 percent of the region's coal in 2018, have already announced retirement dates for a significant number of plants over this period, as competitive electric markets compel a shift to newer, less expensive and cleaner wind, solar and gas generation, increasingly supported with energy storage. Notably, these retirements include the largest single purchaser of Illinois Basin coal, Duke's Gibson plant in Indiana, which will close in phases by 2038.

Gibson's closing will not be unique, however. From the beginning of 2019 through 2024, at least 15 U.S. plants that buy Illinois Basin coal—in Alabama, Florida, Georgia, Indiana, Kentucky, North Carolina and Tennessee—will be fully or partially retired. That number, which only reflects formal announcements by utilities, is likely to grow as the economics of coal-fired generation continue to deteriorate relative to renewables and gas.

Even those plants that remain online are likely to be used less and less, reflecting a trend that has seen capacity factors at most coal-fired power plants in the U.S. decline sharply over the past decade.

Coal exports, seen just a decade ago as a potential growth market, face the same market threats, particularly in Europe which is moving aggressively away from thermal coal. In addition, there is growing competition from foreign coal suppliers such as Russia and Columbia for this shrinking market.

These threats are already having a major impact in the region. Just in the past year, producers have closed or idled mines that produced almost nine million tons of coal in 2018. Further closures are likely, both in the near- and long-term.

The Illinois Basin will clearly be hit hard economically by the structural decline of the region's coal industry. Now is the time for local, state and federal policymakers to be planning for the transition in order to minimize the impact of additional coal mine closures, job losses and mining company financial hardships.

Overview

By 2020, Illinois Basin production will have fallen 40 percent since its peak in 1990, part of a widespread decline in the U.S. (see the chart below). Other major coal-producing regions such as Appalachia[1] and the Powder River Basin[2] [3] are faring even worse, with the drop in Appalachian production expected to hit 70 percent by next year compared to its peak, also in 1990. In the West, the decline has been happening even faster, and on a bigger scale: peak production occurred only a decade ago, in 2008, but by the end of 2020 will have been cut almost in half. The entire U.S. coal sector—long dominant in terms of electricity generation market share—is losing out to cheaper forms of energy that include gas-fired power and renewables (wind and solar), and it is doing so at a quickening pace.[4]

U.S. Regional Coal Production, 1985-2018, With Estimates to 2020

Output has fallen sharply in all three major coal mining regions. From their peak years to 2020 (using the latest estimates from the U.S. Energy Information Administration), production is expected to have fallen by 40 percent in the Interior, which includes the Illinois Basin, 47 percent in the West, and 70 percent in Appalachia.

Source: Energy Information Administration (2019-2020 estimates from Nov. 2019 Short-Term Energy Outlook)

Power markets are modernizing, and traditional coal-fired generation is becoming increasingly anachronistic. In 2018, 15,500 megawatts (MW), or 6 percent of all coal-fired capacity in the U.S., was retired, with an additional 14,000MW retiring this year, and many plants that are still in operation are being used less and less frequently by utilities. This year alone, power generation from coal has fallen by 13.4 percent through September, compared to the same period in 2018.[5] The result has been widespread financial carnage over the past two years for the coal industry,

in which 11 U.S. mining company bankruptcies have occurred. One recent news headline crystallized the trend and put the very future of American coal mining in question—"Bankrupt giants hand unwanted coal mines to unknown firms."[6]

In the Illinois Basin specifically, the pace of mine closure announcements has picked up in recent months. In addition, other Illinois Basin mines have been "temporarily idled," a misleading industry term that suggests those mines will reopen when economic conditions improve, but in fact likely will never return to production. Such idlings, can, however, serve as a way to stave off mandated reclamation.

Put bluntly, declining demand means more mines across the Illinois Basin will need to close in the months and years ahead—just as more coal mines will close nationally—and those closures will likely come at a faster rate than has previously been seen.

The decline of the American coal industry more generally is gaining momentum, pushed out by cheap gas from fracking and rapidly falling costs for wind, solar and storage. These trends are discussed in greater detail in IEEFA's annual coal-outlook report published eight months ago[7] and in regional IEEFA research published this year that has included analysis of the Powder River Basin of Montana and Wyoming and of coal-fired generation in the Southeast U.S. (Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee and Virginia).[8]

The continuing rise of renewables, which are increasingly competitive and in many cases cheaper than coal-fired power, was detailed in a Lazard report published just this month.[9] "That phenomenon has increased this year," a Lazard representative said in a report follow-up.[10] "There are situations where the cost of building new wind and the cost of building new solar are cheaper than keeping a coal or nuclear plant operating. And even on an unsubsidized basis, we're starting to see those costs undercut the marginal cost of coal and nuclear."

Similar sentiments have even been voiced by executives within the coal-mining industry itself. Speaking generally of Illinois Basin coal mines, a Hallador Energy executive, for instance, said on an earnings report call in May of this year, "Some of these assets are not long for this world."[11]

Likewise, executives at big utility companies are openly acknowledging the phase-out of coal-fired generation. The CEO of Xcel Energy, for example, said in a June 2018 speech, "It's not a matter of if we're going to retire our coal fleet in this nation, it's just a matter of when."[12] Xcel is of note for two reasons. One, its size (Xcel sells power across the Upper Midwest and in the West), and, two, its aggressive renewable energy buildout, which S&P Global Market Intelligence concluded in a

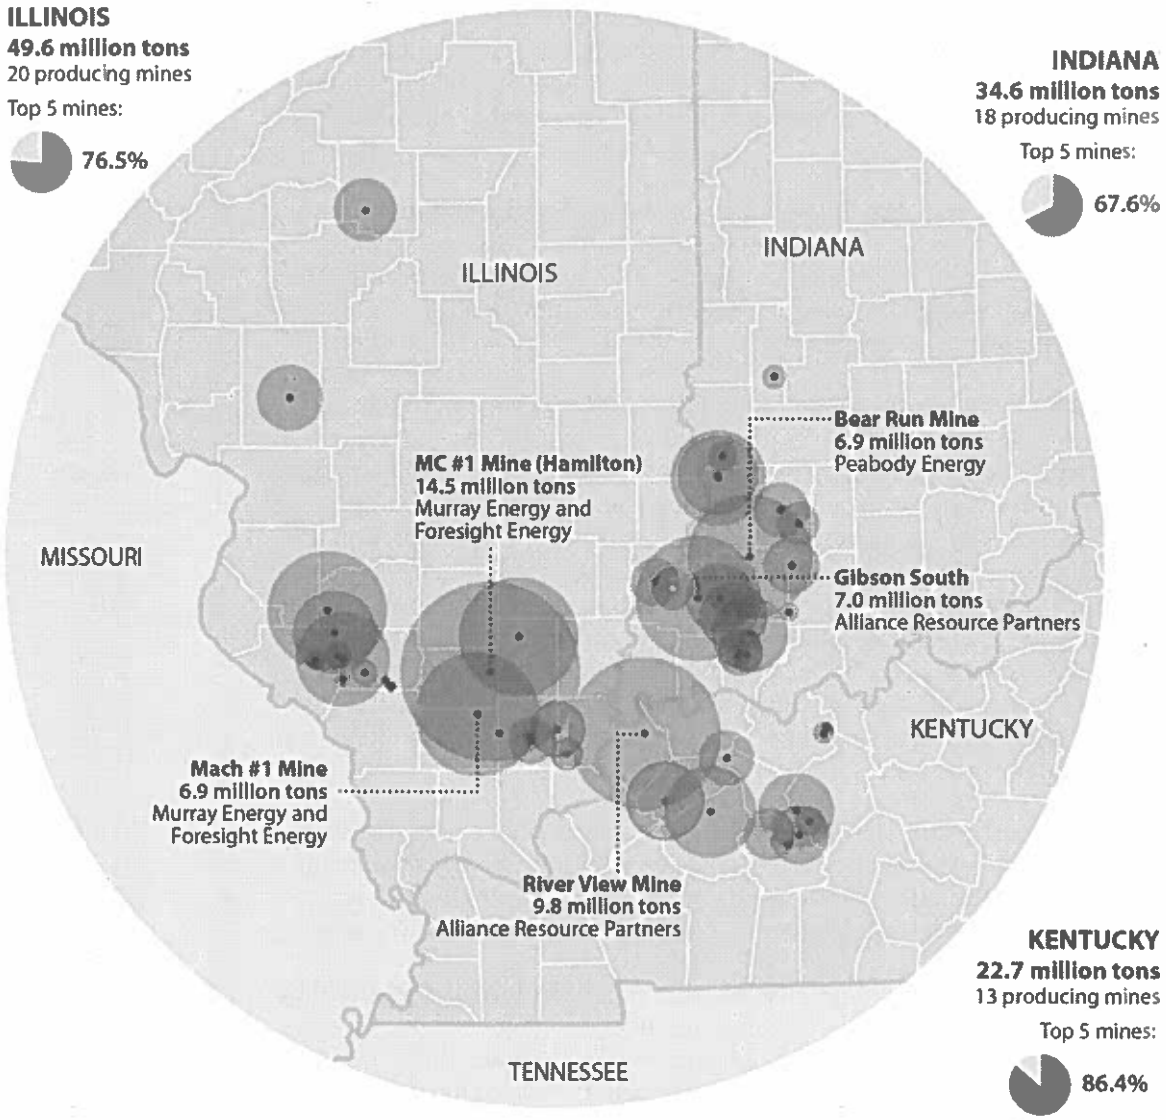
[11] Hallador Energy Company. First Quarter 2019 Earnings Conference Call. May 2017.
[12] Greentech Media. Xcel CEO Says Retiring the US Coal Fleet 'Just a Matter of When'. June 2018

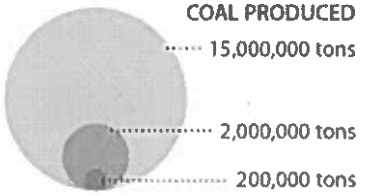
September 2018 analysis "augers well" for Xcel to deliver on its goals of increasing long-term earnings per share by 5 to 6 percent annually and increase dividends annually by 6 to 7 percent.[13]

As the decline in Illinois Basin's coal-production continues, companies that have mines in the region will continue to face market pressure. They include (ranked by amount of Illinois Basin production) Alliance Resource Partners, Murray Energy and its partner Foresight Energy, Peabody Energy, Hallador, Arch Coal and White Stallion.

State-by-state reviews of these companies' utility customers offer another window on why the Illinois Basin coal industry is in such peril. As major customers in states like Florida, for instance, continue to move aggressively away from coal, demand for Illinois Basin coal will weaken further. And export markets aren't likely to be of much help, as Murray Energy executives conceded when the company filed for bankruptcy in October.[14]



The map on page 7 shows recent coal-industry activity across the Illinois Basin.



[13] S&P Global Market Intelligence. With wind at its back, Xcel Energy's renewables build-out augurs well for growth. September 2018.
[14] S&P Global Market Intelligence. Logistics chain adapting to US coal sector's decline, export volatility. November 2014.

Illinois Basin Coal Production, 2018

Total production: **106.8 million tons**

Market forces are beginning to work against the coal-mining industry in the Illinois Basin. Declines in export demand and gathering momentum around retirements of coal-fired plants will affect every state and every company in the basin. Recent mine closures and idlings are part of an emerging long-term trend that will likely result in fewer mines regionally and far less production. On this map, circle sizes are proportional to production; the top five regional mines are labeled.

COAL MINE STATUS
As of November 2019

- Active
- Temporarily idled
- Permanently closed

Institute for Energy Economics and Financial Analysis
IEEFA.org

Sources: Energy Information Administration; S&P Global Market Intelligence

The Company-by-Company View

Alliance, Murray-Foresight, Peabody, Hallador, Arch, White Stallion

The company-by-company maps on the following pages show the geographic presence of the six biggest producers in the basin. Ranked by Illinois Basin production in 2018, they are Alliance Resource Partners (29.9 million tons), Murray/Foresight Energy (28.6 million tons), Peabody Energy (18.6 million tons), Hallador Energy (7.6 million tons), Arch Coal (6.3 million tons) and White Stallion (5.6 million tons); together these companies produced 90 percent of all the coal mine produced in the basin in 2018.

Collectively, the maps suggest stability—that is, they show how most mines in the region remain open. But they also show a developing trend of either permanent closures or companies designating mines as "temporarily idled," a highly misleading term. The reality in today's rapidly changing electric generation market is that these idled mines will probably never reopen.

Thus, the "temporary" idling in November of the Gibson North Mine in Indiana by Alliance likely means this mine will never again produce coal; 185 workers were affected. Gibson North produced nearly 900,000 tons in 2018, and 1.7 million tons in the first nine months of 2019.[15] In August, Alliance permanently closed the Dotiki mine in Kentucky, affecting about 200 workers. At this mine, production in 2018 totalled 2.5 million tons.[16] Similarly, Murray Energy/Foresight Energy ceased production in April at Paradise #9 in Kentucky, which produced 1.1 million tons in 2018, and Peabody in October closed the Somerville Central Mine in Indiana, which produced 2.1 million tons in 2018. In December, Peabody will finish closing its Wildcat Hills mine complex in Illinois, which produced 1.7 million tons in 2018, and the company in the past year has closed two smaller mines—one each in Illinois and Indiana— that together produced 600,000 tons in 2018.

Collectively, then, almost 9 million tons, or 8.4 percent of the Illinois Basin's 106.8 tons of production in 2018 has been taken off the market in the past year or so for lack of demand, and additional production cuts are likely based on the EIA's short-term forecast for 2020, which sees production cuts increasing to 11 million tons.

The effect will be substantial on companies that operate in the Illinois Basin, and the recent mine closures noted above—by Alliance, by the recently bankrupt Murray/Foresight and by Peabody—signal a future in which Illinois Basin producers will continue to lose customers in the U.S. and in foreign markets alike.

State-by-State and Customer-Base Slippage

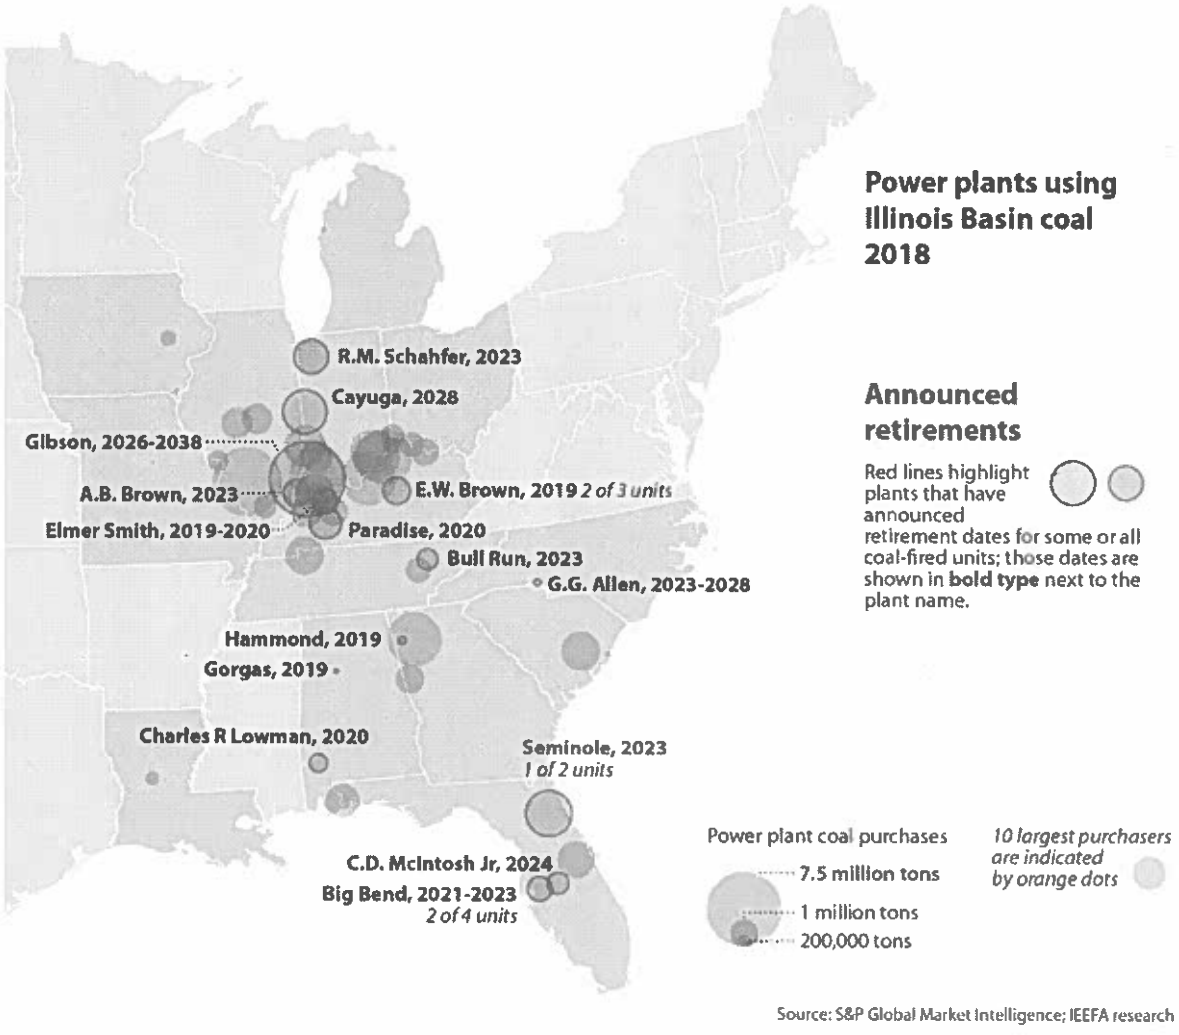
Retirement Dates Loom for More Coal Plants

The problem facing the Illinois Basin coal-mining industry is made clear by focusing on its 49 domestic power-plant customers, which collectively consumed nearly 80 percent of 2018 production and are scattered across states that run from the heart of the Midwest into the Deep South. The 10 largest customers, shown below with orange circles, stretch across Florida, Georgia, Illinois, Indiana and Kentucky, and together use more than half of the coal the basin delivers domestically. The other 39 customers are marked by purple circles. The size of the circles is proportional to the amount of Illinois Basin coal delivered.

Sources: S&P Global Market Intelligence; Energy Information Administration

A significant portion of this customer base will be phased out over the next five years, based on already-announced retirement plans (see the map on page 17).

A clear view of the future of the basin's customer base can be seen in Duke Energy Indiana's June announcement about its retirement plan for the Gibson coal-fired plant. The closure of this plant, the Illinois Basin's largest single coal customer, accounting for almost 10 percent of sales in 2018, almost certainly signals an end date for most of the Illinois Basin coal industry. Situated on the Wabash River across from Mt. Carmel, Ill., the Gibson plant is one of the largest power plants in the U.S., with more than 3,100MW of capacity, and it sits in the heart of Indiana's coal-mining area, very close to Alliance Resource Partners' Gibson coal mine complex.



The dates of the planned closures of the plant's five units, each of which has a nameplate capacity of about 630MW, suggest the timeline the decline of the region's coal industry will follow as well. Unit 4, for example, will now be shut down in 2026, nearly 20 years earlier than its originally-planned retirement in 2044, according to Duke (all the units began operation between 1975 and 1982). Units 3 and 5 will now be shut in 2034, a decade before their previously expected retirements in 2043 and 2047, respectively. The last two units, Units 1 and 2, will be retired in 2038 instead of 2041 and 2040. Yet even these retirement dates may be optimistic: utilities have frequently accelerated their retirement timeframes as coal-plant economics have worsened.

Existing plants have been running less, too. As coal has become less competitive against gas and renewables, larger utilities have been able to fuel-switch across their generation fleets, favoring these cheaper sources whenever they can. As a result, Gibson has been running less than it could. In August, for example, the plant operated at just 33 percent of capacity, its lowest monthly level in at least two decades. In addition, as coal plants like Gibson age, they require more maintenance, and if they are run less, the overall cost of their power goes even higher, making such plants even less competitive.

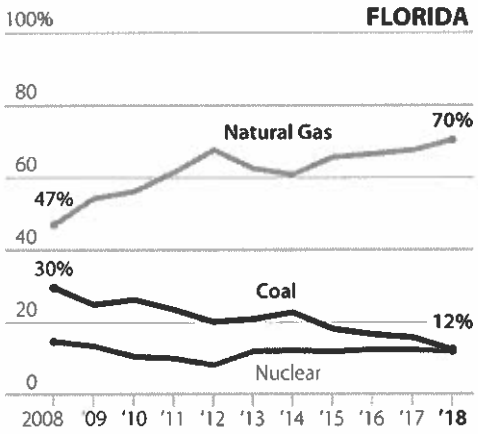
With the economics of coal-fired power deteriorating, more and more utilities have been accelerating retirement dates. In northern Indiana, for instance, the utility NIPSCO recently said it would save $4 billion by retiring its coal plants early and passing those savings on to customers.

It is worth noting that the corporate and financial relationships between the coal-mining companies and the utilities that buy their coal plays a significant role in how quickly coal is being phased out in the Illinois Basin—and across the U.S., for that matter. For the most part, utilities do not have financial stakes in coal mining, and the coal plants they have are usually part of a larger fleet of generation assets that run on a mix of fuels. This encourages them—as is broadly required by state utility oversight agencies—to operate their plants in the most economically efficient way possible, freeing them to cut expensive coal generation without incurring losses when the mines they buy from are closed. They are usually just buyers of fuel, and not in the business of extracting and processing that fuel.

In Illinois, though, there is one major exception: the 1,624MW Prairie State Energy Campus in Washington County. Prairie State is owned by a group of municipalities, public authorities and rural electric cooperatives who also own the neighboring Lively Grove coal mine that supplies the generation station. This practically-new plant, opened in 2012, is the second-largest consumer of Illinois Basin coal, accounting for 8.6 percent of all production in 2018, but it comes entirely from the Lively Grove mine. This self-contained economic structure has locked the owners into very high power costs without much flexibility to shift to cheaper and cleaner generation resources, either from their own renewables or from regional power markets that are increasingly supplying low-cost wind power. IEEFA has written extensively about the situation in past reports.[17] [18]

[17] IEEFA. Cost of Coal From 'Mine-Mouth' Prairie State Plant Isn't the Bargain That Was Promised. April 2015.

[18] IEEFA. 2014, Another Year of Unmet Promises for the Prairie State Energy Campus. February 2015.



Florida, Georgia, Illinois, Indiana, Kentucky

FLORIDA

Coal-fired generation in the Sunshine State is on the way out, as can be seen in well-rooted trends that date back a decade at least. Gas-fired generation now accounts for 70 percent of all electricity production in Florida. Coal-fired plants contributed 30 percent to Florida's power mix as recently as 2008; that number had fallen to 12 percent by 2018.

The 2010 census put the state's population at 18.8 million, and by 2018 that number had risen 6 percent, to 21.3 million.[19] While electricity consumption in the state has climbed with its population boom, none of that demand increase was supplied by coal.[20]

Fuel Share for Electric Power Generation (Utility Scale, All Sectors)

Only fuels with 5% or more share in any year are shown.
Source: Energy Information Administration

While gas-fired generation has taken a bigger and bigger share of the market, the state's three biggest utilities—Duke Energy Florida, Florida Power and Light, and Teco Energy—have plans to install more than 11GW of solar over the next 10 years.[21] While the state comes belatedly to solar—a circumstance rich with irony, considering how Florida's nickname is the Sunshine State—it has recently made a hard pivot toward utility-scale solar. In 2018, the three major utilities brought a total of 876MW of utility-scale solar online,[22] roughly enough capacity to power almost a million homes. Simultaneously, battery storage is coming online in a fast-spreading advance that stands to bolster the uptake of solar.

Florida's coal-fired capacity has fallen by more than half over the past decade to 7,883MW, of which 2,094MW will be retired by 2024, according to utility-company announcements.

[21] Ibid.
[22] Smart Electric Power Alliance. SEPA's 2019 Solar Snapshot Report Finds Florida's Solar Market is Flourishing, June 2019.

GEORGIA

Electricity-generation trends in Georgia are similar to Florida's. Coal-fired generation market share fell from 63 percent in 2008 to 25 percent in 2018. That share will drop further in the near future— and for the same reasons seen in Florida. Gas-fired generation is cheaper, as is utility scale solar (Georgia Power plans to have 2,260MW of utility-scale and distributed solar online by 2024).

Georgia has only three coal-fired generation plants, although two are the largest in the U.S., the 3,392MW Plant Scherer and the 3,200MW Plant Bowen. The third, 1,744MW Plant Wansley, is very likely to follow in the footsteps of Plant McIntosh (142MW) and Plant Hammond (840MW),[23] both of which were retired this past July. Plant Bowen is an especially big Illinois Basin customer, ranking fifth among Illinois Basin users in 2018 (3.93 million tons). Its owner, the Southern Company subsidiary Georgia Power, published an updated integrated resource plan (IRP) this year noting "economic challenges"[24] facing the plant.

ILLINOIS

Illinois has the strongest renewable energy standards of the five states noted here, with a goal of getting 25 percent of its power from renewable sources by 2025.[25]

It is also where markets are driving a wave of coal plant closures that are very quickly reshaping the state's energy economy. Vistra Energy is the prime example, having recently announced that it would close the 585MW E.D. Edwards plant at the end of

Fuel Share for Electric Power Generation (Utility Scale, All Sectors)

Only fuels with 5% or more share in any year are shown.

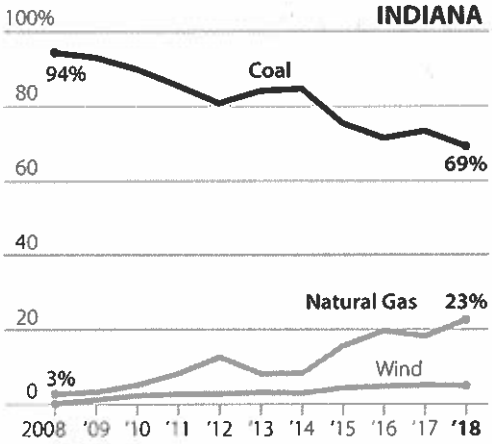
[23] IEEFA. Coal-Fired Power Generation in Freefall Across Southeast U.S., October 2019.
[24] Georgia Power. 2019 IRP, Docket #42310, Section 1-7, Unit Retirements. December 2018, 1-7.
[25] National Conference of State Legislatures. State Renewable Portfolio Standards and Goals. accessed November 2019.

2022.[26] The company had already announced that it would close four other coal-fired plants in Illinois this year with a total capacity of about 2,000MW.

Vistra, an energy behemoth with 10 coal-fired plants in the U.S. that have a total of 11,000MW of generation capacity, in October announced new emissions-reduction goals in which executives at the company said it "anticipates retiring more coal assets."[27]



INDIANA

Indiana is not considered a leader in electricity-generation transition policy, but market-driven changes are occurring, nonetheless.

The state has a formal goal of getting 10 percent of its electricity from "clean energy" by 2025, but the parameters for meeting that target are loosely defined and favor "clean coal" technology and gas-fired generation.

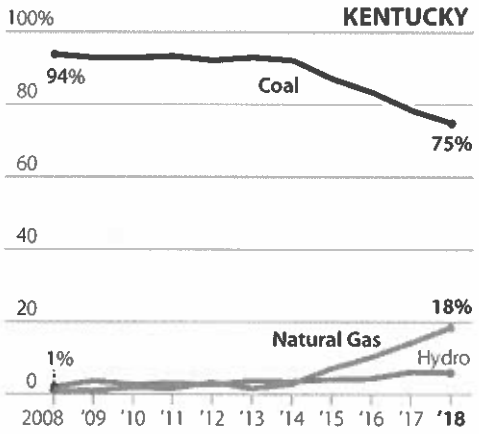
Market changes may outpace state policy, however. The Northern Indiana Public Service Company (NIPSCO) this year announced plans to abandon coal-fired electricity generation entirely and to focus on utility-scale solar generation and other renewable generation. In October, NIPSCO published requests for proposals for development of 2,300MW of solar and 300MW of wind-powered generation.

Fuel Share for Electric Power Generation (Utility Scale, All Sectors)

Only fuels with 5% or more share in any year are shown.
Source: Energy Information Administration

"The driver for how we make decisions is really rooted in economics and costs for our customer," an executive at the company said when the RFPs were announced.[28]

KENTUCKY



Even Kentucky, reliant on coal for 94 percent of its electricity generation a decade ago, is changing. Coal's share of the state's power-generation market dropped 19 points from 2008 to 2018, a shift owing almost entirely to the rise of gas-fired generation.

[26] Utility Dive. Judge OKs $8.6M Vistra coal plant closure settlement seen by NGOs as model for helping impacted communities. November 2019.
[27] Vistra Energy. Vistra Energy Announces Long-Term Emissions Reduction Targets and Support for Market-Based Carbon Reduction Regime. October 2019.
[28] Greentech Media. The Solar Boom Takes Off in the Industrial Midwest. October 2019.

Although Kentucky has deep cultural connections with coal, existing national power-generation trends will likely gain momentum in the state for purely economic reasons. They will be driven also by corporate policy initiatives, as U.S. companies that do business in Kentucky are adopting increasingly stringent requirements on where their electricity comes from.

Utility companies in Kentucky are also evolving. Kentucky Utilities and Louisville Gas & Electric are both subsidiaries of PPL Corporation, which last year announced plans to cut its carbon-dioxide emissions by 70 percent from 2010 levels by 2050. According to the corporation, among the measures that will be needed to reach that goal "include replacing Kentucky coal-fired generation over time with a mix of renewables and natural gas while meeting obligations to provide least-cost and reliable service to customers."[29]

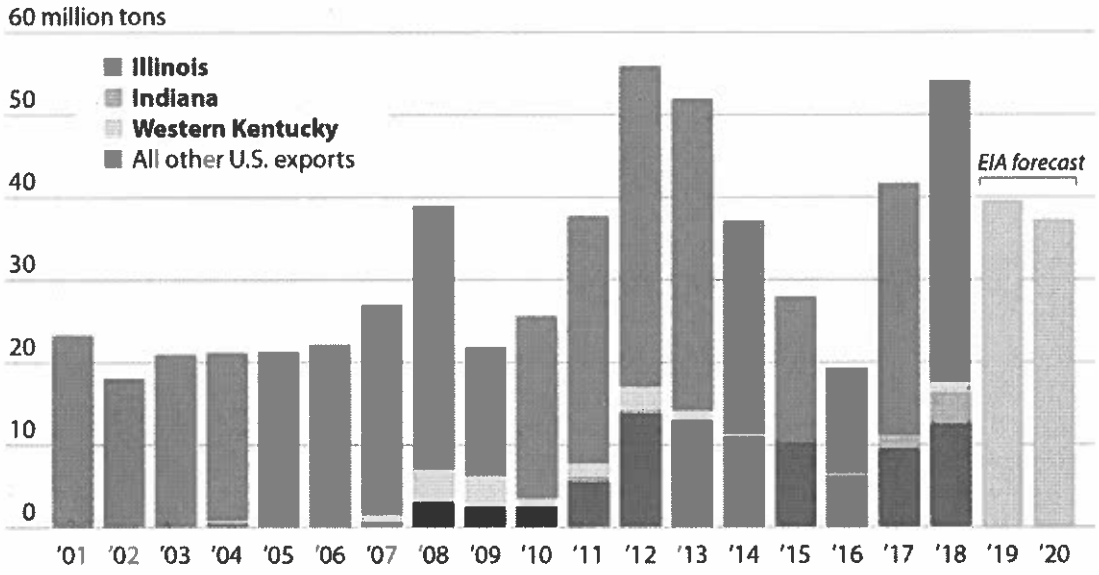
The Export-Market Problem

Market Forces Continue to Work Against Coal Overseas, Too



Beginning about a decade and a half ago, Illinois Basin producers saw potential in shipping coal to Europe, India and elsewhere for power-generation purposes.

These ambitions paid off as European demand for U.S. coal rose—for a while. But the same market forces that are moving against coal in the U.S. are working against European coal-fired generation too. A handful of countries in the 28-member European Union continue to rely heavily on coal-fired power but even nations like Poland, which in some ways is the Kentucky of Europe, are seeing change.[30]

[29] PPL Corporation. 2018 Sustainability Report.
[30] S&P Global Market Intelligence. A way back for onshore wind as Poland revises draft energy policy to 2040. November 2019.

U.S. Thermal Coal Exports, and Exports from the Illinois Basin

Exports from the Illinois Basin have surged over the past decade, rising to roughly one-third of all U.S. exports. Most of that volume is from mines in one state, Illinois.

Source: Energy Information Administration, Annual Coal Distribution Reports

An October report published by the Carbon Tracker Initiative showed how four of five coal-fired power plants in the EU are losing money.[31] The report put EU coal fleet losses at €6.6 billion (US$7.1 billion) in 2019 alone.

"Policymakers and investors should prepare to phase out coal by 2030 at the latest," Carbon Tracker concluded, and—indeed—financiers,[32] political leaders,[33] and even mining companies[34] continue to distance themselves from European coal-fired power.

In addition, competition from other thermal coal-exporting countries is increasing, and they may be better positioned than exporters in the Illinois Basin. For example, Platts recently reported that Colombian and Russian coal is more price competitive in European markets than Illinois Basin, Northern and Central Appalachian coal."[35]

Outside Europe, other countries that are big importers of U.S. thermal coal, including India, South Korea and Japan, are also accelerating their adoption of renewable power in an effort to both cut pollution and reduce dependence on imported energy. As demand for coal declines, it will be increasingly difficult to

sustain Illinois Basin exports.

All U.S. coal exports are highly dependent on international market prices, and volumes have waxed and waned with those price fluctuations, illustrating the fundamental volatility that defines the basin's export market.

U.S. Thermal Coal Exports, Quarterly

U.S. coal export volume has fluctuated considerably in recent years, but has tracked closely with market prices. Forecasts for the fouth quarter of 2019 and 2020 are from the EIA's November Short-Term Energy Outlook.

Source: Energy Information Administration

Conclusion

Structural and Permanent Decline; Opportunity in New Energy Models

The Illinois Basin's coal industry is entering a period of structural decline.

Within the next 20 years, virtually all of the U.S. coal-fired plants that currently buy the basin's coal will be either retired or little used, the result of an economic and technologically driven energy transition in the electric power industry that favors lower-cost and cleaner alternatives. In particular, wind, solar and battery storage—especially when combined—already offer utilities distinct advantages in grid resiliency, modernization and low maintenance, all with zero fuel expenses and declining construction costs. Inexpensive gas from hydraulic fracturing is also playing a major role in this transition, though the cost of renewables has already reached parity or undercut gas in many areas. No new American coal plants will be built.

As a result of this transition, a significant portion of the Illinois Basin's domestic power-plant customers now have dates for retirement within the next few years. IEEFA expects many more retirements beyond those over the next two decades. Further, coal consumption at existing power plants has begun to decline as they become less economically competitive, a trend that will accelerate as the difference in generation cost widens.

Growth in exports, which had masked declines in domestic demand until recently, appear to have peaked and turned lower. The same technology and market-based forces at work in the U.S. are at work as well in many of the basin's current or potential export markets, including Europe, India, Japan and South Korea, where utilities plan to cut coal use while increasing power generation from renewables. This will make it challenging for U.S. thermal coal exports over the long term. As demand in these markets starts to fall, international coal markets will likely be oversupplied, leading to intense price competition. The inherent volatility of the international export market, combined with permanently shrinking domestic demand and the generally weak financial condition of the coal-mining sector will necessarily lead to lower production and fewer companies (either from attrition or consolidation) operating in the region.

Twenty years from now, most of the Illinois Basin coal industry will be gone. While this may seem like a relatively far-off time, the economic impact from the constant drumbeat of coal-plant closures, mine closures and job losses will likely be significant in the region. Limiting the harm—and benefiting from the emerging economic opportunities—from this transition will require leadership, planning and support from federal, state and local officials.

And there are many real benefits, including long-term, non-agricultural income for farmers and counties from renewable power projects, lower electricity costs for individuals and businesses, economic activity from a regional buildout of renewables, improved power-grid resilience and construction and engineering jobs. Policymakers and communities that embrace this transition will be in the best position to gain a long-term advantage from these changes, and better able to offer lasting improvements that will be beneficial for everyone.

The Illinois Department of Natural Resources, Office of Mines and Minerals, Land Reclamation Division (Department), the Regulatory Authority in Illinois under the Surface Mining Control and Reclamation Act of 1977 (Federal Act), 30 U.S.C. Section 1201 *et seq.*, has reviewed Permit Application No. 456 in accordance with the Surface Coal Mining Land Conservation and Reclamation Act (State Act), 225 ILCS 720, and the Department's regulations at 62 Ill. Adm. Code 1700-1850.

The applicant has submitted in writing the modifications required by the Department's letter dated December 20, 2018 (Appendix A). These modifications have been reviewed and approved by the Department. Pursuant to 62 Ill. Adm. Code 1773.19, the Department is approving the application as modified. The Department's decision is based upon a review of the record as a whole, and is supported and documented by the record. The findings and reasons for the Department's decision are set forth below. The period for administrative review under 62 Ill. Adm. Code 1847.3 commences as of the date of this decision.

I. SUMMARY OF APPLICATION

The application proposes a permit on 70.7 acres. The proposed permit area consists of 70.7 acres, of which all the acreage is are proposed to be used for support facilities.

The following is a summary of the pre-mining land uses and the proposed post-mining land uses. NOTE: Land uses are categorized under the definitions found in 62 Ill. Adm. Code 1701.5. Land use classifications under other regulatory programs and agencies may be different.

Land Use	Pre-Mining Acres	Post-Mining Acres
Cropland	16.4	16.4
Water Resources	0.2	0.2
Residential	0.1	0.1
Industrial/Commercial	8.2	8.2
Fish & Wildlife Habitat	45.8	45.8
Total	70.7	70.7

II. SUMMARY OF THE PUBLIC PARTICIPATION PROCESS

The Department finds that the public participation requirements of 62 Ill. Adm. Code 1773.13 and 1773.14 have been met.

The application was filed with the Department on May 25, 2017, and was deemed complete on July 13, 2017. The applicant placed a newspaper advertisement of the proposed operation in the Marion Republican and the Benton News, newspapers of general circulation in the area affected, once a week for four consecutive weeks, beginning on July 18, 2018. The applicant filed two (2) copies of the application with the County Clerks of Williamson County and Franklin County, in accordance with 62 Ill. Adm. Code 1773.13(a)(2), on July 18, 2018. Copies of the application were sent to the following State Agencies: Illinois Department of Agriculture (IDOA), and Illinois Environmental Protection Agency (IEPA), and the United States Department of Agriculture, Natural Resources Conservation Service (NRCS), and the United States Fish and Wildlife Service (USFWS) on July 13, 2018, for review and comment. In addition, copies were circulated with the appropriate Offices within the Illinois Department of Natural Resources (Department). Written notification of the application was given to those governmental agencies and entities required to receive notice under 62 Ill. Adm. Code 1773.13(a)(3).

State Agency comments on this application have been received by the Department, with the source and date of comments as follows: IDOA (September 21, 2018) and IEPA (August 30, 2018).

Comments on this application were also received from the NRCS dated September 12, 2018 and USFWS dated September 4, 2018 and October 2, 2019.

The Department received a request for a public hearing. The Department held a public hearing on October 23, 2018, in the Office of Mines and Minerals, Southern Illinois Regional Office in Benton, Illinois.

All comments received in writing and at the public hearing have been considered by the Department in reviewing this application. The Department's responses to these comments are set forth in Appendix B.

All comments received on this application have been furnished to the applicant, and have been filed for public inspection at the office of the County Clerk of the county in which the application is located.

III. SUMMARY OF THE DEPARTMENT'S FINDINGS

The Department, upon completing its review of the information set forth in the application, the required modifications submitted, if any, and information otherwise available, and made available to the applicant, and after considering the comments of State Agencies, and all other comments received, makes the following findings:

A. Findings Required by 62 Ill. Adm. Code 1773.15

REVIEW OF VIOLATIONS

Section 1773.15(b)(1): Based on a review of all reasonably available information concerning violation notices and ownership or control links involving the applicant, including information obtained pursuant to Sections 1773.22, 1773.23, 1778.13 and 1778.14, the Department has determined that the applicant or a person who owns or controls the applicant is currently in violation of the State Act, Federal Act or other law or regulation referred to in Section 1773.15(b)(1). Pursuant to this Section, the Department has determined that:

Section 1773.15(b)(1)(A): For the identified current violations, the applicant submitted proof that the current violations have been or are in the process of being corrected to the satisfaction of the agency that has jurisdiction over the violations.

Documentation provided by the applicant to comply with Section 1773.15(b)(1)(A) is attached as Appendix E.

Section 1773.15(b)(2): This permit is being conditionally issued on the basis of proof submitted under Section 1773.15(b)(1)(A) that the violation is in the process of being corrected. The conditional issuance is set forth in Part IV.

Section 1773.15(e): The Department received updated compliance information in the applicant's modifications response received October 21, 2019 and updated information on December 2, 2019. Based on the compliance review required by Section 1773.15(b)(1), a review of the OSM Applicant Violator System for outstanding violations, and in light of no new information submitted pursuant to Sections 1778.13(i) and 1778.14(e), the Department reconsidered its decision to approve the application and found that no change in its decision to issue the permit is necessary.

SECTION 1773.15(c)(1) FINDINGS

Section 1773.15(c)(1): The application, as modified, is accurate and complete and all requirements of the Federal and State Acts and the regulatory program have been met.

TOPSOIL SUBSTITUTION FINDING

Section 1817.22(b): The applicant has proposed the use of selected overburden materials as a substitution for, and a supplement to topsoil as delineated in the application. In accordance with Section 1817.22(b), the Department finds that the applicant has adequately demonstrated that the resulting soil medium is equal to, or more suitable for, sustaining vegetation than existing topsoil, and the resulting soil medium is the best available in the permit area to support vegetation. Permission is hereby granted to use the selected overburden as requested.

SEDIMENT POND EXEMPTION

Section 1817.46(e): A sediment pond exemption is requested for an area delineated in the application. The regulations at Section 1817.46(e) allow the Department to grant exemptions from the requirement to pass all disturbed drainage through a siltation structure when:

a. The disturbed drainage area within the total disturbed area is small; and

b. Alternate sediment control measures as described in Section 1817.45(b) are used in lieu of a siltation structure, and the applicant demonstrates that siltation structures are not necessary for drainage from the disturbed area to meet the effluent limitations and water quality standards for the receiving waters set forth in Section 1817.42.

The Department has determined that the area for which a sediment pond exemption is requested meets the criteria established in Section 1817.46(e) and hereby grants an exemption from the use of a sedimentation pond for this area.

STREAM BUFFER ZONE VARIANCE

Section 1817.57(a)(1): The applicant has requested a stream buffer zone variance for an area as delineated in the application. In accordance with Section 1817.57(a)(1), the Department finds that:

a. The original stream channel and its associated riparian vegetation will be restored; and

b. Surface mining activities will not cause or contribute to a violation of Section 1817.42 and will not adversely affect the water quantity and quality or other environmental resources of the stream.

Therefore, the Department authorizes surface mining activities closer than one hundred (100) feet of the top of the bank of the normal channel of the perennial or intermittent stream or through the stream.

SECTION 1773.15(c)(2) – (c)(13) FINDINGS

Section 1773.15(c)(2); The applicant has demonstrated that reclamation as required by the Federal and State Acts and the regulatory program can be accomplished under the reclamation plan contained in the application, as modified.

Section 1773.15(c)(3)(A): The proposed area is not within an area under study or administrative proceedings under a petition, filed pursuant to Section 1764, to have an area designated as unsuitable for surface coal mining operations.

Section 1773.15(c)(3)(B): The proposed area is not within an area designated as unsuitable for mining pursuant to Sections 1762 and 1764 or subject to the prohibitions or limitations of Section 1761.11.

Section 1761.11(a): The proposed area does not include any lands within the boundaries of the National Park System, the National Wildlife Refuge System, the National System of Trails, the National Wilderness Preservation System, the Wild and Scenic Rivers System, or National Recreation Areas designated by Act of Congress.

Section 1761.11(b): The proposed area is not on any Federal lands within the boundaries of any national forest.

Section 1761.11(c): The proposed surface coal mining and reclamation operations will not adversely affect any publicly owned park or any privately owned or publicly owned places included on the National Register of Historic Places.

Section 1761.11(d): The proposed area is within one hundred (100) feet measured horizontally of the outside right-of-way line of public roads in Williamson and Franklin Counties, described as follows: Interstate 57, State Route 37, Williams Prairie Road, Harris School Road, Old Ben Road, Old Frankfort Road, Eberhardt Road, Duncan Road, Monroe Road, Collin Road, Horseshoe Road, Freeman Spur Blacktop (Franklin Co. Rte. 6), Deason Road, Sandburg Road, Freemanspur Road, Gossage Road, Lake Creek Road, and Cheatman Road.

The proposed area is adjacent to the right-of-way of Interstate 57, State Route 37, Williams Prairie Road, Harris School Road, Old Ben Road, Old Frankfort Road, Eberhardt Road, Duncan Road, Monroe Road, Collin Road, Horseshoe Road, Freeman Spur Blacktop (Franklin Co. Rte. 6), Deason Road, Sandburg Road, Freemanspur Road, Gossage Road, Lake Creek Road, and Cheatman Road. The proposed activities in the application area include the installation of pipeline and boring underneath the roads

No approvals from the authority with jurisdiction over the roads were required for areas outside the right of way. The permittee shall be responsible for all permits required from the road authorities necessary for any access and operations performed within the right of way of said roads. See Condition K.

The applicant provided proper public notice and opportunity for a public hearing. A public hearing was held on October 23, 2018 and while many written comments were submitted to the Department, none of the written comments were concerning these roads.

The Department finds the interests of the public and affected landowners will be protected from the proposed mining operations as a result of the measures to be

taken by the applicant as described in the mining operations plan concerning these roads.

Section 1761.11(e): The proposed area is within three hundred (300) feet measured horizontally of several occupied dwellings.

The owners of the dwellings have provided written waivers pursuant to Section 1761.15 consenting to surface coal mining operations closer than three hundred (300) feet.

Section 1761.11(f): The proposed area is not within three hundred (300) feet measured horizontally of any public building, school, church, community or institutional building, or public park from which the applicant will be required to maintain a three hundred (300) foot buffer zone.

Section 1761.11(g): The proposed area is not within one hundred (100) feet measured horizontally of a cemetery.

Section 1773.15(c)(4): This section is applicable to surface mining operations only.

Section 1773.15(c)(5): The Department has assessed the probable cumulative impacts of all anticipated coal mining on the hydrologic balance in the cumulative impact area, in accordance with Part 1784 and finds that the operations proposed under the application have been designed to prevent material damage to the hydrologic balance outside the proposed area (see Appendix C).

Section 1773.15(c)(6): The applicant has not proposed the use of any existing structures in the application requiring compliance with Section 1700.11(d).

Section 1773.15(c)(7): The applicant will submit fees required by these regulations before the permit is issued. The fee required is $1,767.50 for the term of the permit, which may be paid in annual increments. The Department finds that the applicant has paid all reclamation fees from previous and existing operations as required by 30 CFR 870.

Section 1773.15(c)(8): See Part III – Subpart B.

Section 1773.15(c)(9): The applicant has satisfied the requirements for a long-term, intensive agricultural post-mining land use, in accordance with the requirements of Section 1817.111(d).

Section 1773.15(c)(10): The operation as approved will not affect the continued existence of endangered or threatened species or result in destruction or adverse modification of their critical habitats, as determined under the Endangered Species Act of 1973 (16 USC 1531 *et seq.*, see Appendix F).

Section 1773.15(c)(11): The requirements of this section are not applicable as there are no proposed remining operations.

Section 1773.15(c)(12): The effect of the proposed permitting action on properties listed on or eligible for listing on the National Register of Historic Places has been taken into account by the Department.

Section 1773.15(c)(13): The requirements of this section are not applicable as there are no proposed remining operations.

B. Findings Required by 62 Ill. Adm. Code 1785 (Applicable Sections)

PRIME FARMLANDS

A soil survey was submitted by the applicant that shows prime farmland soils identified in this application which have been historically used as cropland. The soil survey prepared by the USDA provides the required soil information.

The applicant has, with respect to prime farmland, satisfied the requirements of Section 1785.17. (See Part B, below, and Appendices D and G.)

Section 1785.17(e)(1): The Department finds that the approved post-mining land use of the prime farmlands is cropland.

Section 1785.17(e)(2): The Department finds that the permit incorporates as specific conditions the contents of the plan submitted under Section 1785.17(c), after consideration of any revisions to that plan suggested by the State Conservationist under Section 1785.17(d).

Section 1785.17(e)(3): The Department finds that the applicant has the technological capability to restore the prime farmland, within a reasonable time, to equivalent or higher levels of yield as non-mined prime farmland in the surrounding area under equivalent levels of management.

Section 1785.17(e)(4): The Department finds that the proposed operations will be conducted in compliance with the requirements of Section 1823 and other environmental protection performance and reclamation standards for mining and reclamation of prime farmland of the regulatory program.

Section 1785.17(e)(5): The Department finds that the aggregate total prime farmland acreage has not been decreased from that which existed prior to mining. Water bodies, if any, are located within the post-reclamation non-prime farmland portions of the permit area and the consent of all affected property owners has been obtained.

Section 1785.20: The requirements of this section are not applicable to this application.

C. Compliance with 62 Ill. Adm. Code 1773.19

Section 1773.19(a)(1): The Department has based its decision to approve, as modified, the application, based on public participation as provided by Sections 1773.13 and 1773.14, compliance with all applicable provisions of Section 1785, and the processing and complete review of the application.

Section 1773.19(a)(3): The Department is providing written notification of its final permit decision to the following persons and entities:

a. The applicant, each person who filed comments or objections to the application, and each party to the public hearing;

b. The County Board of the counties in which the application is located; and,

c. The Office of Surface Mining.

All materials supporting these findings are a part of the public record and are hereby incorporated by reference.

IV. PERMIT CONDITIONS

A. The permittee shall conduct surface coal mining and reclamation operations only on those lands specifically designated as the permit area on the maps submitted with the application and authorized for the term of the permit and that are subject to the performance bond or other equivalent guarantee in effect pursuant to 62 Ill. Adm. Code 1800.

B. The permittee shall conduct all surface coal mining and reclamation operations as described in the approved application, except to the extent that the Department otherwise directs in the permit.

C. The permittee shall comply with the terms and conditions of the permit, all applicable performance standards of the Federal and State Acts, and the requirements of the regulatory program.

D. Without advance notice, delay, or a search warrant, upon presentation of appropriate credentials, the permittee shall allow the authorized representatives of the Department and Secretary of the United States Department of the Interior to:

1. Have the right of entry provided for in 62 Ill. Adm. Code 1840.12; and,

2. Be accompanied by private persons for the purpose of conducting an inspection in accordance with 62 Ill. Adm. Code 1840, when the inspection is in response to an alleged violation reported to the Department by the private person.

E. The permittee shall take all possible steps to minimize any adverse impacts to the environment or public health and safety resulting from noncompliance with any term or condition of this permit, including, but not limited to:

1. Accelerated or additional monitoring necessary to determine the nature and extent of noncompliance and the results of the noncompliance;

2. Immediate implementation of measures necessary to comply; and,

3. Warning, as soon as possible after learning of such noncompliance, any person whose health and safety is in imminent danger due to the noncompliance.

F. As applicable, the permittee shall comply with 62 Ill. Adm. Code 1700.11(d) for compliance, modification, or abandonment of existing structures.

G. The permittee shall pay all reclamation fees required by 30 CFR 870 for coal produced under this permit for sale, transfer, or use.

H. Within thirty (30) days after a cessation order is issued under 62 Ill. Adm. Code 1843.11, for operations conducted under the permit, except where a stay of the cessation order is granted and remains in effect the permittee shall either submit to the Department the following information, current to the date the cessation order was issued, or notify the Department in writing that there has been no change since the immediately preceding submittal of such information:

1. Any new information needed to correct or update the information previously submitted to the Department by the permittee under 62 Ill. Adm. Code 1778.13(c); or

2. If not previously submitted, the information required from a permit application by 62 Ill. Adm. Code 1778.13(c).

I. Species Protection:

1. Issuance of this permit under the Surface Coal Mining Land Conservation and Reclamation Act does not in any way authorize any take of any listed species in violation of the Illinois Endangered Species Protection Act, 520 ILCS 10/1 *et seq*. With respect to the Indiana bat, an Incidental Take authorization has been approved as part of this permitting action consistent with and in compliance with the Endangered Species Act of 1973, 16 USC 1531 *et seq*. The Department has determined that this project may affect the northern long-eared bat, but that any resulting Incidental Take is not prohibited by the Final 4(d) rule and is consistent with the U.S. Fish and Wildlife Service Jan 2016 Programmatic Biological Opinion on the Final 4(d) rule. The Department and the applicant are in compliance with

Section 7 of the Endangered Species Act of 1973, as amended. If any other "take" as defined by these Acts is anticipated to result from permitted activities, it is recommended that the permittee apply for an Incidental Take permit from the Illinois Department of Natural Resources, Office of Resource Conservation for state listed species.

2. Issuance of this permit under the Surface Coal Mining Land Conservation and Reclamation Act does not in any way authorize any take of a bald or golden eagle, including nests or eggs, in violation of the Bald Eagle Protection Act (16 U.S.C. 668 *et seq.*). If "take" as defined by the Bald Eagle Protection Act is anticipated to result from permitted activities, it is recommended that the permittee should apply for an Incidental Take (non-purposeful take) permit from the U.S. Fish and Wildlife Service. The Department and the U.S. Fish and Wildlife Service shall be notified if a bald or golden eagle nest is observed in the permit area or in the vicinity of the permit area.

3. If any onsite stream and/or wetland mitigation is required based on upon U.S. Army Corps of Engineers requirements, then the Department shall be notified to establish appropriate permitting actions under SMCRA.

J. If the permit is conditionally issued under 62 Ill. Adm. Code Section 1773.15(b)(2) on the basis of **(1)** a presumption supported by certification under 62 Ill. Adm. Code Section 1778.14 that the violation is in the process of being corrected; **(2)** proof submitted under 62 Ill. Adm. Code Section 1773.15(b)(1)(A) that the violation is in the process of being corrected; or **(3)** pending the outcome of an appeal described in 62 Ill. Adm. Code Section 1773.15(b)(1)(B), issuance is conditioned as follows:

1. If subsequent to permit issuance applicant is issued a failure-to-abate cessation order, the permit shall be suspended and/or rescinded in accordance with the procedures for 62 Ill. Adm. Code Section 1773.20(c) Improvidently Issued Permits within 30 days of the issuance of the failure-to-abate cessation order.

2. If subsequent to permit issuance the Department is notified by the agency that has jurisdiction over the violation that the violation is no longer in the process of being corrected to the satisfaction of said agency, the permit shall be suspended and/or rescinded in accordance with the procedures for 62 Ill. Adm. Code Section 1773.20(c) Improvidently Issued Permits within 30 days of such notification.

3. If subsequent to permit issuance the circuit or district court reviewing the violation either denies a stay applied for in the appeal or affirms the violation, then the applicant shall submit the proof required under 62 Ill. Adm. Code Sections 1773.15(b)(1)(A) within 30 days after the court's decision or the permit shall be suspended and/or rescinded in accordance with the procedures for 62 Ill. Adm. Code Section 1773.20(c) Improvidently Issued Permits within 30 days of such failure to submit required proof.

K. Pursuant to Section 1778.15, the permittee shall possess all necessary legal rights to enter and conduct surface coal mining and reclamation operations within the permit area until final bond release is obtained.

The permittee has indicated valid permits shall be obtained from the Illinois Department of Transportation and private rail lines. Pursuant to 1778.15(a), and as committed in Attachment I.2.A, the permittee shall provide the Department with valid right of entry agreements with the (1) Illinois Department of Transportation and (2) private railways prior to the commencement of operations in regard to areas controlled by the Illinois Department of Transportation and the private railway lines.

L. The permittee shall commence all groundwater and surface water monitoring approved by this permit upon initial disturbance of lands within the permit area. Monitoring shall be in accordance with the approved permit and/or as outlined in Appendix C of this finding document.

M. The substitute topsoil material referenced in the response to Part II(13) (D and F) of the application shall be limited to the Rend, Bluford, Hickory-Kell, Okaw, Belknap and Orthent soil series where the subsoil texture is a silt loam. In addition, the pH, phosphorus, and potassium of the borrow materials shall be fertilized with rates to achieve a pH of 6.5, and phosphorus and potassium levels of 50 ponds/acre and 260 pounds/acre, respectively.

N. The approved operations plan includes the installation of a pipeline within a defined permit corridor and a diffuser site in the Big Muddy River. As required by 62 Ill. Adm. Code 1784.23 and 1784.30, the permittee shall submit an as-built certification of the pipeline and discharge structure within 30 days of completion of installation of the pipeline. The as-built shall be sealed by a qualified registered professional engineer and at a minimum include the following information:

1. Verification that the pipeline was installed within the permitted corridor at the minimum depths indicated in the Illinois Department of Agriculture's Pipeline Construction Standards and Policies for Agricultural Impact Mitigation (Attachment IV.2.B.3) and in the Typical Stream Crossing Drawing (Attachment IV.7.I) included in the permit application.

2. Location of all monitoring stations on a Surface Operations Map.

3. List of the monitoring equipment installed at each station.

4. Actual diameter of the installed pipeline and/or diameter of sections of the pipeline if different diameters were used.

5. Cross section of the discharge structure/diffuser site if any changes to the approved plan were made to these structures during installation.

O. The approved operations plan includes plans for monthly visual and physical monitoring of the pipeline, as well as an annual testing of the monitoring equipment. To ensure compliance with 62 Ill. Adm. Code 1784.11(b)(6) and 1817.45(a), the applicant shall:

1. Submit to the Department the results of the pressure testing performed prior to putting the pipeline in service. The initial testing results shall be included in the as-built document required by condition N.

2. Submit to the Department the results of the annual pipeline testing of the monitoring system with a clear description of any identified deficiencies and the steps that would be taken to maintain safe pipeline performance. The results of the annual testing of the pipeline monitoring system shall be submitted to the Department within 30 days of completion.

V. CONCLUSIONS

Based upon the information contained in the application, information otherwise available and made available to the applicant, the comments of State Agencies, the foregoing analysis of the probable impact of the proposed operations, all findings and information contained herein and conditions set forth in Part IV, the Department finds that there is a reasonable basis on which to issue a permit for the application, as modified.

Enter on behalf of the Illinois Department of Natural Resources, Office of Mines and Minerals, Land Reclamation Division as Regulatory Authority.

Re: Modification to Permit Application No. 456
Pond Creek Mine

The Department, after reviewing the information contained in the permit application and information otherwise available to the applicant, and after considering all comments received, has determined that modification of Permit Application No. 456 is necessary. The modifications to the application shall comply with the requirements of 62 Ill. Adm. Code 1777.11. The modifications required by the Department are enclosed here. If the applicant does not desire to modify the permit application as described below, it may, by filing a written statement with the Department, deem the permit application denied, and such denial shall constitute final action.

Pursuant to 62 Ill. Adm. Code 1773.15(a)(1)(B)(i), modifications required by the Department shall be received within one year from the date of this letter. Absent the modifications required by the Department, the application does not demonstrate compliance with the requirements of the Illinois Surface Coal Mining Land Conservation and Reclamation Act, Regulations and Regulatory Program and the Department will issue a written finding denying the application.

The period for administrative review (62 Ill. Adm. Code 1847.3) shall commence upon:

- receipt by the applicant of a written decision from the Department, approving the application as modified, or
- if the applicant's modifications are insufficient, or if the applicant fails to submit the required modifications in accordance with 62 Ill Adm. Code 1773.15(a)(1)(B)(i), receipt by the applicant of a written decision from the Department denying the permit application, or
- receipt by the Department of the applicant's denial statement.

The modifications required by the Department are as follows:

1. Pursuant to 62 Ill. Adm. Code 1779.25(b), 1780.14(c), and 1780.25(a), and as required by Part 1.6 of the application, the Department is requiring the applicant to modify the application by submitting engineering certifications where the modifications result in changes to maps, plans, or cross sections submitted under the original application.

2. Pursuant to 62 Ill. Adm. Code 1777.11(c), and as required by Part I.1 of the application, the Department is requiring the submittal of a verification by a responsible official of the applicant for the information being submitted as a result of this modification letter.

3. Pursuant to 62 Ill. Adm. Code 1778.15 and Operator Memorandum 2011-01, the applicant is required to provide a signed notarized waiver from landowners for properties not owned or controlled by the permittee. Information provided in Attachment I.2.A reveals property not under control by the applicant and shall require a landowner waiver.

4. Pursuant to 62 Ill. Adm. Code 1778.13(c), the applicant shall provide information for each person who owns or controls the applicant under the definition of "owned or controlled" and "owns or controls" in 62 Ill. Adm. Code 1773.5. Review of the information provided and available to the Department, the applicant failed to provide ownership and control information for an owner/controller of the applicant, specifically Foresight Energy Services, LLC and Foresight Reserves LP as part owner/controller of Foresight Energy GP, LLC. The applicant shall provide current, updated ownership and control information for Williamson Energy, LLC including the necessary information for Foresight Energy Services, LLC or end date and complete ownership and control for Foresight Reserves LP or update ownership for Foresight Energy GP, LLC removing as part owner.

   Further review of the information provided in the ownership and control should be made by the applicant for other omissions or inaccuracies. The Department finds discrepancies with begin dates for some of the officers listed in the organizations ownership and control information.

5. Pursuant to 62 Ill. Adm. Code 1773.15(b)(1)(A), the applicant shall submit to the Department proof that current violations have been or are in the process of being corrected to the satisfaction of the issuing agency. Specifically, the Department finds two violations listed in Attachment I.9, CO 171025 and CO 171028, that will require additional information regarding the progress of abatement.

   The applicant shall provide proof from the PA Department of Environmental Protection of the progress of these violations. Review shall be made by the applicant to ensure all documents are included for all outstanding violations required to be reported.

6. Pursuant to 62 Ill. Adm. Code 1778.18, an application shall contain a certificate of liability insurance in compliance with 62 Ill. Adm. Code 1800.60. The Department finds the

certificate provided is not with an "authorized" insurer and shall require a revised certificate that is in compliance with the required regulations.

7. The response to Part V.1.B of the application is incomplete. Pursuant to 62 Ill. Adm. Code 1800.14, the applicant shall include the following:

   a. Information on the costs associated with removing the diffuser and all associated items from the Big Muddy River. Include all potential costs (such as possible coffer dam to divert water from the work site, divers to work in the Big Muddy River if needed, etc.)

   b. Information on possible removal costs associated with the pipeline such as air relief valves and other pipeline structure that cannot remain permanently post reclamation.

8. Pursuant to 62 Ill. Adm. Code 1783.21, Part II.13.D of the application, page II-8, must be modified to provide for a minimum topsoil removal thickness of 6 inches or greater where present.

9. Pursuant to 62 Ill. Adm. Code 1783.21, Part IV.2.B.3 of the application, page IV-2, must be modified to identify the qualifications of the person referenced in the soil handling procedure. In addition, the response must clarify it uses the most current version of the IDOA pipeline guidelines during construction.

10. Attachment IV.1 "Figure 2 Water Flow Diagram Proposed System" shows an Outfall 010 referred to as the "Pond Creek Stormwater Mixing Zone." This outfall and mixing zone are also referenced in the Attachment IV.1 narrative. Pursuant to 62 Ill. Adm. Code 1784.14(i) the applicant shall clarify if Outfall 010, "Pond Creek Stormwater Mixing Zone" is proposed as part of Permit Application No. 456.

11. According to Attachment IV.1, the applicant states that the holding cell will hold mine infiltration water as well as decant water from the slurry cell. Pursuant to 62 Ill. Adm. Code 1784.14(i), the applicant shall clarify whether the IEPA mixing zone permit has considered potential constituents contained within the clarified decant water.

12. The following concerns the response to Part III.2.D.1.a. Considering the response to Modification Question 11 and pursuant to 62 Ill. Adm. Code 1784.14(b)(1), the applicant shall provide representative water quality data from the water holding cell and clarify whether the chloride and sulfate data represent only the infiltrating groundwater or a mix of infiltrating groundwater and process water (if applicable).

13. In response to Part III.2.D.1.a, the applicant states an anticipated maximum flow rate of infiltration water from the mine is 3,500,000 gallons per day. Pursuant to 62 Ill. Adm. Code

1784.14(b)(2), the applicant shall clarify what this value represents in relation to the amount of water the company intends to discharge from the facility.

14. The Department is in receipt of a letter addressed to the applicant dated August 30, 2018 from the Illinois EPA (IEPA) requesting changes or clarification. Pursuant to 62 Ill. Adm. Code 1784.14, the applicant shall provide responses to the questions in the IEPA letter. If any response to the IEPA letter results in changes to the permit application, the applicant shall clearly indicate which application part and/or map is being revised.

15. In response to Part IV.1, the applicant references Attachment IV.1 for operations plan information. Page 3 of Attachment IV.1 indicates the preparation plant requires 2,300,000 gpd. In contrast, the water flow diagram proposed system depicts the preparation plant supply to be of 2,880,000 gpd. Pursuant to 62 Ill. Adm. Code 1777.11, clarify the apparent discrepancy in preparation plant volumes.

16. In response to Part IV.5.C.2, the applicant references Attachment IV.5.C.2 for additional information concerning the water management pipeline. Pursuant to 62 Ill. Adm. Code 1817.41(a), the applicant shall provide the following information and update all appropriate responses as necessary:

    a. Locate on the Operations Map automatic and manual shut off valves and pressure gauges.

    b. Provide additional detail on the process to pressure test pipeline integrity after it has been constructed and prior to being placed into operation.

    c. Provide additional detail on the operational monitoring of the pipeline to detect leaks and the actions taken to shut down the pipeline should monitoring indicate a potential leak is occurring.

    d. Provide additional detail on procedures and actions to be taken should a spill occur.

17. In response to Part IV.7.I, the applicant requests a stream buffer variance to multiple streams for the temporary construction practices involved in placing the transport pipeline. Pursuant to 62 Ill. Adm. Code 1817.57, the following additional information shall be provided concerning disturbances in the buffer zone and channel of the Big Muddy River.

    a. The response discusses adequately sized riprap to be keyed into the toe of the embankment. The applicant shall provide minimum sizing design based on expected stream flow velocities to assure a stable bank is maintained.

    b. The applicant shall expand the narrative to address construction steps of the diffuser port within the Big Muddy River channel. Detail on the anticipated extent of the

disturbance during installation and specific steps to control and contain off-site impacts shall be provided.

c. The area not to be disturbed shall be designated a buffer and marked as specified in Section 1817.11.

18. In response to Part IV.7.B, it appears the applicant answered the questions referring to handling of drainage after the pipeline has been put in place and covered by soil material. To ensure compliance with 62 Ill. Adm. Code 1817.45(a), the applicant shall expand the discussion in this response to explain which erosion and sediment control measures will be used to handle drainage from unaffected areas during the construction of the waterline.

19. In Attachment IV.1, the applicant states that monitoring of the water pipeline will include a monthly visual inspection of each road and highway crossing, the Pond Creek crossing and the Big Muddy discharge site. It will also include a physical inspection of the monitoring equipment. Pursuant to 62 Ill. Adm. Code 1817.41(a), the applicant shall provide:

a. A list of all inspection sites and a map defining the inspection site locations.

b. Additional information describing how the entire pipeline corridor will be maintained for access by both the Department's staff to inspect and for company personnel to maintain and make necessary repairs in a timely manner.

c. Specifically what monitoring equipment is intended to be physically inspected.

d. Further information addressing the need to physically inspect air release valve locations and other similar critical junctions in the pipeline system as part of the monthly inspection.

20. Pursuant to 62 Ill. Adm. Code 1780.23 and 1784.15, the applicant shall provide the acreage and capability of each land use within the proposed permit area, employing only land use categories of 62 Ill. Adm. Code 1701.5. Further, the "fish and wildlife" land use category must be subdivided as required by Operator Memorandum 2015-01. Use **only these land uses for completing the land use maps.**

a. The individual land use acreages provided in the Pre-mining Land Use Table in Part II.4 of the application do not calculate to the Total Permit Acreage provided within this table. The applicant shall clarify this discrepancy.

b. The applicant shall revise all Tables, Maps and Figures to reflect **only** the "fish and wildlife" land use categories outlined within Operator Memorandum 2015-01.

21. Pursuant to 62 Ill. Adm. Code 1777.11(a)(3) and as required by Part V.2.A of the application, the applicant shall provide acreage figures for each post-mining land use proposed and designate the post-mining land uses on the Post-Mining Land Use Maps.

    a. The applicant shall revise all Tables, Maps and Figures to reflect **only** the "fish and wildlife" land use categories outlined within Operator Memorandum 2015-01.

    b. The individual land use acreages provided in the Post-Mining Land Use Table in Part V.2.A of the application do not calculate to the Total Permit Acreage provided within this table. The applicant shall clarify this discrepancy.

    c. Acreage for post-mining land uses provided by the applicant in the Post-Mining Land Use Table in Part V.2.A of the application are not the same as that provided in the Pre-mining Land Use Table in Part II.4. The applicant states in multiple locations of the application that post-mining land uses are the same as pre-mining land use. The acreage provided within the tables contradicts this statement and the applicant shall clarify this discrepancy.

22. Pursuant to 62 Ill. Adm. Code 1817.97(f) and required by Part V.B.3, the applicant is required to provide a statement explaining how impact control measures, management techniques, and monitoring methods will be utilized to protect or enhance habitats of unusually high value for fish and wildlife such as wetlands and riparian areas to be affected by the proposed mining and reclamation operations. The applicant shall address the following pertaining to the proposed water management pipeline construction corridor.

    a. In response to Part V.B.3, the applicant states that "no habitats of unusually high value have been observed within the project area". The applicant has provided a Stream and Wetland delineation report as Attachment II.9 to Part II of the application identifying streams and wetlands located within the proposed permit area. The applicant shall provide a statement in Part V.B.3 explaining how impact control measures, management techniques, and monitoring methods will be utilized to protect or enhance these areas.

    b. The applicant has provided a Stream and Wetland delineation report as Attachment II.9 to Part II of the application. Wetland A and Wetland B are not part of this proposed permit and shall be removed from all applicable parts of the application.

    c. As required by Part V.3.B.1, the applicant shall provide information on whether or not ponds on site will contain hazardous concentrations of toxic-forming materials and if so, then describe how control measures, management techniques, and monitoring methods will be used to ensure how wildlife protected under the

Endangered Species Act, Migratory Bird Treaty Act, and the Bald Eagle Protection Act are excluded from these areas or justify why this information is not provided.

23. Pursuant to 62 Ill. Adm. Code 1817.111, 1817.114, and as required by in Part V.1.D.3, the applicant is required to describe methods to be used in planting and seeding.

    a. In response to Part V.1.D.3, the applicant refers to planting of the proposed refuse disposal area. No refuse disposal area is proposed as part of this application. The applicant shall clarify this discrepancy.

    b. In response to Part V.1.D.3, the applicant provides a list of considerations and recommendations to prepare the site for planting. The applicant is required by Part V.6.D.3 to provide the actual methods to be used in planting and seeding rather than considerations and recommendations. The applicant shall revise this response in the application to include the actual methods to be implemented.

24. Pursuant to 62 Ill. Adm. Code 1784.21(a)(2)(A) and 1817.97(b), the applicant is required to provide site specific resource information for threatened and endangered species including but not limited to the Indiana bat *(Myotis sodalis)* (INB) and northern long-eared bat *(Myotis septentrionalis)* (NLEB). This information has been provided in Attachment II.8 and Part V.3.B.4; however, the following information/updates are required:

    a. Attachment II.8 refers to Permit 434 within the title on Page 1. This shall be revised to reflect the correct permit number.

    b. Attachment II.8 and Part V.3.B.4 of the application states that NLEB were not identified within the project area and therefore, in accordance with current USFWS protocol, are not present within the project area. The applicant did not survey the entire project alignment, thus probable absence cannot be assumed within the portions of the project that were not surveyed. The applicant shall update Attachment II.8 and Part V.3.B.4 of the application, including the discussion of whether the project is consistent with the northern long-eared bat *(Myotis septentrionalis)* Final 4(d) Rule published in the Federal Register in January 2016.

    c. The applicant has identified 3.9 acres of forested acres to be disturbed within known INB habitat based on the survey information provided. It is required that at least 70 percent of the total INB habitat that will be lost should be replaced or mitigated off-site as described in the 2013 Indiana bat Protection and Enhancement Guidelines published by the USFWS. The applicant shall update the Long-Term Habitat Replacement section of the INB PEP.

d. Tree Clearing restrictions within the INB PEP state that tree clearing operations will only occur from November 15 to March 31, unless otherwise authorized. These dates are not consistent with those described in the 2013 Indiana bat Protection and Enhancement Guidelines published by the USFWS. The applicant shall clarify this inconsistency.

e. The applicant has stated within the summary of the INB PEP that forested acres cleared during construction operations will be supplemented in the short-term by erecting bat boxes. The applicant shall update the Short-term Habitat Replacement section of the PEP to reflect this statement and provided further details as to the timing and number of bat boxes to be erected.

If you have any questions, please contact this office at (217) 782-4970, or our Southern office in Benton at (618) 439-9111.

Sincerely,

Nick San Diego, Supervisor
Office of Mines and Minerals

APPENDIX B

CONSIDERATION OF COMMENTS AND OBJECTIONS

62 Ill. Adm. Code 1773.13(b) allows submission of written comments on applications. The following are comments received from the State Agencies, County Board and other members of the public and the Department's response to those comments.

Illinois Department of Agriculture

Comment: The Illinois Department of Agriculture (IDOA) has reviewed the above referenced permit application. The application is for a 12.5-mile long 18 and 24-inch water mains to pump water from the underground mine to the Big Muddy River. All water from the mine will go through holding cells before being discharged to the pipeline. The pipeline will follow the railroad right-of-way (ROW), both active and abandoned, a gas pipeline and road ROW. Construction affects 12.67 acres of cropland. The pipeline will be in place for 10-years then removed. The mine has indicated they will follow the IDOA's Pipeline Construction Standards and Policies. The IDOA requests that the revision shown on the agricultural website be used. See: *https://www2.illinois.gov/sites/agr/Resources/LandWater/Documents/pipelinestandardspo/icies.pdf.*

Response: The Department required modification of the application (Appendix A, Modification Question No. 9) to ensure the most current version of the IDOA Pipeline Constructions Standards and Policies were included in the permit.

Illinois Environmental Protection Agency

Comment:

1. To ensure compliance with 62 Ill. Adm. Code 1817.42 as it pertains to mine discharge quality, the Schedule A contained in Part III of the application should be revised as follows:

    a. Iron concentrations are indicated to be within the range of 3.0 - 6.0 mg/1. The applicant should revise this indication to provide an "estimate" of basin discharge Iron concentrations rather than the acceptable range from the Subtitle D regulations.
    b. Total Suspended Solids concentrations are indicated to be within the range of 35.0 - 70.0 mg/1. The Applicant should revise this indication to provide an "estimate" of basin discharge Total Suspended Solids concentrations rather than the acceptable range from the Subtitle D regulations.

2. The pipeline corridor area should be included in the annual stormwater monitoring plan.

Response: Please see the response to Appendix A, Modification Question No. 14.

U.S. Department of Agriculture, Natural Resource Conservation Service

Comment: Any bare soil exposed following surface coal mining should be seeded, limed, fertilized and mulched to minimize soil erosion. Please refrain from using tall fescue or reed canary grass in seeding mixtures and only plant native trees and shrubs for wildlife areas. Following pipeline installation, drainage should be provided where necessary to return the affected areas to their former land use. Wetlands should be returned to historic hydrologic conditions. Prime Farmland acreage should be reclaimed to standards established by the Illinois Surface Coal Mining Land Conservation and Reclamation Act.

Response: This comment has been noted and forwarded to the applicant.

U.S. Department of the Interior, Fish and Wildlife Service

Comment: To facilitate compliance with Section 7(c) of the Endangered Species Act of 1973, as amended, Federal agencies are required to obtain from the Fish and Wildlife Service (Service) information concerning any species, listed or proposed to be listed, that have ranges which include the project area. As the State of Illinois has been delegated the responsibility of issuing mining permits by the Office of Surface Mining, we are providing the following list of threatened and endangered species to assist in your evaluation of the proposed permit. The list for the proposed permit area includes the endangered Indiana bat (Myotis sodalis), endangered piping plover (Charadrius melodus), and threatened northern long-eared bat (Myotis septentrionalis). There is no designated critical habitat in the project area at this time.

Response: Comment noted and forwarded to the applicant.

Comment: Applicants should be directed to our Information, Planning, and Conservation System (IPaC) at the link below to determine whether any federally threatened and endangered species, designated critical habitat, or other natural resources of concern may be affected by a proposed project and to obtain a preliminary or official U.S. Fish and Wildlife species list. For projects that require FWS review, request an official species list from the Regulatory Documents page. https://ecos.fws.gov/ipac/

Response: This comment has been forwarded to the applicant. In addition, the Department has supplied the Service's website to future applicants as an encouraged and available resource.

Comment: Based on the location of the proposed permit area, the Service concurs that the proposed project is not likely to adversely affect the piping plover.

Response: Comment noted and forwarded to the applicant.

Comment: Information in the permit application indicates that 3.9 acres of known Indiana bat habitat will be impacted by the proposed mining activity. Presence of the Indiana bat was documented in a mist net survey conducted in 2017, thus a Protection and Enhancement Plan (PEP) was developed for the proposed mine area that lies within the 2.5 mile buffer of the documented maternity roost tree in accordance with the 2009 Range-wide Indiana Bat PEP Guidelines, as revised in 2013. The PEP includes a number of protection and enhancement measures including avoidance of the majority of wooded habitat within the permit area, winter tree clearing from November 15 to March 31, tree girdling and bat box installation to provide temporary habitat, riparian buffer zone protection, and maintenance of watering areas. The applicant is not proposing to replant the forested habitat acres to be disturbed.

The PEP guidelines state that at least 70 percent of the total Indiana bat forest habitat that will be lost should be replaced or mitigated off-site. The applicant should develop a replacement plan or off-site mitigation measures. Information in the permit application indicates that the post mining acres for fish and wildlife woody will increase and may account for the replacement. The PEP should be reconciled with the post-mining land use in the reclamation plan.

The applicant did not survey the entire project alignment, thus probable absence for the northern long-eared bat cannot be assumed within the portions of the project that were not surveyed. The applicant should include the northern long-eared bat in the PEP or rely upon the finding of the programmatic biological opinion for the northern long-eared bat final 4(d) rule and utilize the streamlined section 7 consultation framework to fulfill their project-specific section 7 responsibilities for the northern long-eared bat. If the applicant utilizes the streamlined consultation framework, then the streamlined consultation form should be completed.

See https://www.fws.gov/midwest/endangered/mammals/nleb/s7.html

Based on the lack of information in the permit application, the Service is not able to provide concurrence for listed bat species at this time. The Service requests the additional information be provided for review and concurrence.

Response: The Department would like to take this opportunity to outline protection an enhancement measures that have changed from the original submittal based on modification requirements.

The Indiana bat (*M. sodalis*) and northern long-eared bat (*M. septentrionalis*) Protection and Enhancement Plan (PEP) located in Attachment II.8 has been updated to address long term habitat replacement requirements. The applicant has

proposed to reforest 2.73 acres, restoring 70% of the known habitat proposed to be removed by this project and therefore complying with the 2013 Guidelines.

Additionally, tree clearing restrictions within the PEP have been modified to state that tree clearing operations will only occur from October 15 to March 31. These dates appropriately reflect those outlined for winter tree clearing in the 2103 guidelines.

The applicant has also modified the PEP to state "the probable absence of the NLEB cannot be assumed". The applicant has included a discussion utilizing the key to the northern long-eared bat 4(d) rule for federal actions to conclude that the proposed actions are not prohibited and therefore a PEP for this species is not required. However, the applicant has chosen to include this species within the PEP found in Attachment II.8 of the application. The applied protection and enhancement measures will potentially be beneficial to the northern long-eared bat.

Based on information provided by the applicant and appropriate agency consultations, the Department has determined that this project may affect the northern long-eared bat, but that any resulting Incidental Take is not prohibited by the Final 4(d) rule and is consistent with the U.S. Fish and Wildlife Service Jan 2016 Programmatic Biological Opinion on the Final 4(d) rule. The Department has completed the IPAC Determination Key: Northern Long-Eared Bat (NLEB) Consultation and 4(d) Rule Consistency, which was submitted to the Service via IPAC on July 31, 2019.

Comment: [Per the follow-up USFWS correspondence dated October 2, 2019] - Based on the lack of information in the permit application, the Service was not able to provide concurrence for listed bat species. We requested additional information be provided for our review and concurrence. Information in your response indicates that the Protection and Enhancement Plan (PEP) was updated to address long-term habitat replacement requirements for the Indiana bat. Based on this information, the Service has determined that the take of 3.9 acres of known habitat is not likely to jeopardize the continued existence of the Indiana bat.

Information in your letter indicates that consultation for the northern long-eared bat was addressed by using our northern long-eared bat determination key within our Information for Planning and Consultation (IPaC) system. Based upon the IPaC submission, the action is consistent with activities analyzed in the Programmatic Biological Opinion on the Final 4(d) Rule for the northern long-eared bat and issuance of the verification letter concludes consultation for the northern long-eared bat. This information sufficiently addresses our comments regarding the northern long-eared bat.

Response: Comment noted and forwarded to the applicant.

Comment: Although the bald eagle has been removed from the threatened and endangered species list, it continues to be protected under the Migratory Bird Treaty Act and the Bald and Golden Eagle Protection Act (BGEPA). The Service developed the National Bald Eagle Management Guidelines to provide landowners, land managers, and others with information and recommendations regarding how to minimize potential project impacts to bald eagles, particularly where such impacts may constitute "disturbance," which is prohibited by the BGEPA. A copy of the guidelines is available at:

http://www.fws.gov/midwest/eagle/pdf/NationalBaldEagleManagementGuidelines.pdf

The Service is unaware of any bald eagle nests in the permit area; however, if a bald eagle nest is found in the permit area or vicinity of the permit area then our office should be contacted and the guidelines implemented.

Response: The applicant has provided a statement outlining that the applicant is unaware of any bald or golden eagle nests within one mile of the project. The applicant includes a discussion committing to contacting the U.S. Fish and Wildlife Service for the development of a protection and enhancement plan if a nest is encountered. See Part V.2.B.2 of the application.

Comment: [Per the follow-up USFWS correspondence dated October 2, 2019] - The Service indicated that it is unaware of any bald eagle nests in the permit area; however, if a bald eagle nest is found in the permit area or vicinity of the permit area then our office should be contacted. The applicant provided a statement that no eagle nests are known within the project area or vicinity. This information sufficiently addresses our comments.

Response: Comment noted and forwarded to the applicant.

Comment: The permit area includes 23.0 acres of cropland, 16.8 acres of fish and wildlife herbaceous, 18.6 acres of fish and wildlife woody, 0.4 acres of fish and wildlife water, 3.7 acres of fish and wildlife wetland, 0.1 acres residential, and 8.2 acres industrial/commercial.

Response: The Department would like to take this opportunity to clarify that information in the modified permit application indicates that the permit area will includes 16.4 acres of cropland, 20.7 acres of fish and wildlife herbaceous, 21.1 acres of fish and wildlife woody, 0.4 acres of fish and wildlife water, 3.6 acres of fish and wildlife wetland, 0.2 acres developed water resources, 0.1 acres residential, and 8.2 acres industrial/commercial.

Comment: [Per the follow-up USFWS correspondence dated October 2, 2019] - Thank you for your letter dated August 6, 2019, providing response to our comments on permit

application No. 456 by Williamson Energy, LCC (Pond Creek Mine), for surface coal mining and reclamation operations in Franklin and Williamson Counties, Illinois. The permit area is 70.7 acres and the proposed mining activity will impact a total of 70.7 acres. The permit area includes 16.4 acres of cropland, 20.7 acres of fish and wildlife herbaceous, 21.1 acres of fish and wildlife woody, 0.4 acres of fish and wildlife water, 3.6 acres of fish and wildlife wetland, 0.2 acres of developed water resources, 0.1 acres residential, and 8.2 acres industrial/commercial. These comments are provided under the authority of and in accordance with the provisions of the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 et seq.); the Endangered Species Act of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.) and, the National Environmental Policy Act (83 Stat. 852, as amended P.L. 91-190, 42 U.S.C. 4321 et seq.).

Response: Comment noted and forwarded to the applicant.

Comment: Information in the permit application indicates that proposed activities will impact a total of 3.7 acres of wetlands including 0.4 acres of unconsolidated bottom wetlands. The proposed post mining land use plan includes 3.7 acres of wetlands.

The Service has no objection to the proposed wetland mitigation.

The Service recommends that the seed mix for emergent wetland restoration include native forbs, which will provide greater benefits to native pollinators and the monarch butterfly.

Response: The Department would like to take this opportunity to clarify that information in the modified permit application indicates that the proposed activities will impact a total of 3.6 acres of fish and wildlife wetland and proposed post mining land use plan includes 3.6 acres of wetlands. The recommendation by the Service to incorporate native forbs into the seeding mix for emergent wetland restoration has been forwarded to the applicant.

Comment: Information in the permit application indicates that the reclaimed area will include 22.1 acres of woody fish and wildlife habitat and 21.0 acres of herbaceous fish and wildlife habitat.

The Service recommends that the planting of any non-native, exotic, and invasive species be avoided.

The Service also recommends the incorporation of native forbs in the seeding mix which will provide greater benefits to native pollinators.

The Service recommends that the applicant include an invasive species control plan in the reclamation plan.

Response: The Department would like to take this opportunity to clarify that information in the modified permit application indicates that the reclaimed area will include 21.1 acres of woody fish and wildlife habitat and 20.7 acres of herbaceous fish and wildlife habitat.

The applicant has proposed native and non-native species for Fish and Wildlife post-mining land uses (PMLUs). See Attachment V.1.D.2.b. of the application that contains species lists and justification for the use of some non-native species. The regulations found at Section 1816.111(a)(2) and (c) allow non-native species if they are necessary to achieve the desired post-mining land use or are necessary for erosion control. In addition, the 2013 Indiana bat guidelines provides the same flexibility in Section 2.4.2.2 item no. 3 for the use of non-native woody area herbaceous ground cover if the applicant demonstrates the proposed species are slow growing and beneficial for wildlife. The applicant has proposed non-native species for temporary/cover crop vegetation. The Department does not have the regulatory authority to require native species for temporary seed mixes. The recommendation by the Service to incorporate native forbs in the herbaceous seeding mix was noted and has been forwarded to the applicant.

Pursuant to Section 1816.116(b)(1) and 1784.15(b)(1), the Department required the applicant to achieve the approved species and/or PMLU vegetation success standards during the applicable period of liability. Undesirable invasive species control will be part of the remedial action plan if deemed necessary by the applicant or the Department.

Comment: [Per the follow-up USFWS correspondence dated October 2, 2019] - The Service recommended that the planting of any non-native, exotic, and invasive species be avoided and that the applicant include an invasive species control plan in the reclamation plan. The Service also recommended the incorporation of native forbs into the seeding mix. Information included in the response sufficiently addresses our comments.

Response: Comment noted and forwarded to the applicant.

Public Comments

The Department has considered and evaluated all comments concerning the effects of mining within the proposed permit areas and adjacent areas. The issues raised that are deemed pertinent to the permit application are addressed below.

Comment 1: Commenters asked if their questions were going to be answered at the hearing, expressed dismay that questions were not answered and requested clarification as to how they will obtain those answers to their questions.

Response: The regulations at 62 Ill. Adm. Code 1773.14(d)(2) states that "The hearing officer shall allow the county board, the applicant, and any interested persons to present data, views, or arguments." The purpose of the hearing is not to inform the public but to allow the public to "present data, views, or arguments" concerning the application to the Department. Comments pertinent to the application are then taken into consideration by the Department, with each specialist in their individual scientific area reviewing the application and addressing those comments in the permit decision document.

Comment 2: Commenters expressed concern over the impact of the project on the quality of the Big Muddy River.

Response: The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the Illinois Environmental Protection Agency's (IEPA). Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 3: A commenter asked what is currently being done with the water generated at the mine.

Response: It is assumed the commenter, by using the term "generated," is referring to mine infiltration water removed from the underground workings. According to the currently approved NPDES Permit IL0077666, the mine infiltration water that is pumped from the underground works is routed to Pond 006. This water is used at the wash plant or stored on the permitted surface area in existing impoundments and ponds.

Comment 4: A commenter asked about details of the water to be discharged and the concentration of pollutants in the water.

Response: Please see the response to Appendix A, Modification Question Nos. 11 and 12.

Comment 5: A commenter asked if the pipeline work had begun and when a decision on the application would be made.

Response: At the time of this comment, the Permit No. 456 application for the pipeline was still under review. Any work related to the pipeline as it relates to the proposed surface coal mining and reclamation operations detailed for this application cannot lawfully begin until the Department approves the application and issues the permit decision. Here, after completion of review, it was determined that modifications of the application were required and the applicant had one year to provide appropriate

responses to the request for modifications. Those responses have since been submitted and approved. This permit findings document memorializes the Department's decision to issue the permit.

Comment 6: Commenters questioned the impact to the water level of the Big Muddy River, including during low flow conditions as a result of the proposed discharge.

Response: Based on information provided in the application, the volume of mine water to be discharged in the Big Muddy River will be dependent on the flow of the river upstream of the point of discharge. Thus, the discharge will be intermittent and will be adjusted accordingly. The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 7: Commenters asked how the concentrations of chlorides and sulfates in the discharge water would impact the receiving stream, adjacent waterways and water courses further downstream, including the anticipated effects on local biota and the public.

Response: The IEPA is the regulatory agency that determines the concentrations of chlorides and sulfates that can be discharged into a water body through its NPDES permitting process. The potential impacts to the receiving stream, adjacent waterways and water courses further downstream, including the anticipated effects on local biota and the public, is an issue for the IEPA to address through that process. Potential impacts resulting from another agency's permitting responsibility is beyond the purview of the Department.

Comment 8: Commenters indicated the hydrologic balance investigation for the application should include the areas included within the longwall panels and that the analysis was an attempt to obscure the effects on the local water table. One of these commenters asked what the actual cone of depression created by the mine pumpage.

Response: This permit application is for the construction and operation of a pipeline to transport underground mine infiltration water to a diffuser system at the Big Muddy River. This permit application does not cover the shadow area encompassed by the longwall mining panels. Nevertheless, the Department does not believe there is a cone of depression as this water is leaking into the mine from cracks in the overlying unit above the coal seam. The water is then physically pumped out of the mine, not the overlying unit.

Comment 9: Commenters were concerned there are, or may be, adverse impacts accruing from the rate of water pumping and area groundwater drawdown, as well as the long-term impacts to local water quantity that may be needed in the future.

Response: There have been no reported issues from surrounding citizens regarding the company pumping out infiltrating groundwater out of the mine. According to data presented in the application, this groundwater is naturally high in chlorides and sulfates, making it unfavorable as a source of potable groundwater. The Department is unaware of any plans or proposals to utilize this water bearing sandstone as a source of potable water.

Comment 10: A commenter indicated Permit No. 375 incorrectly reflected the depth of the coal seam and that the shallower depth of mining negatively impacted his ponds and well. Further, the commenter indicated the Department needed to monitor his well to understand the hydraulic balance of the area.

Response: The issues raised relate to underground mining and subsidence and are not pertinent to the activities proposed in Permit No. 456. Potential subsidence impacts to a well will not provide relevant information on the hydrologic balance of the proposed permit area in this application.

Comment 11: Commenters expressed concerns that the public wasn't given adequate or appropriate notice of the permit application or the public hearing and sufficient time to prepare for the hearing. One stated that "I own a significant amount of land I do not live here full time, but I would have thought that there might be a better communication system to land owners regarding important items such as this. The meeting was quickly called and not very publicized. Your written comment deadline is also too short given that many people have only barely heard of the Big Muddy River pollution by Williamson Energy, LLC, and Pond Creek Mine, and they have not had time to read the application and gather their research and comments on the permit proposal."

Response: The purpose of the public hearing, as stated at 62 Ill. Adm. Code 1773.14(d)(2), is to "allow the county board, the applicant, and any interested persons to present data, views, or arguments." The application has been on file with the Williamson and Franklin Counties Clerk Offices since July 18, 2018. In addition, the application was posted to the Department's website on July 20, 2018. Notice of the application was published by the applicant in the Marion Republican four (4) times, with the first publication on July 18, 2018, and the last on August 8, 2018. The application was available for public review for more than three (3) months prior to the close of the comment period. It is the Department's opinion the public has been provided all the opportunities prescribed by the regulations to review the application and the additional ten (10)-day period afforded after the public hearing provided adequate time for interested parties to review the application and submit written comments.

The regulations at 62 Ill. Adm. Code 1773.14(b) require that "The Department shall publish notice of the hearing in a newspaper of general circulation within the county. Such notice shall be published by the Department at least two (2) weeks prior to the scheduled hearing date."

The notice published for the public hearing explained what application was to be covered by the hearing, and the time, place and location of the hearing. It also provided the Department's contact information. That notice was published October 2, 2018 in the Southern Illinoian.

The Department's requirements for public notification of the public hearing were met.

Comment 12: Commenters indicated that insufficient research had been done to insure irreparable damage to water systems will not occur. Those concerns addressed effects to endangered species that may come to the area (gray wolf, black bear and mountain lion), the redheaded woodpecker, hellbenders, the alligator snapping turtle and other reptiles and amphibians living in and around the waterways which would receive the discharge. Commenters also expressed concern regarding these effects on the LaRue-Pine Hills area and its diverse biota.

Response: The IEPA is the regulatory agency that determines the effluent concentrations that can be discharged into a water body through its NPDES permitting process. The potential impacts to the receiving stream, adjacent waterways and water courses further downstream, including the anticipated effects on endangered species and other local biota, is an issue for the IEPA to address through that process. Potential impacts resulting from another agency's permitting responsibility is beyond the purview of the Department.

Comment 13: A commenter indicated the bond paid for reclamation was insufficient and needed to take into account the value of fishing, boating and the ecosystem impacted by the proposed action.

Response: The regulations at 62 Ill. Adm. Code 1800.14(b) require that "[t]he amount of the bond shall be sufficient to assure the completion of the reclamation plan if the work has to be performed by the Department in the event of forfeiture..." The amount of bond calculated by the Department is in regard to the pipeline installation requested in the proposed permit. Therefore, the topics noted in the comment are beyond the purview of "completion of the reclamation plan." Any determination of the effect of the water on the ecosystem and recreational sports would be outside the scope of the Department's regulatory jurisdiction.

Comment 14: Commenters indicated an on-site water treatment system, or other solutions should be considered by the applicant in lieu of the pipeline. In addition, a commenter indicated the IDNR should require evidence of such assessments. Commenters also

asked what the mine has done to fully review other options to treat the groundwater on-site and suggested that IDNR should request that the mine show serious assessments or other ways of dealing with this water, as there were no clear examples in the permit application of other options that were considered to treat the high chloride and sulfate levels at the mine.

Response: The Department does not have the regulatory authority to require the type of assessments addressed in the comment.

Comment 15: The Douglas School is an old school turned into artists' studio spaces. A commenter expressed concerns that the Old Historic Douglas School could be negatively impacted by high water and water quality during periods of flooding.

Response: The Department does not have the regulatory authority to evaluate the potential downstream effects related to the proposed mixing zone. The authority for such an evaluation is under the regulatory jurisdiction of the IEPA.

Comment 16: The Big Muddy River is indicated as Public Waters by IDNR. Impacts of this added discharge do not appear to have been adequately evaluated and essential information for this application appears to be lacking. There is no information on what the added 2,700,000 to 3,500,000 gallons per day will mean to erosion impacts, river water levels, public use of the river for recreation or other public uses. This river is already prone to flooding and has documented low flows which clearly could mean different impacts from the proposed discharges that have not been adequately assessed. The amount of water that would flow into the Big Muddy River on a daily basis would overwhelm the levy structures in place on the Big Muddy River.

Response: Based on information provided in the application, the volume of mine water to be discharged in the Big Muddy River will be controlled by a diffuser and be metered at any given time based on the actual flow volume in the river as well as the water quality of the discharge and receiving stream.

The IEPA is the regulatory agency that determines the discharge flow volumes and concentrations of monitored parameters that can be discharged into a water body through its NPDES permitting process.

Several measures are proposed to reduce erosion impacts from the discharge flow. The design of the diffuser includes 5 ports that will be submerged to maximize dispersion and minimize effects on the receiving water. The diffuser ports will be mounted on a steel structure that will be supported by piles. A 50-inch-thick revetment with a D50 riprap size of 25 inches has been proposed to be used on the river bank where the diffuser will be located. Other temporary sediment control measures to be used during construction of the diffuser site include: silt fences, silt socks, straw/hay bales and removal and storage of subsoil and topsoil. The

Department will monitor the performance of the erosion control measures and take appropriate action should erosion become an issue.

Comment 17: A commenter suggested the mining operations should be converted from longwall mining to room and pillar mining and potentially avoid the mine water generation to begin with.

Response: The concern expressed would be better directed to the applicant. The Department is not involved in business decisions made by private entities.

Comment 18: Commenters questioned if the applicant intentionally located the pipeline diffuser below the closest gauging station and if the Department had given consideration to the volume of water proposed to be discharged and its effect on the public's right to use the river. These comments also suggested that by putting the outlet downstream of the Plumfield gauging station the Corps of Engineers would not have a true reading of the of the water level and may release more water at Rend Lake, causing more flooding downstream.

Response: Based on information provided in the application, the volume of mine water to be discharged in the Big Muddy River will be dependent on the flow of the river upstream of the point of discharge. Thus, the discharge will be intermittent and will be adjusted accordingly. The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 19: A commenter asked what the current levels of chlorides and sulfates are in the Big Muddy River.

Response: This is outside the scope of the Department's regulatory purview. The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 20: A commenter asked if full consultation with other divisions within IDNR had been conducted.

Response: The Land Reclamation Division of IDNR (LRD), upon receipt of a complete application, notifies various offices within the IDNR, as well as other State, local and Federal agencies, allowing each to submit comments to be taken in to consideration during the application review process. Here, LRD forwarded

notification to the other offices within IDNR on July 20, 2018. All agency comments have been considered in LRD's review of the application and are addressed in the Part III Summary of the Department's Findings.

Comment 21: A commenter asked why IDNR or EPA would ever allow water with elevated chlorides or sulfates to further pollute the Big Muddy River.

Response: The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 22: Commenters expressed opinions about the poor quality of old mines and asked if IDNR or EPA had been successful in cleaning up pollution caused by old mines.

Response: LRD is involved in the regulation of active coal mining operations. The reclamation of "old" mines, or lands impacted by mining prior to the permanent program rules and regulations is under the jurisdiction of the Department's Abandoned Mine Lands Division. Questions related to IEPA's involvement with "cleaning up pollution caused by old mines" should be directed to that agency.

Comment 23: Commenters asked about how climate change would impact the need for water in the future and how this proposal would affect the local water supply.

Response: The concern expressed related to climate change is outside the regulatory purview of the Department.

Comment 24: A commenter indicated the mining industry caused public health issues and this proposal would exacerbate that issue.

Response: The concern expressed is outside the regulatory purview of the Department. This comment has been forwarded to the applicant.

Comment 25: A commenter indicated that the sulfate and chloride concentrations presented throughout the application were inconsistent, and the final discharge concentration was well in excess of those concentrations expressed elsewhere in the application.

Response: Please see the responses to Appendix A, Modification Questions Nos. 11 and 12.

Comment 26: A commenter asked if the applicant is pumping to a tributary of Pine Creek (as the permit indicates) is working why do they need this application.

Response: The Department is unaware of a "Pine Creek" in the vicinity of the Pond Creek Mine, and therefore assumes that the commenter is referring to Pond Creek. The

Pond Creek Mine does not pump water directly into a tributary of Pond Creek. However, water from the mine's sediment ponds (Outfalls 001, 002, 003, 004, 005, 006, 007, and 008) can discharge into an unnamed tributary of Pond Creek. Please refer to the Department's response to Comment 3 above for a description of the mine's current handling of infiltration water from the underground works. According to the application, Williamson Energy, LLC has a finite capacity to store water and expects to encounter an increase in groundwater infiltration as mining progresses.

Comment 27: One commenter questioned why the mine is attempting to pump high sulfate and high chloride water to the Big Muddy when an earlier request for a mixing zone was rejected years ago.

Response: The IEPA is the regulatory entity that approves mixing zones. The Department permits any actual conveyance system that would be necessary for such a mixing zone. The Department received a permit application (No. 455) for such a conveyance system January 30, 2017 which the applicant subsequently withdrew on March 2, 2017. This application was withdrawn by the applicant prior to review and not denied as the commenter alludes. Any other actions taken by the IEPA on Permit No. 455 are best addressed by that agency.

Comment 28: Commenters stated that the Big Muddy River is already listed as impaired on the 2018 Illinois EPA 303(d) list and is given a medium rating. Their concern is that the river is already at risk from pollutants and there does not appear to be adequate consideration of a full range of mine alternatives to the discharges requested in this permit application or other best practices the mine could utilize are not provided in any significant variety or detail.

Response: The Department does not have the regulatory authority to require the type assessment addressed in the comment. The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 29: Commenters questioned what will the proposed daily discharge of high levels of chlorides and sulfates do to existing fish and aquatic life in the Big Muddy River and to other downstream uses? Those commenters indicated that additional pollution loading of this river, particularly at times of low flow, are a concern to us in addition to the known problems high levels of chlorides cause for fish and other aquatic life. Chlorides are stated in some sources to be accumulative. There is nothing in the application that was found to assess what the daily and long-term biological and water quality impacts of the high levels of chlorides and sulfates will do.

Response: The IEPA is the regulatory agency that determines the concentrations of chlorides and sulfates that can be discharged into a water body through its NPDES permitting process. The potential impacts the receiving stream, adjacent waterways and water courses further downstream, including the anticipated effects on local biota, such as fish and other aquatic life, is an issue for the IEPA to address through that process. Potential impacts resulting from another agency's permitting responsibility is beyond the regulatory purview of the Department.

Comment 30: Commenters had questions regarding what fish and aquatic species are currently utilizing the proposed discharge section of the Big Muddy River and are there any locations downstream that have mussel populations? What are the biological and environmental impacts of the high chloride levels? The Big Muddy River is also listed as having varieties of mussels and information on any mussel beds and what impacts the discharges could mean is lacking.

Response: The IEPA is the regulatory agency that determines the concentrations of chlorides and sulfates that can be discharged into a water body through its NPDES permitting process. The potential impacts the receiving stream, adjacent waterways and water courses further downstream, including the anticipated effects on local biota, such as fish and other aquatic species, is an issue for the IEPA to address through that process. Potential impacts resulting from another agency's permitting responsibility is beyond the regulatory purview of the Department.

Comment 31: A commenter asked what different mining practices could be done to reduce the amount of groundwater infiltrating the mine?

Response: The scope of the commenter's question falls beyond the regulatory purview of the Department. The comment has been forwarded to the applicant.

Comment 32: Commenters indicated the diffuser is located on a cut bank of the river, which could potentially experience expedited erosion and bank stability problems risking infrastructural damages.

Response: Engineering practices at the river bank will be utilized to reduce significant erosion impacts and enhance aquatic habitat. The diffuser ports will be mounted on a steel structure that will be supported by piles. Stream bank stabilization proposed for the bank of the Big Muddy River consist of a 50-inch-thick revetment using median riprap size of 25 inches. The riprap will be keyed into the toe of the slope with native plantings on the banks above. This bank stabilization will help prevent further erosion due to the stream channel and protect the water management facilities and infrastructure. The Department will monitor the performance of the erosion control measures and take appropriate action should erosion become an issue.

Comment 33: Commenters indicated it is unclear what heavy metals or other possible contaminants such as arsenic or radioactive materials and what the cumulative effect of additional pollutants will be. The application is also unclear about whether there is a chance of this water mixing with acid mine drainage.

Response: Please consult with the IEPA regarding what other parameters were reviewed for this mixing zone. The Department finds that the chance of acid mine drainage mixing with the water destined for the mixing zone is low to negligible.

Comment 34: A commenter indicated the Stream Protection Rule was created to clarify vague and problematic components of SMCRA, but even though it was rescinded it should be used to mitigate the damage caused by Foresight Energy.

Response: The Department cannot enforce regulations that have not been promulgated or are not in force.

Comment 35: A commenter asked how will the low water quality with its high sulfates and chlorides effect timber along the river and who would be responsible for the monetary loss to land owners?

Response: The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenter's concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Monetary loss to landowners based on water quality issues resulting from another agency's permitting responsibility is beyond the regulatory purview of the Department.

Comment 36: A commenter asked if they drain water into the Big Muddy, will it be via Pond Creek? If so, who will be responsible for cleaning up the creek due to the number of log jams on it.

Response: The application proposes a pipeline to pump mine water from underground into the Big Muddy River. The concerns expressed regarding the log jams are beyond the regulatory purview of the Department.

Comment 37: Commenters indicated the average concentrations listed for Chloride (2237 mg/l) and Sulfate (1940 mg/l) in the effluent, coupled with the discharge rate equal approximately 22,700 kg/d Cl2- and 19,400 kg/d SO42- were significant quantities when considering the hydrological characteristics of the Big Muddy River at this point in its watershed.

Response: The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 38: A commenter indicated the negative charges of Chloride and express a high affinity to remobilize any positively charged cations in channel sediments of the Big Muddy River. This becomes an important concern when considering metals like Manganese, Magnesium, Iron, Cadmium, Arsenic, Lead, etc. can be present in riverbed sediments. The negative charges extract these positive charged cations, causing elements that would otherwise be immobile, to be brought back into solution and transported downstream. This topic is not discussed anywhere in the application, yet is a real concern considering the quantity, concentration, and duration the mine anticipates the point source effluent to be active.

Response: The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenters' concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 39: A full Environmental Impact Statement should be conducted to determine the full effects of this proposed pipeline.

Response: An environmental impact statement is not required under 62 Ill. Adm. Code Parts 1700-1850 for this proposed surface coal mining and reclamation operation.

Comment 40: Drinking water pollutant levels are more restrictive than river water; the proposed discharges fail to meet drinking water standards, which mean public uses of Big Muddy River water could incur additional treatment costs in the years ahead.

Response: The concern expressed is beyond the regulatory purview of the Department. The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenter's concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

Comment 41: Commenters indicated that we share concerns about the lack of regulatory enforcement that most mines in Illinois have not been inspected in 12 years.

Response: The regulations at 62 Ill. Adm. Code 1800.11(a-b) require that "(a) The Department shall conduct an average of at least one partial inspection per month of each active surface coal mining and reclamation operation under its jurisdiction and shall

conduct partial inspections of each inactive surface coal mining and reclamation operation under its jurisdiction to ensure enforcement of the approved State program... (b) The Department shall conduct an average of at least one complete inspection per calendar quarter of each active or inactive surface coal mining and reclamation operation under its jurisdiction..."

The Department continues to meet its inspection mandate.

Comment 42: A commenter questioned how much affect would this have on tourism which is another major resource of southern Illinois?

Response: The effects on tourism are outside scope of the Department's regulatory purview.

Comment 43: Commenters asked if the pipeline be granted eminent domain or will the mine owner purchase easements from landowners?

Response: Eminent domain is not applicable to the proposed pipeline. It is the applicant's responsibility to obtain the necessary right of entry for the project.

Comment 44: Commenters questioned that since the pipeline crosses over the county line, if the pipeline breaks in one county does the other county have to pay for the cleanup and what recourse will farmers have when the pipeline breaks and damages their field?

Response: Operators of such pipelines are responsible for cleanup of any spillage as well as damages.

Comment 45: A commenter asked what will happen to their property when the Big Muddy River floods again with the extra salt and sulfides and dead wildlife washing in? The river will flood again without the extra 2.5 million gallons of water from the Pond Creek Mine.

Response: The Department's review of the application is conducted pursuant to 62 Ill. Adm. Code Parts 1700 – 1850. The commenter's concerns relate to the discharge of water into rivers and streams, which is an activity regulated by the IEPA. Please consult with IEPA to address issues related to maximum discharge quantities, river loading capacities, proposed mixing zones, and other related matters.

APPENDIX C

Williamson Energy, LLC, Pond Creek Mine
Application for Permit No. 456
And Permit Nos. 375 & 417
And Revisions No. 1, 2, 3, 5, 6, 9, 10, and 11 to Permit No. 375
Assessment and Findings of Probable Cumulative Hydrologic Impacts

Williamson Energy, LLC (hereinafter referred to as "permittee" or "applicant" as applicable) was required to submit a determination of probable hydrologic consequences of the proposed mining and reclamation operations, both on and off the permit area, pursuant to 62 Ill. Adm. Code 1784.14(e) for underground mines.

Pursuant to 62 Ill. Adm. Code 1773.15(c)(5), the Department must make an assessment of the probable cumulative impacts of all anticipated coal mining on the hydrologic balance in the cumulative impact area, in accordance with 62 Ill. Adm. Code 1784.14(f), and find in writing that the proposed operation has been designed to prevent material damage to the hydrologic balance outside the permit area.

The following assessment and findings are intended to fulfill the above requirements.

I. GENERAL INFORMATION

A. Historical Coal Mines (ISGS)

Several coal mines have operated in the vicinity of the Pond Creek Mine. Former coal mines were present to the west, south and east of the Pond Creek Mine.

Both surface and underground mines operated in the area, with operations dating back to 1944.

1. Ziegler No. 4 Mine (1944-1980)

To the south and west of the Permit No. 375 area is the former Ziegler No. 4 underground mine. This mine encompasses approximately 4,726 acres and operated as a room and pillar mine.

2. Orient No. 4 Mine (1952-1987)

Also to the south of the Permit No. 375 area, the former Orient No. 4 underground mine operated. This mine was approximately 6,530 acres in size and operated as a room and pillar mine from 1952 to 1987.

3. Malone No. 1 Mine (1976-1979)

This former surface mine is located to the east of the permit area. The Malone mine operated as a small surface mine from 1976 to 1979 and was approximately 82 acres in size.

4. Phoenix No. 1 Mine (1988-1993)

To the east, occupying the same general location as the form Malone No. 1 surface mine, the Phoenix No. 1 Mine was present. Two permits were issued by the Department. Permit No. 200 was issued in 1988 and Permit No. 270 was issued in 1992. The mine ceased operations in 1993 and in 2008, the Department placed the permit areas into forfeiture status.

B. Active Coal Mines

Pond Creek Mine (2005-current)

1. Permit No. 375 (issued 2005)

The original Pond Creek Mine permit was issued for an underground coal mining operation. Permit No. 375 was originally for approximately 540 acres to be used as surface support facilities for an underground coal mining operation. The surface support facilities include a coal preparation plant, parking lots, access roads, drainage control structures, office buildings, changing rooms, assembly rooms, warehousing facilities, storage facilities, ventilation facilities, refuse disposal areas, power distribution facilities, power lines, water lines, stockpile areas and other associated facilities. Williamson Energy extracts the Herrin No. 6 Coal Seam, at a depth ranging from 450 to 600 vertical feet from the surface, utilizing room and pillar and longwall mining within the originally permitted 4,631 (approximately) acre shadow area. The room and pillar mining is designed to prevent subsidence and/or to be areas of unplanned subsidence, while the longwall mine area is planned subsidence.

2. Permit No. 375, Significant Revision Nos. 1, 3, 5, 6, 7, and 9 (issued 2007, 2010, 2011, 2012, 2013, and 2014, Respectively)

Revision Nos. 1, 3, 5, 6, 7 and 9 to Permit No. 375 approved additional shadow area to allow for both room and pillar developmental and longwall mining operations. The additional shadow area totals approximately 10,588 acres.

3. Permit No. 375, Significant Revision No. 2 (issued 2009)

Revision No. 2 to Permit No. 375 converted previously approved permit area to Refuse Disposal Area No. 2 for the mine.

4. Permit No. 375, Significant Revision No. 4 (Withdrawn)

This proposed revision was withdrawn by the applicant and not issued.

5. Permit No. 375, Significant Revision No. 8 (Withdrawn)

Revision No. 8 to Permit No. 375 is a proposal to inject coal slurry into the former underground works of the Pond Creek Mine. This application has been withdrawn.

6. Permit No. 417 and Significant Revision No. 10 to Permit No. 375 (issued 2015)

Permit No. 417 and Significant Revision No. 10 to Permit No. 375 added approximately 230 acres for an additional refuse disposal area, to be known as Refuse Disposal Area No. 3.

7. Permit No. 375, Significant Revision No. 11 (issued 2018)

Significant Revision No. 11 to Permit No. 375 added 10,913.7 acres of shadow area to the existing mining operations. To date, 57 Insignificant Permit Revisions (IPRs), 84 Incidental Boundary Revisions (IBRs), and 14 minor field decisions have been issued by the Department since the original permit was issued. The IPRs were issued for a variety of reasons, including, but not limited to: surface drainage modifications; pond design changes; rail loop load-out modifications; underground boreholes for rockdust, power supplies and ventilation; installation/replacement of groundwater monitoring wells; changes to the existing refuse disposal areas.

The IBRs were also issued for a variety of reasons, including but not limited to: refuse disposal area changes; borehole installation; soil stockpile changes; addition of diversion ditches, and other surface water drainage; mine ventilation changes and shadow area expansions of 20 acres or less. Through IBRs, Williamson Energy has added approximately 229.3 acres to the original surface facilities permit area and approximately 592 acres of shadow area.

The total surface facilities permit area is now approximately 1,070 acres, whereas, the total shadow area is approximately 25,715 acres.

8. Application for Permit No. 456

The Application for Permit No. 456 proposes to add a 12.5-mile pipeline from the currently approved water holding cells on the western boundary of the mine site to the Big Muddy River. According to the application, the pipe size will be a minimum of 18 inches throughout its total length. The permittee also has an application pending with the Illinois Environmental Protection Agency (IEPA) for a mixing zone. According to the application, the mixing zone is being requested due to the inability to dispose of water infiltrating into the mine. This water has naturally elevated chloride and sulfate concentrations. The amount of water that can be discharged into the Big Muddy River at any given moment is dependent on the chloride concentration of the mine effluent,

the chloride concentration in the receiving stream, and the flow of the receiving stream. However, the maximum pumping rate for this facility will be limited to 5,000 gallons per minute according to the draft NPDES permit and the Application for Permit No. 456 documentation.

II. PROBABLE CUMULATIVE HYDROLOGIC IMPACT ASSESSMENT (CHIA) OF APPLICATION FOR PERMIT NO. 456

A. Cumulative Impact Area (CIA) Evaluation

For purposes of a Cumulative Hydrologic Impact Assessment (CHIA), the Cumulative Impact Area (CIA) is defined as follows:

> The area, including the permit area, within which impacts resulting from the proposed operation may interact with the impacts of all anticipated mining on surface and groundwater systems. Anticipated mining shall include, at a minimum, the entire projected lives through bond release of:
>
> the proposed operation;
>
> all existing operations;
>
> any operation for which a permit application has been submitted to the Department.

This is based upon baseline geologic and hydrologic information. See 62 Ill. Adm. Code Sections 1701.Appendix A and 1784.14.

1. Office of Surface Mining Guidance

The Federal Office of Surface Mining Mid-Continent Region (OSM-MCR) developed a document in June 2007 entitled *Hydrologic Considerations for Permitting and Liability Release, a Technical Reference for the Mid-Continent Region*. In determining whether a CHIA is required, OSM-MCR states that "the operative word in the CHIA concept is *cumulative* which seemingly necessitates the potential interaction of two or more anticipated mining operations." (p. 17) Further OSM-MCR states, "While it may be possible that for a single hydrologically isolated mine the probable hydrologic consequences determination made by the operator would be adopted by the regulatory authority as the CHIA, nevertheless such a conclusion must be reached by the regulatory authority on a case-by-case basis." (p.17)

2. CIA Determination for Application for Permit No. 456

Please see the CHIA for Significant Revision No. 2 to Permit No. 375 for baseline information regarding the original permit and shadow areas and for the Department's determination of the CIA for Permit No. 375. The proposed 12.5 – mile pipeline encompasses a total of 70.51 acres that will terminate at a mixing zone in the Big Muddy River. The proposed pipeline route will cross the

following HUC-12 watersheds, West Frankfort - Pond Creek, Lake Creek, Chittyville - Pond Creek, and Cambon Lake - Big Muddy River. Although the pipeline crosses these four watersheds the assessment area was only expanded to the permit boundaries of the proposed Application for Permit No. 456 area.

According to the Water Management Operations section in the application, the infiltrating groundwater is from an overlying sandstone which has naturally elevated concentrations of chlorides and sulfates. Part III of the application states, chloride concentration generally varies between 1,699 mg/L and 2,799 mg/L, whereas the sulfate values range between 820 mg/L and 2,120 mg/L. As mentioned previously, this water cannot be discharged through the existing sediment ponds on site without exceeding the NPDES permit limits. Therefore, the mine is seeking to discharge this water into the Big Muddy River via a pipeline and a mixing zone (pending IEPA approval).

According to the application and the draft NPDES permit, the volume of mine effluent that can be discharged to the Big Muddy River will be dependent on the flow of the Big Muddy River, chloride concentration of the Big Muddy River, and chloride concentration of the mine discharge water. The maximum pumping rate from the facility has been limited to 5,000 gallons per minute. The application states, the proposed pipeline will be an 18-inch high-density polyethylene (HDPE) pipe that will be buried and capable of handling 125 psi of pressure. The pipeline will be installed using both open trench and boring techniques. The applicant has committed to installing a secondary containment pipe outside of the transport pipe within the 100-foot stream buffer zone of Pond Creek. The applicant has additionally committed to minimize impacts to agricultural lands according to the Standards and Policies for Agricultural Mitigation.

The applicant states the pipeline will be monitored for leaks or potential problems using ultrasonic or similar technology flow meters. These flow meters will be clamped to the pipe and hooked into a telemetry or fiber optic network that can relay real-time information back to the mine. This system will also be tied to an alarm system that activates if a specific difference in flow rate is exceeded. The system will utilize pressure gauges and air release valves to release any potentially trapped air in the pipeline. In the event excessive pressure is measured, the pumps will be shut off, according to the application. The applicant has additionally committed to monthly inspections of the pipeline at road boring sites, the Pond Creek boring site, the Big Muddy River discharge site, and the monitoring stations housing the flow meters, air valves, and pressure gauges.

As mentioned previously, the proposed pipeline route will cross four watersheds. In determining a CIA area, the Department first evaluated the area encompassed by these four watersheds. However, given the construction parameters of the pipeline, the monitoring constraints, and the applicant's commitment to monthly inspections and/or maintenance, the Department does not expect there to be any negative impacts to the hydrologic balance from the proposed operations. The construction activities as proposed in the application will only temporarily affect the area encompassed by the proposed permit. The Department does not expect the surface water and groundwater will be negatively impacted by the temporary construction activities proposed for the installation of the pipeline. As such, the Department is expanding the CIA for the Application for

Permit No. 456 by 70.51 acres, which is the acreage of the proposed pipeline. The Department has determined that as long as the applicant properly operates the pipeline per the commitments given in the application, there should be minimal to no impact to the surface water or groundwater within the CIA area. Further, the Department expects no impacts outside the CIA area.

The CIA acreage has also been expanded to encompass surface IBRs previously not included in the assessment area. These surface IBRs include additional area for vertical turbine pumps, pipelines, boreholes, man/material shafts, and ventilation shafts. The original surface water and groundwater assessment areas were within the Town of West Frankfort – Pond Creek HUC-12 watershed. The additional surface IBRs spread the facility into the following watersheds: Tilley Creek – Ewing Creek, Prairie Creek – Middle Fork Saline River, Gassaway Branch – Middle Fork Saline River, Brushy Creek, and Buckley Creek – Crab Orchard Creek. The Department evaluated the above listed watersheds to account for the mine expansion and to possibly extend the assessment area. However, the Department determined that expanding the assessment area beyond the permit areas in the watersheds would make the CIA too large for the relatively minor facilities approved by the aforementioned IBRs. These IBRs were approved for facilities and the Department assumes they will not fail. Thus, the CIA has been expanded to only include the additional permitted acreage.

The new CIA acreage is 4,245 acres and depicted on Map 1. This includes the original Permit No. 375 area, Permit No. 417 area, all the surface IBRs previously not included, and the proposed Application for Permit No. 456 area.

B. Assessment of the Probable Hydrologic Consequences (PHC)

1. Permit Area and the Shadow Area

Previously, the Department conducted the required hydrologic assessment on the original Permit No. 375 permit area, shadow area, and their respective adjacent areas, as well as Significant Revision No. 11 to Permit No. 375, which added additional shadow area. Application for Permit No. 456 does not propose any additional shadow area, therefore, the Department is not revising the assessment at this time.

Per 62 Ill. Adm. Code Section 1701.Appendix A, the following terms are defined:

The "permit area" is defined as:

> [T]he area of land and water within the boundaries of the permit which are designated on the permit application maps, as approved by the Department. This area shall include all areas which are or will be affected by the surface coal mining and reclamation operations during the term of the permit indicated on the approved map which the operator submitted with the operator's application and which is required to be bonded under 62 Ill. Adm. Code 1800 and where the operator proposes to conduct surface coal mining and reclamation operations under the permit, including all disturbed areas; provided, that areas adequately

> bonded under another valid permit may be excluded from a permit area. The permit area excludes the area defined in this Part as the shadow area.

The "shadow area" is defined as:

> [A]ny area beyond the limits of the permit area in which underground mine workings are located. This area includes all resources above and below the coal that are protected by the State Act that may be adversely impacted by underground mining operations including impacts of subsidence.

The "adjacent area" is defined as:

> [T]he area located outside the permit area, or shadow area, where a resource or resources, determined according to the context in which adjacent area is used, are or reasonably could be expected to be adversely impacted by proposed mining operations.

As described in Section I.B.8 above, the proposed permit area for the Application for Permit No. 456 consists of 70.51 acres. The permittee provided information obtained from the Illinois State Geological Survey on domestic groundwater wells within ½ mile of the proposed permit area. As mentioned previously in Section II.A.2, the CIA was also expanded to encompass the acreage approved by the surface IBRs previously not included in the assessment area. Given the minimal disturbance expected from the proposed operations and the facilities approved by the aforementioned IBRs, for the purposes of this CHIA, the Department has determined there is no adjacent area as no impacts are expected outside of the proposed permit area or the IBR areas being added to the assessment area.

a. Regional Hydrologic Area

The existing permit and shadow areas, as well as the proposed permit area are located in the glaciated upland area of northern Williamson County. It is situated at the headwaters of the major drainage systems of the region. Unnamed tributaries of Pond Creek, named and unnamed tributaries of Middle Fork Saline River, as well as unnamed tributaries of the Big Muddy River pass near and through the existing and proposed permit and the existing shadow area.

b. Permit Area Surface Waters Assessment Area

The Permit Area Surface Water Assessment Area was evaluated in the CHIA for Permit No. 375 Revision No. 10 and Permit No. 417 but has been revisited by the Department for Application for Permit No. 456. The Permit Area Surface Water Assessment Area has been defined as the approximately 4,245 acres which includes the existing Permit No. 375 area, Permit No. 417 area, the surface IBR areas previously not included in the assessment area, and the Application for Permit No. 456 area (Map 1). An explanation of the delineation of the original surface water assessment area in the Pond Creek Watershed can be found in the CHIA for Permit No. 417 and Revision No. 10 to Permit No. 375. As mentioned in Section II.A.2, the Department extended the

assessment area to include the permit areas encompassed by the surface IBRs east of Permit No. 417 and the Application for Permit No. 456 area. Since all these areas are for facilities related to the mining operation (pipeline, borehole, shafts, etc.), the Department is assuming these operations will not fail and will not negatively impact the hydrologic balance.

c. Permit Area Groundwater Assessment Area

Based upon the assumption that shallow groundwater mimics the topography in the area, the Permit Area Groundwater Assessment Area is the same as has been described in II.B.1.b above and as depicted in Map 1.

d. Shadow Area Surface Waters Assessment Area

The Shadow Area Surface Waters Assessment Areas were evaluated in the CHIAs for Significant Revision Nos. 9 and 11 to Permit No. 375. The Shadow Area Surface Waters Assessment Area, associated with Significant Revision No. 11 to Permit No. 375, is approximately 17,625 acres. The Shadow Area Surface Waters Assessment Area associated with Significant Revision No. 9 to Permit No. 375 is approximately 22,441 acres. This application does not propose to modify any of the previously approved shadow area permits. Please refer to the CHIAs for Significant Revision Nos. 9 and 11 to Permit No. 375 for discussion of the Shadow Area Surface Waters Assessment Areas.

e. Shadow Area Groundwater Assessment Area

The Shadow Area Groundwater Assessment Areas are the same as the Shadow Area Surface Water Assessment Areas. The Shadow Area Groundwater Assessment Areas were evaluated in the CHIA's for Significant Revision Nos. 9 and 11 to Permit No. 375. The Shadow Area Groundwater Assessment Area, associated with Significant Revision No. 11 to Permit No. 375, is approximately 17,625 acres. The Shadow Area Groundwater Assessment Area associated with Significant Revision No. 9 to Permit No. 375 is approximately 22,441 acres. This application does not propose to modify any of the previously approved shadow area permits. Therefore, they will no longer be discussed in this CHIA. Please refer to the CHIAs for Significant Revision Nos. 9 and 11 to Permit No. 375 for discussion of the Shadow Area Groundwater Assessment Areas.

2. Geologic Information Required by 62 Ill. Adm. Code 1784.22

a. Baseline Information

Application for Permit No. 456 provides similar information on the regional bedrock geology of the area as the original Permit Application for Permit No. 375 did. The geology of the area consists of typical Pennsylvanian system formations, where approximately sixty percent of the Pennsylvanian strata is classified as sandstones and the remaining forty percent is classified as siltstones and shales. Of this forty percent, coal and/or limestones make up approximately one

percent of this material. The Cottage Grove Fault System is located in the region but is not within the existing or proposed permit areas.

Unconsolidated deposits within the proposed permit area are Pleistocene in age and range from 4 to 33 feet thick. These deposits consist mainly of clay, silt and till materials, but known, limited areas of sand can be found. Surface topography in the proposed permit area is relatively flat-lying, with the southern portion of the area topographically higher than the northern portion of the area.

Site-specific geology, was provided in the boring and corehole logs submitted with the original permit application, as well as the Applications for Permit No. 417 and Significant Revision No. 10 to Permit No. 375. The Herrin No. 6 Coal seam is overlain by alternating layers of shale and limestone.

As stated in the Application for Permit No. 456, the infiltrating groundwater is from a saline zone within the Anvil Rock or Gimlet Sandstone units. The interburden between the Herrin No. 6 coal seam and the base of the Anvil Rock varies between 10 feet and 60 feet. The applicant believes the sandstone units are mostly discontinuous and the caved zone above the mined longwall panels extends into these sandstone units which leads to the water infiltrating into the mine.

b. Geologic Information Findings

The applicant presented no acid base accounting data with this application since the applicant is not proposing any changes in the coal refuse management. The applicant has committed to constructing the pipeline using the best management construction techniques that follow the provisions of Standards and Policies for Agricultural Mitigation.

The applicant also presented information on the sandstone units overlying the Herrin No. 6 coal seam that is the source of the infiltrating groundwater. To protect the miners underground, the operator must pump this water out of the mine. Since the water is naturally high in chlorides and sulfates the applicant is requesting a mixing zone from the IEPA. Otherwise, this water could not be discharged from the existing NPDES outfalls on site without exceeding compliance limits. The Department finds as long as the pipeline is properly constructed, maintained, operated, and the limits of the NPDES permit are adhered to, any impacts to the hydrologic balance should be minimized.

3. Hydrologic Information Required by 62 Illinois Adm. Code 1784.14

a. Baseline Information

i. Surface Water Quantity Baseline Information

No baseline surface water quantity information from stream monitoring points in the vicinity of the proposed permit area was presented in this application. The applicant did provide data for the existing stream monitoring points in the vicinity of the main surface facilities. Surface water

quantity information was previously discussed in the CHIAs for the original permit application and Permit No. 417. The applicant is expecting minimal impacts to the surface water quantity in the vicinity of the proposed permit area during the construction of the pipeline and little to no impacts when the pipeline is operational. According to Attachment IV.1 of the application, the applicant will monitor the pipeline for leaks using a network of flow meters. Additionally, the plan has provisions to double wall the pipeline within the Pond Creek stream buffer zone. Attachment IV.1 of the application also states the mine can discharge as much as 5,000 gallons per minute into the Big Muddy River via a diffuser system based on the flow of the river and other conditions specified in the NPDES permit.

ii. Surface Water Quality Baseline Information

No baseline surface water quality information from stream monitoring points in the vicinity of the proposed permit area was presented with this application. The applicant did provide data for the existing stream monitoring points in the vicinity of the main surface facilities. The applicant is expecting minimal impacts to the surface water quality in the vicinity of the proposed permit area during the construction of the pipeline and little to no impacts when the pipeline is operational given the provisions discussed in the previous section.

The applicant did provide the water quality expected out of the water holding cell prior to entering the pipeline. Table III.2.D.1.a in the application displays representative data obtained from the water holding cell which could contain a mixture of mine infiltration water, process water from the preparation plant, and decant water from the slurry cells. The chloride concentration varied between 1,699 mg/L and 2,799 mg/L, whereas the sulfate concentration varied between 820 mg/L and 2,120 mg/L. According to Attachment IV.1 of the application, the water that will be discharged will be process water and mine infiltration water. The document goes on to say an Anti-Degradation document was submitted to IEPA on November 18, 2016 and the clarified decant water from the slurry cell was considered in the analysis. Surface water quality for the main surface facilities was previously discussed in the CHIAs for the original permit application and Permit No. 417 and will not be changed due to this application.

iii. Groundwater Quantity Baseline Information

The applicant installed no groundwater monitoring wells for this permit application. The applicant felt the minimal disturbance from the construction activities should not affect the shallow groundwater quantity in the vicinity of the proposed permit area. The applicant surveyed the Illinois State Geological Survey (ISGS) public water well records to identify users who may be utilizing the groundwater. In Attachment III.2.B.1 and the Hydrologic Maps of the Application for Permit No. 456, the applicant identified eight private water wells and their respective users within ½ mile of the proposed permit boundary. One of the wells is noted to be plugged according to the information the applicant obtained from the ISGS records. The applicant did not conduct a door – to – door survey given the minimally invasive construction methods and protections that will be employed to install the pipeline. As such, the applicant does not expect any listed well owner to experience groundwater quantity issues as a result of this operation.

In Attachment IV.1 of the application, the applicant states the daily quantity of mine infiltration water required to be pumped out amounts to 2,700,000 gallons per day. The applicant anticipates the maximum flow of mine infiltration water to be 3,500,000 gallons per day. The application notes the applicant is not aware of any groundwater users using the water from the Anvil Rock or Gimlet Sandstone units. Most private groundwater well users are utilizing the shallow groundwater from the unconsolidated layer. The applicant noted one user who has a well drilled down to these sandstones, however it appears it was drilled deep for additional storage capacity in the well according to the application.

iv. Groundwater Quality Baseline Information

As mentioned in the previous section, the applicant notes the construction methods to install the pipeline should be minimally invasive. As such, the applicant does not believe the shallow groundwater quality will be affected by the proposed operations. The application states the infiltrating groundwater has elevated chloride and sulfate levels that would not otherwise be allowed to discharge through the outfalls currently approved in the NPDES permit. Table III.2.D.1.a in the application displays representative data obtained from the water holding cell which could contain a mixture of mine infiltration water, process water from the preparation plant, and decant water from the slurry cells according to Attachment IV.1 of the application. The chloride concentration varied between 1,699 mg/L and 2,799 mg/L, whereas the sulfate concentration varied between 820 mg/L and 2,120 mg/L according to the application.

The applicant is assuming the primary driver for the elevated chloride and sulfate concentration is the infiltrating groundwater. Since this water has naturally elevated chlorides and sulfates, the applicant notes there are no known private users of this groundwater. As mentioned in the previous section, the applicant notes one user who has a well that is drilled into this interval, but the applicant asserts this was done for additional storage capacity in the well rather than utilization of the unit for water.

b. Findings

i. Surface Water Quantity Findings

Previous surface water assessments can be found in the CHIAs for Permit Nos. 375 and 417. The applicant presented information in the application to indicate the construction of this pipeline will be minimally invasive. Additionally, the applicant has committed to provisions in the pipeline construction and operation to prevent leaks and ensure reliable operation. Therefore, the Department finds the construction of this pipeline will cause little to no impact to the surface water quantity in the vicinity of the proposed permit area. This conclusion also applies to the previously approved surface IBRs now being included in the assessment area.

The application states up to 5,000 gallons per minute can be discharged into the Big Muddy River depending on the flow of the river and other conditions specified in the draft NPDES

permit for this mine. The mixing zone is currently pending approval by IEPA, however the draft NPDES permit suggests their analysis found the additional volume of water would not negatively affect the Big Muddy River. Therefore, the Department will not comment any further on the volume of water going to the Big Muddy River.

Shadow Area

Application for Permit No. 456 will have no impact on the surface water quantity that may be present within the existing shadow areas.

ii. Surface Water Quality Findings

Given the relatively non-invasive construction, maintenance commitment, and operational provisions of the pipeline to prevent leaks, the Department finds the surface water quality will be minimally affected or not affected at all by the proposed operations. This conclusion also applies to the previously approved surface IBRs now being included in the assessment area.

Table III.2.D.1.a in the application gave representative water quality data for the holding cell and showed elevated chloride and sulfate values. Attachment IV.1 of the application stated the water holding cell could contain a mixture of mine infiltration water, process water from the preparation plant, and decant water from the slurry cells. The applicant also stated this was considered in the Anti-Degradation Analysis conducted by IEPA for the mixing zone into the Big Muddy River. According to the draft NPDES permit, the IEPA determined the mixing zone will not negatively affect the Big Muddy River, as such, the Department will not comment further on their analysis. Therefore, the Department finds as long as the applicant follows and meets the provisions laid out in the NPDES permit, the surface water quality should not be negatively affected.

Shadow Area

Application for Permit No. 456 will have no impact on the surface water quality that may be present within the existing shadow areas.

iii. Groundwater Quantity Findings

It is not anticipated the shallow groundwater quantity will be significantly impacted by the proposed operations. Attachment III.2.B.1 and the Hydrologic Maps of the Application for Permit No. 456 identified eight private water wells and their respective users within ½ mile of the proposed permit boundary. One of the wells is noted to be plugged according to the information the applicant obtained from the ISGS records. The Department does not expect the groundwater quantity of the private well users to be impacted by the proposed operations. Given the relatively non-invasive construction, maintenance commitment, and operational provisions of the pipeline to prevent leaks, the Department finds the groundwater quantity will be minimally affected or not affected at all by the proposed operations. This conclusion also applies to the previously approved surface IBRs now being included in the assessment area.

As stated in previous CHIAs for this mine, the groundwater infiltrating in the mine works originates in sandstone aquifers that are currently (and historically) not in use by local residents for two reasons. The first is the cemented nature of the sandstone creates low aquifer yield and the second is the documented poor quality of this water. Local residents tend to obtain their drinking water from surface sources due to the highly mineralized water that is present in this sandstone unit.

Therefore, the effect of the pumping of this groundwater that infiltrates the mine workings is not anticipated to have a negative impact on any current drinking, domestic, or usable aquifer quantity.

Shadow Area

Application for Permit No. 456 will have no impact on the groundwater quantity that may be present within the existing shadow areas.

iv. Groundwater Quality Findings

Similar to the Groundwater Quantity Findings, it is not anticipated the shallow groundwater quality will be significantly impacted by the proposed operations. Attachment III.2.B.1 and the Hydrologic Maps of the Application for Permit No. 456 identified eight private water wells and their respective users within ½ mile of the proposed permit boundary. One of the wells is noted to be plugged according to the information the applicant obtained from the ISGS records. The Department does not expect the groundwater quality of the private wells users to be impacted by the proposed operations. Given the relatively non-invasive construction, maintenance commitment, and operational provisions of the pipeline to prevent leaks, the Department finds the groundwater quality will be minimally affected or not affected at all by the proposed operations. This conclusion also applies to the previously approved surface IBRs now being included in the assessment area.

As mentioned in the previous section, the groundwater infiltrating in the mine works originates in sandstone aquifers that are currently (and historically) not in use by local residents due to low aquifer yield and poor quality. Local residents tend to obtain their drinking water from surface sources due to the highly mineralized water that is present in this sandstone unit. Therefore, the effect of the pumping of this groundwater that infiltrates the mine workings is not anticipated to have a negative impact on any current drinking, domestic, or usable aquifer quality.

Shadow Area

Application for Permit No. 456 will have no impact on the groundwater quality that may be present within the existing shadow areas.

III. CONCLUSION

The surface water and groundwater monitoring programs have been designed to provide sufficient lead time for notification of any potential impacts, as well as to provide ample time for investigation and mitigation of any impacts prior to reaching off-site. Both the groundwater and surface water monitoring programs are dynamic and as such, the Department reserves the right to add monitoring parameters or monitoring locations should the need arise. The applicant/permittee is required to monitor the surface water and groundwater throughout the life of the mine, up to and including the time of final bond release.

The Department has now conducted a hydrogeologic assessment on the proposed additional acreage described in the Application for Permit No. 456 and the previously approved surface IBRs now being included in the assessment area. As noted in the discussions throughout this document, the Department has concluded that the additional proposed surface facilities permit area will not have a negative impact on either the surface water or groundwater regimes.

Neither the surface water nor groundwater within the assessment areas will be materially damaged unless the quantity and/or quality of water is degraded on a long-term or permanent basis, beyond the applicable standards or a long-term or permanent loss of use is reported. Material damage occurs when the impact is immitigable. Neither the applicant/permittee, nor the Department anticipates that this will occur.

Therefore, the cumulative hydrologic impact assessment finds that the proposed operations have been designed to prevent material damage to the hydrologic balance beyond the permitted areas.

In summary, the assessment and findings of the probable cumulative impact of all anticipated mining in the area on the hydrologic balance finds that this operation has been designed to prevent material damage to the hydrologic balance outside the permit areas.

APPENDIX D

DECISION ON PROPOSED POST-MINING LAND USE OF PERMIT AREA

The pre-mining and post-mining land use acreage of the permitted area is as follows*:

	Pre-mining	Post-mining
Cropland	16.4	16.4
Water Resources	0.2	0.2
Residential	0.1	0.1
Industrial/Commercial	8.2	8.2
Fish & Wildlife Habitat**	45.8	45.8
Total	70.7	70.7

*The Department notes that other agencies with environmental and land use authority may use land use definitions other than 62 Ill. Adm. Code 1701.5. Reports for those agencies which may be included in the application will classify and tabulate land uses based on their definitions. As a result, those land use tabulations may not directly correlate with the above tables.

** To facilitate the assessment of the revegetation success performance standards, the post-mining land use of Fish and Wildlife Habitat is broken out as follows:

Wildlife-Herbaceous	Wildlife-Woody	Wildlife-Wetland	Wildlife-Water
20.7	21.1	3.6	0.4

The Department thus finds the areas affected by surface coal mining operations will be restored in a timely manner to conditions that are capable of supporting the use which they were capable of supporting before mining or to higher or better use achievable under the criteria and procedures of 62 Ill. Adm. Code 1817.133, or as noted above. The plan of restoration submitted by the applicant does not present any actual or probable hazard to public health or safety nor does it pose any actual threat of water diminution or pollution as indicated in Appendix C, and the proposed land uses following mining are not impractical or unreasonable as all the post-mining land uses existed prior to mining and are compatible with the surrounding areas. The land uses are consistent with applicable land use policy and plans known to the Department and no objections were received from any governmental agency with such authority. The plan does not involve unreasonable delay

in implementation and is not in violation of any other applicable law known to the Department. Federal court decisions, commonly known and the "Flannery decisions" and current regulations provide for the distinct difference between surface and underground mining. In this permit the operations will involve the trenching and burying of a pipeline through the permit area. Reclamation by soil replacement and revegetation will occur shortly afterward as part of the operation with the exception of any surface access areas. There are no land use or land capability changes requested by the permitee. These disturbances are considered minor in comparison to surface mining and the removal of overburen and coal.

COMMONWEALTH OF PENNSYLVANIA
DEPARTMENT OF ENVIRONMENTAL PROTECTION

In The Matter Of:

Canterbury Coal Company 46226 National Road Saint Clairsville, OH 43950	: : : :	Compliance Order No. 171028 Permit No. 03841302 - License No. 5006 Kiskiminetas Township Armstrong County

CONSENT ASSESSMENT OF CIVIL PENALTY

This Consent Assessment of Civil Penalty ("CACP") is entered into this 23 day of August 2017, by and between the Commonwealth of Pennsylvania, Department of Environmental Protection ("Department") and Canterbury Coal Company ("Canterbury Coal").

The Department has found and determined the following:

A. The Department is the agency with authority to administer and enforce [The Clean Streams Law, Act of June 22, 1937, P.L. 1987, *as amended*, 35 P.S. §§ 691.1--691.1001]; [the Surface Mining Conservation and Reclamation Act, Act of May 31, 1945, P.L. 1198, *as amended*, 52 P.S. §§ 1396.1--1396.19a ("Surface Mining Act")]; [the Coal Refuse Disposal Control Act, Act of September 24, 1968, P.L. 1040, *as amended*, 52 P.S. §§ 30.51--30.66 ("Coal Refuse Act")]; [the Noncoal Surface Mining Conservation and Reclamation Act, Act of December 19, 1984, P.L. 1093, *as amended*, 52 P.S. §§ 3301 -- 3326 ("Noncoal Act")]; [the Bituminous Mine Subsidence and Land Conservation Act, Act of April 27, 1966, P.L. 31, *as amended*, 52 P.S. §§ 1406.1--1406.21 ("Bituminous Subsidence Act)]; Section 1917-A of the Administrative Code of 1929, Act of April 9, 1929, P.L. 177, *as amended*, 71 P.S. § 510-17, and the rules and regulations promulgated thereunder.

Office of Mines and Minerals
Land Reclamation Division

H. On May 5, 2017 as evidenced by Sample No. 4137-091, Canterbury Coal caused or allowed a discharge of water at the David/Dianne Mine, from outfall 001, with an aluminum concentration of 1.524 mg/L which exceeds the permit limit of 0.75 mg/L.

I. Canterbury Coal's conduct set forth above constitutes a violation of Sections 301, 307, 315, and 611 of the Clean Streams Law, 35 P.S. §§ 691.301, 691.307, 691.315, 691.611 and Section 86.13 of the Rules and Regulations, 25 Pa. Code § 86.13.

J. The violations described in Paragraph(s) F through I above constitute unlawful conduct under Section 611 of the Clean Streams Law, 35 P.S. § 691.611 and Section 17a of the Bituminous Subsidence Act, 52 P.S. § 1406.17a and subject Canterbury Coal to a claim for civil penalty liability under Section 605 of the Clean Streams Law, 35 P.S. § 691.605 and Section 17 of the Bituminous Subsidence Act, 52 P.S. § 1406.17.

After full and complete negotiation of all matters set forth in this CACP and upon mutual exchange of the covenants herein, the parties desiring to avoid litigation and intending to be legally bound, it is hereby ASSESSED by the Department and AGREED to by Canterbury Coal as follows:

1. Assessment. In resolution of the Department's claim for civil penalties, which the Department is authorized to pursue under Section 605 of the Clean Streams Law, 35 P.S. § 691.605, and Section 17f of the Mine Subsidence Act, 52 P.S. § 1406.17(f). The Department hereby assesses a civil penalty of TWO THOUSAND FIVE HUNDRED SEVENTY-TWO DOLLARS ($2,572), which Canterbury Coal hereby agrees to pay.

AUG 2 4 2017

Received Electronically
Dept. of Natural Resources
October 21, 2019

Land Reclamation Division

2. Civil Penalty Settlement. Canterbury Coal consents to the assessment of the civil penalty assessed in Paragraph 1, which shall be paid in full upon signing this CACP. This payment is in settlement of the Department's claim for civil penalties for the violations set forth in the paragraphs above for the date[s] set forth therein. The payment shall be by corporate check or the like, made payable to the Commonwealth of Pennsylvania and sent to Compliance Specialist, PA DEP – New Stanton District Office, 131 Broadview Road, New Stanton, PA 15672.

3. Findings.

a. Canterbury Coal agrees that the findings in Paragraphs A through J are true and correct and, in any matter or proceeding involving Canterbury Coal and the Department, Canterbury Coal shall not challenge the accuracy or validity of these findings.

b. The parties do not authorize any other persons to use the findings in this CACP in any matter or proceeding.

4. Reservation of Rights. The Department reserves all other rights with respect to any matter addressed by this CACP, including the right to require abatement of any conditions resulting from the events described in the Findings. Canterbury Coal reserves the right to challenge any action which the Department may take, but waives the right to challenge the content or validity of this CACP.

IN WITNESS WHEREOF, the parties have caused this CACP to be executed by their duly authorized representatives. The undersigned representatives of Canterbury Coal certify, under penalty of law, as provided by 18 Pa. C. S. § 4904, that they are authorized to execute this CACP on behalf of Canterbury Coal, that Canterbury Coal consents to the entry of this CACP as

Re: Notice of Non-Issuance of Compliance Commitment Agreement
Violation Notice: W-2019-50002
Sugar Camp Energy
W0558010004

Dear Mr. Schuerger:

The Illinois Environmental Protection Agency ("Illinois EPA") has reviewed the proposed Compliance Commitment Agreement ("CCA") terms submitted by **Sugar Camp Energy** in a letter dated **June 26, 2019**, in response to the Violation Notice dated **March 25, 2019**, and has decided not to issue a proposed CCA for these violations. Due to the nature and seriousness of the violations, the Illinois EPA has determined that these violations may not be able to be resolved without the involvement of the Office of the Attorney General or the State's Attorney.

Because the violations remain the subject of disagreement between the Illinois EPA and **Sugar Camp Energy**, this matter will be considered for referral to the above-referenced prosecutorial authorities for formal enforcement action and the imposition of penalties.

Questions regarding this matter should be directed to Greg Spencer at 217/782-9871. Written communications should be directed to:

Illinois EPA – Division of Water Pollution Control

RE: The Marshall County Coal Company
6 South 1 Airshaft
U200707 NOV 6

Mr. Harvey,

This letter is in response to the remedial measures stated in NOV 6 for The Marshall County Coal Company's 6 South #1 Airshaft, WVDEP Permit U200707.

As you are aware, the completion of the site has taken longer than planned. This is largely due to the amount of unsuitable material encountered during construction. Another significant factor has been the performance of the on-site contractor. This contractor has since been removed from the project and a replacement contractor has resumed construction. The new contractor has since installed five additional culverts and removed the Trans Canada gas line that was intersecting the access road.

Currently the development of the drainage control system continues. Much of the pad and access road is at final grade and a number of culverts have been installed. Enclosed is a status report of the drainage components proposed in the design. At this time The Marshall County Coal Company requests a thirty day extension of the October 4th abatement date in order to complete the installation of the remaining ditches and culverts.

Regards,

Joe Williams
Environmental Engineer

INSPECTION COMMENTS

NOV Follow-up. The permittee has provided a letter detailing the amount of soil removed from the 5N #3 site. It is estimated 20 cubic yards of topsoil and 486 cubic yards of subsoil were removed and taken to the ball field. They also provided plant nutrient testing results of the soil. A potential site has been identified to find replacement soil. The NOV will be extended to complete the required work.

Dear The Muhlenberg County Coal Co LLC:

The Kentucky Department for Environmental Protection (DEP) has issued the enclosed Notice of Violation for violations discovered at your facility for the 2018 monitoring period attached (see 2nd page). Please review the Notice of Violation carefully to ensure that all remedial measures are completed by the specified deadlines.

Your cooperation and attention to this matter is appreciated. If you have any questions, please contact me at 502-782-6852 or linda.metts@ky.gov.

Sincerely,

Linda Metts

No person shall, directly or indirectly, throw, drain, run or otherwise discharge into any of the waters of the Commonwealth, or cause, permit or suffer to be thrown, drained, run or otherwise discharged into such waters any pollutant, or any substance that shall cause or contribute to the pollution of the waters of the Commonwealth in contravention of the standards adopted by the cabinet or in contravention of any of the rules, regulations, permits, or orders of the cabinet or in contravention of any of the provisions of this chapter. [KRS 224.70-110]

Description of Non Compliance:
Failing to comply with 401 KAR 5:065, Section 2(1), which cites to 40 CFR 122.41(a), by failing to comply with the KPDES permit limits for **Total Recoverable Iron (TRFe)**, for permit KYGW40062. The permitted limits for TRFe are a monthly average of 3.0 mg/l and a daily maximum of 4.0 mg/l. The reported results are as follows:

Outfall 001: a monthly average of 5.509 mg/l and a daily maximum of 10.7 mg/l for December of 2018.

The remedial measure(s), and date(s) to be completed by are as follows:
The Muhlenberg Co Coal Co LLC shall comply with the terms and conditions of the current KPDES permit of the facility, KYGW40062. [KRS 224.70-110]

Violations of the above cited statute(s) and/or regulation(s) are subject to a civil penalty per day per violation. Violations carry civil penalties of up to $25,000 per day per violation depending on the statutes/regulations violated. In addition, violations may be concurrently enjoined. Compliance with remedial measures and their

RE: Murray Maple Eagle Coal, LLC
Permit Renewal
S-6020-89 NOV 63

Mr. Thomas,

This letter is in response to the remedial measures stated in NOV 63 for Murray Maple Eagle Coal, LLC's permit renewal on WVDEP Permit S-6020-89. At this time, Murray Maple Eagle Coal, LLC has submitted an application for permit renewal, and is currently working on replying to the corrections sent by the DEP.

Murray Maple Eagle Coal, LLC requests a 30 day extension of the abatement date in order to finish the corrections.

I recommend approval up to 12-12-19.

11-12-19

11 14 19

Regards,

Hodge Hunter

INSPECTION COMMENTS

Marshall County Coal Company - 6S #1. Company has requested an additional 30-day extension of NOV 6 to allow completion of abatement requirements. Aerial overflight inspection on 10/24 showed significant progress on the road and ditches. An additional 30 days is being granted putting the new abatement date at 11/29/2019.

APPENDIX F

THREATENED AND ENDANGERED SPECIES
Endangered Species Act of 1973, 16 USC 1531, et seq.
62 Ill. Adm. Code 1773.15(c)(10)

The Department reviewed Permit Application No. 456 for potential effects of coal mining operations and reclamation activities on federally listed threatened and endangered species. The following factors were considered for all species that could potentially be adversely affected: status of species in the proposed permit area and adjacent area, site specific resource information, direct and indirect effects, and cumulative effects.

Five primary sources were utilized to identify federally listed threatened and endangered species that could potentially be affected by the proposed coal mining operations and reclamation activities. These sources include threatened and endangered species review information submitted by the applicant, public comments, the U.S. Fish and Wildlife Service (USFWS), the Illinois Department of Natural Resources/Division of Real Estate Services and Consultation/Office of Realty and Capital Planning (ORCP), and Department records.

Information Submitted by the Applicant

The threatened and endangered species review srubmitted by the applicant as a requirement of the Department's UCM-1 application addressed state listed species known to occur in Williamson County, Franklin County, and applicable adjacent areas using records obtained from the Illinois Natural Heritage Database. Records for fourteen state listed threatened or endangered species, the barn owl (*Tyto alba*), the bewick's wren (*Thryomanes bewickii*), the ornate box turtle (*Terrapene ornate*), the chuck-will's widow (*Caprimulgus carolinensis*), the least bittern (*Ixobrychus exilis*), the little blue heron (*Egretta caerulea*), the river cooter (*Pseudemys cancinna*), the river redhorse (*Moxostoma carinatum*), the yellow-crowned night heron (*Nyctanassa violacea*), climbing milkweed (*Matelea decipiens*), dull meadow beauty (*Rhexia mariana*), eryngo (*Eryngium prostratum*), false bugbane (*Cimicfuga racemose*), and green trillium (*Trillium viride*) were deemed by the applicant as possible to occur on the proposed project area. The applicant provided Site Specific Resource Information and Protection and Enhancement Plan for each of these species. None of these species are currently listed as federally threatened or endangered.

Information in the permit application indicates that 3.9 acres of known Indiana bat habitat will be impacted by the proposed mining activity. Presence of the Indiana bat was documented in a mist net survey conducted in 2017, thus a Protection and Enhancement Plan (PEP) was developed for the proposed permit area that lies within the 2.5-mile buffer of the documented maternity roost tree in accordance with the USFWS revised 2013 edition of the "2009 Range-wide Indiana Bat Protection and Enhancement Plan Guidelines" (Guidelines).

Information in the permit application indicates that probable absence of the northern long-eared bat cannot be assumed. The project will not impact known northern long-eared bat hibernacula or disturb known northern long-eared bat maternity roost trees or trees within a quarter mile of a known maternity roost tree. Therefore, the project is consistent with the northern long-eared bat Final 4(d) rule (Federal Register, January 2016) and subsequent "no critical habitat" determination (Federal Register, April 2016) issued by the USFWS. Although the project is consistent with the 4(d) rule, the applicant chose to include the northern long-eared bat in the PEP because the species will also benefit from the outlined protection and enhancement measures.

Public Comments

Public comments were recorded from the requested Public Hearing held on October 23, 2018 and written comments submitted to the Department relevant to this application. Comments supplied by the public were focused on the effects of allowable discharge into adjacent waterways, which is not an approvable action by the Department. The Illinois Environmental Protection Agency (IEPA) is the regulatory agency that determines the effluent concentrations that are allowed to be discharged into a water body through its NPDES permitting process. The potential impacts the receiving stream, adjacent waterways and water courses further downstream is an issue for the IEPA to address through that process. Effects and potential impacts resulting from another agency's permitting responsibility is beyond the purview of the Department. Comments received by the public are further addressed within Appendix B of this findings document.

U.S. Fish and Wildlife Service

The USFWS provided comments on this application in a letter dated September 4, 2018 and follow up comments and concurrence in a letter dated October 2, 2019. The USFWS identified three federally listed species for the proposed permit area, the endangered Indiana bat, the endangered piping plover, and the threatened northern long-eared bat. The USFWS concluded that there is "no designated critical habitat in the project area at this time."

The USFWS stated that "based on the location of the permit area, the Service concurs that the proposed project is not likely to adversely affect the piping plover."

Based on confirmed presence of the Indiana bat, as documented in a mist net survey conducted in 2017, an Indiana bat PEP was developed for the proposed permit area that lies within the 2.5-mile buffer of the documented maternity roost tree. This includes 3.9 acres of known Indiana bat habitat. The USFWS stated that "The PEP includes a number of protection and enhancement measures including avoidance of the majority of wooded habitat within the permit area, winter tree clearing from November 15 to March 31, tree girdling and bat box installation to provide temporary habitat, riparian buffer zone protection, and maintenance of watering areas. The applicant is not proposing to replant the forested habitat acres to be disturbed." Upon on permit modifications supplied by the applicant as required by the Department the USFWS stated that "that the Protection and Enhancement Plan (PEP) was updated to address long-term habitat replacement requirements for the Indiana bat." Based on this information the USFWS indicated that "the Service has determined

that the take of 3.9 acres of known habitat is not likely to jeopardize the continued existence of the Indiana bat."

The Department completed the USFWS's Information Planning and Consultation (IPaC) Determination Key: Northern Long-Eared Bat (NLEB) Consultation and 4(d) Rule Consistency, which was submitted to the Service via IPaC on July 31, 2019. The USFWS stated that "Based upon the IPaC submission, the action is consistent with activities analyzed in the Programmatic Biological Opinion on the Final 4(d) Rule for the northern long-eared bat and issuance of the verification letter concludes consultation for the northern long-cared bat. This information sufficiently addresses our comments regarding the northern long-eared bat."

Illinois Office of Realty and Capital Planning

Pursuant 17 Ill. Adm. Code Section 1075 the Department consulted with ORCP (previously the Office of Realty and Environmental Planning) via the online EcoCAT (Ecological Compliance Assessment Tool) system regarding state listed species within the permit boundary and adjacent area. The initial consultation was conducted on December 5, 2018, and a termination letter was provided on December 17, 2018, which concluded that adverse effects to the protected resources identified are unlikely. Taking into account the consultation termination issued by ORCP, the Department concurs that the operations as approved are unlikely to adversely affect any species protected under the Illinois Endangered Species Protection Act (520 ILCS 10/1 *et seq.*).

Department Records and Determination

The Department utilized the Illinois Department of Natural Resources DIRT (Detailed Impact Review Tool) mapping system to review whether or not the project lies within the buffer zone of documented occurrences of any state or federally listed threatened or endangered species.

The applicant submitted the required information to the Department regarding the Indiana bat and the northern long-eared bat including summer survey data documenting the presence of the Indiana bat, suitable habitat determination, and an Indiana bat PEP. The Department has determined that the applicant correctly and diligently followed the protocol specified in the Guidelines (USFWS, 2013); by following these guidelines the applicant is in compliance with the USFWS and Office of Surface Mining Reclamation and Enforcement (OSMRE) 1996 Biological Opinion on the implementation of the Surface Mining Control and Reclamation Act of 1977 (PL 98-87) with regard to assuring compliance with the Endangered Species Act. The Department determined that a PEP was necessary for the known Indiana bat habitat within the proposed permit area that lies within the 2.5-mile buffer of the documented maternity roost tree. The applicant documented presence of the Indiana bat and followed the Guidelines (USFWS, 2013) to develop the PEP. The Department utilized the key to the northern long-eared bat 4(d) rule for federal actions to conclude that proposed actions are not prohibited, therefore a PEP for this species was not required, however the applicant chose to include the northern long-eared bat in the PEP.

The Department considered site specific resource information, information provided by the applicant, concurrence by the USFWS that adverse effects to federally listed species are not likely, termination of the ORCP Section 1075 consultation, and Department records. The Department has determined the proposed mining operations and reclamation activities will not affect the continued existence of threatened or endangered species or result in destruction or adverse modification of their critical habitats, as determined under the Endangered Species Act of 1973 (16 USC 1531 *et seq.*).

Status of Potentially Adversely Affected Species

Indiana bat

The Guidelines (USFWS, 2013) specify the necessity to consider whether known or suitable winter habitat (hibernacula) and/or suitable summer habitat (maternity roosting/feeding) and/or swarming habitat (mating behavior/assessment of hibernacula suitability (Van Schaik, 2015)) of the endangered Indiana bat are located within the proposed permit area. Winter hibernation habitat for the species includes caves, abandoned underground mine workings, and railroad tunnels. Summer maternity roosting habitat includes trees or snags greater than or equal to 5 inches diameter at breast height (dbh) with exfoliating bark (USFWS, 2013) under which female bats, usually numbering less than 100 individuals, roost (Menzel, et al 2001). Suitable swarming habitat consists of forested areas with the described trees that are located within a 10 mile radius of any potential hibernacula (USFWS, 2013).

A major cause of the decline of the Indiana bat is associated with impediments to functioning hibernacula including blocked cave entrances, improper bat gate designs which may impede bat flight into caves or impede proper air flow through caves (USFWS, 1999 and Federal Register, 2007). Arousal following human disturbance to hibernating bats can lead to premature emergence from hibernacula, decreased body condition, and decreased survival (Menzel, et al 2001). Additional causes of decline in the species can be attributed to disturbances or removal of active maternity roost trees and loss of critical habitat. More recently, White Nose Syndrome (WNS) has been identified as having a negative effect on Indiana bat populations.

The range of the Indiana bat covers most of the eastern half of the United States with the majority of roosting colonies in Indiana, Kentucky, and Missouri (USFWS, 2014). For the Indiana bat, recent population data comparing 1997 estimates with historic levels indicate that the range wide population is less than half of historical levels. Indiana bats have declined significantly in some states including Kentucky and Missouri, but have increased in some states, most notably Indiana. Population estimates show an increase of about 30% in Illinois from historical levels to the present (Clawson 2002, Clawson 2004). In 2012 the Service reported an increase in Indiana bats in Illinois from 21,677 in 2001 to 55,956 in 2011.

Northern long-eared bat

Suitable winter habitat for this species includes caves and underground mines with high humidity, no air currents, and a constant temperature range (USFWS, 2015). The USFWS indicated in the *Federal Register* (April 2016) that a critical habitat designation is not necessary for this species, however Appendix H (USFWS, 2014) does define suitable summer roosting habitat as any forested area or isolated live tree or snag that is "≥ 3 inches dbh with exfoliating bark, cracks, crevices, and/or cavities". Suitable swarming habitat is typically within 5 miles of a known or potential hibernaculum and can include linear features such as fence rows, riparian buffers, or other travel corridors (USFWS, 2014).

The USFWS indicates that because the above described roosting habitat for the northern long-eared bat is not limited, habitat loss is not a significant threat to the species. The Final 4(d) Rule (Federal Register, January 2016) prevents "take" during sensitive life stages and prohibits incidental take where WNS occurs under these circumstances: if the take occurs within a hibernaculum, if the take occurs from tree removal within 0.25 miles of a known hibernaculum, or if the take occurs from the removal of a known/occupied maternity roost tree or tree within 150 foot radius of the maternity tree between June 1st and July 31st.

The range of the northern long-eared bat in the United States extends across 37 states in the eastern and north-central areas of the country, including Illinois (Federal Register, 2015 and USFWS, 2015). A contributing factor to the overall decline of the species is WNS, a fungal disease affecting hibernating bats with widespread mortality (USGS, 2015). First observed in New York in 2006, WNS has rapidly spread throughout the Northeast and Midwest; northern long-eared bat populations have been reduced by 99% in parts of its range (USFWS, 2015). The first documented observance of WNS in Illinois affecting a northern long-eared bat occurred in LaSalle County in 2013; WNS has since been documented in at least ten additional Illinois counties (IDNR, 2015). The Federal Register Final Rule (2015) listing the species as federally threatened indicates that "overall, summer surveys from Illinois have not documented a decline due to WNS to date".

Site Specific Resource Information

A survey was conducted to assess the presence or absence of the Indiana bat and northern long-eared bat within the proposed permit area. The survey was conducted by a qualified wildlife biologist from May 18, 2017 through May 25, 2017 with tracking persisting through July 1, 2017. The survey was conducted in accordance with the USFWS's 2107 Range-Wide Indiana Bat Summer Survey Guidelines (USFWS 2017). During this survey, one pregnant/female Indiana bat was captured and tracked to a roost north of the proposed permit area, thus identifying a 2.5-mile protective buffer around the documented maternity roost tree in accordance with the USFWS Guidelines. The Department determined that a PEP was necessary for the 3.9 acres of known Indiana bat habitat within the proposed permit area that lies within the 2.5-mile buffer. The survey confirmed that the Indiana bat is present in the proposed permit area and will be adversely affected and possibly "taken" as defined in the Endangered Species Act; federal guidelines requires the applicant to obtain Incidental Take authorization for the 3.9 acres of known Indiana bat habitat within the proposed permit.

Information in the permit application indicates that no northern long-eared bats were captured during this survey, but probable absence of the northern long-eared bat cannot be assumed. Furthermore, no known caves or underground openings where northern long-eared bats hibernate or could potentially hibernate exist within the permit area. No known/occupied maternity roost tree data is known near the project area for the northern long-eared bat. The Department utilized the key to the northern long-eared bat 4(d) rule for federal actions to conclude that proposed actions are not prohibited.

Direct and Indirect Effects

Take of an Indiana bat and/or a northern long-eared bat is a possible consequence of the proposed mining operations and associated activities. Take could result from killing or injuring bats if roost trees were knocked down while occupied by vulnerable females and/or young; in areas identified as known habitat the applicant has committed to honor a "no cut" period during the time of year bats could be present in trees to minimize the likelihood of such take. Removal of feeding habitat, even if done when the bats are not present, could have indirect effects on the species until this feeding habitat can be restored. The applicant has proposed to replace the required 70% of pre-mining known habitat that is removed during the course of proposed mining operation and associated activities. Emphasis will be placed on planting tree species that are recommended in the Guidelines (USFWS, 2013) for the benefits they provide to threatened and endangered bat species. Habitat modifications resulting from clearing trees in general could also be interpreted as take under the Endangered Species Act (Romanik, 2010); the applicant has requested an Incidental Take authorization to account for this broader definition of take. Incidental Take authorization for the Indiana bat is hereby granted under the authority of the 1996 Biological Opinion issued by the USFWS to OSMRE (USFWS 1996). In addition, the Department has determined that this project may affect the northern long-eared bat, but that any resulting Incidental Take is not prohibited by the Final 4(d) rule. Therefore this project is consistent with the USFWS January 2016 Programmatic Biological Opinion on the Final 4(d) rule. The Department and the applicant are in compliance with Section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*).

The applicant has committed to the following measures to be implemented within the identified known habitat which should serve to minimize disturbances and adverse impacts to Indiana bats and northern long-eared bats:

1. The applicant will limit tree clearing to October 15 through March 31 of any calendar year to avoid take of a female and/ or young Indiana bat or northern long-eared bat.

2. The applicant will provide short-term roosting habitat by girdling 24 trees adjacent to the project area as described in the Indiana bat and northern long-eared bat PEP.

3. The applicant will provide long term habitat replacement by restoring 70% of the known habitat with woody species known to be beneficial to threatened and endangered bat species as described in the reclamation plan and northern long-eared bat PEP.

4. The applicant will utilize herbaceous ground cover species as described in the Indiana bat PEP that will provide cover and resources for wildlife, reduce competition for tree seedlings/saplings, and provide soil stability and erosion control.

Cumulative Effects

Cumulative effects under the Endangered Species Act are defined at 50 CFR Section 402.02 which states "Cumulative effects are those effects of future state, or private activities, not involving federal activities, that are reasonably certain to occur within the action area of the federal action subject to consultation." In the case of a mining permit being issued by the State of Illinois to a private company to develop a privately owned coal reserve, there is no federal action subject to consultation. Therefore, there are no cumulative effects to consider as that term is defined under Section 402.02. The Department nevertheless has considered other future state, county, township and private activities that are reasonably certain to occur within the adjacent land area. Adjacent and nearby land consists of active coal mining operations, agricultural crop land, scattered residential areas, county roads, small lakes, streams, and forested areas. Most of the adjacent acreage is owned and managed by private entities other than the active underground mining operations which are currently owned by permittee. In regards to adjacent and nearby land holdings, the Department has no reason to believe that detrimental cumulative effects to any threatened or endangered bat species would result from state, county, township, and/or private land management practices or activities. If the applicant chooses to submit a new application to the Department for surface effects on nearby lands that contain streams or forested acres, then new threatened and endangered species reviews and PEPs will be required. The Department is not aware of any state, county, township or private activities that would reasonably be certain to occur in the area adjacent or close to the proposed permit area that would adversely affect any threatened or endangered bat species.

Summary

The Department considered the status of the federally endangered Indiana bat and the federally threatened northern long-eared bat, both with the potential to be adversely impacted by the proposed mining operations and associated activities. Although overall populations continue to decline, the Indiana bat population in Illinois is stable or increasing (Clawson, 2004 and USFWS, 2011). Northern long-eared bat population data in the Midwest is limited, however estimates indicate possibly as many as four million northern long-eared bats in 6 states of the Midwest; 21 hibernacula have been documented in Illinois, mostly from the southern region (Federal Register, 2015).

The Department has considered site specific resource information; a survey confirmed that the Indiana bat is present in the proposed permit area and will be adversely affected and possibly "taken" as defined in the Endangered Species Act; federal guidelines requires the applicant to obtain Incidental Take authorization for the 3.9 acres of known Indiana bat habitat within the proposed permit. The USFWS determined that the take of 3.9 acres of known habitat is not likely to jeopardize the continued existence of the Indiana bat. No northern long-eared bats were captured

during survey efforts, but probable absence of the northern long-eared bat could not be assumed. The Department utilized the key to the northern long-eared bat 4(d) rule for federal actions to conclude that proposed actions are not prohibited.

The Department considered direct and indirect effects of proposed operations on the Indiana bat and northern long-eared bat; the most significant threat to these species from mining operations and associated activities is take due to disturbance of an occupied maternity roost tree. The applicant has committed to honor a "no-cut" restriction period within the areas identified as known habitat to prevent the possibility of this type of take. Removal of trees may also affect feeding habitat; the best technology currently available for replacement of feeding habitat includes planting trees during reclamation. The applicant has committed to this post-mining reclamation activity along with other provision set forth in the Indiana bat PEP.

The Department has considered cumulative effects as defined under 50 CFR 402.02 and has considered future state and private activities reasonably certain to occur in the adjacent area and is not aware of any such activities which could adversely affect the Indiana bat or the northern long-eared bat.

Conclusion

Pursuant to Section 1817.97(a), the applicant has proposed to minimize disturbances and adverse impacts to the Indiana bat and the northern long-eared bat by implementing measures described above, while using the best technology currently available. Following these measures will minimize and appropriately mitigate adverse impacts to the Indiana bat and northern long-eared bat. Incidental Take for the Indiana bat is authorized by the Department via this permitting action and the Department has determined that any Incidental Take of the northern long-eared bat is not prohibited by the Final 4(d) Rule.

The Incidental Take as authorized is a take provided for by the Endangered Species Act of 1973 (16 USC 1531 *et seq.*) and is not a violation of this Act. Except as specifically authorized, no other take of a federally listed species is allowed; the applicant remains subject to the prohibitions found at Section 1817.97(d) of taking a federally listed species protected under the Endangered Species Act. Unauthorized take is a violation of Section 1817.97(d); in addition, failure of the applicant to implement the measures specified in the approved plan as part of this permit will subject the applicant to enforcement measures under Sections 1773.17(b), 1817.97(a), and in the case of a take in violation of the Endangered Species Act, Section 1817.97(d).

After having considered the status of the Indiana bat and northern long-eared bat, site specific resource information, direct and indirect effects, and cumulative effects, and in the context of the applicant's commitments for measures to minimize and mitigate disturbances and adverse impacts to the Indiana bat and northern long-eared bat and conditions imposed by the Department, the Department finds that the operation will not affect the continued existence of endangered or threatened species or result in destruction or adverse modification of their critical habitats, as determined under the Endangered Species Act of 1973 (16 USC 1531 *et seq.*).

APPENDIX G

FINDINGS ON THE OPERATOR'S TECHNOLOGICAL CAPABILITY TO RESTORE PRIME FARMLAND

The original permit application and subsequent modification of the application addressed the requirements of Section 1785.17. Pursuant to Section 1785.17(c), the applicant submitted detailed plans for the mining and restoration of the prime farmlands affected by surface mining activities.

1785.17(c)(1): The applicant has submitted a soil survey of the permit area which meets the standards of the National Cooperative Soil Survey. Itemized prime farmland soil map units and soil descriptions can be obtained from the Custom Soil Survey Report provided in the application. Additional reference documents include the NRCS Web Soil Survey and the University of Illinois Agricultural Experiment Station - Bulletin 811, which were used as references to evaluate the pre-mining data.

1785.17(c)(2): The proposed method and type of equipment to be used for removal, storage, and replacement of the soils were described pursuant to Sections 1823.12 and 1823.14. The A, B and C horizons will be removed by conventional equipment used for pipeline installation. Replacement will be with the same equipment.

1785.17(c)(2): Soil will be temporarily stockpiled adjacent to the excavation; plans for identifying the prime soils and plans for soil stabilization before redistribution were submitted in conformance with 1823.13. Stockpile stabilization will occur by establishment of a vegetative cover and mulch, if necessary; these measures will minimize erosion.

1785.17(c)(3): Documents were reviewed supporting the use of B/C horizon mixtures in place of the original B horizon. This information supports the belief that the proposed methods of reclamation will achieve, within a reasonable time, equivalent or higher levels of yield than those of non-mined prime farmland in the surrounding area.

Christ, Richard, 1980, "The Effect of Soil from B and C Horizons on Yield Potential of Soybeans", Unpublished Thesis, Dept. of Plant and Soil Sci., Southern Ill. Univ. Carbondale, Il.

Spindler, D. and J. Bauer, 1986 Prime Farmland Restoration Plans - Planning and Information Needs" Proc. Nat. Assoc. State Land Recl., Sept 1986, Columbia, S.C.

In addition to relying on the above data, the Department has relied on the expertise of its Land Reclamation Division and the fact that thousands of acres of prime farmland and high capability land have met the cropland productivity performance standards using a B/C soil horizon mix. Pipeline and drainage tile installation type activities have a minimum impact on farmland due to the small area of disturbance. The applicant will be following the Illinois Department of Agriculture guidelines for pipeline installation. Based on this evidence, the Department considers it quite probable that the applicant will meet bond release requirements on the prime farmland areas which will be mined and reclaimed.

1785.17(c)(4): Due to the narrow size of the individual fields, yield data was not available for the fields within the permit area. The operator will be required to lime and fertilize the reclaimed prime farmland and cropland fields as needed to bring them to levels required under an optimum level of management. In addition, to satisfy the requirements of Section 1785.17(c)(4), the Department consulted the productivity indexes for each of the soil types on the permit area in "Optimum Crop Productivity Ratings for Illinois Soil", University of Illinois, Bulletin 811.

The Department has determined the soil productivity after mining will be returned to equivalent levels of yield as non-mined prime farmlands of the same soil type in the surrounding area under equivalent management practices, as discussed hereafter.

The Federal Act specifically requires in Section 5l0(d)(1) that two findings be made by the Regulatory Authority in granting a permit to mine on prime farmland; the Department regulations at Section 1785.17 also require a prime farmland finding. Section 510(d)(1) states:

> "In addition to finding the application in compliance with subsection (6) of this section, if the area proposed to be mined contains prime farmland pursuant to Section 507(b)(16), the Regulatory Authority shall, after consultation with the Secretary of Agriculture, and pursuant to regulations issued hereunder by the Secretary of Interior with the concurrence of the Secretary of Agriculture, grant a permit to mine on prime farmland if the Regulatory Authority finds in writing that the operator has the technological capability to restore such mined area, within a reasonable time, to equivalent or higher levels of yield as non-mined

> prime farmland in the surrounding area under equivalent levels of management and can meet the soil reconstruction standards in Section 515(b)(7). Except for compliance with subsection (b), requirements of this paragraph (1) shall apply to all permits issued after the date of enactment of this Act."

The first requirement concerns the operator's technological capability to restore the mined area, within a reasonable time, to equivalent or higher levels of yield as non-mined farmland in the surrounding area under equivalent levels of management. The Department, or the Regulatory Authority has reviewed other data not submitted by the operator which supports the Regulatory Authority's finding:

> Dancer, W. S. and I. Jansen. 1981 "Greenhouse evaluation of solum and substratum materials in the southern Illinois coal field: I Forage crops", Jour. Environ. Qual. 10:396-400.
>
> Powell, J., et al., 1985, "Reclamation of Prime Farmland in Kentucky", Pres Nat. Mtg. of Am. Soc. Surf. Min. and Recl. Oct, Denver, Co.
>
> Spindler, Dean, 1981, "Three Case Studies on Rowcrop Production on Mined Land" prepared for the Symposium on Surface Mining Hydrology, Sedimentation and Reclamation, University of Kentucky, Lexington, KY, December 7-11.

The Regulatory Authority has also reviewed the information from its testing program that thousands of acres of prime farmland and high capability land have met the cropland productivity performance standards. These documents are available for inspection at the Land Reclamation Division Office in Springfield.

The second requirement of Section 510(d)(1) concerns soil reconstruction standards in Section 515(b)(7). The Regulatory Authority has reviewed the application concerning the operator's plan to comply with these requirements and find it complies with Section 515(b)(7) of the Federal Act and Sections 1785.17 and 1823 of the Department's regulations. In addition, the Regulatory Authority has considered the method and equipment to be utilized and has found that the planned method is appropriate to successfully comply with the requirements of 510(d)(1) and Section 1823 of the Department's regulations.

1785.17(d): The Regulatory Authority has consulted with the USDA, Natural Resource Conservation Service (NRCS), designated representative of the Secretary of Agriculture. The Department's consideration of the NRCS comments are addressed in Appendix B.

1785.17(e)(1): The approved post-mine land use of the reclaimed prime farmlands will be cropland.

1785.17(e)(2): The Department has considered the comments of the representative of the U.S. Secretary of Agriculture (NRCS).

1785.17(e)(3): As previously discussed, the Department believes the applicant has the technological capability to restore prime farmland, within a reasonable time, to equivalent or higher levels of yields as non-mined prime farmland.

1785.17(e)(4): The special requirements for prime farmland restoration of Section 1823 have been addressed below in accordance with Section 1785.17(e)(4). Some of the subsections in Section 1823 have been previously addressed by Section 1785.17 discussions. Only those items not previously discussed will be below.

1823.14(a)(1): The minimum depth of the reconstructed prime farmland soil will be 60 inches.

1823.14(a)(2): This section is applicable to the Ava series. The proposed B/C mix for root media will meet or exceed high capability standards.

1823.14(b): Topsoil will be replaced to its premining thickness after the root medium replacement and the area is returned to final grade.

1823.14(c): Compaction will be minimized by handling the soil during dry weather and/or the Department will require a compaction alleviation plan if it is determined that excessive compaction is causing low yields.

1823.14 (d): The permittee will be excavating the B and C horizons immediately underneath the B horizons as part of the pipeline trenching. Pipeline and drainage tile installation type activities have a minimum impact on farmland due to the small area of disturbance. The applicant will be following the Illinois Department of Agriculture guidelines for pipeline installation. The subsoil will be returned to its required thickness.

1823.14 (e): The original A horizon will be replaced. The operator has proposed multiple soil series sources of supplemental topsoil material in the proposed permit area. The department has limited that substitute material to the Rend, Bluford, Hickory-Kell, Okaw, Belknap and Orthent soil series where the subsoil texture is a silt loam. In addition, the pH, phosphorus, and potassium of the borrow materials shall be fertilized with rates to achieve a pH of 6.5, and phosphorus and potassium levels of 50 ponds/acre and 260 pounds/acre, respectively. Please see Part IV Condition No. M. Topsoil will be returned to the required thickness and suitably protected from erosion.

1823.14(f): The applicant has made a commitment for fertilization based on soil tests.

1823.15: The applicant will comply with the seeding and mulching requirements pursuant to Sections 1823.15, 1816.113 and 1816.114.

In making this finding, the Regulatory Authority has relied on available data and opinions of experts, as found relevant to this application. In addition, the Regulatory Authority has relied on the expert technical opinion of its staff. Such reliance was intended by Congress as is apparent in

the legislative history of the Federal Act. At page 105 of the House Conference Report No. 95-493, the Conferees state:

> "It is the intention of the Conferees that the written finding that the regulatory authority is required to make before a permit is granted to mine on prime farmland can be based in part on the expert opinion of the regulatory authority, the operator has the technological capability to perform the soil reconstruction standards of Section 515(b)(7) and the performance of those standards will result in the restoration of the mined area to equivalent or higher levels of agricultural yield as non-mined prime farmland in the surrounding area under equivalent levels of management. This does not mean that mining and restoration must have taken place in the surrounding area, but simply that the operator can show by agricultural school studies, or other data for comparable areas that equivalent yields can be obtained after mining."

This finding is based on significant and substantial evidence and is in keeping with the standards for prime farmland review approved by the Office of Surface Mining. (See letter from Acting Director Reeves to Illinois Director Evilsizer, dated April 7, 1980, which is incorporated by reference.)

This finding is based solely upon characteristics peculiar to this particular operator and the prime farmland soil types involved.

All materials supporting this finding are a part of the public record and are hereby incorporated by reference.

Based upon the foregoing analysis of the probable impact of the proposed operations and a review of the application and Interagency and public comments thereon, the Department finds that there is a reasonable basis on which to issue the permit as requested by the applicant.

Enter on behalf of the Illinois Department of Natural Resources, Office of Mines and Minerals, Land Reclamation Division, as the Regulatory Authority.

If an emerging growth company, indicate by check mark if the registrant has elected not to use the extended transition period for complying with any new or revised financial accounting standards provided pursuant to Section 13(a) of the Exchange Act. ☐

Item 1.01 Entry into a Material Definitive Agreement.

As previously disclosed, on December 13, 2019, Foresight Energy LLC and Foresight Energy Finance Corporation (wholly owned subsidiaries of Foresight Energy LP (the "**Partnership**")) (together, the "**Issuers**") solicited the consent of the holders (the "**Holders**") (such solicitation, the "**Consent Solicitation**") of the Issuers' 11.50% Second Lien Senior Secured Notes due 2023 (the "**Notes**") to amend (such amendments, the "**Amendments**") the indenture governing the Notes (as amended, supplemented or otherwise modified from time to time, the "**Indenture**"), as more fully described below. The Consent Solicitation expired at 5:00 p.m., New York City time, on December 19, 2019 (the "**Expiration Time**").

As of the Expiration Time, the Issuers had received consents to the Amendments from Holders of at least a majority in aggregate principal amount of the outstanding Notes not owned by the Issuers or their affiliates. As a result, on December 19, 2019, the Issuers, the guarantors party thereto and Wilmington Trust, National Association, the trustee (the "**Trustee**") for the Notes, entered into a second supplemental indenture (the "**Second Supplemental Indenture**") providing for the Amendments to the Indenture.

The Amendments (i) amend Section 6.01(b) of the Indenture to extend the grace period for payment of interest due on the Notes from 90 days to 150 days and (ii) amend Section 4.03 of the Indenture to eliminate the requirement that the Issuers periodically hold a publicly accessible conference call to discuss the Issuers' financial information for the relevant fiscal period.
The Partnership continues to engage in discussions with its creditor constituencies and explore potential restructuring alternatives.

The foregoing descriptions of the Amendments, the Second Supplemental Indenture and the Indenture are qualified in their entirety by reference to the full text of the Second Supplemental Indenture, the First Supplemental Indenture dated as of October 30, 2019 and the Indenture, each of which is incorporated herein by reference to **Exhibit 4.1**, **Exhibit 4.2** and **Exhibit 4.3** to this Current Report on Form 8-K, respectively.

Item 3.03 Material Modification to Rights of Security Holders.

The disclosure set forth in Item 1.01 of this Current Report on Form 8-K is incorporated into this item by reference.

CAUTIONARY STATEMENT REGARDING FORWARD-LOOKING STATEMENTS

Certain statements and information in this Current Report on Form 8-K and certain oral statements made by our representatives from time to time may constitute "forward-looking statements." The words "propose," "believe," "expect," "anticipate," "plan," "intend," "foresee," "outlook," "estimate," "potential," "continues," "may," "will," "seek," "approximately," "predict," "anticipate," "should," "would," "could" or other similar expressions are intended to identify forward-looking statements, which are generally not historical in nature. Forward-looking statements also include statements about our liquidity, our capital structure and expected results of operations. These forward-looking statements are based on the Partnership's current expectations and beliefs concerning future developments and their potential effect on us. While management believes that these forward-looking statements are reasonable as and when made, there can be no assurance that the future developments affecting us will be those that we anticipate.

We continue to experience substantial financial, business, operational and reputational risks that threaten our ability to continue as a going concern and could materially affect our present expectations and projections. For additional information regarding known material factors that could cause our actual results to differ from those contained in or implied by forward-looking statements, please see the section entitled "Risk Factors" in the Partnership's Annual Report on Form 10-K for the year ended December 31, 2018, filed with the Securities and Exchange Commission on February 27, 2019 and subsequent Quarterly Reports on Form 10-Q.

You are cautioned not to place undue reliance on forward-looking statements, which are made only as of the date hereof. We undertake no obligation to publicly update or revise any forward-looking statements after the date they are made, whether as a result of new information, future events or otherwise, except as required by law.

Item 9.01 Financial Statements and Exhibits.

Section 2: EX-4.1 (EX-4.1)

EXHIBIT 4.1

SECOND SUPPLEMENTAL INDENTURE

SECOND SUPPLEMENTAL INDENTURE to the Indenture (as defined below) (the "*Supplemental Indenture*"), dated as of December 19, 2019, is made by and among Foresight Energy LLC, a Delaware limited liability company (the "*Company*"), Foresight Energy Finance Corporation, a Delaware corporation ("*Co-Issuer*, and together with the Company, the "*Issuers*"), the guarantors party hereto (the "*Guarantors*") and Wilmington Trust, National Association, as trustee (in such capacity, the "*Trustee*"), and amends the Indenture, dated as of March 28, 2017, among the Issuers, the Guarantors and the Trustee, as amended by the First Supplemental Indenture, dated as of October 30, 2019 (as further amended and supplemented from time to time, the "*Indenture*").

RECITALS:

WHEREAS, pursuant to the Indenture, the Issuers have issued $425,000,000 in aggregate principal amount of 11.50% Second Lien Senior Secured Notes due 2023 (the "*Notes*");

WHEREAS, the Issuers have requested consents of the Holders of the Notes to amend the terms of the Indenture as set forth in Article I herein (the "*Proposed Amendments*");

WHEREAS, pursuant to Section 9.02 of the Indenture, the written consent of Holders of at least a majority in aggregate principal amount of the outstanding Notes (the "*Requisite Consents*") is sufficient to adopt the Proposed Amendments set forth in Article I;

WHEREAS, the holders of at least a majority in aggregate principal amount of the Notes outstanding (which excludes any Notes owned by the Issuers or their affiliates) have validly tendered consents and not validly withdrawn their consents to the adoption of the Proposed Amendments effected by this Supplemental Indenture in accordance with the provisions of the Indenture;

WHEREAS, having received the Requisite Consents for all of the Proposed Amendments, the Issuers and the Guarantors desire to amend the Indenture as provided herein;

WHEREAS, the Issuers have delivered to the Trustee, pursuant to Section 9.02 of the Indenture, an Officer's Certificate stating that the Issuers have received the Requisite Consents, and have provided certification of such receipt to the Trustee;

WHEREAS, the Issuers have also delivered to the Trustee, pursuant to Sections 7.02(b), 9.02 and 9.05 of the Indenture, (i) a resolution of the Board of Directors of the Company authorizing the execution of this Supplemental Indenture, and (ii) an Officer's Certificate and an Opinion of Counsel, each stating that the execution of this Supplemental Indenture is authorized or permitted by the Indenture and that all conditions precedent to the execution and delivery of this Supplemental Indenture have been satisfied; and

WHEREAS, all other conditions and requirements necessary to make this Supplemental Indenture a valid, binding and legal instrument enforceable in accordance with its terms have been performed and fulfilled by the parties hereto, and the execution and delivery thereof have been in all respects duly authorized by the parties hereto.

NOW, THEREFORE, in consideration of the foregoing and for other good and valuable consideration, the receipt and sufficiency of which are hereby acknowledged, the parties mutually covenant and agree for the equal and ratable benefit of the Holders of the Notes as follows:

ARTICLE I
AMENDMENTS

Section 1.01. Amendments to Indenture.

(i) Section 6.01(b) of the Indenture is hereby amended and restated in its entirety to read as follows:

"(b) the Issuers default in the payment of interest on any Note when the same becomes due and payable, and the default continues for a period of 150 days;"

(ii) Section 4.03(d) of the Indenture is hereby deleted and amended and restated to read in its entirety as set forth below:
"(d) [Intentionally omitted]."

(iii) Section 4.03(e) of the Indenture is hereby amended to delete the reference to ", and a publicly accessible quarterly conference call of such Parent".

(iv) The first sentence of Section 4.03(f) of the Indenture is hereby amended to (i) add the word "and" immediately before the word "furnishes", (ii) delete the reference to ", and holds a publicly accessible quarterly conference call" and (iii) replace the reference to "Sections 4.03(a) and (d)" with "Section 4.03(a)".

ARTICLE II
MISCELLANEOUS

Section 2.01. Effectiveness. This Supplemental Indenture shall become effective upon the execution and delivery of the Supplemental Indenture by the parties hereto.

Section 2.02. Confirmation. Except as expressly amended hereby, the Indenture is in all respects ratified and confirmed and all the terms, conditions and provisions thereof shall remain in full force and effect. For the avoidance of doubt, this Supplemental Indenture shall not impair or affect the contractual right of any Holder of a Note or Notes to receive any principal payment or interest payment on such Holder's Note or Notes, on or after the Stated Maturity thereof, or to institute suit for the enforcement of any such payment. Upon the execution and

delivery of this Supplemental Indenture by the Issuers, the Guarantors and the Trustee, this Supplemental Indenture shall form a part of the Indenture for all purposes, and every Holder of Notes heretofore or hereafter authenticated and delivered shall be bound hereby. Any and all references to the Indenture, whether within the Indenture or in any notice, certificate or other instrument or document, shall be deemed to include a reference to this Supplemental Indenture (whether or not made), unless the context shall otherwise require.

Section 2.03. Counterparts. The parties may sign any number of copies of this Supplemental Indenture. Each signed copy shall be an original, but all of them together represent the same agreement. The exchange of copies of this Supplemental Indenture and of signature pages by facsimile, .pdf transmission or other electronic means shall constitute effective execution and delivery of this Supplemental Indenture for all purposes. Signatures of the parties hereto transmitted by facsimile or .pdf transmission or other electronic means shall be deemed to be their original signatures for all purposes.

Section 2.04. Capitalized Terms. Capitalized terms used herein without definition shall have the meanings assigned to them in the Indenture.

Section 2.05. GOVERNING LAW. THIS SUPPLEMENTAL INDENTURE SHALL BE GOVERNED BY AND CONSTRUED IN ACCORDANCE WITH THE LAWS OF THE STATE OF NEW YORK.

Section 2.06. Effect of Headings. The section headings herein are for convenience only and shall not affect the construction hereof.

Section 2.07. Acceptance by the Trustee. The Trustee accepts the amendments to the Indenture effected by this Supplemental Indenture and agrees to execute the trusts created by the Indenture as hereby amended, but only upon the terms and conditions set forth in the Indenture; *provided, however*, that to the extent the Requisite Consents of Holders of Notes to any amendment effected by or delivered in connection with this Supplemental Indenture are determined by a court of competent jurisdiction to have not been validly obtained in accordance with the Indenture or applicable laws, such amendment shall not be deemed to have occurred.

Section 2.08. Trustee Disclaimer. The recitals contained herein and the statements made in any Officer's Certificate shall be taken as the statements of the Issuers, and the Trustee assumes no responsibility for their correctness, and none of the recitals contained herein or the statements made in any Officer's Certificate are intended to or shall be construed as statements made or agreed to by the Trustee. The Trustee makes no representations as to the validity or sufficiency of this Supplemental Indenture or the consequences of any amendment provided herein.

IN WITNESS WHEREOF, the parties hereto have caused this Supplemental Indenture to be duly executed and attested, all as of the date first above written.

Coal analysts say bankruptcy filing is 'increasingly likely' for Illinois Basin's Foresight Energy

November 25, 2019

S&P Global Market Intelligence ($):

One of the few major U.S. coal companies to dodge the bankruptcy court may soon need to file for Chapter 11 restructuring if the current market and economic forces working against the coal industry persist, according to recent securities filings.

Over the past few weeks, Foresight Energy LP exercised an option to delay a $24.4 million interest payment and negotiated the right to skip a publicly accessible quarterly call to discuss its third-quarter finances. As management of the Illinois Basin coal miner management works to restructure its balance sheet, the New York Stock Exchange delisted its stock and Foresight affiliate Murray Energy Corp. filed for a bankruptcy reorganization.

"With a significant debt load and a near-term pricing recovery increasingly unlikely, a Chapter 11 bankruptcy filing appears increasingly likely," B. Riley FBR analyst Lucas Pipes wrote in a Nov. 14 note.

While some coal companies struggled to sell assets even through bankruptcy auctions, Pipes noted that Foresight still owns some attractive mining assets, with its longwall mines capable of producing coal at a lower cost than its peers. However, the company has about $1.25 billion in gross debt on its balance sheet.

"The partnership continues to engage in discussions with its creditor constituencies and is exploring potential restructuring alternatives," Foresight wrote in a Nov. 12 securities filing. "As a result of these discussions and potential restructuring efforts, it may be necessary for us to file a voluntary petition for relief under Chapter 11 of the United States Bankruptcy Code in order to implement a restructuring, or our creditors, under certain circumstances, could force us into an involuntary bankruptcy or liquidation."

Illinois Basin producers turned to a recent boom in export markets to make up for a decline in domestic demand, but that demand is retrenching. In the third quarter of 2018, Foresight captured $140.8 million in international coal sales. In the third quarter of 2019, it reported $34.8 million from export markets, a 75.3% decline. Domestic sales fell from $151.2 million to $146.7 million in the same period.

Responses to Incomplete Comments
Permit Application 456
Williamson Energy, LLC
Williamson County, Illinois

Dear Mr. San Diego:

On behalf of our client, Williamson Energy LLC, Alliance Consulting, Inc. is submitting a copy with original signatures and one duplicate copy to address the Incomplete Comments dated May 18, 2018 (attached).

Response to Comment 1 - Attachment I.2.A. has been revised. Acreage has been added to the table.

Response to Comment 2 - Parcel 11-32-100-003 has been added to Attachment I.2.A.

Response to Comment 3 - Boring operations will be conducted outside of the 100 feet road right-of-way for all road crossings. All references to trenching through roads have been removed from the Hydrology-Mining Operation Maps (Drawing Nos. B17-222-M13 – M16) and Part I.12.B.4 has been revised to indicate no roads will be closed.

Response to Comment 4 - Boring operations will be conducted outside of the 100 feet road right-of-way for all road crossings. No agreements will be needed from the county highway department.

Response to Comment 5 - The public notice has been revised per the comment.

Response to Comment 6 - The narrative for Part I.12.C.4 has been revised. All references to trenching across the roads have been removed. Boring operations will be conducted outside the 100 feet road buffer zones. A

124 Philpott Lane ▯ Raleigh County Airport Industrial Park ▯ Beaver, WV 25813-9502 ▯ TELE (304) 255-0491 ▯ FAX (304) 255-4232

	variance is requested for construction/installation operations for areas adjacent to the public roads.
Response to Comment 7 -	Typical cross sections have been included in Attachment IV.7.I.
Response to Comment 8 -	All references to "preliminary designs" have been removed.
Response to Comment 9 -	Part IV.7.I has been revised to address ephemeral streams.
Response to Comment 10.a. -	Refer to the revised Attachment II.8 for the requested information.
Response to Comment 10.b. -	Part V.3.B.4 has been revised to include the requested information.
Response to Comment 10.c. -	Refer to the revised Attachment II.8 for the requested information.
Response to Comment 11 -	Attachment V.1.D.2.b has been revised to include a permanent wetland vegetation species list and reclamation plan.

If you have any questions, or require additional information, please contact us.

Sincerely,

Re: Application No. 456
Response Dated April 2018

Dear Mr. Pollastro:

This letter will serve as notice that the permit application for Pond Creek Mine, submitted in response to the Department's incomplete letter dated November 6, 2017, under the Surface Coal Mining Land Conservation and Reclamation Act and the promulgated rules and regulations, is **not** administratively complete for review.

The following points must be addressed by the applicant for the Department to continue its review process:

1. Response to Part I.2 and I.3, property owners and locations, appears to be incomplete. Attachment I.2.B indicates many property owners have Easements with the applicant and others do not. The applicant is required to provide land owner waiver documents from surface property owners for areas the applicant does not control, for inclusion in the application for an application to be deemed administratively complete. Additionally, the applicant did not provide acreage figures to determine percentage of controlled/uncontrolled property.

2. One parcel ID No. 11-32-100-003, indicated on Identification of Interest Map 4, shows a portion of the proposed boundary from the NW before crossing under Lake Creek Road. This property is not listed in Attachment I.2.B. The applicant shall verify whether this is a mapping error or revise/update Attachment I.2.B.

   Additionally, if this parcel is to be included, the applicant shall provide the required information indicating right of entry or landowner waiver for inclusion in the application.

3. The applicant has provided agreements with the local road authorities for operations within the road right of ways. The agreements indicate all crossings to be bored under. The applicant indicates road crossings will be bored under and trenched through. Road agreements provided from Williamson and Franklin County Highway Departments indicate operations shall be within the right of way of the roads and do not allow trenching. The Hydrology - Mining Operations Maps indicate some areas to be trenched and roads closed. This information conflicts with the road authority agreements and shall require attention.

   Further, Part I.12.B.4 indicates roads will be closed. Review of the road agreements does not indicate the applicant has the authority to close roads. If the applicant is to close roads, the public notice must be revised to indicate an approximate time and duration of the closure for each road to be closed.

4. Review of the Ownership Identification Map Drawings M1, M2, M3 and M4 indicates public roads not discussed in the Franklin County Highway Department agreement. The applicant needs to clarify the crossings and locations of Horseshoe Road, Deason Road, Sandburg Road, Gossage Road Lake Creek Road and Cheatman Road. The Applicant needs to verify whether operations for crossing these roads are within each road's right of way or within 100 feet of the outside right of way.

5. The Department found discrepancies in the locations of the following roads:

   The public notice indicates Deason Road is in the NE/4 T7S, R2E, Section 28 and SW/4 Sec 27. Review of the map indicates Deason Road runs N/S at the corners; Sec28, SE; Sec 27, SW; Sec 34, NW; Sec 33 NE. The applicant will need to revise the notice.

   Similarly, Lake Creek Road is along the north border of Sections 32, 31 and 30; and south borders of Sections 29 and 30. The public notice states the road is in the NE/4 of Section 30.

6. The applicant requests a variance for operations within 100 feet of the right of way of a road, in response to Part I.12.C.4. The operations proposed do not allow for a variance.

7. The applicant failed to provide a cross section depicting stream crossings, as requested per Comment 21 of the Incomplete Letter sent by the Department on November 6, 2017. Pursuant to 62 Ill. Adm. Code 1784.23(b)(6), the applicant shall provide design cross sections of the stream crossings proposed for the perennial stream Pond Creek and the 8 intermittent and the ephemeral streams' crossings. All stream crossings' cross sections shall include details, including but not limited to: the depth at which the waterline will be buried under the streambed, the watershed area that the stream is draining at the point of

construction, and any protection measures to be used on stream crossings to prevent water pollution and damage to public and private property.

8. The applicant provided preliminary engineering design in response to Part IV.5.C.2 and stated that specifics of the waterline hydraulic design such as pipe sizes and location of fittings will be provided before the installation of the pipeline. To ensure compliance with 62 Ill. Adm. Code 1784.30, the applicant shall provide detailed engineering design before the application can be deemed approved after technical review. The applicant shall provide a schedule with the dates when any detailed design plans for the waterline that are not submitted with the general plan will be submitted to the Department. The Department shall have approved, in writing, the detailed design plan for the water pipeline before construction of the structure begins.

9. The applicant has supplied a Wetland and Stream Delineation Report as Attachment II.9 in Part II of the application. The report identified 9 streams categorized as ephemeral to be disturbed. The applicant has failed to provide a justification for any stream characterized as ephemeral based on Department regulations as requested in Comment 10 (b.) of the Incomplete Letter sent by the Department on November 6, 2017. Please refer to Operator Memorandum No. 2017-06 for further explanation regarding ephemeral stream justifications. The names and qualifications of the person(s) making the determination shall be supplied. Should any of the streams not meet the criteria of an ephemeral stream based on Department regulations, a request to be exempt from the 100 ft. buffer requirements should be included.

10. The application indicates a total of 20.1 acres of Wildlife Woody pre-mining land use and the description of this habitat supplied in Part II(9) of the application includes woody species that are suitable summer Indiana bat and northern long-eared bat habitat. The applicant shall supply the following information in **Part V(3)(B)(4)** of the application:

    a. The applicant has included the bat survey results as Attachment V.3.B.4., but has failed to update the response to **Part V(3)(B)(4)** that states the proposed permit area is scheduled to be surveyed for threatened and endangered bat species beginning May 17, 2017.

    b. The applicant has provided an Indiana Bat Protection and Enhancement Plan in Part II of the application but failed to include an Incidental Take authorization request for the Indiana bat meeting the specifications of the "Range-wide Indiana Bat Protection and Enhancement Plan Guidelines" (revised 2013) developed by the U.S. Fish and Wildlife Service and the Office of Surface Mining, or justify why an incidental take authorization request is not required under those guidelines. If needed, the incidental take table provided in the 2013 Guidelines should be included with the PEP.

c. The applicant failed to update Part V(3)(B)(4) discussing whether or not the project is consistent with the northern long-eared bat Final 4(d) Rule (January 2016).

11. The applicant has failed to supply a Wildlife Wetland species list or wetland reclamation plan, as requested in Comment 12 of the Incomplete Letter sent by the Department on November 6, 2017. The applicant has supplied a Wetland and Stream Delineation Report as Attachment II.9 in Part II of the application. The report delineated 31 wetlands totaling approximately 6.73 acres to be disturbed. Upon review, Attachment V.1.D.2.b does not include a Wildlife Wetland species list or reclamation plan. The applicant shall provide measures to comply with 62 Ill. Adm. Code 1816.97(f) and include a permanent wetland vegetation species list and reclamation plan that is compatible with the Corp of Engineers Wetland Delineation Manual.

Upon submission of a new application, complete with the above listed information included, the Department will again review the permit application to determine if it is administratively complete.

Should you have any questions, please contact this office.

Sincerely,

Nick San Diego, Supervisor
Land Reclamation Division

Responses to Incomplete Comments
Permit Application 456
Williamson Energy, LLC
Williamson County, Illinois

Dear Mr. San Diego:

On behalf of our client, Williamson Energy LLC, Alliance Consulting, Inc. is submitting a copy with original signatures and one duplicate copy to address the Incomplete Comments dated November 6, 2017 (attached).

Response to Comment 1 - Document information has been added to Attachment I.2.A.

Response to Comment 2 - The Identification of Interests Maps (Drawing Nos. B17-222-E1 through E4) and Attachments I.2.A & B have been revised per Williamson and Franklin Counties GIS property database.

Response to Comment 3 - Refer to the revised Ownership and Control information being submitted.

Response to Comment 4 - The public notice has been revised to address mining activities within 100 feet the right of way of roads.

Response to Comment 5 - The public notice refers to activities around "Horseshoe Road along the northeast quarter of Township 7 South, Range 2 East, Section 34 and the southwest quarter of Township 7 South, Range 2 East, Section 34". The public notice has been revised to reference activities around "Horseshoe Road along the northeast quarter of Township 7 South, Range 2 East, Section 34 and the ***northwest*** quarter of Township 7 South, Range 2 East, Section 34". No reference was found for activities around Horseshoe Road and southwest quarter of Section *28* and 34.

124 Philpott Lane □ Raleigh County Airport Industrial Park □ Beaver, WV 25813-9502 □ TELE (304) 255-0491 □ FAX (304) 255-4232

Response to Comment 6 - Refer to Attachment I.12.B.4 – Illinois Department of Transportation for additional information concerning the road utility permits.

Response to Comment 7 - Part I.12.C.1 has been revised. The reference to 1761.14(d) has been corrected and the narrative now refers to Section 1761.14(b).

Response to Comment 8 - Refer to the revised narrative in Part III.2.A.1. for the clarification.

Response to Comment 9 - Part II.13.D has been revised per the comment.

Response to Comment 10.a. – f. - Refer to the revised Attachment II.8 for the requested information.

Response to Comment 11.a. – c. - Refer to the revised Attachment V.3.B.4 for the requested information.

Response to Comment 12 - Attachment V.1.D.2.b has been revised to include a permanent wetland vegetation species list and reclamation plan.

Response to Comment 13.a - The map legend has been corrected.

Response to Comment 13.b - The Cumulative Impact Area drainage area has been added to the CIA map (Drawing No. B17-222-E2). A drainage area for the pipeline installation was not delineated because of the short-term disturbance associated with the pipeline installation. The map legend has been corrected.

Response to Comment 14 - The six stream monitoring points, which are existing, are utilized for the existing cumulative impact area (mine area) and not for the proposed Water Management Pipeline. Per a conference call on July 15, 2017 with the IDNR hydrologist, it was discussed and agreed that the pipeline would not affect the currently approved CIA because the pipeline would not impact the surface and groundwater systems. Part III.2.D.1.a. states that the pipeline will not change the surface water and groundwater systems, drainage patterns and storm water runoff characteristics. This statement has been added to the narrative located under the Cumulative Hydrologic Impact Area section of Part III.2.D.1.a. – Water Management. The narrative in Part III.2.D.1.a. – Surface Water Sampling Points has been revised to indicate that Sites PC-1 and

PC-2 will be the only surface water sites associated with the Water Management Pipeline.

Response to Comment 15 - Per the comment, Part I.1.G has been revised to indicate the pipeline is a Support Facility and Part IV.5.B. have been revised to indicate the pipeline is a Mine Support Area.

Response to Comment 16 - A signed Engineering Certification has been included.

Response to Comment 17 - Copies of the Franklin County road agreements are included.

Response to Comment 18 - Part II.1 has been revised per the comment.

Response to Comment 19.a - Refer to the revised Attachment IV.1, which addresses installation of the pipeline crossing railroads

Response to Comment 19.b - Refer to Attachment IV.1 for information concerning the location of the gas line.

Response to Comment 20.a - A small soil storage area has been shown on the Hydrologic/Mining Operations Map – Sheet 4 (Drawing No. B17-222-M16). Refer to Attachment IV.1 under the narrative for the Big Muddy River for additional information.

Response to Comment 20.b - A proposed power line will be located within the permit boundary and will run from the intersection of Lake Creek Road to the proposed maintenance building/pump house. The power line has been added to the Hydrologic/Mining Operations Map – Sheet 4 (Drawing No. B17-222-M16). Refer to Attachment IV.1 under the narrative for the Big Muddy River for additional information.

Response to Comment 21 - Refer to Part IV.7.I for information on measures to be taken to prevent erosion, water pollution and stream channel stability.

Response to Comment 22 - Part IV.7.K.2 has been revised and contact will be made with IDNR-OWR for the Pond Creek crossing.

Response to Comment 23.a - Refer to Part IV.5.C.2 for additional information concerning the installation Water Control Structure at the Diffuser site

Response to Comment 23.b - Refer to the revised Part IV.5.C.2 narrative for additional information. Use word "wyes" has been removed and replaced with the word "elbows". At this time no wyes are proposed.

Refer to Attachment IV.5.C.2 for a description of the design for the pipeline and diffuser site.

If you have any questions, or require additional information, please contact us.

Sincerely,

ALLIANCE CONSULTING, INC.

Carson Pollastro
Williamson Energy, LLC
PO Box 99
Johnston City, IL 62951

Re: Application No. 456, Incomplete

Dear Mr. Pollastro:

This letter will serve as notice that the permit application for Pond Creek Mine, submitted under the Surface Coal Mining Land Conservation and Reclamation Act and the promulgated rules and regulations, is **not** administratively complete for review.

The following points must be addressed by the applicant in order for the Department to continue its review process:

1. The applicant, in its response to Part I.2.A, Property Ownership within the proposed boundary, did not provide the acreage for each of the surface owners, type of document conveying right of entry or landowner waiver to have the property included in the application. The applicant shall update Attachment I.2.A to include each property owner's acreage in the proposed area, the date of, and type of document that allows the applicant to enter and operate as proposed, and if no agreement has been reached with a property owner, a waiver allowing the applicant to include the property in the application.

2. Upon review of the Ownership Identification Map Drawings in conjunction with Attachment I.2.A, the reviewer finds several parcels listed on the maps that are not included in the list. Conversely, review indicates listings in Attachment I.2.A that cannot be located on the maps; one parcel located on Map 4 is listed as two different property owners. The list and maps must be updated to reflect correct information for location and property ownership.

3. The applicant, in response to Part I.9 has provided lists of violations for companies owned/controlled by the applicant and owners/controllers of the applicant. Review of the lists indicates several violations that are not marked "terminated" or "abated" and have no documentation whether the violations are being corrected in good faith with the issuing agency. The applicant shall, for all active violations listed (those not indicated as

"terminated" or "abated") provide current documentation to indicate the company is working with the issuing agency to resolve the issue.

During completeness review the Department finds a cessation order issued to Maple Creek Mining, Inc. which has links with the ownership of the applicant. Although this violation occurred after the submittal of your application, the Department is notifying you this violation will be included in technical review if it has not been abated.

4. The applicant indicates roads may be temporarily closed, in response to Part I.12.B.4. Upon review of the Hydrology – Mining Operations Map and public notice submitted, the reviewer finds the public notice inadequate as it does not indicate specific operations within 100 feet of the outside right of way of each road.

Further, the public notice provided indicates activities around Horseshoe Road in the SW/4 of Sec 28 and 34, T7S, R2E. Hydrology – Mining Operations Map does not indicate the proposed area in this location.

Public notice will be reviewed for compliance upon receipt of all changes outlined in this letter.

6. The applicant indicates copies of road agreements shall be provided upon execution with the road authorities. Agreements were received from the Williamson County Highway Department and Illinois Department of Transportation. Agreements with the Illinois Department of Transportation indicate operations shall be completed within 180 days of approval or agreements are null and void. Agreements were signed February of 2017.

7. The applicant, in response to Part I.12.C.1 indicates, "Variance of Section 1761.14(d) is requested." This is not a valid regulation and shall be corrected.

8. Pursuant to 62 Ill. Adm. Code 1783.12, Attachment II.10.A must be modified to reflect any updates to the status of the Cultural and historical survey.

9. Pursuant to 62 Ill. Adm. Code 1783.21, Part II.13.D, page II-7 must be modified to agree with the topsoil removal thickness handling procedure outlined in Part IV.2.B.3, page IV-2.

10. The response to Part II.8 of the application references Attachment II.8. The applicant is required to provide information on site specific resources such as threatened and endangered species, other protected species, and potential habitats of high value. An EcoCAT Consultation has been provided as part of this application in Attachment II.8. This document only provides locality data for recorded occurrences. The applicant is required to update Part II.8 of the application with, at minimum, the following information:

a. For Wildlife Wetland Pre-Mining Land Use located within the proposed permit area, discuss how these areas will be avoided or replaced, and enhanced where applicable and provide general information on the steps taken to comply with the Section 404 of the Clean Water Act (1784.13(b)(9)). In addition, any wetland assessments conducted should be included in the application.
b. Based on aerial maps, the proposed pipeline appears to cross several streams/surface water bodies. The applicant shall characterize each of these streams using the definitions of ephemeral, intermittent, and perennial streams found in Appendix A Section 1701 of the Department regulations. Further, for any stream characterized as ephemeral a justification must be supplied for this determination based on Department regulations. The names and qualifications of the person(s) making the determination shall be supplied. If an ephemeral stream justification is applicable, please refer to Operator Memorandum No. 2017-06 for further explanation.
c. Should any of the streams meet the criteria of intermittent or perennial all applicable parts of the application shall be completed. This includes, but is but not limited to, adherence to or request to be exempt from the 100 ft. buffer requirements and Part 6 of the application regarding stream diversions/relocations.
d. Provide a complete threatened and endangered species list for both state and federally listed species that are known to occur within the county(ies) of the proposed permit area and each adjacent county. This information may have been submitted as part of previous approved permit applications. Referencing this material is acceptable, however the materials must be provided for Department review and evaluation per Operator Memorandum No. 90-08. The following resource is also suggested; https://www.dnr.illinois.gov/ESPB/Documents/ET_by_County.pdf
e. For each threatened and endangered species listed provide a determination based on species habitat requirements regarding the likelihood that the species may occur within the proposed permit and adjacent half mile area. In addition, provide the rationale justifying the determination. The names and qualifications of the person(s) making the determination shall be supplied.
f. For any state or federally listed threatened or endangered species deemed likely to occur in the permit or adjacent area provide a Protection and Enhancement Plan or justify why one is not necessary (not including the Indiana bat and northern-long eared bat as these species are handled in Part V of the application).

11. The application indicates a total of 20.1 acres of Wildlife Woody pre-mining land use and the description of this habitat supplied in Part II.9 of the application includes woody species that are suitable summer Indiana bat and northern long-eared bat habitat. The applicant shall supply the following information in Part V.3.B.4 of the application:

a. The response to Part V.3.B.4 states that the proposed permit area is scheduled to be surveyed for threatened and endangered bat species beginning May 17, 2017. The applicant shall update this response to include any results from these surveys.
b. Provide a Protection and Enhancement Plan and an Incidental Take authorization request for the Indiana bat meeting the specifications of the "Range-wide Indiana Bat

Protection and Enhancement Plan Guidelines" (revised 2013) developed by the U.S. Fish and Wildlife Service and the Office of Surface Mining, or justify why a Protection and Enhancement Plan and Incidental Take authorization request are not required under those guidelines.

c. Discuss whether or not the project is consistent with the northern long-eared bat Final 4(d) Rule (January 2016), and if not then provide a Protection and Enhancement Plan and Incidental Take authorization request that is consistent with the 2013 Indiana bat guidelines referenced above.

12. Attachment V.1.D.2.b does not include a Wildlife Wetland species list or reclamation plan. Should the applicant plan to disturb wetland habitat, a permanent wetland vegetation species list and reclamation plan that is compatible with the Corp of Engineers Wetland Delineation Manual shall be supplied.

13. The following concern the response to Part III.2.D.1.a:

a. On page 6, the applicant labeled Permit 417 as "Area No. 4", however, on the Cumulative Impacts Area Map, the area is labeled as "Area No. 3". Pursuant to 62 Ill. Adm. Code 1783.25 the applicant shall correct this discrepancy.
b. The applicant describes the cumulative impact area as the currently permitted area, the proposed pipeline, and the upstream drainage area of the unnamed tributary to Pond Creek as well as the downstream watershed areas leading to stream monitoring point PC-2. The cumulative impact area map only shows the currently permitted area and the pipeline as the cumulative impact area. Pursuant to 62 Ill. Adm. Code 1784.14(c) the applicant shall address this discrepancy.

14. The applicant has proposed to utilize six stream monitoring points in the vicinity of Permit No. 375. Pursuant to 62 Ill. Adm. Code 1784.14(i)(2) the applicant shall discuss how these stream monitoring points will be used to determine the impacts of the proposed pipeline.

15. In response to Part I.1.G, the applicant indicated the type of disturbance proposed is "other" and associated acreage for this type of disturbance to be 70.7 acres. Also, in response to Part IV.5.B, the applicant indicates that the type of support facility of the proposed waterline is "other". Pursuant 62 Ill. Adm. Code 1761.16(b)(1)(D), the applicant shall revise the response in Part I.1.G to define the proposed acreage to be affected by the installation of a water pipeline as a "Support Facility" type of disturbance. The applicant shall also revise response in Part IV.5.B to described proposed operations as construction of a "Mine Support Area".

16. Pursuant 62 Ill. Adm. Code 1783.25(b), the engineering certification shall include the signature and seal of a qualified registered professional engineer.

17. The applicant has provided road and highway authority agreements for operations within 100 feet of the ROW of Interstate 57, State Route 37 and Williamson County roads. However, an agreement with the Franklin County Road Authority was not included. Pursuant 62 Ill. Adm. Code 1761.14(b)(2), the applicant shall provide an agreement with the Franklin County Road Authority for operations within 100 feet of the ROW of Horseshoe Road, County Highway 6, Deason Road, Sandburg Road, Freeman Spur road, Gossage Road Lake Creek Road and Cheatman Road.

18. Pursuant 62 Ill. Adm. Code 1817.11, response in Part II.1 shall be revised to explain how the permit area perimeter will be marked and how perimeter markers will be set along it.

19. To ensure compliance with 62 Ill. Adm. Code 1817.180, the applicant shall address the following items:

    a. The Hydrology/Mining Operations maps show that the proposed water pipeline will cross two railroad tracks, one about 500 feet north of the Johnston City limits, and another railroad track about 770 feet west of Deason Rd, northwest of Freeman Spur. The applicant shall expand the narrative in response to Part IV.1 to provide details on how the waterline will pass through the railroads and what provisions will be taken to minimize damage or destruction to the railroad tracks and to minimize or prevent disruption of the railroad services.
    b. The Hydrology/Mining Operations maps also show a gas line that seems to be right next to, or in some sections, overlapping with the proposed water pipeline at different locations. Describe measures that will be taken to minimize damage or destruction to the gas line, prevent disruption of the gas line service and protect the public and the environment from any gas line rupture.

20. Drawing M16 shows a plan view of the 'Diffuser Site'. The applicant shall address the following items:

    a. The applicant has failed to provide a narrative in response to Part IV.2.B on how topsoil and subsoil from the area of the Diffuser Site will be removed and stored. To ensure compliance with 62 Ill. Adm. Code 1784.13(b)(4), the applicant shall explain how it will handle the soil material on the Diffuser Site and show location of topsoil and subsoil stockpiles on the plan view of the area.
    b. Power lines and power poles are depicted on the plan view of the 'Diffuser Site'. The power lines and power poles seem to continue along the water pipeline from the Diffuser Site to the east. The applicant shall clarify if power lines and power poles will be installed along the entire extent of the water line in response to Part IV.1. If power lines and power poles will be installed, this construction operation needs to be described and, power line and power poles along the water pipeline shall be depicted on the Mining Operations maps.

21. Response in Part IV.7.I states the water pipeline will be bored under Pond Creek and that there will be other crossings of ephemeral streams. Pursuant 62 Ill. Adm. Code 1784.30, the applicant shall provide details on how the water pipeline will cross Pond Creek and all the other ephemeral streams that are anticipated to be crossed. Details should be provided in the narrative in response to Part IV.1 about measures that will be taken to prevent erosion, water pollution and stream channel stability when boring under the streams. Appropriate cross sections of the stream crossings shall also be provided.

22. The point at which the applicant is proposing to cross Pond Creek serves an area of approximately 36 square miles. The applicant shall revise the response in Part IV.7.K.2 to answer positively. The applicant shall also contact the Office of Water Resources to discuss the need of obtaining a permit for the proposed construction activities under Pond Creek.

23. Pursuant 62 Ill. Adm. Code 1784.11(b)(6), the applicant shall provide more specifications on the operation of the proposed water pipeline. Details shall be provided on:

    a. Water control structure that are necessary for the operations of the Water Management Pipeline as mentioned on Page 3 of Attachment IV.1 and that will be installed at the Diffuser Site.
    b. Engineering design of pumping and piping system including location and design of anticipated provisions stated by the application in response to Part IV.5.C.2 such as air valves, joints, thrust blocks and wyes.

Upon submission of a new application complete with the above listed information included, the Department will again review the permit application to determine if it is administratively complete.

Should you have any questions, please contact this office.

Sincerely,

Scott K. Fowler, Supervisor
Land Reclamation Division

Re: Williamson Energy, LLC - Permit Application 456 for Water Management Pipeline

Dear Mr. San Diego:

This letter authorizes Alliance Consulting, Inc. (Alliance), and its representatives, permission to perform work on, receive comments and submit corrections on the above referenced permit application. Please send copies of any comments to Alliance Consulting, Inc. at 124 Philpott Lane, Beaver, WV 25813, as well as Williamson Energy, LLC at the above address.

Thank you for your cooperation.

Sincerely,

WILLIAMSON ENERGY, LLC

Mark Schuerger
Authorized Agent

Office of Mines and Minerals
Land Reclamation Division
One Natural Resources Way
Springfield, IL 62702-1271

APPLICATIOPN FOR SURFACE COAL MINING AND RECLAMATION OPERATIONS
PERMIT – UNDERGROUND OPERATIONS
UCM-1

PART I

(Application to be submitted 120 days (180 days for NPDES) prior to the desired effective date of the permit)

DATE: **7-13-18**

NOTICE
This state agency is requesting disclosure of information that is necessary to accomplish the statutory purpose as outlined under Ill. Rev. Stat. 1989, ch. 96 1/2, par. 7901 et seq. Disclosure of this information is voluntary, however failure to comply may result in this form not being processed. This form has been approved by the Forms Management Center.

1) A) General Information

(~~I~~) (~~We~~) (The) **Williamson Energy, LLC**
(Name of Company, Corporation, Partnership or Individual)
P. O. Box 99, Johnson City, IL 62951 **(618) 983-3020**
(Address) (Telephone Number)

hereby submit application # 456 for a permit to mine during a permit term of 5 years.

Type of Application:

[X] Underground Mining
[ ] Revision No. _____ to Permit No. _____
[ ] Shadow Area Addition
[ ] Renewal No._____ to Permit No. _____
[ ] Transfer of Permit No. _____
[ ] Acres to be added under renewal

Applicant's Social Security No. _____ (Voluntary) and/or Federal Employer Identification No. **20-0888529**.

Name of Mine **Pond Creek 1 (Mach #1 Mine)**.

MSHA ID No. **11-03141(Mine);**
IL08-03141-02 (Refuse Facility No. 2) & IL08-03141-03 (Refuse Facility No. 3).
List the Mine Safety and Health Administration (MSHA) number(s) for all mine associated structures that require MSHA approval.

I, **Mark Schuerger** _____ **Authorized Person**
Name Signature Title

under penalties of perjury declare that I have examined this application, including accompanying statements and documents and to the best of my knowledge it is true, and correct. (Signee must be at least a vice president or duly authorized representative for NPDES 35 Ill. Adm. Code 309.103(e))

This application is also to be used to apply for a:

IEPA Subtitle D (State) Permit Yes _____ No X NPDES Yes _____ No X

New _____
Renewal No. _____ Date: _____
Renewal No. _____ Date: _____
Modification No. _____ Date: _____
Modification No. _____ Date: _____

If this is an application for a NPDES permit, the Consolidated Permits Program - Application Form 2C (renewal), Form 2D (new), or Form 2E (sanitary) must be completed.

B) I _____
(vice president or his duly authorized representative)

hereby waive my right of the 90-day permit issuance deadline as required by the Illinois Environmental Protection Act, Section 39(a)(4) and the Illinois Pollution Control Board Rules and Regulations, 35 Ill. Adm. Code 309.225(c).

C) Who will be the operator of the permit site?
Name **Mach Mining, LLC**

Pursuant to 62 Ill. Adm. Code 1701.5 an operator is any person engaged in coal mining who removes or intends to remove more than 250 tons of coal.

If the operator is different from the applicant, provide the following information.

1) Operator's address **P. O. Box 300**
Johnston City, IL 62951

2) Operator's telephone No. **(618) 983-3020**

3) Operator's Social Security No.
(voluntary) and/or Federal Employer Identification No. **73-1734826**.

D) Who will extract coal under this permit?
Name **Mach Mining, LLC**

If different from applicant or operator provide the following:

1) Address **N/A**

2) Telephone No. _____
3) Social Security No. (Voluntary) and/or federal employer Identification No. _____

E) Who will pay abandoned mine land reclamation fees?
Name **Williamson Energy, LLC**

If the person paying the abandoned mine land reclamation fee is different from the applicant, provide the following information.

1) Address _____

2) Telephone No. _____

3) Payee's Social Security No. _____
(voluntary) and/or Federal Employer Identification No. _____

F) The permittee requests a permit on the following area as shown on the permit map.

				Location		
Mine Address	Pit No. or Name	Acres to be Permitted	Sec.	Twp.	Range	County
16468 Liberty School Road, Marion, IL 62959	**Water Management Pipeline**	**4.5**	**1**	**T8S**	**R2E**	**Williamson**
		4.7	**2**	**T8S**	**R2E**	
		3.0	**12**	**T8S**	**R2E**	
		6.4	**7**	**T8S**	**R3E**	
		3.4	**8**	**T8S**	**R3E**	
		4.9	**9**	**T8S**	**R3E**	
		2.1	**11**	**T8S**	**R3E**	
		4.1	**14**	**T8S**	**R3E**	
		6.3	**15**	**T8S**	**R3E**	
		0.9	**16**	**T8S**	**R3E**	
		4.0	**17**	**T8S**	**R3E**	
		1.9	**27**	**T7S**	**R2E**	**Franklin**
		6.2	**28**	**T7S**	**R2E**	
		3.7	**29**	**T7S**	**R2E**	
		0.1	**30**	**T7S**	**R2E**	
		4.9	**31**	**T7S**	**R2E**	
		0.4	**32**	**T7S**	**R2E**	
		5.6	**34**	**T7S**	**R2E**	
		3.6	**35**	**T7S**	**R2E**	

Total Acres **70.7**

G. Indicate the type of disturbance and associated acreage.

Acres		Type of Disturbance
0.0		Deep Mine Entries, Ventilation, Air Shafts
0.0		Mine Waste Areas
70.7		Processing Areas & Support Facilities
0.0		Access, Haul Roads, & Transport Facilities
0.0		Soil Storage Areas
0.0		Diversions
0.0		Other
0.0		Not to be Disturbed

H) For each phase (permit) of the proposed surface coal mining and reclamation operation over the life of the mine provide the anticipated or actual starting and termination date and the anticipated number of acres to

be affected. Designate the boundaries of each phase on the pre-mining land use map or other designated map.

Phases (Permits)	Starting Date	Termination Date	Acres to be Affected
Water Management Pipeline	**06/18**	**End of Mining**	**70.7**

2) A) Provide name and address of every legal or equitable owner of record of the permit area, and the mineral property to be mined.

RESPONSE: **Refer to Attachment I.2.A. for a list of surface owners. No mineral will be removed and no mineral owners are listed.**

B) Provide name and address of the owner of record for all surface and subsurface areas contiguous to any part of the proposed permit area.

RESPONSE: **Refer to Attachment I.2.B. for a list of contiguous surface owners. No mineral will be removed and no mineral owners are listed.**

C) Show location of owners of record of those lands, both surface and subsurface, included in or contiguous to the permit area on premining land use map or another map, if necessary.

RESPONSE: **Refer to the Ownership Identification map (Drawing Nos. B17-222-M1, M2, M3 and M4).**

3) A) Provide name and address of any holder of record of leasehold interest for the permit area, and the mineral property to be mined.

RESPONSE: **Mineral property will not be disturbed. This application addresses the surface facilities associated with the adjacent Permit 375 site.**

B) Provide a statement of all lands, interest in lands, options or pending bids on interest held or made by the applicant for lands, which are contiguous to the permit area.

RESPONSE: **N/A**

4) Provide name and address of any purchaser of record under a real estate contract of the property for the permit area.

RESPONSE: **N/A.**

5) A) The applicant is: _____**X**_____ corporation, _____ partnership, _____ single proprietorship, _____ association or other business entity.

B) For the resident agent who will accept service of process for the applicant provide the following information.

1) Name of resident agent **Illinois Corporation Service Company**.

2) Address **801 Adlai Stevenson Drive, Springfield, IL 62703**

3) Telephone No. **(800) 877-2556**

4) Social Security No. _____ (voluntary) and/or Federal Employer Identification No. **81-0669143**.

6) OWNERSHIP AND CONTROL INFORMATION

Ownership and control is evidenced by being the permittee of a surface coal mining operation, or by being the owner of record of 50 percent or more of an entity controlling a surface coal mining operation or by having any relationship, which gives direct or indirect authority over an entity controlling a surface coal mining operation.

Ownership and control is presumed if an entity is an officer or director; is an operator of a surface coal mining operation; has the authority to commit the financial or real property assets or working resources of an entity; is the owner of record of ten (10) through fifty (50) percent of an entity; is a general partner of a partnership; owns or controls coal to be mined by another entity and has the right to receive that coal after mining; or has the authority to determine how the surface coal mining operations will be conducted.

For an entity to refute a presumed ownership and control relationship, the entity must demonstrate to the satisfaction of the Department that the entity subject to the presumption does not have the authority directly or indirectly to determine the manner in which the relevant surface coal mining operation is conducted.

A) For each entity who owns or controls the applicant provide the following information.

1) Name of entity _____.

2) Address _____
_____

3) Social Security No. _____ (voluntary) and/or Federal Employer Identification No._____.

4) The entity's specific ownership and control relationship with the applicant _____

If more than one ownership and control relationship exists, list each relationship separately under this part providing all information requested.

a) Percentage of ownership if any _____.

b) Location in organizational structure _____
_____.

c) Position title _____.

i) Date position was assumed _____.

ii) Date of departure from position _____.

RESPONSE: **Refer to Attachment Part I; Item 6.A. for the ownership and control information.**

B) For each surface coal mining and reclamation operation in the United States either presently owned or controlled or owned or controlled within the five (5) years preceding the date of the application by the entity listed in (A) above provide the following information.

RESPONSE: **Refer to Attachment Part I; Item 6.A. for the list of coal mining and reclamation operations owned and/or controlled within the last 5 years.**

1) Name _____.

2) Address _____.

3) Name of regulatory authority _____.

4) Identification number.

a) Social security No. _____ (voluntary) and/or federal employer identification No. _____.

b) Federal permit No. _____.

c) State permit No. _____.

d) MSHA No. _____ and date of issuance _____.

7) For each surface coal mining operation in the United States owned or controlled by the applicant provide the following information.

RESPONSE: **Refer to Attachment Part I; Item 6.A. for the list of coal mining operations owned or controlled by the applicant.**

a) Name of Operation _____.

b) Address of Operation _____.
_____.

c) Name of regulatory authority _____.

d) Identification number:
i) Social Security No. _____ (voluntary)
and/or Federal Employer Identification No. _____.

ii) Federal permit No. _____.

iii) State Permit No. _____.

iv) MSHA No. _____ and date of issuance _____.

8) A) Has the applicant, any subsidiary, affiliate or entity controlled by or under common control with the applicant had:

1) A State or Federal coal mining permit suspended or revoked in the five (5) years prior to the date of submission of the application?
Yes _____ No X

2) A forfeiture of a performance bond under a coal mining permit?
Yes _____ No X

B) If the response to A)1) or 2) was yes, provide the following information:

1) Provide the identification number of the permit.

2) Provide the date of permit issuance.

3) Provide the date of permit suspension or revocation and/or the date of bond forfeiture.

4) Provide the name of regulatory authority who suspended or revoked the permit and/or forfeited the bond.

5) Provide a statement of the reason for the suspension, revocation and/or forfeiture action.

6) Provide the current status of the permit and/or bond.

7) For any administrative or judicial proceedings initiated concerning the suspension, revocation, and/or forfeiture provide the following:

a) Date of proceeding,

b) Location of proceeding, and

c) Current status of proceedings.

C) If the response to A)2) was yes, provide information on the applicant's present financial condition to provide assurances satisfactory to the Department that forfeiture will not again be necessary.

9) Violation history

A) For the three (3) year period preceding the date of submission of the application, provide a listing of Notices of Violation received for any provision of the Federal Act or any Federal State law, rule, or regulation pertaining to air or water environmental protection incurred in connection with any surface coal mining operations. The listing shall include the following:

1) Notice of violation number or other identifier.

2) Date of NOV issuance.

3) Permit identification number.

4) MSHA number.

5) Name of entity to whom NOV was written.

6) Name of regulatory authority or agency which issued the NOV.

7) A brief description of the alleged violation.

8) For any administrative or judicial proceedings initiated concerning the violation, provide the following:

a) Type of proceedings.

b) Date of proceedings

c) Location of proceedings.

d) Current status of proceedings.

9) Actions, if any, to abate the alleged violation.

RESPONSE: **Refer to Attachment Part I; Item 6.A. for the 3-year violation history.**

B) For any unabated cessation orders or unabated air and water quality violation notices received prior to the date of submission of the application for any surface coal mining and reclamation operation owned or controlled by the applicant or by any entity which owns or controls the applicant, provide a listing of the unabated cessation orders or violation notices which include the following:

1) Cessation order or notice of violation number or other identifier.

2) Date of CO or NOV issuance.

3) Permit identification number.

4) MSHA number

5) Name of entity to whom CO or NOV was written

6) Name of regulatory authority or agency which issued the CO or NOV.

7) A brief description of the alleged cessation order or violation.

8) For any administrative or judicial proceedings initiated concerning the cessation order or violation, provide the following:

a) Type of proceedings.

b) Date of proceedings

c) Location of proceedings

d) Current status of proceedings.

9) Actions, if any, to abate the alleged cessation order or violation.

RESPONSE: **N/A. There have been no unabated cessation orders or unabated air and water quality violation notices.**

10) Affidavits, Certifications, Insurance Certificate

A) Complete affidavit regarding applicant's legal right to enter and begin surface coal mining and reclamation operations in the permit area and whether that right is the subject of pending litigation. Identify the documents upon which affidavit is based by type and date of execution and identify specific lands to which each document pertains and explain the legal rights claimed by the applicant (Section 1778.15(a)). If the private mineral estate to be mined has been severed from the private surface estate, provide copies of the documents required under Section 1778.15(B)(1)-(3). On the permit map or other designated map show the boundaries of land within the permit area upon which the applicant has the legal right to enter and begin mining activities.

RESPONSE: **Refer to Attachment Part I.10.A**

B) Complete certification for engineering aspects of the application. In addition to the general certification, three specific certifications are included which are applicable only if the box in front of each is marked. The first two cover special permit requirements and should be marked only when they occur for the proposed permit. The third certification covers the Illinois Environmental Protection Agency permit requirements. In most cases, an Illinois registered engineer will be required to certify I.E.P.A. permit requirements. Except a otherwise provided all maps, plans and cross-sections included in the permit application shall be prepared by, or under the direction of, and sealed by a qualified registered professional

engineer licensed under the Illinois Professional Engineering Act, a qualified registered structural engineer licensed under the Illinois Structural Engineering Act or if authorized by state law, a qualified registered professional land surveyor licensed under the Illinois Land Surveyors Act with assistance from experts in related fields.

RESPONSE: Refer to Attachment Part I.10.B

C) A certificate of liability insurance or evidence that the applicant is self-insured is required prior to permit issuance. The certificate may be submitted with the application or when fee and bond are submitted. Minimum insurance coverage required is for bodily injury $300,000 for each occurrence, and $500,000 aggregate and for property damage $300,000 each occurrence, and $500,000 aggregate.

RESPONSE: Refer to Attachment Part I.10.C

11) Provide a draft copy of proposed newspaper notice, and the name of local newspaper of general circulation in which advertisement of the application will be published. Certificate of publication is to be submitted not later than four weeks after the last date of publication.

RESPONSE: Refer to Attachment Part I.11

12) Areas Designated Unsuitable for Mining

A) Does proposed permit area include and/or shadow area include --

Areas designated unsuitable for surface coal mining and reclamation operations, or under study for designation in an administrative proceeding as unsuitable for surface coal mining and reclamation operations? (Sections 1762 and 1764)

Yes _____ No __X__

B) Does proposed permit area include and/or shadow area include --

1) Lands within boundaries of the National Park System, National Wildlife Refuge System, the National System of Trails, the National Wilderness Preservation System, the Wild and Scenic Rivers System, and National Recreation Areas, etc. (Section 1761.11(a))?

Yes _____ No __X__

2) National Forest land?
Yes _____ No __X__

3) Any land which will adversely affect any publicly-owned park or places included in the National Register of Historic Places, etc. (per Sections 1761.11(c))?

Yes _____ No __X__

If yes, complete Part II, Section 10, B) and C).

4) Any public roads, which are to be removed, relocated or temporarily closed?

Yes _____ No __X__

Indicate on the pre-mining land use map or other designated map the location of the public roads and attach a copy of the written agreement from the appropriate authority authorizing the

relocation, removal or temporary closure. Describe the measures to be used to insure that the interest of the public and land owners affected will be protected.

RESPONSE: **The locations of the crossings are shown on the Hydrology - Mining Operations Map (Drawing No. B17-222-M13 through M16). Indicated on this map are proposed locations where the waterline will be bored under the roads. Prior to any construction for boring beneath State Route 37 and Interstate 57, valid IDOT permits will be renewed and copies will be submitted to the Department. Installation and construction activities will be within 100 feet of public roads, but will be completed over a short period of time. Beginning and ending boring operations will be conducted outside of the public road right of way. Once completed, there will be no further construction activities. During construction/ installation activities, no equipment will be allowed to endanger the public or the landowner. Traffic control signage will be used when work is in progress, as needed.**

C) Within the proposed permit area will Surface Coal Mining and Reclamation operations be located --

1) Within 100 feet of the right-of-way line of any public road?

Yes ___X___ No _____

If yes, explain proposed procedures for complying with regulation Section 1761.14(b), including request for variance, if relevant. Provide location of public roads on pre-mining land use map or other designated map. Describe the measures to be used to insure that the interest of the public and land owners affected will be protected.

RESPONSE: **Disturbance for the installation of the Water Management Pipeline is proposed within 100 feet of several public roads as shown on the Hydrology - Mining Operations Map (Drawing No's B17-222-M13 and B17-222-M16). Disturbance within 100 feet of the right of way of all public roads will be associated with the boring under each road for the installation of the proposed waterline. A variance of Section 1761.14(b) is requested for being within 100 feet of a public road right of way. Construction activities will be within 100 feet of the road right of way, however, beginning and ending boring operations will be conducted outside of the public road right of way. Installation and construction activities will be completed over a short period of time. Once completed, there will be no further construction activities. During construction and installation activities, no equipment will be allowed to endanger the public or the landowner. Traffic control signage will be used when work is in progress, as needed.**

The public notice will provide for a public hearing in accordance with Section 1761.14. Refer to Attachment I.11 for the public notice.

2) Within 300 feet measured horizontally from any occupied dwelling?
Yes ___X___ No _____

If so, is waiver provided meeting requirements of Section 1761.15(d)?

RESPONSE: **The proposed permit boundary will be within 300 feet of occupied dwellings. The 300 foot buffer zones are shown on the Hydrology - Mining Operations Map (Drawing No. B17-222-M13 through M16). Refer to Attachment I.12.C.2 for a list of the waivers.**

3) Within 300 feet measured horizontally of any public building, school, church, community or institutional building or public park?
Yes _____ No ___X_____

4) Within 100 feet measured horizontally of a cemetery?
Yes _____ No ___X_____

D) Are valid existing rights claimed for any part of the permit area?
Yes _____ No _____X_____

If yes, provide documentation to substantiate claim.

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
IDNR	IL0061727	NOV 58-04-15	6/29/2015	TACC	Failure to meet effluent limits at Outfall 002 with pH of 4.97 (below 6.0 minimum) and chlorides of 5834 1 mg/L (above 2000 maximum).		Abated	Treatment ongoing at Pond 002
DOGM	ACT007041	NOV #21156	9/10/2015	UEI	Permittee failed to follow the required monitoring plan during the mining of longwall panels #18, #20, and #21. Immediately implement monitoring.		Abated	
IDNR	257	NOV 58-01-16	2/18/2016	TACC	Slurry uncontrollably deposited to unauthorized areas within and outside of the permitted area.		Abated	
IDNR	43	NOV 67-3-16	3/30/2016	Consolidation CC	Items from the 2015 reclamation schedule were not completed on time. NOV 67-3-16 issued for not meeting the March 1, 2016 deadline.		Abated	A plan with reasonable deadlines set in 2015, 2016, 2017, 2018, and 2019 has been established to complete the reclamation requirements associated with NOV 67-3-16.
IEPA	A-2016-00017	A-2016-00017	4/4/2016	TACC	CAAPP permit requirements were not met and a complete updated CAAPP permit application to include a railcar loadout operation must be submitted.		Abated	
DOGM	ACT015032	NOV #21175	4/19/2016	UEI	Failure to submit and receive approval from UDOGM for the installation of a metal/chain-link fence around the warehouse (as well as update MRP).		Abated	Abated with submittal and approval by UDOGM
IDNR	IL0036021	CO 01-16	7/6/2016	Consolidation CC	Failure to abate NOV 67-3-16 within extension time granted. CO 01-16 abatement actions are required by August 8, 2016.		Abated	De-watering requirement began. A plan with reasonable deadlines was established to complete the reclamation requirements associated with NOV 67-3-16. CO 01-16 abated.
IDNR	255, 257, 352	NOV 58-02-16	10/4/2016	TACC	Failure to submit the renewal applications in a timely manner. The notification system that IDNR uses to alert permit holders of their permit expiration dates failed to send the "180 day letters" to us		Abated	This NOV will be vacated as soon as the signed and sealed copies from the Saline County courthouse reach the IDNR office. NOV abated 10/21/16
IDNR	2	58-1-17	2/21/2017	TACC	Failure to include flow from Sediment Basin 002E from the quarterly reports for October, November, and November.		Abated	Discharge monitoring reports for the basin must be submitted by March 21, 2017.

R05752

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
IDNR	399	38-01-17	3/3/2017	Hillsboro	Failure to report flow from Sediment Basin 002 (NPDES Outfall 002) for the month of November 2016 in the quarterly discharge monitoring reports. (The Department documented flow during the Nov. 10, 2016 inspection.) Failure to report flow from Smith Reservoir (NPDES Outfall 007) for the month of November 2016 in the quarterly discharge monitoring reports. (The Department documented flow during the Nov. 7, 2016 inspection.)		Abated	
IDNR	56	72-1-17	3/7/2017	Macoupin			Abated	
IDNR	202	67-1-17	5/8/2017	Consolidation CC	Failue to complete final grading, seeding, and mulching required on former Pond 005		Abated	Final grade, seeding, and mulching must occur by June 1, 2017
IDNR	401	58-2-17	5/8/2017	TACC	Coal waste was deposited in unauthorized area in an uncontrolled manner impacting an adjacent ephemeral stream diversion and receiving stream		Abated	Remove all coal refuse from diversion ditch, remove material downstream, provide a summary of events that contributed to the receiving of NOV,and provide a plan to the department detailing the construction practicesto ensure downstream slopes will be maintained by June 1, 2017. Regreade and shape the downstream slope of the bunkhouse according to the plan by July 1, 2017
IDNR	401	58-3-17	6/8/2017	TACC	permit renewal application for IDNR permit 401 was not submitted 180 days before expiration		Abated	
KDMRE	875-0030		1/30/2015	MCLEAN	An unpermitted haul road was used to haul in topsoil for reclamation purposes. Extended to allow time to obtain permit revision for affected area.		Abated	Obtaining permit revision to permit the affected area
KDMRE	889-9004		3/17/2015	KRI	Data for CYP-8 and CYP-9 sites were not submitted in surface and groundwater monitoring reports. NNC 13-0942 issued for failure to report		Abated	Abated
KDMRE	889-9004		3/17/2015	KRI	Sediment basin #2 discharging water at pH 2.88 NNC 13-0943 issued for failure to maintain effluent limits.		Abated	Abated as discharged was stopped

R05753

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
KDMRE	889-9004		4/21/2015	KRI	1st Quarter 2015 Gob Pile Certification received late (was due 4/14, received 4/15). NNC #13-0945 as KDMRE "non-correctable", but effectively is abated.		Abated	Report was submitted, but one day late. KDMRE files missing deadlines as "non-correctable", but the report has been received, and is effectively "abated."
KDMRE	889-5009		5/6/2015	KRI	Sediment basin KY-M-269 was discharging at pH of 4.47 into receiving wetlands and there is therefore no up- or downstream measurments.		Abated	Discharge stopped, violation abated.
KDEP	KYG045591		6/1/2015	KRI	Various water quality exceedances and unheeded monitoring requirements noted.		Abated	Agency "non-remedial" is effectively abated with payment of penalty
KDEP	KY0105562		6/1/2015	KRI	Various water quality exceedances and unheeded monitoring requirements noted.		Abated	Agency "non-remedial" is effectively abated with payment of penalty
KDMRE	889-9004		7/13/2015	KRI	Failure to pass all surface drainage through sediment control structures with water escaping the permit area with iron greater than 10mg/L.		Abated	Discharge contained
KDMRE	889-5009		8/17/2015	KRI	Permittee has mined coal on 5 unpermitted cemetary tracts. NNC #13-0966 issued. Revise the permit to include the undermined cemetaries.		Abated	Extended with provisions to add areas to permit boundary. Permitting process is lengthly, extension granted. Abated on 8/22/2016
KDMRE	889-5009		8/24/2015	KRI	Failure to submit groundwater monitoring point data for 8003-1725 on 2nd quarter monitoring. Agency "Non-correctable" (effectively abated)		Abated	Corrected report sent. Agency "non-correctable" (effectively abated).
KDMRE	889-9004		8/24/2015	KRI	Failure to submit groundwater monitoring points 24 and 24A on 2nd quarter monitoring. Corrected report sent. Agency "non-correctable (effectively abated)		Abated	Corrected report sent. Agency "non-correctable" (effectively abated).
KDMRE	889-5011		8/24/2015	KRI	Failure to submit groundwater well data for 8003-1725 on 2nd quarter monitoring. Agency "Non-correctable" (effectively abated).		Abated	Corrected report sent. Agency "non-correctable" (effectively abated).
KDMRE	KY0105562		8/28/2015	KRI	Various water quality exceedances and unheeded monitoring requirements noted. Same issues as noted above with 2015001 violations issued June 1, 2015.		Abated	Agency "non-remedial" is effectively abated. Working to combine this violation with the previous violation 2015001 issued on June 1, 2015. May still require additional payment.
KDMRE	889-9004		11/12/2015	KRI	Water discharging from sediment basin SB-1 with a pH of 4.49		Abated	

R05754

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
KDMRE	889-9004		11/12/2015	KRI	Drainage bypassing approved sediment control structure. Water leaving the soututhern edge of the permit with iron concentration greater than 10 mg/L.		Abated	
KDMRE	889-5009		11/16/2015	KRI	Well 8003-1725 reported dry for three (3) consecutive quarters Within 30 days, well must be rehabilitated or must submit an application to replace well.		Abated	
KDMRE	889-5011		11/16/2015	KRI	Well 8003-1725 reported dry for three (3) consecutive quarters. Within 30 days, well must be rehabilitated or must submit an application to replace well.		Abated	
KDMRE	889-9004		3/24/2016	KRI	Substandard water flowing off-permit from the southern dam of CFD-1. Also, Gullies were present on the southern face of the gob pile NNC 13-1434 issued.		Abated	Dozer work completed on the souther dam of CFD-1 and the seep is no longer flowing. Abatement of NNC 13-1434
KDMRE	889-0147		3/29/2016	KRI	Water discharging from sediment basin #2 with a pH of 9.6, and diversion ditches DD1 and DD3 have been eroded and no longer meet specifications.		Abated	Remedial work has been completed per KDMRE inspection report on 5/27 NNC 13-1435 abated
KDMRE	889-9004		6/1/2016	KRI	Failure to submit annual certifications of maintenance for slurry impoundments CFD-1 and CFD-2 Written as NNC 13-1437 on the insp. rpt. but is actually 13-1438		Abated	Paperwork submitted.
KDMRE	889-5011		10/26/2016	KRI	Permittee has failed to maintain sediment structure SB-5. The primary spillway has blown out		Abated	Principle spillway portion of dam was washed out and we have until 11/28/16 to repair it. Mike sent contractor to site 10/27/16
KDMRE	889-9004		11/9/2016	KRI	Permittee has failed to operate CFD-1 according to the plan approved in permit. Permitee overfilled south end of CFD-1 with slurry and placed a berm across the spillway which stoped the discharge.		Abated	Permitee must cease the pumping of slurry into the south end of CFD-1. Permitee must either remove the alteration to the spillway or obtain a permit revisionto approve alterations made.
KDMRE	889-5009		11/21/2016	KRI	Permittee has failed to submit surface and groundwater 3rd quarter reports, GW-4 reports, and AM-02 monitoring reports withing the required deadline.		Abated	Monitoring reports were submitted. See Violation sheet.

R05755

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
KDMRE	889-9004		11/23/2016	KRI	Permittee has failed to begin seeding sites SB#2, the non-toxic material pile near CRD-1, the outslopes of CRD-1, and areas on CRD-1 where erosion was repaired within the 7 days given to do so.		Abated	Permittee must seed, mulch, and maintain around areas SB#2, the non-toxic material pile near CRD-1, the outslopes of CRD-1, and areas on CRD-1 where erosion was repaired. Permittee must then reseed in the spring of next year.
KDMRE	889-5009		2/2/2017	KRI	Permitee has allowed the accumulation of mud and coal dust to occurr in the right of way of hwy 181 and the associated road ditches		Abated	Permittee has 30 days to remove and dispose of all material from permit that has accumulated. KRI is continueing work. The agency extended till April 6, 2017.
ODNR	D-0360	NOV #29963	9/30/2015	TOVCC	Water flowing from coal stockpile down to area below SR 148 bridge. Required remedial action: clean up material, install sumps, reinstall silt fence / build dyke.		Abated	Abated with completion of remedial actions.
ODNR	2382	29435	4/5/2016	OAEI	Water discharging through the embankment beneath the principal spillway pipe of structure 005.		Abated	Abated with repairs.
ODNR	D-0360	29971	12/19/2016	TOVCC	pH of pond was 3.0 when it should be between 6.5-9.0.		Abated	Pond must be treated to a pH of 6.5-9.0 prior to discharge by 12/27/16. Water from pond must not be discharged until effluent limits are met
ODNR	D-0425	CO I-13083	6/14/2017	AEC	Drilling fluid was discharged beyond the permit limits and sediment was found in unnamed tributaryand Jakes Run stream on the Wharton and Bettinazzi property		Abated	Cease all mining activities beyond permit limits, including drilling activity causing off site discharges. Take all measures necessary to stop discharge of sediment into the stream.
PADEP	3841302	N/A	2/2/2015	Canterbury CC	Compliance Order: October DMRs self-report		Abated	
PADEP	30841312 / PA0013790	C.O 151023A	5/11/2015	Consolidation CC	Outlet 022 discharging with Aluminum concentration of 3.189 mg/L, exceeding the 1.1 mg/L limit. Compliance Order (C.O.) docket # 151023A issued. Amended to fix information on 5/22.		Abated

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
PADEP	30841312 / PA0013790	NOV 06/30/15	6/30/2015	Consolidation CC	Monthly average and instant maximum aluminum concentration at outfall 005 was exceeded on first quarter DMRs. NOV issued and lifted		Abated	Lifted immediately after issued
PADEP	30841312 / PA0013790	NOV 8/27/15	8/27/2015	Consolidation CC	DMRs showed a no-flow at Outfall 022 in April and at 005 in June, conflicting with inspector sampling data (sometimes finds it flowing when we do not)		Abated	NOV issued and lifted
PADEP	30841312 / PA0013790	NOV 10/27/15	10/27/2015	Consolidation CC			Abated	
PADEP	30841312 / PA0013790	NOV 4/29/16	4/29/2016	The Monongalia County Coal	Effluent characterization for special condition requirements of Part B of the NPDES permit, required 2 years after NPDES issuance, was not submitted		Abated	Required effluent characterization has been provided to PADEP.
PADEP	63743702 / PA0214248	NOV 4/29/16	4/29/2016	The Washington County Coal	Effluent characterization for special condition requirements of Part B of the NPDES permit, required 2 years after NPDES issuance, was not submitted.		Abated	Data had been previously submitted to the department. NOV abated (should probably technically have been withdrawn)
PADEP	03743701	NOV 5/5/16	5/5/2016	Canterbury CC	Operator has not begun desludging the sediment basins as noted in previous inspection reports. NOV issued to require desludging by 5/12.		Abated	Abated with the start of the desludging process.
PADEP	03951601	NOV 5/18/16	5/18/2016	MKPI	Impoundment certifications expired 5/4/16. NOV cited requiring the submission of the annual impoundment certifications by 6/17/16		Abated	Abated with the submission of the certifications
PADEP	03841302	NOV 6/28/16	6/28/2016	Canterbury CC	Sample collected on 6/2/16 showed a manganese concentration of 2.867 mg/L, over the limit of 2.5		Abated	Abated with manganese concentration returning to compliant levels
PADEP	03841302	NOV 8/3/16	8/3/2016	Canterbury CC	NOV issued for exceeding manganese limit at Outfall 001 on sample collected 6/15. Immediately lifted as compliant sample was taken 6/28.		Abated	Compliant sample collected 6//28 shows Manganese limits were being met. NOV lifted.
PADEP	30841312 / PA0013790	NOV 8/24/16	8/24/2016	The Monongalia County Coal	Effluent limits on outfall 023 were not reported when the HMR/DMR's were submitted for the second qtr 2016.		Abated	
PADEP	03951601	NOV 9/23/16	9/23/2016	MKPI	requires operator to submit a request for temporary cessation		Abated	submitted temporary cessation
PADEP	03841302	CO 12/20/16	12/20/2016	Canterbury CC	NOV issued for exceeding manganese limit at Outfall 001 on sample collected 12/20/16		Abated	Operator must provide proper treatmentto ensure discharges are meeting effluent standards.
PADEP	03841302	C O 161067	1/9/2017	Canterbury CC	Manganese concentraionat outfall 001 was recorded at 3.635 mg/L when the effluent limit is 2.5 mg/L		Abated

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
PADEP	30841312 / PA0013790	CO #171012	3/3/2017	The Monongalia County Coal	CO issued for reporting No Flow when the inspector found a flow		Abated	
PADEP	30841312 / PA0013790	CO #171013	3/3/2017	The Monongalia County Coal	Water exceeded effluent limits at outfall 022 with an aluminum concentration of 2.6 mg when, and an aluminum concentraition of 2.06 mg when the limit is 1.1mg. Water exceedded effluent limit at outfall 023 with an aluminum concentration of 5.9mg and 1.46mg when the limit is set at 1.3mg		Abated	
PADEP	03841302	C.O. 171025	6/6/2017	Canterbury CC	Outfall 001 was discharging water with an aluminum concentration of 1.449 mg/L which exceeds the limit of 0.78mg/L. Sample collected on 4/17/17		Satisfactory Progress	Operator must provide proper treatmentto ensure discharges are meeting effluent standards.
PADEP	03841302	C.O. 171028	6/20/2017	Canterbury CC	Outfall 001 discharging with an aluminum concentration of 1.524 mg/L which exceeds the limit of 0.75 mg/L.		Satisfactory Progress	Operator must provide proper treatmentto ensure discharges are meeting effluent standards.
PADEP	30841312 / PA0013790	C.O. 171029	6/26/2017	The Monongalia County Coal	Outfall 023 discharged water with an aluminum concentration of 3.758 mg?l when the effluent limit is 1.3 mg/L.		Abated	
PADEP	30841312 / PA0013791	CO #171029	6/26/2017	The Monongalia County Coal	Outfall 023 exceeded the aluminum concentration of 1.3 mg/L with a concentration of 3.758 mg/L.		Abated	
PADEP	63733706	CO #171030	7/11/2017	MCMI	Failure to have an approved reclamation plan.		Terminated	
PADEP	03951601	C.O. 171032	8/8/2017	MKPI	Discharged water from an area disturbed by mining did not meet effluent limits with a Iron concentration of 42.582 mg/L when the limit is 7.0 mg/L, and a Manganese concentration of 11.119 mg/L which exceeds the limit of 5.0 mg/L.		Abated	Operator must provide proper treatment to ensure discharges are meeting effluent standards.
WVDEP	U007883	U007883 (52)	1/12/2015	Consolidation CC	Black water / coal fines discharging into Paw Paw Creek, discoloring water, disturbing hydrologic balance		Abated	Coal fine discharge stopped, no longer causing hydrologic balance. Abatement period extended to allow for a written plan to minimize potential for a repeat event

R05758

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
WVDEP	U004684	U004684 (36)	1/22/2015	Consolidation CC	Outfall 002 pH 9.7 (limit is 9.0)		Withdrawn	Follow-up inspection 002 was not discharging. Operator submitted justification to DEP outlining how access to the pond had been restricted and pump malfunctioned. Resolved
WVDEP	P203514	P203514 (1)	1/26/2015	AMEI	Prospect permit Hole P-01 caused degredation of groundwater quality from a nearby landowner water well		Abated	Extended with permittee checking and purging the well, waiting for it to clear.
WVDEP	U007883	IHCO #53	2/10/2015	Consolidation CC	Contractor spill at 1-D borehole construction site. IHCO #53 issued for excessive contribution of suspended solids into tributary. Modified to NOV #55		Abated	Abated with stopped discharge from the site and no remaining water with high solids was located. "Slug" has dissipated. Abated
WVDEP	U007883	NOV #55	2/10/2015	Consolidation CC	Contractor spill at 1-D borehole construction site. IHCO #53 issued for excessive contribution of suspended solids into tributary. Modified to NOV #55		Abated	Abated with stopped discharge from the site and no remaining water with high solids was located. "Slug" has dissipated. Abated
WVDEP	U007883	NOV #54	2/10/2015	Consolidation CC	Contractor spill at 1-D borehole construction site. NOV #52 issued for failure to install proper temporary E&S controls		Abated	Abated with installation of adequate sediment control for the site
WVDEP	U043100	NOV #7	2/13/2015	Consolidation CC	RO break flowed off-permit allowing chlorides to enter an unnamed tributary of Campbell Run. NOV #7 issued for disturbance to hydrologic balance		Abated	Discharged to Campbell Run was stopped. Pipeline break was temporarily repaired. A more permanent repair will occur when weather permits
WVDEP	O102392	NOV #28	3/4/2015	Consolidation CC	Outlet 006 discharging at pH of 3.85 (below the minimum limit), and Iron at 5.0 (above maximum limit). NOV #28 issued for failure to maintain effluent limits		Abated	Outlet 006 was pumped down to stop discharge. NOV extended until lab results are received.
WVDEP	O100100	NOV #12	3/4/2015	Consolidation CC	Outlet 020 discharging iron at 3.5 mg/L. NOV#12 issued for exceeding effluent limit.		Abated	Outlet 020 was pumped down to stop discharge. Inspector sample lab data received, NOV terminated.
WVDEP	U102591	NOV #51	3/9/2015	Consolidation CC	Emergency Warning Plan for Brown's Run Slurry Impoundment expired 3/8/2015. NOV #51 issued for failure to submit and obtain approval for new plan		Abated	EWP was submitted but WVDEP requires a filing fee with submission, extended. Abated with fee submission and plan is now being reviewed by WVDEP
WVDEP	U010483	NOV #88	3/16/2015	Consolidation CC	Pipe burst released water & material into Robinson Run. NOV #88 issued for failure to minimize disturbance to hydrologic balance		Abated	Line was repaired. NOV terminated.

R05759

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
WVDEP	U010483	NOV #89	3/25/2015	Consolidation CC	Outlet 032 discharging muddy water into and discoloring Sam's Run and the South Fork of Fish Creek NOV #89 issued.		Abated	Filtration system installed; extended Abated with filtration & floc treatment.
WVDEP	U007083	NOV #43	4/8/2015	Consolidation CC	Power to pmp was interrupted, sump overflowed, untreated mine water left permit area and stained ditch leading to UNT of Dent's Run NOV #43 issued.		Abated	When power was restored, our pump was unable to keep up with accumulated water, so we installed a bigger pump.
WVDEP	U004684	NOV #37	4/22/2015	Consolidation CC	Failure to stabilize refuse benches in that a large "erosion gully" (actually a temp. ditchline) developed above the new flume ditch. NOV #37 issued.		Abated	Repaired, abated
WVDEP	U004684	NOV #38	4/22/2015	Consolidation CC	Failure to spread and compact refuse material in layers not exceeding two feet (top of refuse not spread/compacted due to mine idle) NOV #38 issued		Withdrawn	Spread and compacted, abated.
WVDEP	U004684	NOV #39	4/22/2015	Consolidation CC	Unapproved materials (some combustible debris, some noncombustible) were disposed of in refuse pile. Needs removed. NOV #39 issued		Abated	Materials removed. Abated
WVDEP	U102591	NOV #52	6/13/2015	Consolidation CC	Pump failed and drainage sump discharged black water from outlet 015 into Ohio River NOV #52 issued		Withdrawn	Abated with cleanup and pump restoration NOV withdrawn as it is essentially the same as NOV 53
WVDEP	U102591	NOV #53	6/13/2015	Consolidation CC	Pump failure allowed black water discharge from outlet 015 into Ohio River NOV #53 issued for conditions not allowable in waters of the state		Abated	Abated with cleanup and pump restoration
WVDEP	U003383	NOV #72	7/22/2015	Consolidation CC	Outlet 005 discharging with TSS at 228.0 (above 70 maximum) and total aluminum at 2 20 mg/L (above 0.75 maximum) due to water line rupture disrupting treatment		Abated	The line has been replaced and the line will be inspected during pond cleanings to prevent non-compliant discharge.
WVDEP	U102692	NOV #6	8/12/2015	Consolidation CC	Outlet 030 discharge exceeding maximum aluminum concentration.		Abated	Laboratory report of subsequent sample shows compliance is being met. Violation abated.
WVDEP	U200707	NOV #1	8/24/2015	Consolidation CC	Air Blast exceeded maximum decibel level of 133 dB (at 134 4 dB)		Abated	Abated with reoccurance provention plan submittal and with subsequent air blasts shown to be within decibel limits. (Contractor responsibility)
WVDEP	O201806	NOV #5	9/4/2015	Consolidation CC	Filtration socks were removed by a storm drain, allowing sediment laden water during washdown procedure to drain into Boggs Run and discolor the stream		Abated	Sediment control socks reinstalled around the drain grates. Violation abated.

R05760

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
WVDEP	O102591	NOV #54	12/1/2015	Consolidation CC	Outlet 015 and 023 discharges exceeding their respective aluminum concentration limits. NOV #54 issued		Abated	
WVDEP	U010483	NOV #90	12/7/2015	Consolidation CC	Water line break caused orange staining in the unnamed tributary of Quaker Fork. NOV issued for causing conditions not allowable in state waters		Abated	
WVDEP	U102692	NOV #7	12/8/2015	Consolidation CC	Outlet 415 discharge had an amonia/nitrogen level of 20 23 mg/L, exceeding the limit of 6 mg/L. NOV #7 issued.		Abated	
WVDEP	U003383	NOV #73	12/17/2015	Consolidation CC	Outlet 029 discharging with aluminum concentration of 1 27 mg/L, exceeding the limit of 0.75 mg/L. NOV #73 issued.		Abated	
WVDEP	O200706	NOV #1	12/21/2015	Consolidation CC	Contractor pushed coal fines into a perimeter ditch resulting in unallowable discharge to US waters. NOV #1 issued. Contractor to reimburse penalty.		Abated	
WVDEP	O102592	NOV #29	12/30/2015	Consolidation CC	Discharge at Outlet 419 B.O.D was 12 2 mg/L, exceeding the limit of 10 mg/L. NOV #29 issued		Abated	
WVDEP	U003383	NOV #74	1/26/2016	Consolidation CC	Pump failure caused Outlet 005 to discharge water with iron concentration greater than 5 00 mg/L. NOV #74 issued.		Abated	A new pump was installed and discharge from 005 ceased. NOV #74 abated
WVDEP	U010483	IHCO #91	3/23/2016	The Harrison County Coal Co	Freshwater contaminated with dust suppressant flowed into UNT of Bartholomew creek. Foam present Cease discharge Immediately		Abated	Discharge was ceased. New valve was installed on the end of the pipe preventing the occurrence of accidental discharges in the future.
WVDEP	AIR PERMIT	AIR QUALITY 4/7/16	4/7/2016	The Ohio County Coal Co	Failure to inspect facility for asbestos prior to demolition. Failure to notify the WVDEP Division of Air Quality at least ten days prior to demolition.		Abated	Letter has been sent to DAQ. Awaiting response/abatement. DAQ response email no further actions needed
WVDEP	WV0004201	NOV #1	5/3/2016	The Ohio County Coal Co.	Outlet 003 was sampled and lab analysis returned a chloride concentration of 607 mg/L, although the field testing kit showed much less		Withdrawn	Re-run of sample showed a level of 56.9 mg/L, well under permitted limit. It is likely there was a decimal placement error in the original laboratory analysis. Agency withdrawn.
WVDEP	U003383	NOV #75	7/12/2016	The Marshall County Coal Co	Failure to obtain approval to subside tract 3-16-2 prior to mining in excess of 60% extraction within 30° angle of draw of a cemetery		Abated	Abated with submission of legal right to subside tract 3-16-2 and obtained approval from WVDEP.

R05761

TABLE 1.5.3
List of Violations by Applicant the Past 3 Years

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
WVDEP	U010483	NOV #1	7/18/2016	The Harrison County Coal Co	AMD line break caused mine water to flow to an UNT of Quaker Fork Orange staining on ground and creek, some vegetation killed NOV #1 issued		Abated	Permittee has repaired the pipeline break, has regraded, seeded, and mulched the eroded area due to pipeline break. NOV #1 terminated
WVDEP	U003383 / WV0020834	NOV #2	7/22/2016	The Harrison County Coal Co	NOV #2 issued for conditions not allowable in state waters in that seeps from the impoundment were discharging black water into Cunningham Run		Abated	Abated as diversion and sump were installed to collect water and pump water back to the slurry cell. Slurry cell is being pumped down to elimate the source of black water.
WVDEP	O104491	IHCO #5 / NOV #6	7/26/2016	The Marion County Coal Co.	IHCO #5 issued for discharge from Outlet 002 resulting in fish kill in Sugar Run and Paw Paw Creek		Abated	Ponds pumped down to eliminate the source of discharge. IHCO #5 was converted to NOV #6, and NOV #6 was terminated.
WVDEP	WV0004201	NOV #2	8/4/2016	The Ohio County Coal Co.	Brown's run impoundment (Outlet 009) is discharging orange water, field tested to be greater than 10 mg/L. NOV #2 issued		Abated	Installed a control system to control discharging from outlet 009. NOV#2 was terminated
WVDEP	U004684	NOV #40	8/11/2016	The Monongalia County Coal	Failed to maintain sediment capacity in ponds one and two.		Abated	Ponds one and two were cleaned and brought back to sediment capacity.
WVDEP	O104491	NOV #2	9/2/2016	The Marion County Coal Co	NOV #2 issued for high conductivity and chloride seepage from 1st treatment pond at St. leo.		Abated	Fixed sump collection system at St Leo. Conductivity & Chlorides have decreased in the UNT of south fork. NOV #2 abated on 10/3/16
WVDEP	WV1017799	NOV #1	10/24/2016	The Ohio County Coal Co.	NOV 1 issued. Sediment found in Bogg's Run stream and on stream bottom		Abated	
WVDEP	WV0004201	11/01/55	11/1/2016	The Ohio County Coal Co.	Outlet 401 was out of compliance for BOD 5 day		Abated	NOV Abated 12/13/16
WVDEP	U0102392 / WV0020834	NOV #31	1/20/2017	Marshall County Coal Compa	IHCO modified to NOV. Black residue fond in ditch and delta of Fish Creek.		Extended	
WVDEP	U0102392 / WV0020834	NOV #32	1/24/2017	Marshall County Coal Compa	Failed to maintain effluent limitations from outfall 035 blackwater discharging		Abated	
WVDEP	U003383 / WV0020834	NOV 676	1/30/2017	Marshall County Coal Compa	Failed to maintain proper drainage of pond 4 (associated with outlet 017).		Abated	The pipe will be removed and an open channel spillway will be constructed
WVDEP	U007883	NOV #56	2/23/2017	Consolidation CC	Failed to minimize disturbance to prevailing hydrologic balance at mine site and associated off site areas. Harvey 1 impoundment was contributing tp grey black solid material in Harvey Run		Abated	Reduced suspended solids to be within effluent limit.

R05762

Issuing Agency	State and Permit No. or MSHA Number	State Violation No. or MSHA Violation No.	Issue Date	Name of Company or Person to Whom Violation Issued	Description of the Violation	Date, Location and Type of Administrative or Judicial Proceeding	Violation Status	Abatement Actions
WVDEP	O102392	NOV #34	3/2/2017	Marshall County Coal Compa	Failed to maintain effluent limit at Conner Run outlet 006		Abated	Stop discharging water non-compliant water out of outlet 006.
WVDEP	O102392	NOV #33	3/15/2017	Marshall County Coal Compa	Failed to maintain hydrologic balance in Conner Run with black water discharging into Conner Run from outlet 035		Abated	Remove black water and residue from Conner Run.
WVDEP	O102591	NOV #56	4/18/2017	The Ohio County Coal Co	Did not meet Effluent limits at outlet 017 TSS was 117mg the limit is 70mg.		Abated	
WVDEP	O102592	NOV# 57	4/18/2017	The Ohio County Coal Co	Did not meet Effluent limits at outlet 017 Total Aluminum was 0.82 mg the limit is 0.75mg.		Abated	
WVDEP	U003383	NOV #77	5/22/2017	Marshall County Coal Compa	A large slip formed below the shaft pad Material from the slip partially blocked the right hand sediment ditchfor 10 feet and completely blocked the ditch for another 10 feet		Abated	Ditch must be cleaned out and slip must be repaired
WVDEP	U003383	NOV #78	5/22/2017	Marshall County Coal Compa	NOV issued for not installing proper sediment control		Abated	
WVDEP	U003383	NOV #79	5/22/2017	Marshall County Coal Compa	NOV issued for not stabilizing slopes to prevent erosion		Abated	
WVDEP		NOV #35	5/23/2017	Marshall County Coal Compa	Sediment left the permitted area and entered a wetland area. 1/4 of the wetland has been impacted		Abated	
WVDEP	O200211	NOV #1	6/1/2017	Marshall County Coal Compa	Permittee failed to certify an approved drainage system, and construction of the sediment pond and drainage ditches prior to the commencement of mining operations		Abated	Submit and obtain approval for the certifications of the drainage and control structure for this permit
WVDEP	O200211	NOV #2	6/1/2017	Marshall County Coal Compa	Permittee failed to monitor the article 3 surface surface water monitoring point DGR. This point was not monitored for Acidity and alkalinity as required by section U-1 of the SMA premit.		Abated	
WVDEP	U004684	NOV #41	6/23/2017	The Monongalia County Coal	Unapproved material on course refuse pile		Abated	
WVDEP	U010483	NOV #92	7/11/2017	The Harrison County Coal Co	TSS score of disharge from sediment pond 001 did not meet the effluent lims.		Abated	
WVDEP	U010483	NOV #93	7/21/2017	The Harrison County Coal Co	Discharge at pond 001 did not meet effluent limits		Abated	
WVDEP	U0102392 / WV0020834	NOV #36	8/3/2017	Marshall County Coal Compa	Failed to maintain effluent limitations from outfall 035 blackwater discharging		Abated	Stop the discharge from outlet 035 and clean the spillway to prevent additional sediment from entering conners run
WVDEP	U007083 / WV0038288	NOV #44	8/3/2017	Arkwright	Failure to maintain hydrologic Balance in Little Indian Creek located north of pump #24		Abated	Pump must be repaired before operations can continue

ENGINEERING CERTIFICATION

ENGINEERING CERTIFICATION

I hereby certify the engineering design used in preparation of this application, attachments, and supplements were done by me or under my direct supervision.

I certify that I am familiar with all of the plans, specifications, reports, and maps submitted as part of this application and that said information is accurate.

I certify to the best of my knowledge all such design is in accordance with all applicable local, state and federal laws, rules and regulations.

I further certify that all applicable maps and/or drawings have been individually sealed in accordance with the Professional Engineering Act, 225 ILCS 325/15.

PART I ATTACHMENT I.12.B.4
HIGHWAY AUTHORITY AGREEMENTS

Attachment I.12.B.4

The two attached utility permits from the Illinois Department of Transportation were granted to Adena Resources, LLC, which is a land/utility company for Foresight Energy, LLC.

Adena Resources, LLC and Williamson Energy, LLC are subsidiaries of Foresight Energy, LLC. Adena Resources provides support services to mining companies operating under Foresight Energy, such as Williamson Energy.

WILLIAMSON COUNTY HIGHWAY DEPARTMENT AGREEMENT

RE: County Highway Permit To Install Waterlines
Dated 18th day of January, 2017 ("Permit")
By and Between:
Williamson Energy LLC ("Williamson Energy"), and,
Williamson County Highway Department ("County Highway Department")
(collectively the "Parties")

Dear Mr. Smothers and County Officials:

Pursuant to the subject referenced Permit, Williamson Energy and the County Highway Department desire to reach further mutual understanding and agreement corresponding to certain matters set forth therein. Accordingly, and Parties desire to enter into this Letter Agreement to amend said Permit as follows.

For and in consideration of the mutual benefits to be derived herefrom, Williamson Energy and County Highway Department amend the Permit as follows:

1. Page 2, 1st Paragraph reads as follows:
"It is anticipated that these utilities will be operated for a period of up to 10 years from the date of this permit. Once these utilizes are no longer being used, it is anticipated that they will be removed from the roadway right of ways within the following year."

   The Parties hereby amend Page 2, 1st Paragraph to read as follows:
"The term of the Permit shall be in force and have effect for a period of 10 years from the date of this Permit, and as long thereafter as mining operations continue to be conducted by Williamson Energy, its successor and assigns, under IDNR Permit #375. Upon termination and abandonment of the utilities operated by Williamson Energy under the Permit; Williamson Energy shall either remove its utilities, or alternatively, transfers and assigns to the County Highway Department all rights, title and interest in and to the utilities to the County Highway Department corresponding to only those areas said County owns in and to its rights of ways under the Permit, as directed by the County Highway Department."

2. Page 3, Item No. 10. reads as follows:
"A performance bond in the amount of $150,000 will be kept on file with the Williamson County Highway Department throughout the life of the installation and operation activities of these permitted utilities. Once the utilities are abandoned and removed, the bond will be returned to Williamson Energy."

The Parties hereby amend Page 3, Item No. 10. to read as follows:
The Parties hereby state that the performance bond in the amount of $150,000.00 under that certain agreement titled, ***Agreement Between the County of Williamson, State of Illinois and Williamson Energy LLC Authorizing Subsidence of County Roads and Highways by Williamson Energy, LLC****, dated the 22nd day of January, 2008, shall be held by the County Highway Department for the life of the installation and operations activities of the Permit.*

Williamson Energy and the County Highway Department acknowledge that the Permit is currently in effect, and, except as amended herein, that the Permit shall remain in full force and effect according to its terms.

Williamson Energy greatly appreciates your continued cooperation with respects to all matters to satisfy this undertaking.

Thank you.

Very truly yours,
WILLIAMSON ENERGY, LLC

COUNTY HIGHWAY PERMIT TO INSTALL WATERLINES

WHEREAS, **Williamson Energy**, has requested permission to construct/install and operate a new 18" - 24" water line across **Liberty School Road, (TR 548), Williams Prairie Road (TR 550), Harris School Road (TR 556), Old Ben Road (TR 340), Old Frankfort Road (TR 344), Eberhardt Road (TR 041), Duncan Road (TR 334), Monroe Road (TR 332) and Collins Road (TR 318)** in Williamson County which is subject to the jurisdiction and authority of said County and its officers.

WHEREAS, the proposed construction consists of installation of new 18" - 24" waterline to be placed along and/or under the following roadway under jurisdiction of the Williamson County Highway Department **Liberty School Rd, Williams Prairie Rd, Harris School Rd, Old Ben Rd, Old Frankfort Rd, Eberhardt Rd, Duncan Rd, Monroe Rd and Collins Rd in Williamson County**

The locations are as follows:

- **Site 1** – Liberty School Road in the SW¼ of the SW¼ of Section 12, T8S, R3E (Lake Creek Township) and the SE¼ of the SE¼ of Section 11, T8S, R3E (Lake Creek Township)
  - Proposed Road Bore
- **Site 2** – Williams Prairie Road in the NE¼ of the NW¼ of Section 14, T8S, R3E (Lake Creek Township)
  - Proposed Road Bore
- **Site 3** – Harris School Road in the NW¼ of the NW¼ of Section 15, T8S, R3E (Lake Creek Township) and the NE¼ of the NE¼ of Section 16, T8S, R3E (Lake Creek Township)
  - Proposed Road Bore
- **Site 4** – Old Ben Road in the NW¼ of the NE¼ of Section 17, T8S, R3E (Lake Creek Township)
  - Proposed Road Bore
- **Site 5** – Old Frankfurt Road in the NE¼ of the NW¼ of Section 17, T8S, R3E (Lake Creek Township)
  - Proposed Road Bore
- **Site 6** – Eberhardt Road in the SE¼ of the SW¼ of Section 8, T8S, R3E (Lake Creek Township)
  - Proposed Road Bore

- **Site 7** – Duncan Road in the NE¼ of the SW¼ of Section 7, T8S, R3E (Lake Creek Township)
    - Proposed Road Bore
- **Site 8** – Monroe Road in the NW¼ of the SW¼ of Section 7, T8S, R3E (Lake Creek Township)
    - Proposed Road Bore
- **Site 9** – Collins Road in the NW¼ of the SW¼ of Section 1, T8S, R2E (Herrin Township) and the NE¼ of the SE¼ of Section 2, T8S, R2E (Herrin Township)
    - Proposed Road Bore

It is anticipated that these utilities will be operated for a period of up to 10 years from the date of this permit. Once these utilizes are no longer being used, it is anticipated that they will be removed from the roadway right of ways within the following year.

THEREFORE, be it permitted and granted by the County Engineer of Williamson County, Illinois, that permission be granted to proceed with said construction and operations, subject to the following conditions:

1. That the petitioner shall furnish all materials, do all work and pay all costs of such work.

2. That one-way traffic be maintained during the period of construction and adequate protection for the safety of the public be provided. This includes all necessary signing, flagmen or other traffic control.

3. That the petitioner or his assigns shall assume all risks and liability for accidents and damages that may occur to persons or property on account of said work and utilities.

4. That this permit is effective insofar only as the County has jurisdiction and does not presume to release the petitioner from compliance with the provisions of any existing statute relative to the work involved.

5. That the said work shall be constructed to the satisfaction of the County Engineer.

6. That the work shall be performed so as not to permanently impair the existing road, and that any damage to the said road that might be done during the time of construction shall be repaired to the satisfaction of the County Engineer.

7. That the water line shall be a minimum of four (4) feet below the present grade of the road and four (4) feet below the existing ground line if located outside of the roadbed but within the R.O.W.

8. That the water line shall be relocated at no expense to the County if such a move is needed for future maintenance or construction work on the subject road.

9. Crossings under all nine of the roadway crossings must be made utilizing directional bore and the waterline must be encased in steel conduit.

10. A performance bond in the amount of **$150,000** will be kept on file with the Williamson County Highway Department throughout the life of the installation and operation activities of these permitted utilities. Once the utilities are abandoned and removed, the bond will be returned to Williamson Energy.

11. All trenching or open cuts made within county right of way must be repaired/restored to its prior condition or better. This includes but is not limited to restoring damage to any drainage ways, entrances, roads, signs, shoulders, slopes, culverts, silting, as well as seeding and mulching these disturbed areas to restore proper ground cover.

12. Care must be taken to prevent damage to drainage structures/pipes resulting from trenching or direct boring operations. Open cuts must be a narrow as possible (no greater than 2') to limit damages to surrounding features.

13. Any future damages to these roads resulting from the operation of these utilities on the right of ways will be the responsibility of Williamson Energy to repair to restore the roadway to its previous condition.

PERMIT REQUESTED BY: _____
Williamson Energy, LLC

IN WITNESS WHEREOF, I have hereunto set my hand and seal as the County Engineer of Williamson County, Illinois, this 18TH day of January, 2017

Gregory S. Smothers
County Engineer
Williamson County Highway Dept.

FRANKLIN COUNTY HIGHWAY DEPARTMENT AGREEMENT

PETITION

WHEREAS, Williamson Energy, LLC , in the County of Franklin and State of Illinois, their successors and assigns, under the laws of the State of Illinois hereinafter termed "The Petitioner" request permission and authority to locate, construct, operate and maintain a water management pipeline on and across Franklin County Right-of-Way in Franklin County, State of Illinois, described as follows:

- **A 22" HDPE DR13.5 water management pipeline to be installed across Freeman Spur Blacktop and Freeman Spur Road.**

WHEREAS, it is understood that the cost of construction, location, operation and maintaining of said water management pipeline will be borne by the Petitioner.

NOW THEREFORE BE IT RESOLVED, by the Franklin County Engineer, who is authorized to grant said Petitioner, their successors and assigns, permission and authority to locate, construct, operate and maintain a water management pipeline on and across the roads on Franklin County Right-of-Way, in accordance with Section 561 of the "Standard Specifications for Road and Bridge Construction" adopted January 1, 2016. This permission is given accordingly to the stipulations set forth by the County Board to all utilities, subject to the following conditions and restrictions:

FIRST: That said water management pipeline be located as close to the R.O.W. lines as conditions will permit, it being understood that the location and construction of said water management pipeline shall be satisfactory to the Franklin County Engineer.

SECOND: That said Petitioner shall assume all risks and liabilities for accidents and damages that may accrue to persons or property during the prosecution of the work and at

any time during the life of the working permit by reasons of the locations, construction, operation or maintenance of said water management pipeline.

THIRD: That should it be necessary to damage any roads in Franklin County mentioned above, then the said Petitioner shall make such repairs to the road and will restore substantially to the same condition as it was formerly, or pay to the County the actual cost of repairs for damages done to the roads, it being understood that this repair work will be satisfactory to the Franklin County Engineer.

FOURTH: That if it be necessary to relocate or adjust said water management pipeline due to road improvements; said Petitioner shall relocate the water management pipeline promptly at the expense of the Petitioner.

FIFTH: It is specified that a working permit substantially in the form set forth in "Exhibit A" attached and made a part hereof be issued for each individual installation and must bear the approval of the Franklin County Engineer. Working Permit shall be signed by the Superintendent of Williamson Energy, LLC.

SIXTH: All water management pipeline road crossings shall be installed by the simultaneous boring and jacking methods with protective casing and no open trenches will be allowed. The length of the casing should go from ditchline to ditchline.

SEVENTH: When final inspection of work is made by the Petitioner and the Contractor, the Franklin County Engineer shall be notified of the time and place of final inspection, so that they can go along to make sure all items of work pertaining to the County can be inspected and approved by said Franklin County Engineer.

EIGHTH: Petitioner shall be a member of J.U.L.I.E.

NINTH: That one-ay traffic be maintained during the period of construction when possible and adequate protection for the safety of the traveling public be maintained at all times. IDOT Local Road traffic standards shall be used if road closures are necessary.

TENTH: It being understood that this permission is given only insofar as the Franklin County Engineer have jurisdiction over said County Roads.

Permission is hereby granted this 7th day of March, 2018

Franklin County Engineer

ACCEPTED:

Williamson Energy. LLC. - Authorized Person

I (We) Adena Resources, LLC (Name of Applicant) . PO Box 99 (Mailing Address)

Johnston City (City) . Il (State & Zip) . hereinafter termed the Permittee,

request permission and authority to occupy, and to do certain work herein described on, the right-of-way of the State highway

known as FAI 57(Interstate 57) . Section (X1-4) 1 T8S R2E .

from 36+31 to _____ in Williamson County.

The work is described in detail below and/or on the attached sketch or plans.

Jack and Bore 22" diameter casing with 18" diameter HDPE SDR-17 carrying pipe (non-potable water) under FAI Route 57 at or near station in Williamson County. Location is approximately 2.4 miles north of the Johnston City interchange (Exit 59).
Proposed installation shall be shown on the attached Plan and Profile detail.
Access from through travel lanes for installing or servicint of utility facilities will not be allowed.
Applicant will utilize a Licensed Professional Engineer to ensure the proper placement and construction of the proposed water main.

This permit covers the operation and presence of specified equipment, material or facility on the right-of-way that may be related to the authorized work. A copy of this permit must be present when crews or equipment occupy highway right-of way. Failure to comply may result in the cessation of all construction.

This permit is subject to conditions and restrictions of Part 530 of Title 92 of the Illinois Administrative Code, Accommodation of Utilities on Right-of-Way of the Illinois State Highway System. The removal, relocation or modification of facilities permitted to occupy the right-of-way is governed by Section 9-113 of the Illinois Highway Code, as amended by Public Act 92-0470. The Permittee agrees to comply with the requirements of these laws and with all terms and conditions established by this permit. This permit is subject to revocation by the Department on violation of the terms and conditions governing its use.

Jeffrey L Keirn
Department of Transportation — 2/22/17 Date

Printed 2/14/2017

OPER 1113 (Rev. 08/07)

This permit is subject to the conditions and restrictions established in accordance with the Illinois Highway Code and Part 530 of Title 92 of the Illinois Administrative Code including but not limited to the following:

(1) The applicant represents all parties in interest and shall furnish material, do all work, pay all costs and shall in a reasonable length of time restore the damaged portions of the highway to a condition similar or equal to that existing before the commencement of the described work, including any landscape restoration necessary. (See Section 530.250 of Title 92).

(2) The proposed work shall be located and constructed to the satisfaction of the Regional Engineer or his duly authorized representative. No revisions or additions shall be made to the proposed work on the right-of-way without the written permission of the Regional Engineer or his duly authorized representative (See Section 530.200 of Title 92). In certain circumstances the Department may require that the construction plans and/or the as-built documents be sealed by an Illinois Registered Professional Engineer. Typical of such projects would be petroleum or gas pipelines.

(3) The applicant shall at all times conduct the work in such a manner as to minimize hazards to vehicular and pedestrian traffic. All signs, barricades, flaggers, etc., required for traffic control shall be furnished by the applicant. (See Section 530.240 of Title 92).

(4) The applicant must ascertain the presence of Highway Authority Agreements established in accordance with 35 Ill. Admin. Code Section 742.1020 in the path of its proposed installation and take precautions to protect its workers, human health and the environment in those areas. (See Section 530.240 of Title 92). Where contamination is encountered through excavation in the ROW, it should be managed offsite and IDOT's generator number for the appropriate county may be used.

(5) The applicant shall not trim, cut or in any way disturb any trees or shrubbery along the highway without the approval of the Regional Engineer or his duly authorized representative. (See Section 530.600 of Title 92).

(6) The facilities authorized to occupy the right-of-way by this permit are subject to removal, relocation or modification by the permittee at no expense to the State on notice given by the Department in accordance with Section 9-113 of the Illinois Highway Code, as amended. Participation by the permittee in the UTILITY Coordination Council identified on page one of this permit is required as a condition of this permit. Permittee shall cooperate with the Department with the scheduling of any removal, relocation or modification deemed necessary for highway or highway safety purposes, and, if Utility Coordination Council participation is required by this permit, with the activities of the council identified on the first page of this permit. (See Section 9-113 of the Illinois Highway Code.) Use of and compliance with current IDOT Traffic Control Standards will be required.

(7) If the applicant and the District cannot agree either on whether the permit should be issued or on what conditions would be appropriate, the applicant may, within 30 days of the issuance of written notice of the District's position, appeal the District's determination to the Chief of the Department's Central Bureau of Operations. (See Section 530.900 of Title 92).

(8) The permittee agrees to fully comply with the following legal obligations in advance of entering and while upon any Right-of-way within the Illinois State Highway System.

a) Only a permit issued by the Department under this Part will satisfy the "written consent" requirement of Section 9-113 of the Illinois Highway Code (the Code).
b) A permit from the Department grants a license only to undertake certain activities in accordance with this Part on a State right-of-way, and does not create a property right or grant authority to the permittee to impinge on the rights of others who may have an interest in the right-of-way. Such others might include an owner of an underlying fee simple interest if the right-of-way is owned as an easement or dedication of right of way, an owner of an easement, or another permittee.
c) It shall be the responsibility of the permittee to ascertain the presence and location of existing above-ground or underground facilities on the highway right-of-way to be occupied by their proposed facilities. The Department will make its permit records available to a permittee for the purpose of identifying possible facilities. When notified of an excavation or when requested by the Department, a permittee shall locate, physically mark, and indicate the depth of its underground facilities within 48 hours excluding weekends and holidays.
d) The permittee shall avoid conflicts with any existing underground or above-ground facilities on or near the highway right-of-way. Both the Department and J.U.L.I.E. are to be contacted for assistance during the application process.
e) The permittee shall comply with all other applicable laws relating to the placement of utility lines.
f) The issuance of a utility permit by the Department does not excuse the permittee from complying with any existing statutes, local regulations or requirements of other Department (e.g., oversize and overweight vehicles) or the requirements of other State agencies including, but not limited to, the following:

Illinois Commerce Commission, Illinois Department of Agriculture
Illinois Department of Natural Resources, Illinois Department of Mines and Minerals
Illinois Environmental Protection Agency, Illinois Historic Preservation Agency

g) Rights of abutting and underlying property owners are protected by common law and Sections 9-113 and 9-127 of the Code. The permittee will address these rights prior to initiating activities on State right-of-way. The Department will not be a party in any negotiations between the utility and abutting property owners.
h) In no case shall the permit give or be construed to give an entity any easement, leasehold or other property interest of any kind in, upon, under, above or along the State highway right-of-way.
i) Each person responsible for a utility, in place on the effective date of this Part, on a State highway right-of-way shall notify the Department in writing, if that facility does not comply with this Part. The Department shall treat such a notice as a request for a variance under Section 530.130. Until informed that a variance will not be granted, a person responsible for a pre-existing utility will not be in violation of this Part. The failure to provide such notice constitutes a violation of this Part and of the utility accommodation permit (if any) and would justify the imposition of the sanctions set forth in Section 530.810.

Code Section 742.1020 in the path of its proposed installation and take precautions to protect its workers, human health and the environment in those areas. (See Section 530.240 of Title 92). Where contamination is encountered through excavation in the ROW, it should be managed offsite and IDOT's generator number for the appropriate county may be used.

(5) The applicant shall not trim, cut or in any way disturb any trees or shrubbery along the highway without the approval of the Regional Engineer or his duly authorized representative. (See Section 530.600 of Title 92).

(6) The facilities authorized to occupy the right-of-way by this permit are subject to removal, relocation or modification by the permittee at no expense to the State on notice given by the Department in accordance with Section 9-113 of the Illinois Highway Code, as amended. Participation by the permittee in the UTILITY Coordination Council identified on page one of this permit is required as a condition of this permit. Permittee shall cooperate with the Department with the scheduling of any removal, relocation or modification deemed necessary for highway or highway safety purposes, and, if Utility Coordination Council participation is required by this permit, with the activities of the council identified on the first page of this permit. (See Section 9-113 of the Illinois Highway Code.) Use of and compliance with current IDOT Traffic Control Standards will be required.

(7) If the applicant and the District cannot agree either on whether the permit should be issued or on what conditions would be appropriate, the applicant may, within 30 days of the issuance of written notice of the District's position, appeal the District's determination to the Chief of the Department's Central Bureau of Operations. (See Section 530.900 of Title 92).

(8) The permittee agrees to fully comply with the following legal obligations in advance of entering and while upon any Right-of-way within the Illinois State Highway System.

a) Only a permit issued by the Department under this Part will satisfy the "written consent" requirement of Section 9-113 of the Illinois Highway Code (the Code).
b) A permit from the Department grants a license only to undertake certain activities in accordance with this Part on a State right-of-way, and does not create a property right or grant authority to the permittee to impinge on the rights of others who may have an interest in the right-of-way. Such others might include an owner of an underlying fee simple interest if the right-of-way is owned as an easement or dedication of right of way, an owner of an easement, or another permittee.
c) It shall be the responsibility of the permittee to ascertain the presence and location of existing above-ground or underground facilities on the highway right-of-way to be occupied by their proposed facilities. The Department will make its permit records available to a permittee for the purpose of identifying possible facilities. When notified of an excavation or when requested by the Department, a permittee shall locate, physically mark, and indicate the depth of its underground facilities within 48 hours excluding weekends and holidays.
d) The permittee shall avoid conflicts with any existing underground or above-ground facilities on or near the highway right-of-way. Both the Department and J.U.L.I.E. are to be contacted for assistance during the application process.
e) The permittee shall comply with all other applicable laws relating to the placement of utility lines.
f) The issuance of a utility permit by the Department does not excuse the permittee from complying with any existing statutes, local regulations or requirements of other Department (e.g., oversize and overweight vehicles) or the requirements of other State agencies including, but not limited to, the following:

Illinois Commerce Commission, Illinois Department of Agriculture
Illinois Department of Natural Resources, Illinois Department of Mines and Minerals
Illinois Environmental Protection Agency, Illinois Historic Preservation Agency

g) Rights of abutting and underlying property owners are protected by common law and Sections 9-113 and 9-127 of the Code. The permittee will address these rights prior to initiating activities on State right-of-way. The Department will not be a party in any negotiations between the utility and abutting property owners.
h) In no case shall the permit give or be construed to give an entity any easement, leasehold or other property interest of any kind in, upon, under, above or along the State highway right-of-way.
i) Each person responsible for a utility, in place on the effective date of this Part, on a State highway right-of-way shall notify the Department in writing, if that facility does not comply with this Part. The Department shall treat such a notice as a request for a variance under Section 530.130. Until informed that a variance will not be granted, a person responsible for a pre-existing utility will not be in violation of this Part. The failure to provide such notice constitutes a violation of this Part and of the utility accommodation permit (if any) and would justify the imposition of the sanctions set forth in Section 530.810.

INFORMATION ONLY

R05799

Acceptable - This is an example of an **acceptable** sign. It may be new, or in new condition. There are abrasions on the surface but very little loss of lettering. There has been no touch-up of the lettering.

Marginal - This is an example of a sign with **marginal** acceptability. Of the many surface abrasions throughout the sign face, many are within the individual letters of the message. The sign surface is free of any residue. Although some color fading is evident, the background color and reflectivity are still apparent at night.

Unacceptable - This is an example of an **unacceptable** sign. Signs with asphalt splatter and/or cement slurry or any combination of missing and/or covered reflective material similar in area presented make a sign **unacceptable**. Some letters have a loss of more than 50 percent. There is noticeable color fading.

Please Note: Orange work zone signs shall be fluorescent orange in color. Signs shall have retroreflective sheeting. Signs with bends and dents that alter the size and/or shape of the sign are unacceptable. These photos are examples of the condition of the sheeting.

PART I ATTACHMENT I.11
PUBLIC NOTICE

Williamson Energy, LLC
Attachment I.11.

PUBLIC NOTICE

Pursuant to the Surface Coal Mining Land Conservation and Reclamation Act (PA-81-1015, as amended) and the Rules and Regulations of the Act, Williamson Energy LLC, P. O. Box 300, Johnston City, IL 62951, hereby gives notice that on _____ 2018, a permit application (Permit 456) was determined to be complete by the Illinois Department of Natural Resources, Office of Mines and Minerals, to construct a water management facility.

The permit areas are located in:

Williamson County, Township 8 South, Range 2 East, Sections 1, 2 & 12; Township 8 South, Range 3 East, Sections 7, 8, 9, 11, 14, 15, 16 & 17 and Franklin County, Township 7 South, Range 2 East, Sections 27, 28, 29, 30, 31, 32, 34 & 35.

Approval is also requested to operate within 100 feet of the outside right-of-way of public roads which are located as follows:

Liberty School Road along the southeast side of Township 8 South, Range 3 East, Section 11; Williams Prairie Road along the northwest quarter of Township 8 South, Range 3 East, Section 14; Harris School Road along the northwest quarter of Township 8 South, Range 3 East, Section 15 and northeast quarter of Township 8 South, Range 3 East, Section 16; Old Ben Road along the northeast quarter of Township 8 South, Range 3 East, Section 17; Intersection of Old Frankfort Road and Eberhardt Road along the northwest quarter of Township 8 South, Range 4 East, Section 17; Eberhardt Road along the northwest quarter of Township 8 South, Range 3 East, Section 8; Duncan Road and Monroe Road in the southwest quarter of Township 8 South, Range 3 East, Section 7; State Route 37 along the northeast quarter of Township 8 South, Range 2 East, Section 12; Interstate 57 in the southwest quarter of Township 8 South, Range 2 East, Section 1; Collin Road in the southwest quarter of Township 8 South, Range 2 East, Section 1 and northeast quarter of Township 8 South, Range 2 East, Section 2; Horseshoe Road along the northeast quarter of Township 7 South, Range 2 East, Section 34 and the northwest quarter of Township 7 South, Range 2 East, Section 34; State Route 6 along the northwest quarter of Township 7 South, Range 2 East, Section 34; Deason Road runs north/south at the corners of southeast quarter of Township 7 South, Range 2 East, Section 28, southwest quarter of Township 7 South, Range 2 East, Section 27, northwest quarter of Township 7 South, Range 2 East, Section 34 and the northeast quarter of Township 7 South, Range 2 East, Section 33; Sandburg Road in the southwest quarter of Township 7 South, Range 2 East, Section 28 and the northwest quarter of Township 7 South, Range 2 East, Section 33; Intersection of Freeman Spur Road and Lake Creek Road in the southeast quarter of Township 7 South, Range 2 East, Section 29 and the northeast quarter of Township 7 South, Range 2 East, Section 32; Intersection of Gossage Road and Lake Creek Road in the southeast quarter of Township 7 South, Range 2 East, Section 29 and the northeast quarter of Township 7 South, Range 2 East, Section 32; Lake Creek Road runs along the south border of Township 7 South, Range 2 East, Section 29 & 30 and the north border Township 7 South, Range 2 East, Sections 31 and 32; Intersection of Cheatman Road and Lake Creek Road in the southwest quarter of Township 7 South, Range 2 East, Sections 29, the southeast quarter of Township 7 South, Range 2 East, Sections 30, northeast quarter of Township 7 South, Range 2 East, Sections 31 and the northwest quarter of Township 7 South, Range 2 East, Section 32

Activities to be conducted within 100 feet of the outside right-of-way of public roads can include, but not be limited to, the construction/installation of a pipeline. Construction activities will include the boring beneath roads, trenching adjacent to roads, laying pipeline, backfilling trenches and vegetating disturbances.

Copies of the application for this permit request are available for inspection at the following locations:

Williamson County Clerk's Office, Marion, IL 62959, Franklin County Clerk's Office, 100 Public Square, Benton, IL and Illinois Department of Natural Resources, Office of Mines and Minerals, Land Reclamation Division, One Natural Resources Way, Springfield, Illinois 62702-1271.

Written comments, objections, request for informal conferences, or request for public hearings may be submitted to the Department at the above addresses.

Note: The above public notice is to be published in the Marion Daily Republican newspaper and Benton Evening News.

Top Pollutants by Pounds (DMR, 2018)

Pollutant Name	Total Pounds (lb/yr)	Max Allowable Load (lb/yr)
Sulfate	149,025	46,570
Chloride	149,025	46,570
Iron	104	279
Manganese	13.41	93.14
Solids, total suspended	0	3,260
Acidity, total (as CaCO3)	0	

Top Pollutants by Toxic-Weighted Pounds (TWPE) (DMR, 2018)

Pollutant Name	Total TWPE (lb-eq/yr)	Max Allowable Load (lb-eq/yr)
Chloride	3.63	1.13
Manganese	1.38	9.59
Sulfate	0.8345	0.2608
Iron	0.5837	1.56
