e-mail:ccarson@aquaterra-env.com

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**6657**
Material(s) Tested:	(21) Heat Fusion Weld Seam(s) (2) Single Extrusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Jennifer Tenney
Project Manager
Geosynthetic Services Division

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**6704**
Material(s) Tested:	(47) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**6752**
Material(s) Tested:	(23) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**6820**
Material(s) Tested:	(54) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Jennifer Tenney

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**6887**
Material(s) Tested:	(14) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Jennifer Tenney

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**6903**
Material(s) Tested:	(11) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Melissa Hunter

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**7010**
Material(s) Tested:	(11) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Project # : 4923.10

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**7160**
Material(s) Tested:	(26) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

Jennifer T. Tenney

Dear Mr. Carson,

Thank you for consulting with TRI/Environmental, Inc. (TRI) for your geosynthetics testing needs. TRI is pleased to submit this final report for laboratory testing.

Project:	**Ameren Fly Ash Closure Pond 3**
TRI Job Reference Number:	**7192**
Material(s) Tested:	(12) Heat Fusion Weld Seam(s)
Test(s) Requested:	SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

Codes:	
AD	Adhesion Failure (100% Peel)
BRK	Break in sheeting away from Seam edge.
SE	Break in sheeting at edge of seam.
AD-BRK	Break in sheeting after some adhesion failure - partial peel.
SIP	Separation in the plane of the sheet (leaving the bond intact).
FTB	Film tearing bond (all non "AD" failures).
NON-FTB	100% peel.

If you have any questions or require any additional information, please call us at 1-800-880-8378.

Sincerely,

MPatel

Mansukh Patel
Sr. Laboratory Coordinator

DESTRUCTIVE SEAM QUALITY ASSURANCE TEST RESULTS

TRI Client: Aquaterra Environmental Solution

Project: Ameren Fly Ash Closure Pond 3

Material: 40mil. LLDPE

SAME DAY Peel and Shear (ASTM D 6392/GRI GM19/D 4437/NSF 54/882 mod.)

TRI Log#: 7192

	TEST REPLICATE NUMBER						
PARAMETER	1	2	3	4	5	MEAN	Proj.Spec.
Sample ID: DS-231 | Weld: Heat Fusion							
Side: A						**Peel A**	
Peel Strength (ppi)	73	73	71	70	71	**72**	50 min.
Peel Incursion (%)	<5	<5	<5	<5	<5		
Peel Locus Of Failure Code	SE	SE	SE	SE	SE		
Peel NSF Failure Code	FTB	FTB	FTB	FTB	FTB		
Side: B						**Peel B**	
Peel Strength (ppi)	68	71	71	71	69	**70**	50 min.
Peel Incursion (%)	<5	<5	<5	<5	<5		
Peel Locus Of Failure Code	SE	SE	SE	SE	SE		
Peel NSF Failure Code	FTB	FTB	FTB	FTB	FTB		
Shear						**Shear**	
Shear Strength (ppi)	82	84	79	76	84	**81**	60 min.
Shear Elongation @ Break (%)	>50	>50	>50	>50	>50		
Sample ID: DS-232 | Weld: Heat Fusion							
Side: A						**Peel A**	
Peel Strength (ppi)	75	75	74	74	74	**74**	50 min.
Peel Incursion (%)	<5	<5	<5	<5	<5		
Peel Locus Of Failure Code	SE	SE	SE	SE	SE		
Peel NSF Failure Code	FTB	FTB	FTB	FTB	FTB		
Side: B						**Peel B**	
Peel Strength (ppi)	72	72	72	70	71	**71**	50 min.
Peel Incursion (%)	<5	<5	<5	<5	<5		
Peel Locus Of Failure Code	SE	SE	SE	SE	SE		
Peel NSF Failure Code	FTB	FTB	FTB	FTB	FTB		
Shear						**Shear**	
Shear Strength (ppi)	76	76	78	79	76	**77**	60 min.
Shear Elongation @ Break (%)	>50	>50	>50	>50	>50		

The testing is based upon accepted industry practices as well as the test method listed. Test results reported herein do not apply to samples other than those tested. TRI neither accepts responsibility for nor makes claims as to the final use and purpose of the material. TRI observes and maintains client confidentiality. TRI limits reproduction of this report, except in full, without prior approval of TRI.

RE: Topsoil and Imported Fill Letter
Ameren Venice Ash Pond Closure Phase II / Final Cover
Venice, Illinois
SCI No. 2011-3186.00

Dear Mr. Plocher:

SCI Engineering, Inc. (SCI) has performed laboratory testing on soil samples for compliance with topsoil and imported fill specifications for the referenced project. Topsoil samples were obtained from Schoolhouse Road (B2592) and the Port District (B2593). Both samples meet the specified requirements for topsoil. Table 1 below lists the individual test results.

Table 1 – Topsoil

Category	Test Standard	Specification	Sample B2592	Sample B2593
Organic Content (Percent)	AASHTO T 194	1 – 10	3.5	8.3
Percent Passing #10 Sieve	AASHTO T 27	Minimum 90 percent	99	99
pH	ASTM D 4972	5.0 – 8.0	7.0	7.2

A sample of imported fill material was also obtained from the Schoolhouse Road borrow site. The initial sample (B2590) failed with a plasticity index of 6. Two retest samples (B2596 & B2597) were then obtained and tested. Both retest samples met the specifications. We understand you will obtain additional samples periodically to verify compliance. Table 2 below lists the individual results.

Table 2 – Imported Fill

Category	Test Standard	Specification	Initial Sample B2590	Sample Retest 1 B2596	Sample Retest 2 B2597
Soil Classification	ASTM D 2487	CL, SC, ML, or any combination	ML	CL	CL
Plasticity Index	ASTM D 4318	8 – 30	6	11	12

Electronic Filing: Received, Clerk's Office 09/28/2020

FYI

With this new topsoil source, we expect the overwhelming majority of the material required to finish the project (both clay and topsoil) to come from the Fort Belle site.

Mark & Scott,

Here are the lab test results for the Fort Belle topsoil sample.

pH	6.0
% Passing #10 Sieve	>99%
Organic Content	3.0%

This sample meets the project specifications. Please let me know if you have any questions.

Thanks,

Josh Eckart

1. INTRODUCTION

1.1 Background

This report has been prepared for AmerenEnergy Medina Valley Cogen, LLC (Ameren) for the former Hutsonville Power Station (Hutsonville). Ameren completed closure activities for Ash Pond D in 2012 in accordance with the site-specific closure requirements of 35 Illinois Administrative Code (IAC) 840. Closure activities for Ash Pond D included placement of a 40-mil high density polyethylene (HDPE) cap covered with a three-foot thick vegetative soil layer, construction of surface water control structures, and construction of a groundwater collection system (i.e., Collection Trench). Operation of the Collection Trench began in April 2015. Closure activities for the remaining coal combustion waste (CCW) ponds consisting of Ash Pond A, Ash Pond B, Ash Pond C, and the Bottom Ash Sluice Pond were completed in October 2015 in accordance with the Ash Ponds Closure, Closure Plan, dated September 15, 2014, and the site-specific Ash Pond D rule 35 IAC 840 to the extent feasible.

Ash Pond B, Ash Pond C, and the Bottom Ash Sluice Pond were clean-closed by relocating accumulated ash to Ash Pond A and re-grading the pond areas for proper drainage. Ash Pond A, originally constructed with an 80 mil HDPE liner, was in service between 1986-2011 to receive sluiced fly ash and provide subsequent treatment. Closure activities for Ash Pond A included placement of ash transferred from the other ash ponds and spoils from clean-up of the coal yard, grading according to the Closure Plan, and capping with a low permeability geosynthetic (40-mil HDPE) membrane covered with protective soil. Since Ash Pond B, Ash Pond C, and the Bottom Ash Sluice Pond were clean-closed, the post-closure groundwater monitoring plan and associated annual reports are for Ash Pond A. This is the fourth annual report for Ash Pond A due to the time needed to collect sufficient quarterly data needed for the statistical analysis required by the Ash Ponds Closure, Groundwater Monitoring Plan, dated September 15, 2014 (Groundwater Monitoring Plan), and the Ash Ponds Closure, Post-Closure Care Plan, dated September 8, 2014 (Closure Plan).

Groundwater has been monitored at the site since 1984. The groundwater monitoring system for Ash Pond A, as defined by the Groundwater Monitoring Plan, originally consisted of two background monitoring wells, MW-10 and MW-10D, and ten downgradient compliance monitoring wells[1], MW-2R, MW-2D, MW-3, MW-3D, MW-4, MW 5, MW-12, MW-22S, and MW-22D. Background wells MW-10 and MW-10D were destroyed due to construction unrelated to Ameren operations after the first quarter, 2016 monitoring period. No trace of the former background wells was found using a metal detector, probes, or digging. As a result, these wells were replaced with background monitoring wells MW-23S and MW-23D in November 2017. In addition, several other monitoring wells and piezometers located at Hutsonville are measured for groundwater level so that groundwater elevation contour maps can be created for the entire site. Ash Pond A is located near the southwest portion of the Hutsonville site, as shown on Figure 1-1, with the sampled monitoring wells shown on Figure 1-2.

In conjunction with Ameren's request for approval of the Closure Plan, Ameren submitted a request to establish a groundwater management zone (GMZ) pursuant to 35 IAC 620.250(a)(2): Ash Ponds Closure, Groundwater Management Zone Application, dated September 8, 2014, which

[1] Note that in the 2017 Annual Report, well MW-9 was mistakenly listed as a compliance well. Well MW-9 is used for groundwater elevation, only.

Electronic Filing: Received, Clerk's Office 09/28/2020

was approved along with the Closure Plan. The GMZ is a three-dimensional region containing groundwater being managed to mitigate impacts from a potential release of leachate from the facility. Observed impacts during 2011-2014 included concentrations for boron, sulfate, manganese, and Total Dissolved Solids (TDS) higher than Class I groundwater quality standards within the GMZ. The GMZ is shown on Figure 1-2.

The Groundwater Monitoring Plan, in accordance with 35 IAC 840.114 and 35 IAC 840.116, outlines groundwater monitoring and sampling procedures, establishes the parameters and methods to be used for analyzing the groundwater samples, and describes evaluation methods to assess post-closure groundwater quality and trends to demonstrate compliance with the applicable groundwater standards. The Groundwater Monitoring Program Schedule is provided in Table 1-1.

Monitoring well locations, installation dates, construction information, and the groundwater zone they monitor are provided in Table 1-2. Field and laboratory parameters for evaluating groundwater quality are shown in Table 1-3.

This annual report includes the following elements:

- A summary of groundwater monitoring data collected in 2018 and 2019. Data tables are included in Appendix A.
- Quarterly Site Inspection Forms, including observations and descriptions of any maintenance activities performed on the pond cap, embankment, and groundwater collection trench and discharge system (Appendix B).
- Annual trend and statistical analysis results per Section 7.2.1 of the Groundwater Monitoring Plan, including an assessment of any statistically significant increasing trends (Appendix C).

1.2 Applicable Groundwater Quality Standards

1.2.1 On-Site Groundwater Standards

A GMZ has been established around the maximum predicted area of on-site groundwater impacts associated with Ponds A, B, and C. As described in Section 5.1.1 of the Groundwater Monitoring Plan and pursuant to 35 IAC 840.16(a):

- Prior to the completion of the post-closure care period, the on-site applicable groundwater quality standards at Ash Pond D are the greater of either the actual groundwater monitoring result, or the Class I Potable Resource Groundwater standard set forth in 35 IAC 620.410.
- After completion of the post-closure care period, the on-site concentrations of contaminants from Ash Pond A as determined by groundwater monitoring, if those concentrations exceed the numeric standards for Class I Potable Resource Groundwater set forth in 35 IAC 620.410, are the applicable groundwater standards at the Hutsonville site if the following criteria are addressed to the satisfaction of the Illinois EPA:
  - To the extent practicable, the exceedance has been minimized and beneficial use, as appropriate for the class of groundwater, has been returned on-site.
  - Any threat to public health or the environment on-site has been minimized.
  - An institutional control prohibiting potable uses of groundwater is placed on the Hutsonville site in accordance with the Uniform Environmental Covenants Act (765 Illinois Compiled Statutes (ILCS) 122) or an alternative instrument authorized for environmental uses under

Electronic Filing: Received, Clerk's Office 09/28/2020

Illinois law and approved by the Illinois EPA. Existing potable uses of groundwater may be preserved as long as such uses remain fit for human consumption in accordance with accepted water supply principles.

1.2.2 Off-Site Groundwater Standards

For off-site groundwater compliance, the groundwater quality standards are the Class I potable resource groundwater standards [35 IAC 620.410]. Although the established GMZ does not extend south of the Hutsonville Power Station's property boundary, an agreement[2] exists between Ameren and the south property owner regarding shallow well drilling. This restriction covers the first 25 ft. of the water table and lies within a 500-ft offset south of the southern property boundary of the Hutsonville site.

1.3 Demonstration of Compliance

Compliance will be based on attainment of groundwater quality that meets the numeric standards for Class I potable resource groundwater as set forth in 35 IAC 620.410. Groundwater quality that does not meet the Class I standard will be considered in compliance when no statistically significant increasing trend can be attributed to the ash ponds at the compliance GMZ boundary for four (4) consecutive years, which must be approved by the Illinois EPA. Post-closure groundwater compliance monitoring will continue for a minimum of ten years from the Illinois EPA's approval of the Closure Plan.

1.3.1 Compliance Determination

As described in Section 7.2.1 of the Groundwater Monitoring Plan:

- GMZ compliance is demonstrated by performing an annual trend analysis for each monitoring well located at the down-gradient boundaries of the Hutsonville site (Table 1-2) for all constituents listed in Table 1-3. The analysis shall use Sen's Estimate of Slope and be performed on a minimum of four consecutive samples.
- If the results of sampling and analysis show a positive slope at any compliance monitoring well located at the downgradient boundaries of the Hutsonville site, a Mann-Kendall test will be performed at 95 percent confidence to determine whether or not the increasing slope represents a statistically significant increasing trend. Ameren will investigate the cause of a statistically significant increasing trend as described below.
  - If the investigation attributes a statistically significant increasing trend to a superseding cause, Ameren will notify the Illinois EPA in writing, stating the cause of the increasing trend and providing the rationale used in such a determination.
  - If there is no superseding cause and the statistically significant increasing trend continues to be observed over two or more consecutive years, a hydrogeologic investigation (and additional site investigation(s), if necessary) will be performed.

Based on the outcome of the investigation above, Ameren will take action to mitigate statistically significant increasing trends that are causing, threatening or allowing exceedances of off-site groundwater quality standards. Such actions will be proposed as a modification to the post-closure care plan within 180 days after completion of the investigation activities described above.

2. DATA ANALYSIS

2.1 Groundwater Flow

Groundwater flow for 2019 is represented using groundwater elevation contour maps for each quarterly sampling event (Figures 2-1 through 2-4). Groundwater in the upper (shallow) zone generally flowed from west to east and northeast towards the Wabash River during 2019, which is consistent with past evaluations. The Groundwater Collection Trench began operation in April 2015, and following startup, groundwater elevations have exhibited localized flow toward the trench with groundwater elevations generally lower near the trench (Table 1-2). In the depictions of groundwater elevation contours dashed lines have been used to infer the localized drawdown of groundwater levels resulting from trench operation, which is necessary with limited wells situated laterally along the length of the trench.

The horizontal hydraulic gradient in the upper migration zone beneath the northern extent of Ash Pond A ranged from 0.0033 to 0.0047 ft/ft during 2019. There was little variability in horizontal hydraulic gradient across Ash Pond A between sampling events. Horizontal hydraulic gradient was not calculated near the southern end of the pond due to the potential influence of the trench of groundwater flow.

Groundwater flow within the lower (deep alluvial) migration zone along the edge of the Wabash River valley was not contoured since all the deep alluvial monitoring wells are within a narrow zone between Ash Pond D and the Wabash River. Groundwater within the lower zone generally flows from southwest to northeast towards the Wabash River.

2.2 Review of Analytical Data

Table 2-1 presents a site-wide statistical summary of all laboratory analytical data collected in 2018 and 2019. All field and laboratory analytical results are tabulated in Appendix A. Sampling anomalies, such as wells that were dry, had water levels too low for sampling, or were not sampled during a sampling event for other reasons, are noted below.

- MW-3: Not sampled in the first quarter of 2018 due to insufficient water level. Not sampled in the first, second, third, and fourth quarters of 2019 due to insufficient water level.
- MW-10 and MW-10D: Not sampled after the 2016 first quarter sampling event because the off-site wells were destroyed by others.
- MW-23D and MW-23S: These wells were installed in November 2017 and were sampled for the first time during the fourth quarter sampling event in December of 2017. MW-23D and MW-23S analytical data were compared to historical MW-10 and MW-10D data. There is no evidence of ash leachate impacts to monitoring wells MW-23S and MW-23D and they appear to be appropriate replacement upgradient/background wells.

Antimony, total cyanide, mercury, silver, thallium, and vanadium were detected in fewer than 10% of the groundwater samples. In addition to these constituents, beryllium, cadmium, chromium, copper, and lead were detected in fewer than 30% of the samples. A summary of wells and parameters with exceedances of Class I groundwater standards in 2018 and 2019 is shown on Table 2-2.

Electronic Filing: Received, Clerk's Office 09/28/2020

Parameters of Concern

Parameters of concern include the constituents that exceeded the Class I groundwater quality standard when the GMZ was established: boron, sulfate, manganese, and TDS. These constituents are discussed below:

- Boron: Boron is a primary indicator constituent for coal ash leachate impacts to groundwater. Downgradient monitoring wells MW-3D, MW-22D and MW-22S exceeded the Class I Potable Resource standard (2.0 milligrams per liter [mg/L]) for most of the 2018-2019 sampling events (Table 2-2 and Figure 4-1). Downgradient monitoring wells MW-2R and MW-3 exceeded the Class I standard, but the last exceedance was in 2018. Background monitoring wells MW-23D and MW-23S exceeded the Class I standard for the fourth quarter 2019 sampling event. The highest boron concentrations were detected in monitoring wells MW-22S and MW-22D. Time series plots of boron at these well locations are shown in Figure 5-1.
- Manganese: Manganese concentrations in downgradient monitoring wells MW-3D, MW-12, MW 22D, and MW-22S had exceedances of the Class I standard (0.15 mg/L) during the 2018-2019 monitoring period (Table 2-2 and Figure 4-2). Concentrations are highest in monitoring well MW-3D, followed by monitoring wells MW-22S, MW-22D and MW-12. Background wells MW-23S and MW-23D also exceeded the Class I standard for the fourth quarter 2019 sampling event (Figures 5-2a and 5-2b). Manganese is commonly present in native soils and is highly sensitive to redox conditions. Prior investigations at the Hutsonville site indicate that elevated manganese concentrations may also be indicative of coal or coal stockpile impacts.
- Sulfate: Sulfate can be an indicator constituent for coal ash; however, there are other anthropogenic sources for elevated sulfate concentrations in groundwater, and sulfate concentrations can decrease in groundwater under strongly reducing conditions. These caveats make sulfate a less reliable indicator for coal ash leachate than boron. Sulfate concentrations at Ash Pond A exceeded the Class I standard (400 mg/L) at MW-3, MW-3D, MW-22D, and MW-22S, where boron concentrations are also high compared to the other monitoring wells (Figure 4-3 and Figure 5-3). The Class I standard was also exceeded at downgradient well MW-12 in the second quarter of 2018 along with background wells MW-23D and MW-23S in the fourth quarter of 2019.
- Total Dissolved Solids (TDS): TDS exceeded the Class I standard of 1,200 mg/L at monitoring wells MW-3, MW-3D, MW-22D, and MW 22S, which also have the highest concentrations of boron and sulfate measured in groundwater (Figure 4-4 and Figure 5-4). The Class I standard was also exceeded at background wells MW-23D and MW-23S in the fourth quarter of 2019.

Other Parameters

Other parameters which had at least one exceedance in 2018-2019 (Table 2-2) in the Ash Pond A monitoring wells are discussed below:

- Arsenic: There were two exceedances of the arsenic Class I standard of 0.01 mg/L for the second and third quarters, 2019 monitoring period at MW-2D. Although neither of the sample results were identified as potential outliers, the fourth quarter sample result at this location was below the standard (Figure 4-5).
- Beryllium: Downgradient monitoring well MW-22S had beryllium concentrations that exceeded the Class I groundwater standard of 0.004 mg/L for most of the 2018 and 2019 sampling

Electronic Filing: Received, Clerk's Office 09/28/2020

events. Background monitoring well MW-23S had one exceedance of the Class I standard during the fourth quarter 2019 sampling event (Figure 4-6).

- Cadmium: There were two exceedances of the cadmium Class I standard of 0.005 mg/L for the first quarter sample event 2018 and the third quarter 2019 sample event at MW-3D. Background monitoring well MW-23S had one exceedance of the Class I standard during the fourth quarter 2019 sampling event (Figure 4-7).
- Iron: Three downgradient wells and two background wells had exceedances of the Class 1 standard of 5.0 mg/L for dissolved iron (Figure 4-8). Well MW-3D exceeded the standard for the fourth quarter 2018 sampling event. Well MW-22D exceeded the Class 1 standard for all sampling events, except for the fourth sampling event of 2019. Well MW-22S exceeded the Class 1 standard for all sampling events, except for the second and fourth sampling events of 2019. Two potential outliers were identified at background wells MW-23D and MW-23S for the fourth 2019 sampling event. Both of the background wells also had low pH exceedances. Since iron solubility increases with acidity, it would be expected that the wells with the highest iron concentrations also have the lowest pH across the Hutsonville site.
- Lead: The Class I standard for lead of 0.0075 mg/L was exceeded once in downgradient wells MW-22S and MW-22D during the third quarter 2018 sampling event (Figure 4-9). These well also has the lowest pH compared to the other Ash Pond A monitoring wells (Figure 4-12). Low pH may increase the solubility of lead.
- Nickel: Wells MW-3D, MW-22S, and MW-23S all had exceedances of the Class I standard of 0.1 mg/L for nickel. MW-3D had seven exceedances, MW-22S had three exceedances in 2018, and MW-23S had one exceedance in 2019 (Figure 4-10).
- pH: The lower Class I standard for pH of 6.50 standard units (Std.) was exceeded at monitoring wells MW-3D, MW-22D, MW-22S, MW-23D, and MW-23S. Well MW-3D exceeded the lower Class I standard for all of the 2018-2019 sampling events. MW-22S and MW-22D exceeded the lower Class I standard for every event except the fourth quarter 2019 sampling event. Background wells MW-23D and MW-23S exceeded the lower Class I standard only during the fourth quarter 2019 sampling event (Figure 4-11). Since low pH increases the solubility of most metals, it is not surprising that these five wells also have all the Class I exceedances for metals with the exceptions of arsenic at MW-2D, and manganese at MW-12.

2.3 Statistical Analyses

Analytical data were evaluated for trends following a three-step procedure:

1. Test for outliers using the Grubbs Outlier test.
2. Determine Sen's estimate of slope.
3. Perform a Mann-Kendall trend analysis for any cases (monitoring well/constituent) with a positive slope.

2.3.1 Outlier Analysis

The Grubbs outlier test determines whether or not there is statistical evidence that an extreme high or low observation does not fit the remaining data. The test methodology and results are listed in Appendix C1 and summarized in Table 2-3. The Grubbs test, like all statistical tests, provides statistical evidence of potential outliers, but cannot be used alone to determine whether

Electronic Filing: Received, Clerk's Office 09/28/2020

or not a value is a true outlier that should be excluded from future statistical analysis. Corroborating evidence needed to exclude values includes a very high value relative to all other values for a particular monitoring well/parameter case—which suggests a discrete data reporting or analytical error, or numerous values from a single sample event that are higher than all other sample events for that parameter—which indicates potential laboratory bias. Absent corroborating evidence, the flagged values are considered true but extreme values in the data set. No results were eliminated from statistical analysis due to the Grubbs outlier evaluation.

2.3.2 Sen's Estimate of Slope

Sen's estimate of slope is a non-parametric estimator of trend. It is the median of all slopes between all possible unique pairs of individual data points in the time period being analyzed. The slopes represent the rate of change of the measured parameter, with the y-axis being the parameter value and the x-axis being calendar time. The method is robust, and fairly insensitive to the presence of a small fraction of outliers and non-detect data values. The test methodology and results are listed in Appendix C2 and summarized in Table 2-4.

Data collected in 2018-2019 show 45 cases with positive slopes, 69 cases with negative slopes, and 136 cases with no slope (Table 2-5). Sen's Estimate of Slope requires a minimum of four consecutive samples. The 45 cases with positive slopes were tested using the Mann-Kendall test to determine if the positive slopes represented statistically significant increasing trends.

2.3.3 Mann-Kendall Trend Analysis

The Mann-Kendall test is a non-parametric, two-sided test to determine whether or not a dataset has a statistically significant increasing or decreasing trend. The test methodology and results are listed in Appendix C3 and summarized in Table 2-5. Statistically significant increasing trends are flagged in Table 2-4.

Ten cases with a statistically significant increasing trend were identified in the analysis covering samples collected in 2018-2019. The ten cases are identified by constituent below:

- Boron: MW-23S has a statistically significant increasing trend for boron. Boron concentrations at MW-23S were below the Class I standard for all the 2018-2019 sampling events but exceeded the Class I standard in the fourth quarter 2019 sampling event (Figure 4-1). Figure 5-1 shows a time series plots for MW-23S, along with plots for wells that have exceeded the Class I boron standard at some time since completion of closure activities (MW-2R, MW-12, MW-3, MW-3D, MW-22D, and MW-22S).
- Chloride: Chloride at well MW-5 has a statistically significant increasing trend; however, the concentrations at MW-5 are lower than Class I groundwater levels.
- Copper: MW-23S has a statistically significant increasing trend for copper. Copper concentrations at well MW-23S were not detected up until the third quarter sampling event of 2019; however, the concentrations at MW-23S are lower than Class I groundwater levels.
- Iron: Iron at wells MW-4, MW-12, MW-23D, and MW-23S have statistically significant increasing trends. The concentrations at wells MW-4 and MW-12 are lower than Class I groundwater levels. The concentrations at MW-23D and MW-23S exceed the Class I standard of 5 mg/L only during the fourth quarter 2019 sampling event. As a note, the Grubb's Outlier Test noted that those two exceedances could be potential high outliers (Figures 5-5a and 5-5b).

Electronic Filing: Received, Clerk's Office 09/28/2020

- Manganese: Manganese at MW-2R has a statistically significant increasing trend; however, the concentrations at MW-2R are lower than Class I groundwater levels.
- Nitrate: MW-2D and MW-3D have a statistically significant increasing trends for nitrate but both are lower than the Class I standard of 10 mg/L and concentrations at MW-2D are an order of magnitude lower than the Class I standard.

2.4 Site Inspection

The Post-Closure Care Plan requires quarterly inspection until completion of the post-closure period. Inspections are also required after storm events defined as a 25-year, 24-hour event, or approximately 5.37 inches of precipitation. Discontinuance of Hutsonville site inspections will occur after Illinois EPA approval of the certified Post-Closure Care Report.

Hutsonville site inspections include assessment of the condition and need for repair of final cover and vegetation, as wells as fencing, monitoring points, and surface water control features. The inspection reports for 2019 are included in Appendix B.

The Hutsonville site inspection performed on December 4, 2019 noted a small area of erosion at the bottom of the north cap drainage drop that is to be repaired. No other notes were mentioned for the site inspections performed on March 31, 2019; June 27, 2019; and September 26, 2019.

Electronic Filing: Received, Clerk's Office 09/28/2020

3. EVALUATION OF COMPLIANCE

3.1 Review of Statistically Significant Increasing Trends

The post-closure groundwater monitoring began in March 2017. This report focuses on the eight quarters of groundwater quality data that were collected in 2018-2019. Since post-closure operation began, downgradient monitoring wells MW-2D, MW-22S, MW-22D, and upgradient wells MW-23S and MW-23D were installed. The Sens Estimate of Slope and Mann-Kendall Trend Analysis were performed for all downgradient monitoring well locations; and these analyses require a minimum of four consecutive data points. The former upgradient monitoring wells (MW-10 and MW-10D) were destroyed, so no samples were collected or analyzed for statistical trends in 2018 or 2019. Because of this, analyses for statistically significant increasing trends were performed at the new upgradient monitoring wells (MW-23S and MW-23D) that were installed in November of 2017. Analyses for statistically significant increasing trends were also performed at downgradient monitoring wells MW-2R, MW-3D, MW-4, MW-5, and MW-12.

The following ten cases with statistically significant increasing trends sorted by monitoring well location, were identified in the analysis covering samples collected in 2018-2019.

- MW-2D: nitrate
- MW-2R: manganese
- MW-3D: nitrate
- MW-4: iron
- MW-5: chloride
- MW-12: iron
- MW-23D: iron
- MW-23S: boron, copper, iron

Of these ten cases of statistically significant increasing trends, only concentrations of boron at MW-23S, iron at MW-23D, and iron at MW-23S exceeded their respective Class I standards.

In addition to having three statistically significant increasing trends at monitoring well MW-23S, there were also exceedances of Class I standards for beryllium, cadmium, manganese, nickel, pH, sulfate, and TDS all during the fourth quarter 2019 sampling event. Although MW-2D did not have any significantly increasing trends that exceeded Class I standards, it did have two Class I exceedances for arsenic. Similarly, MW-3 did not have sufficient samples to perform statistical analyses but it did have two Class I exceedances for boron, and three Class I exceedances for sulfate and TDS. MW-3D, MW-22D, MW-22S, MW-23D, and MW-23S also have exceedances for boron and sulfate, the primary indicator constituents for coal ash leachate. These wells also shared exceedances for iron, manganese, nickel, pH, and TDS. Monitoring well MW-12 has one statistically significant increasing trend for iron and has six exceedances for manganese and one exceedance for sulfate.

Given the Class I exceedances for the coal ash indicators boron and sulfate, combined with those parameters with increasing trends, it is likely that wells MW-2R, MW-3, MW-3D, MW-12, MW-22D, MW-22S, MW-23D, and MW-23S remain impacted by a release of coal ash leachate.

Electronic Filing: Received, Clerk's Office 09/28/2020

These wells (with exception of upgradient wells MW-23D and MW-23s) are located within the GMZ established for mitigation of impacts from a potential release from Ash Pond A. Elevated concentrations of boron, sulfate, and TDS at these locations are consistent with constituents of concern identified during establishment of the GMZ. Monitoring wells MW-3D, MW-22D, MW-22S, MW-23D, and MW-23S all have exceedances of Class I standards for multiple metals. Exceedances in metals at wells MW-3D, MW-23D, and MW-23S may be a result of lower pH at these locations. Acidic conditions increase the solubility of most metals that may be present in both coal ash and soil. Elevated nitrate concentrations are attributed to off-site agricultural sources. Elevated manganese concentrations may be attributed to both impacts from Ash Pond A and naturally occurring conditions.

Electronic Filing: Received, Clerk's Office 09/28/2020

4. CONCLUSIONS

GMZ compliance is demonstrated by the absence of statistically significant increasing concentration trends or the identification of a to a superseding cause of a statistically significant increasing concentration trend as discussed in Section 1.3.1. Statistical analyses of concentration results for groundwater samples collected in 2018 and 2019 at the Hutsonville Ash Pond A identified ten cases of statistically significant increasing trends:

- MW-2D: nitrate
- MW-2R: manganese
- MW-3D: nitrate
- MW-4: iron
- MW-5: chloride
- MW-12: iron
- MW-23D: iron
- MW-23S: boron, copper, iron

With the exception of the upgradient wells MW-23D and MW-23S, all of the wells with constituent concentrations appearing in statistically significant increasing trends are located within the GMZ established for mitigation of impacts from a potential release from Ash Pond A.

Observed impacts during 2011-2014 included concentrations for boron, sulfate, manganese, and TDS higher than Class I groundwater quality standards within the GMZ. Recent elevated concentrations of boron, manganese, sulfate, and TDS at these locations are consistent with the constituents of concern identified during establishment of the GMZ.

There were significant increasing trends at upgradient wells, along with Class I exceedances, for boron at MW-23S, iron at MW-23D, and iron at well MW-23S. There are no Class I exceedances associated with statistically significant increasing trends for chloride, copper, manganese or nitrate.

This is the third annual report following the completion of Ash Pond A closure activities. Only one well (MW-3) had insufficient data for statistical evaluation in the 2019 annual report. The Groundwater Monitoring Plan requires a hydrogeologic investigation if a statistically significant increasing trend occurs over a period of two or more consecutive years since closure that cannot be attributed to a superseding cause. Since the only three statistically significant increasing trends for 2017-2018 (boron at MW-2R, sulfate at MW-12, and lead at MW-22S) were not also significantly increasing in 2018-2019, no action, other than submittal of this report, is required per Section 5.2.3 of the Groundwater Monitoring Plan (Compliance Determination).

Electronic Filing: Received, Clerk's Office 09/28/2020

Notes:

1. Well survey data collected by Lamac Engineering November 30, 2017 to December 1, 2017.
2. BGS = below ground surface; MSL = mean sea level.
3. TOC = top of casing
4. Screen elevations presented in the table reflect values provided in boring logs or well construction forms and assume no changes to the screen elevations occurred after well installation.
5. The total well depth is assumed to be equal to the depth to the bottom of screen from ground surface when data is not available in boring logs or well construction forms.
6. UZ = Upper Zone, LZ = Lower Zone (deep alluvial aquifer); s = sand or sandy, s&g = sand and gravel, si = silt or silty, ss = sandstone, sh = shale
7. Background wells MW-10 and MW-10D were damaged and replaced with background wells MW-23D and MW-23S.

Notes: [O: RAB 1/13/2020, C:YMD 1/15/2020]

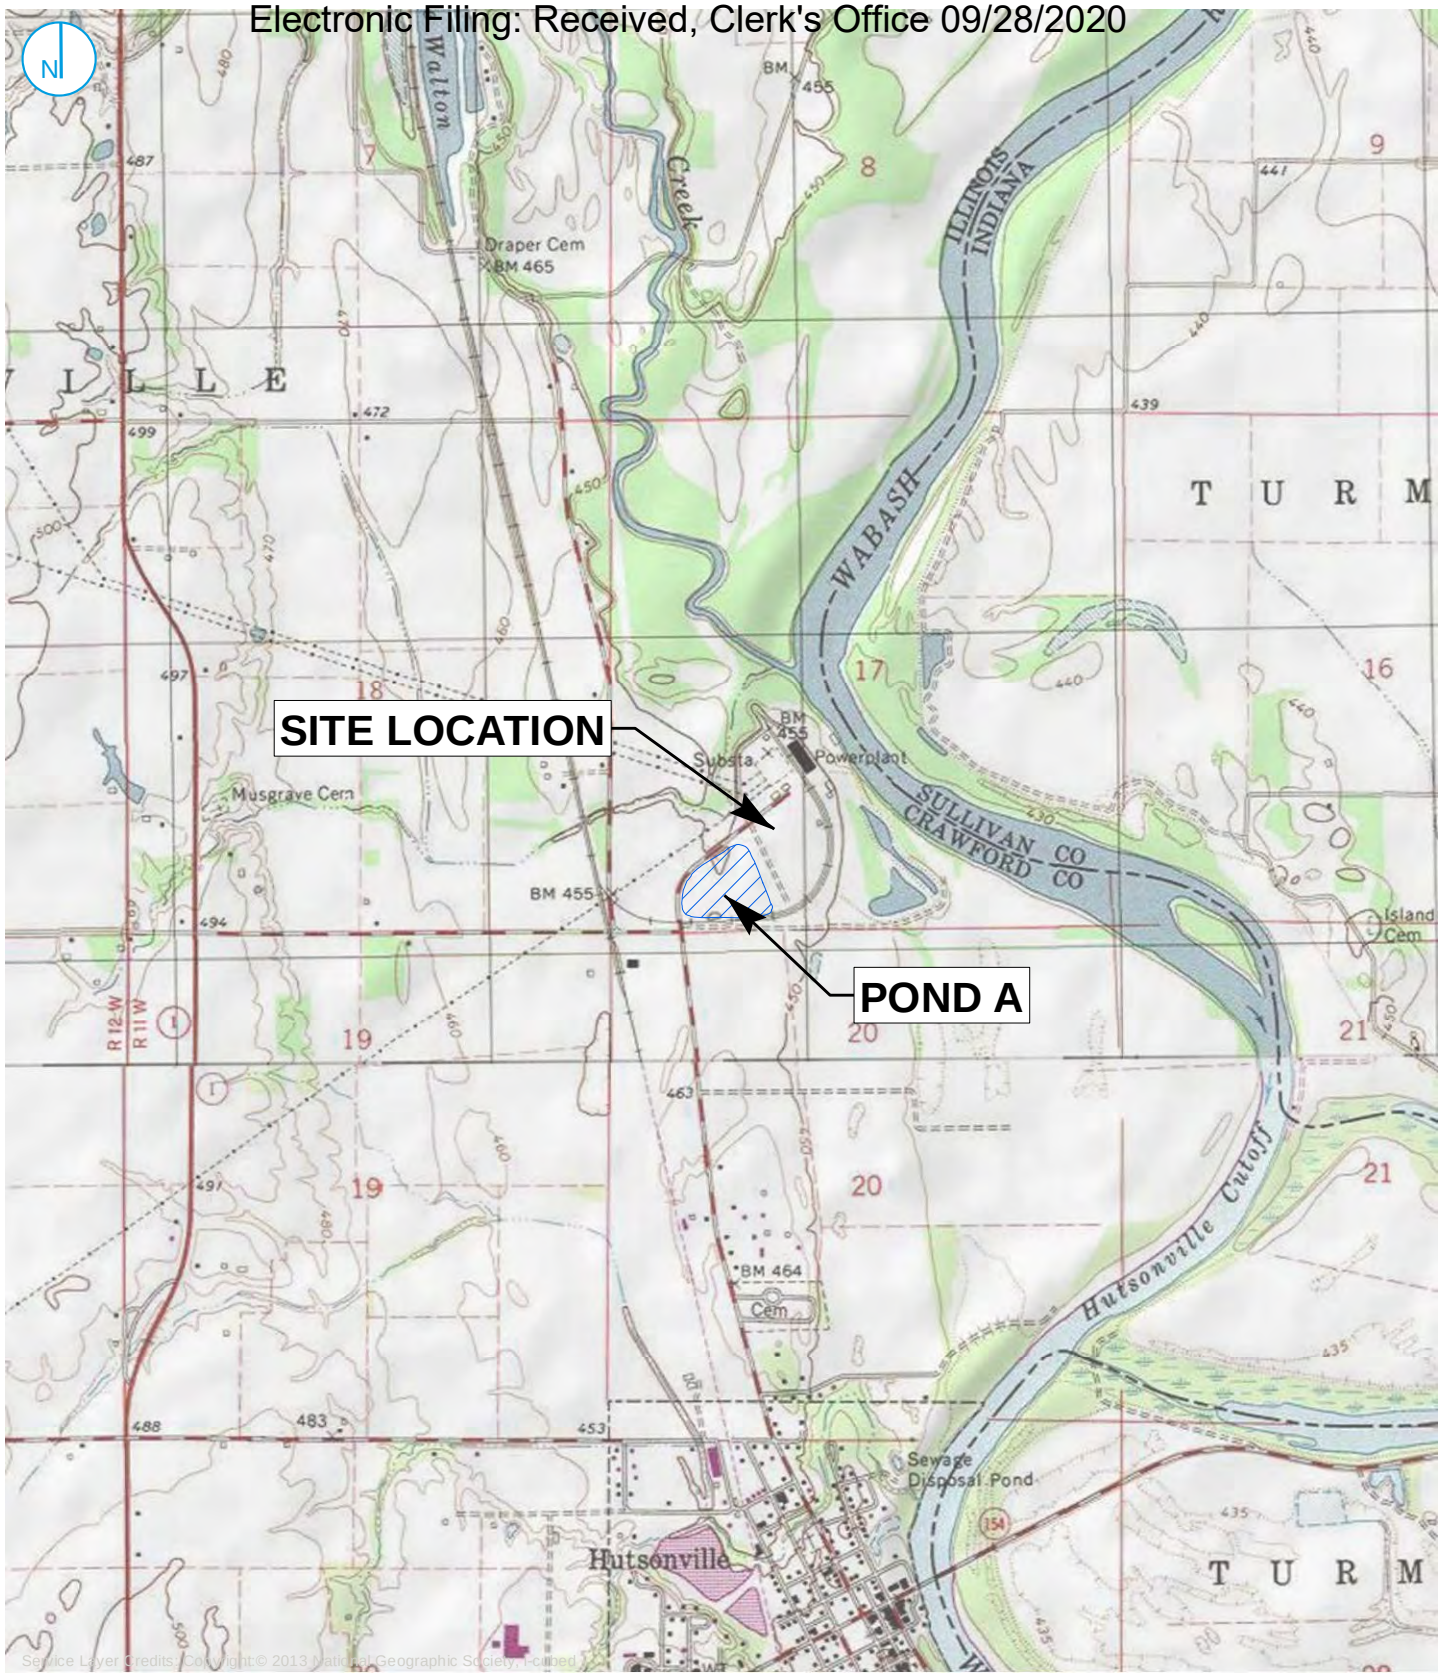
- "positive", "negative", and "none" describe the slope as calculated using Sen's median estimate of slope; slopes that are statistically significant (see below) are indicated by the MK prefix.
- MK trend analysis done with non-detects at one half the detection limit.
1. MANAGES 4.1 output displays 0.0 for the median slope; however the direction of the slope was confirmed to be positive by evaluating the data set.
2. MANAGES 4.1 output displays a statistically signficiant positive trend, but further investigation revealed that the designation was due to the reporting limit changes between subsequent sampling events. Therefore, these counts are included into the "none" category in Table 2-5 as there were no trends.

- Green shading indicates increasing positive trends that are statistically significant as determined using the Mann-Kendall test at 95% confidence for constituents with maximum concentration lower than the Class I groundwater quality standard.

- Yellow shading indicates increasing positive trends that are statistically significant as determined using the Mann-Kendall test at 95% confidence for constituents with maximum concentration higher than the Class I groundwater quality standard.

- ID indicated that there was insufficient data to perform Sen's Estimate of Slope

Table 2-5. Summary of Trend Analyses
2019 Annual Report
Former Hutsonville Power Station - Ash Pond A



Time Period	Slope			Statistically Significant Increasing Trends
	Negative	None	Positive	
2016-2017	33	42	25	8
2017-2018	82	127	66	9
2018-2019	69	136	45	10

[O:RAB 1/14/2020, C:YMD 1/15/2020]

Notes:
Trends based on data collected during the specified periods.
The number of samples per well location are noted on Table 2-4.

APPENDIX B
SITE INSPECTION REPORTS

Hutsonville Power Station

Ash Pond A Closure Cap - Post-Closure Care Plan

Quarterly Site Inspection Checksheet

Date	12/04/2019
Inspector	LGH
Temperature	45 degrees F
Weather	Sunny

	Item	Condition Code *	Comments
Pond Cap	Vent Pipes	GC	
	Drainage Berms	GC	
	Vegetation	GC	
	Erosion	MM	Small area of erosion at bottom of north cap drainage drop to be repaired.
	Liner	GC	
	Water Control Features (rip-rap, paved flumes, etc.)	GC	
	Other	GC	
Embankment	Vegetation	GC	
	Liner	GC	
	Erosion	GC	
	Fencing	GC	
	Drainage Channels (rip-rap, paved flumes, etc.)	GC	
	Other	GC	
Groundwater Collection Trench and Discharge System	Control Panels	NI	See Pond D checklist.
	Drainage Sumps / Manholes	NI	See Pond D checklist.
	Pumps	NI	See Pond D checklist.
	Groundwater Monitoring Wells	NI	See Pond D checklist.
	Flow Meter Totalizer	NI	N/A - meters are being read remotely.
	Diver-Mate Data Collector (data download)	NI	N/A - meters are being read remotely.
	Other	NI	See Pond D checklist.

Condition Codes

IM = Item needing immediate maintenance. Remediation/repair should be completed within 1 month.
MM = Item needing minor maintenance and/or repairs within the year.
OB = Condition requires regular observation to ensure that the condition does not become worse.
GC = Good Condition. Working properly.
NE = No evidence of a problem.
NI = Not Inspected. Reason should be stated in comment.

Gray Area not inspected - data capture is via remote electronic signal.

Looking northerly across southeast toe

Looking west along south berm

Looking at east drainage drop

Looking down east drainage drop toward former Ash Pond B

Looking northwest across east berm

Looking west across cap

Looking at southwest cap drainage drop

Looking east up western cap face

Looking northeast along west berm

Looking at north cap drainage drop on north toe, small area of erosion at bottom of drainage drop

Looking south across cap

Drainage area along west berm, facing southwest

APPENDIX C2
SEN SLOPE AND MANN KENDALL TESTS

Hutsonville Ash Impoundment
Mann-Kendall Trend Analysis

User Supplied Information

Location ID:	**MW12**	**Parameter Code:**	**00515**
Location Class:		**Parameter:**	**Total Dissolved Solids**
Location Type:		**Units:**	**mg/L**
Confidence Level:	**95.00%**		

Date Range: 01/01/2018 to 12/31/2019

Trend Analysis

Trend of the least squares straight line

Slope (fitted to data):	0	mg/L per period
R-Squared error of fit:	0	

Sen's Non-parametric estimate of the slope (two-tailed test)

Median Slope:	0	mg/L per period
Lower Confidence Limit of Slope, M1:	-1	mg/L per period
Upper Confidence Limit of Slope, M2+1:	0	mg/L per period

Non-parametric Mann-Kendall Test for Trend

S Statistic:	-2
Z test:	2
At the 95.0 % Confidence Level (two-tailed test):	Downward

Hutsonville Ash Impoundment
Mann-Kendall Trend Analysis

User Supplied Information

Location ID:	**MW12**	**Parameter Code:**	**00618**
Location Class:		**Parameter:**	**Nitrate nitrogen, dissolved**
Location Type:		**Units:**	**mg/L**
Confidence Level:	**95.00%**		

Date Range: 01/01/2018 to 12/31/2019

Trend Analysis

Trend of the least squares straight line

Slope (fitted to data):	0.001	mg/L per period
R-Squared error of fit:	0.067	

Sen's Non-parametric estimate of the slope (two-tailed test)

Median Slope:	0.001	mg/L per period
Lower Confidence Limit of Slope, M1:	-0.002	mg/L per period
Upper Confidence Limit of Slope, M2+1:	0.005	mg/L per period

Non-parametric Mann-Kendall Test for Trend

S Statistic:	0.997
Z test:	1.645
At the 95.0 % Confidence Level (two-tailed test):	None

STATISTICAL ANALYSIS

Stand-Alone Statistical Tests

Statistical Evaluation Report

The Statistical Evaluation Report is comprised of a series of subreports as described below.

User Selections:

- One location.
- Sample date range for data selection.
- Interval length: the length of the averaging period in months (1,2,3,4, or 6).
- One parameter.
- Non-detect processing: multiplier between 0 and 1.
- One-sided confidence $(1-\alpha)$ level – 0.90, 0.95 or 0.99.
- Limit type: used in the statistical overview to determine exceedances.

Mann-Kendall Trend and Seasonal Analysis Tests

The Mann-Kendall test for trend is insensitive to the presence or absence of seasonality. The test is non-parametric and does not assume any type of data distribution. Nonetheless, two forms of the test are provided in MANAGES, one ignoring data seasonality even if it is present, and one considering data seasonality. In the test, the null hypothesis, H_0, is that the Sen trend is zero, and the alternate hypothesis, H_a, is that the trend is non-zero.

In general, the Mann-Kendall test considering seasonality indicates a larger range for allowable Sen estimate of trend when seasonality is actually present than the range indicated by the test performed ignoring seasonality.

In the Mann-Kendall Trend Analysis, available in under the Statistical Evaluation Report and in the Statistical Procedure for Detection Monitoring, and Mann-Kendall Seasonal Analysis, found under the Statistical Evaluation Report, MANAGES first calculates the Sen slope and the upper and lower confidence limits of the Sen slope, and then determines whether the Sen slope is statistically significant. Slope is statistically significant if it is non-zero.

Mann-Kendall Test for Sen Slope Significance – a two-sided, non-parametric method for data sets as small as 10, unless there are many tied (e.g., equal, NDs are treated as tieds) values (Gilbert, 1987; p. 208)	
Indicator Function $\text{sgn}(x_{ij} - x_{jk})$	= 1 if $(x_{ij} - x_{jk}) > 0$ = 0 if $(x_{ij} - x_{jk}) = 0$ = -1 if $(x_{ij} - x_{jk}) < 0$ where $x_{i1}, x_{i2}, \ldots, x_{in}$ are the time ordered data (n_i is total of data in the i-th season).
Mann-Kendall Statistic, S_i	$= \sum_{k=1}^{n_i-1} \sum_{j=k+1}^{n_i} \text{sgn}(x_{ij} - x_{jk})$
Variance of S_i $VAR(S_i)$	$VAR(S_i) =$ $\frac{1}{18}\left\{ n_i(n_i-1)(2n_i+5) - \sum_{p=1}^{g_i} t_{ip}(t_{ip}-1)(2t_{ip}+5) - \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)(2u_{iq}+5) \right\}$ $+ \frac{\sum_{p=1}^{g_i} t_{ip}(t_{ip}-1)(t_{ip}-2) \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)(u_{iq}-2)}{9n_i(n_i-1)(n_i-2)}$ $+ \frac{\sum_{p=1}^{g_i} t_{ip}(t_{ip}-1) \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)}{2n_i(n_i-1)}.$ The variable g_i is the number of tied groups (equal-valued) data in the i-th season, t_{ip} is the number of tied data in the p-th group for the i-th season, h_i is the number of sampling times (or time periods) in the i-th season that contain multiple data, u_{iq} is the number of multiple data in the q-th time period in the i-th season, and n_i is the number of data values in the i-th season.

Test Statistic, Z	If $S' = \sum_{i=1}^{K} S_i$, where K is the number of seasons, then the test statistic Z is computed as: $$Z = \begin{cases} \dfrac{S'-1}{[VAR(S')]^{1/2}} & \text{iff } S' > 0 \\ 0 & \text{iff } S' = 0 \\ \dfrac{S'+1}{[VAR(S')]^{1/2}} & \text{iff } S' < 0 \end{cases}$$ Where "iff" is an acroym meaning: if-and-only-if. A positive Z value means an upward trend and a negative Z value means a negative trend.
Hypothesis Test: H_0 = no trend H_a = trend present This is a two-sided test at the α significance level.	Accept the null hypothesis H_0 of no trend if $\lvert Z \rvert \leq Z_{1-\alpha/2}$ Reject the null hypothesis H_0 if $\lvert Z \rvert > Z_{1-\alpha/2}$ where $Z_{1-\alpha/2}$ is obtained from Table A1 in Gilbert (1987; p. 254).

Kruskal-Wallis Analysis (Test for Seasonality)

To perform the Kruskal-Wallis test for data seasonality, data points are first segmented according to season (Gilbert, 1987). The null hypothesis, H_0, is that all seasons have the same mean value. The alternative hypothesis, H_a ,is that at least one season has a mean larger or smaller than the mean of at least one other season. Montgomery et al. (1987) provide additional information on groundwater data seasonality. This is a two-sided, non-parametric test.

In MANAGES, the Kruskal-Wallis Test for Seasonality is found under Data Review // Non-Parametric Methods // Kruskal-Wallis Analysis. It determines whether the seasonal means for the specified parameter at the specified location are statistically the same.

	or $Z_i \geq SCL$.

Outlier Tests

Outlier tests are useful in detecting inconsistencies of measurement within a data set. An outlier is defined as an observation that appears to deviate markedly from other values of a sample set. There are many possible reasons for the presence of an outlier, including 1) the presence of a true but extreme value from a single population, resulting from random variability inherent in the data; 2) an improper identification of the underlying distribution describing the population from which the sample set comes from; 3) the occurrence of some unknown event(s) such as a spill, creating a mixture of two or more populations; 4) a gross deviation from prescribed sampling procedures or laboratory analysis; 5) a transcription error in the data value or data unit of measurement.

USEPA (1989; p. 8-11) states that the purpose of a test for outliers is to determine whether or not there is statistical evidence that an observation that appears extreme does not fit the distribution of the rest of the data. If an observation is identified as an outlier, then steps need to be taken to determine whether it is the result of an error or a valid extreme observation. If a true error, such as in transcription, dilution, or analytical procedure, can be identified, then the suspect value should be replaced with its corrected value. If the source of the error can be determined but no correction is possible, then the observation is deleted and the reason for deletion is reported along with any statistical analysis. If no source of error can be documented, then it must be assumed that the observation is a true but extreme value of the data set. If this is the case, the outlier observation(s) must not be altered or excluded from any statistical analysis. Identification of an observation as an outlier but with no error documented could be used to suggest resampling to confirm the value (USEPA, 1989; p. 8-13).

The outlier tests provided in MANAGES are based on either the single outlier test of Grubbs (1969), which is used by USEPA (1989; pp. 8-10 to 8-13) or the single outlier test of Dixon (1951, 1953), which is used by USEPA (2000; pp. 4-24) and by ASTM (1998). The outlier tests assume the data come from a normal distribution. Only one outlier, either an extreme low or an extreme high, can be detected during a single analysis of a data set. Additional outliers can be detected by temporarily removing a previously detected outlier from a data set and then repeating the test on the remaining, reduced, data set. During each pass of the outlier test, the sample mean, standard deviation, and sample size used in the test statistics are computed using only the data remaining in the set. The process can be continued until there is either an insufficient amount of data remaining (a minimum of 3 values) or when no additional outliers are found. When using MANAGES, the user will be asked how many outliers are to be checked and it will then automatically perform all of the recursive calls and data reductions with the Grubbs or Dixon routine. When done, a report can be generated that will show each outlier marked with a flag indicating the sequential order in which the outliers were identified.

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Critical values used in the one-sided Grubbs test are taken directly from those in Grubbs and Beck (1972) for sample sizes smaller than 147 observations. Critical values for sample sizes larger than 147 were generated numerically using a Monte Carlo routine, where each sampling event was simulated 100,000 times. Sample sizes ranging from 148 to 5,000 where used and then their resultant test statistic T_n curve fitted at specific significance levels. By this method, it was possible to match Grubbs results to at least four significant digits for corresponding tabulated values.

Critical values used in the one-sided Dixon outlier test are taken directly from tables given in Dixon (1951), Dixon (1953; page 89), and USEPA (2000; p. A-5, Table A-3). The critical values were then curve fitted for every sample size between 3 and 25 as a function of the significance level. By this method, it was possible to match Dixon's results to at least four significant digits for corresponding tabulated values. Note that the Dixon test assumes the data are either normally or lognormally distributed. Hence, sample sizes can only range between 3 and 25, inclusive. Dixon never developed an outlier test for sample sizes larger than 25.

User Selections:

- One or up to 100 locations: a separate test is performed for each location.
- One or up to 100 parameters: a separate test is performed for each parameter.
- Evaluation date range.
- Confidence $(1-\alpha)$ level: 0.90, 0.95 or 0.99.
- Non-detect processing: multiplier between 0 and 1.
- Data transformation option: none and log (base e).
- Number of outliers: one, two, first 5%, first 10%. Selecting any option other than one causes MANAGES to rerun the test, with outliers from prior tests removed, until either no outliers are detected or the specified number of outliers are detected.

Technical Details

Grubbs Outlier Test – The Grubbs outlier test determines whether there is statistical evidence that an observation does not fit the remaining data (USEPA, 1989; p. 8-11). This significance test looks at either the highest or the lowest observation in normal samples.	
The number of observations taken during a specified scoping period; n	*n*

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Mean of the observed data during the scoping period; $\overline{X}$	$\overline{X} = \frac{1}{n}\sum_{i=1}^{n} X_i$ where X_i is the i-th observation.
Standard deviation of observed data; S_x.	$S_x = \sqrt{\frac{1}{(n-1)}\sum_{i=1}^{n}(X_i - \overline{X})^2}$
Test statistics: T_l & T_n	Sort the data into ascending order, then compute the statistics $T_l = (\overline{X} - X_l)/S_x$ $T_n = (X_n - \overline{X})/S_x$ where X_l is the smallest value of the n observations and X_n is the largest value of the n observations.
One-sided test with a (1-α) confidence level that there is a single extreme outlier within the n observations.	Grubbs single, one-sided test of either an extreme low outlier : X_l *is an outlier if* $T_l \geq T_{cr(1-\alpha,n)}$ or an extreme high outlier: X_n *is an outlier if* $T_n \geq T_{cr(1-\alpha,n)}$. The function $T_{cr(1-\alpha,n)}$ is the critical value, given in Grubbs and Beck (1972; Table 1) and USEPA (1989; p. B-11, Table 8) . Note that the critical value assumes that the mean and standard deviation are computed from the sample being tested.

Dixon Outlier Test – The Dixon outlier test determines whether there is statistical evidence that an extreme observation does not fit the remaining data (USEPA, 2000; p. 4-24 and ASTM D6312, 1998). This significance test looks at both the highest and the

lowest observations in a sample data set. However, the routine will only perform the outlier tests if several conditions are first satisfied. For example, the Dixon outlier algorithm checks the distribution of the sample data for both normality and lognormality using the Shapiro-Wilk W-test. The outlier routine will not proceed with a data set if the W-test fails. In addition, the Dixon outlier test is limited to a minimum of 3 and a maximum sample size n of 25 data values.	
The number of observations taken during a specified scoping period; n	Number of observations, n, where $3 \le n \le 25$.
Sorting the sample data	Sort the data into ascending order, with the minimum data value $X_{(1)}$ first and the maximum data value $X_{(n)}$ last. Use the natural log of the data values if data are lognormally distributed, i.e., $X_{(j)} = Ln[X_{(j)}]$.
Goodness-of fit tests	After temporarily excluding either the minimum or maximum value of the data set, the Shapiro-Wilk's W-test is used to determine if the remaining $n-1$ values are normally or lognormally distributed. If not, the Dixon outlier test can't be used.
Test statistic, T_s, for the minimum data value	Compute the T_s test statistic for $X_{(1)}$ as an outlier: $T_s = \frac{X_{(2)} - X_{(1)}}{X_{(n)} - X_{(1)}}$ *for* $3 \le n \le 7$ $T_s = \frac{X_{(2)} - X_{(1)}}{X_{(n-1)} - X_{(1)}}$ *for* $8 \le n \le 10$ $T_s = \frac{X_{(3)} - X_{(1)}}{X_{(n-1)} - X_{(1)}}$ *for* $11 \le n \le 13$ $T_s = \frac{X_{(3)} - X_{(1)}}{X_{(n-2)} - X_{(1)}}$ *for* $14 \le n \le 25.$
Test statistic, T_s, for the maximum data value	Compute the T_s test statistic for $X_{(n)}$ as an outlier:

	$T_s = \frac{X_{(n)} - X_{(n-1)}}{X_{(n)} - X_{(1)}}$ *for* $3 \le n \le 7$ $T_s = \frac{X_{(n)} - X_{(n-1)}}{X_{(n)} - X_{(2)}}$ *for* $8 \le n \le 10$ $T_s = \frac{X_{(n)} - X_{(n-2)}}{X_{(n)} - X_{(2)}}$ *for* $11 \le n \le 13$ $T_s = \frac{X_{(n)} - X_{(n-2)}}{X_{(n)} - X_{(3)}}$ *for* $14 \le n \le 25$.
Critical value T_c	USEPA (2000; p. A-5, Table A-3) lists the critical values of the Dixon test as a function of sample size for a one-sided extreme value test at the significance levels α of 0.1, 0.05, and 0.01.
One-sided test with a (1-α) confidence level that there is a single extreme outlier within the n observations.	Dixon's single, one-sided test for statistical evidence of either an extreme low-valued outlier: $X_{(1)}$ *is an outlier if* $T_s \ge T_c$ or an extreme high-valued outlier: $X_{(n)}$ *is an outlier if* $T_s \ge T_c$. The function T_c is the critical value, given in Dixon (1953; page 89) and USEPA (2000; p. A-5, Table A-3). Note that the critical value assumes that the data are either normally or lognormally distributed.

Other Statistical Calculations Used in MANAGES

Sen Estimate of Slope

The Sen estimate of slope is the median of all slopes between all possible unique pairs of individual data points in the time period being analyzed (Gilbert, 1987). The slopes represent the rate of change of the measured parameter, with the y-axis being the parameter value and the x-axis being calendar days. Sen's estimate of slope is a non-parametric estimator of trend. The method is robust, and fairly insensitive to the presence of a small fraction of outliers and non-detect data values. In contrast, linear regression and other least squares estimators of slope are significantly more sensitive, and more likely to give erroneous slope indications, even when only a few outlier values are present.

When data averaging is not activated, the Sen slope is calculated using individual data points and actual sampling dates. When data averaging is activated, multiple data points within each specified season period are reduced to one data point by arithmetic averaging over each of the season periods. These averaged values are then assigned to the day that corresponds to the middle of that season's period.

The approximate lower and upper confidence limits for the Sen slope can also be calculated using normal theory (Gilbert, 1987). It should be noted that confidence limits for the Sen slope are not necessarily symmetrical about the estimated slope since ranked values of slope are used in the calculation.

MANAGES calculates Sen slope in the Sen Slope Overlay Graph, Statistical Summary reports and in the two Mann-Kendall tests performed under the Statistical Evaluation Report.

Sen's Estimate of Slope – two-sided, non-parametric method that calculates the trend of a single data series. It is less sensitive to outliers and non-detect values than linear regression (Gilbert, 1987; p. 217).	
Slope, Q	$= \frac{x_{i'} - x_i}{i' - i}$ where $X_{i'}$ and x_i are data values at times i' and i, respectively, and where $i'>i$. Typically, i' and i are expressed in units of either days for trend analysis or years for seasonal analysis.
N′	Number of unique data point pairs that can be made for the observations in the data set, for $i'>i$. For n monitoring events, N′ is given as: N′ = n(n-1)/2

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Sen's Slope Estimate	Sen's slope estimator = median slope $= Q_{[(N'+1)/2]}$ if N' is odd $= \frac{1}{2}(Q_{[N'/2]} + Q_{[(N'+2)/2]})$ if N' is even where the Q values have first been ranked from smallest to largest.
$Z_{1-\alpha/2}$	Statistic for the cumulative normal distribution (Gilbert, 1987; p. 254) for the two-sided, α significance level.
Variance estimate of the Mann-Kendall S Statistic, VAR(S)	VAR(S) $= \frac{1}{18}\left[n(n-1)(2n+5) - \sum_{p=1}^{g} t_p(t_p-1)(2t_p+5)\right]$ where g is the number of tied groups, t_p is the number of data in the pth group, and n is the number of data values.
C_α	$= Z_{1-\alpha/2}\sqrt{VAR(S)}$
Sen's Slope , a two-sided test at the α significance level	$M_1 = \frac{(N'-C_\alpha)}{2}$ $M_2 = \frac{(N'+C_\alpha)}{2}$ Lower limit of confidence interval is the M_1-th largest slope, and upper limit of confidence interval is the (M_2+1)-th largest of the N′ ordered slope estimates.

Coefficient of Skewness for Normality

The coefficient of skewness is another measure for data normality (Gilbert, 1987). MANAGES provides the value of the coefficient of skewness in the Statistical Evalueation Report, Statistical Overview. Additional information on data normality is given by Montgomery, et al. (1987).

1. INTRODUCTION

1.1 Background

This report has been prepared for AmerenEnergy Medina Valley Cogen, LLC (Ameren) for the former Hutsonville Power Station (Hutsonville). The Hutsonville Ash Pond D (Figure 1-1) received coal combustion waste (CCW) from the coal fired power plant between 1968 and 2000. Ameren completed closure activities for Ash Pond D in 2012 in accordance with the site-specific closure requirements of 35 Illinois Administrative Code (IAC) 840. Closure activities included placement of a 40-mil high density polyethylene (HDPE) cap covered with a three-foot thick vegetative soil layer, construction of surface water control structures, and construction of a groundwater collection system (i.e., Collection Trench). It is important to note that Ameren was unable to initiate operation of the Collection Trench until they received authorization for the associated discharge under Hutsonville's renewed National Pollutant Discharge Elimination System (NPDES) permit (IL0004120) with an effective date of March 1, 2015. Operation of the Collection Trench began in April 2015. Hutsonville Ash Pond D post closure care requirements were established in the Post-Closure Care Plan and the Groundwater Monitoring Plan, both dated July 26, 2011.

Groundwater has been monitored at the Hutsonville site since 1984. The groundwater monitoring system established in the Groundwater Monitoring Plan for Ash Pond D consisted of two background monitoring wells, MW-10 and MW 10D, and nine downgradient compliance monitoring wells[1], MW-6, MW-7, MW-7D, MW-8, MW 11R, MW-14, MW 115S, MW-115D, and MW-121 (Figure 1-2). However, background wells MW-10 and MW-10D were destroyed due to construction unrelated to Ameren operations after the first quarter, 2016 monitoring period. No trace of the former background wells was found using a metal detector, probes, or digging. As a result, these wells were replaced with new background monitoring wells, MW-23S and MW-23D, in November 2017. In addition to the compliance monitoring wells, several other monitoring wells and piezometers located at Hutsonville are measured for groundwater level so that groundwater elevation contour maps can be created for the entire site. Ash Pond D is located near the southeast portion of the Hutsonville site, as shown on Figure 1-1, with the sampled monitoring wells shown on Figure 1-2.

The Groundwater Monitoring Plan, in accordance with 35 IAC 840.114 and 35 IAC 840.116, outlines groundwater monitoring and sampling procedures, establishes the parameters and methods to be used for analyzing the groundwater samples, and describes evaluation methods to assess post-closure groundwater quality and trends to demonstrate compliance with the applicable groundwater standards.

The sampling frequency is quarterly for the first five years following completion of the post-closure activities. Table 1-1 outlines the initial sampling frequency and requirements that must be met to request reduced sampling frequency from the Illinois Environmental Protection Agency (EPA). Monitoring well locations, installation dates, construction information, and the groundwater zone they monitor are provided in Table 1-2. Field and laboratory parameters for evaluating groundwater quality are shown in Table 1-3.

[1] Note that in the 2017 Annual Report, Section 1.1, well MW-7D was mistakenly left off the list of compliance wells.

Electronic Filing: Received, Clerk's Office 09/28/2020

This is the seventh annual report since completion of closure activities, includes the most recent 8 quarters of sampling data, and is the sixth annual report to include statistical analysis of the data. It includes the following elements:

- A summary of groundwater monitoring data collected in 2018 and 2019. Data tables are included in Appendix A.
- Quarterly Site Inspection Forms, including observations and descriptions of any maintenance activities performed on the pond cap, embankment, and groundwater collection trench and discharge system (Appendix B).
- Annual trend and statistical analysis results per Section 5.2 of the Groundwater Monitoring Plan, including an assessment of any statistically significant increasing trends (Appendix C).

1.2 Applicable Groundwater Quality Standards

1.2.1 On-Site Groundwater Standards

As described in Section 5.1.1 of the Groundwater Monitoring Plan and pursuant to 35 IAC 840.16(a):

- Prior to the completion of the post-closure care period, the on-site applicable groundwater quality standards at Ash Pond D are the greater of either the actual groundwater monitoring result, or the Class I Potable Resource Groundwater standard set forth in 35 IAC 620.410.
- After completion of the post-closure care period, the on-site concentrations of contaminants from Ash Pond D as determined by groundwater monitoring, if those concentrations exceed the numeric standards for Class I Potable Resource Groundwater set forth in 35 IAC 620.410, are the applicable groundwater standards at the Hutsonville site if the following criteria are addressed to the satisfaction of the Illinois EPA:
  - To the extent practicable, the exceedance has been minimized and beneficial use, as appropriate for the class of groundwater, has been returned on-site.
  - Any threat to public health or the environment on-site has been minimized.
  - An institutional control prohibiting potable uses of groundwater is placed on the Hutsonville site in accordance with the Uniform Environmental Covenants Act (765 Illinois Compiled Statutes (ILCS) 122) or an alternative instrument authorized for environmental uses under Illinois law and approved by the Illinois EPA. Existing potable uses of groundwater may be preserved as long as such uses remain fit for human consumption in accordance with accepted water supply principles.

1.2.2 Off-Site Groundwater Standards

As described in Section 5.1.2 of the Groundwater Monitoring Plan and pursuant to 35 IAC 840.116(b):

- Off-site groundwater quality standards are the Class I Potable Resource standards [35 IAC 620.410] for the upper zone (defined during rulemaking as the fine-grained sediments directly beneath Ash Pond D) and the 35 IAC 620 Subpart C non-degradation standards for the lower zone, unless a groundwater management zone (GMZ) has been established as provided in 35 IAC 620.250. Currently, no GMZ is established for Pond D.

Electronic Filing: Received, Clerk's Office 09/28/2020

1.3 Demonstration of Compliance

1.3.1 On-Site Groundwater Compliance

As described in Section 5.2.1 of the Groundwater Monitoring Plan:

- Compliance with on-site groundwater quality standards will be achieved when no statistically significant increasing trend that can be attributed to Ash Pond D is detected in the concentrations of all constituents monitored at the compliance (down-gradient) boundary of the Hutsonville site for four consecutive years after changing to an annual monitoring frequency.

1.3.2 Off-Site Groundwater Compliance

As described in Section 5.2.1 of the Groundwater Monitoring Plan:

- For off-site groundwater, the following compliance criteria must be met:
  - Statistically significant decreasing trends in concentration for all constituents monitored in accordance with 35 IAC 840.114 in the upper zone of the aquifer at the compliance boundary are detected for a period of four consecutive years after changing to annual monitoring.
  - No statistically significant increasing trend that can be attributed to Ash Pond D is detected in the concentrations of all constituents monitored in accordance with 35 IAC 840.114 in the lower zone of the aquifer at the compliance boundary for a period of four consecutive years after changing to an annual monitoring frequency.
  - All concentrations of constituents monitored in accordance with 35 IAC 840.114 are at or below the applicable groundwater quality standard as provided in 35 IAC 840.116(b) at the down-gradient boundaries of the Hutsonville site.

1.3.3 Compliance Determination

As described in Section 5.2.3 of the Groundwater Monitoring Plan:

- Compliance is demonstrated by performing an annual trend analysis for each monitoring well located at the down-gradient boundaries of the Hutsonville site for all constituents monitored in accordance with 35 IAC 840.114. The analysis shall use Sen's Estimate of Slope and be performed on a minimum of four consecutive samples.
- If a GMZ is established for off-site groundwater in the future, the demonstration of compliance will be set forth in the GMZ approved by the closure or post-closure care plan.
- If the results of sampling and analysis show a positive slope at any compliance monitoring well located at the downgradient boundaries of the Hutsonville site, a Mann-Kendall test will be performed at 95 percent confidence to determine whether or not the increasing slope represents a statistically significant increasing trend. Ameren will investigate the cause of a statistically significant increasing trend as described below. If the statistically significant increasing trend occurs during post-closure care, the investigation will include more frequent inspection of the surface of the cover system and evaluation of background concentrations.
  - If the investigation attributes a statistically significant increasing trend to a superseding cause, Ameren will notify Illinois EPA in writing, stating the cause of the increasing trend and providing the rationale used in such a determination.

Electronic Filing: Received, Clerk's Office 09/28/2020

  - If there is no superseding cause for the statistically significant increasing trend and sampling frequency has been reduced pursuant to semi-annual or annual sampling, a quarterly sampling schedule will be reestablished. After four consecutive quarterly samples show no statistically significant increasing trend, the frequency of groundwater monitoring will return to either semi-annual or annual, whichever frequency was utilized prior to the return to quarterly sampling.
  - Notifications concerning statistically significant increasing trends and revisions of the sampling frequency will be reported to Illinois EPA in writing within 30 days after making the determinations.
- If a statistically significant increasing trend is observed to continue over a period of two or more consecutive years and there are no superseding causes for the trend, then Ameren will perform the following:
  - A hydrogeologic investigation
  - Additional site investigation, if necessary

Based on the outcome of the investigation above, Ameren may take action to mitigate statistically significant increasing trends. Such actions will be proposed as a modification to the post-closure care plan within 180 days after completion of the investigation activities described above.

Electronic Filing: Received, Clerk's Office 09/28/2020

2. DATA ANALYSIS

2.1 Groundwater Flow

Groundwater flow for 2019 is represented using groundwater elevation contour maps for each quarterly sampling event (Figures 2-1 through 2-4). Groundwater in the upper (shallow) zone generally flowed from west to east and northeast towards the Wabash River during 2019, which is consistent with past evaluations. The Groundwater Collection Trench began operation in April 2015, and following startup groundwater elevations have exhibited localized flow toward the trench with groundwater elevations generally lower near the trench (Figure 3). In the depictions of groundwater elevation contours dashed lines have been used to infer the localized drawdown of groundwater levels resulting from trench operation, which is necessary with limited wells situated laterally along the length of the trench.

The horizontal hydraulic gradient in the upper migration zone beneath Ash Pond D ranged from 0.0033 to 0.0047 ft/ft during 2019. Horizontal hydraulic gradient was calculated near the northern extent of Ash Pond D to limit the influence of the trench to the south in gradient values. The highest gradient occurred during May 2018 when groundwater elevation was lowest. Conversely, the lowest gradient occurred when groundwater elevation was highest in March 2018.

Groundwater flow within the lower (deep alluvial) migration zone along the edge of the Wabash River valley was not contoured since all the deep alluvial monitoring wells are within a narrow zone between Ash Pond D and the Wabash River. Groundwater within the lower zone generally flows from southwest to northeast towards the Wabash River.

2.2 Review of Analytical Data

Table 2-1 presents a site-wide statistical summary of all laboratory analytical data collected in 2018 and 2019. All field and laboratory analytical results are tabulated in Appendix A. Sampling anomalies, such as wells that were dry, had water levels too low for sampling, or were not sampled during a sampling event for other reasons, are noted below.

- MW-6: Not sampled in the 3rd and 4th quarter sampling events of 2018 due to insufficient water level.
- MW-11R: Not sampled in the 4th quarter sampling event of 2018 due to insufficient water level.

Antimony, beryllium, cadmium, chromium, cobalt, total cyanide, lead, mercury, silver, thallium, and zinc were detected in fewer than 10% of the groundwater samples. In addition to these constituents, copper and selenium were detected in fewer than 30% of the samples. A summary of wells and parameters with exceedances of Class I groundwater standards in 2018 and 2019 is shown on Table 2-2.

Parameters of Concern

Parameters of concern (POCs), which correspond to mandatory monitoring parameters per 35 IAC 840.114(a) and as identified in prior reports, are discussed below:

- Boron: Boron is a primary indicator constituent for coal ash leachate impacts to groundwater. Downgradient monitoring well MW-8 exceeded the Class I Potable Resource standard (2.0 milligrams per liter [mg/L]) during all 2018-2019 sampling events (Table 2-2). The highest boron concentrations were also detected in downgradient monitoring well MW-8 during

Electronic Filing: Received, Clerk's Office 09/28/2020

this reporting period (Figure 4-1). Background monitoring wells MW-23S and MW-23D had one exceedance during this monitoring period. Downgradient monitoring wells MW-6 and MW-11R had one and two exceedances during 2018-2019 respectively. Time series plots of boron concentrations at wells MW-6, MW-8, MW-11R, MW-23S, and MW-23D are shown in Figure 5-1A-B.

- Iron: There was one exceedance of the iron Class I standard (5.0 mg/L) at MW-23S and MW-23D during the fourth quarter of 2019 (Figure 4-2A-B). Time series plot for these wells are shown in Figure 5-2A-B.
- Manganese: Manganese concentrations in downgradient monitoring wells MW-7D, MW-115S, and MW-121 exceeded the Class I standard (0.15 mg/L) during all 2018-2019 sampling events (Figure 4 3A-B). Monitoring well MW-14 had six exceedances; monitoring wells MW-8 and MW-115D had five exceedances; and monitoring wells MW-6, MW-23D, and MW-23S each had one exceedance in 2018-2019 monitoring period. Time series plots of manganese concentration at these wells are shown in Figure 5-3A-B. Manganese is commonly present in native soils and is highly sensitive to redox conditions. However, prior investigations at the Hutsonville site indicate that elevated manganese concentrations may also be indicative of coal or coal stockpile impacts.
- Sulfate: Sulfate can be an indicator constituent for coal ash; however, there are other anthropogenic sources for elevated sulfate concentrations in groundwater, and sulfate concentrations can decrease in groundwater under strongly reducing conditions. These caveats make sulfate a less reliable indicator for coal ash leachate than boron. Sulfate concentrations at Ash Pond D are the highest at MW-8, where boron concentrations are also high compared to most of the other monitoring wells (Figure 4-4). Sulfate concentrations were elevated above the Class I standard (400 mg/L) at MW-8 during all eight sampling events in 2018-2019. There was also one sulfate exceedance of the Class I standard at downgradient monitoring well MW-7 in 2018 and at both background monitoring wells in 2019 (Figure 54A-B). MW-11R, located downgradient of the Collection Trench, routinely exceeded the Class I standard prior to operation of the Collection Trench. Although sulfate concentrations at MW-11R have been below the Class I standard since operation of the Collection Trench began in April 2015, during the fourth quarter of 2019, the sulfate concentration was higher than the Class I standard (Figure 5-4A-B).
- pH: There was one exceedance of the lower pH Class I standard (6.5 standard units (Std.)) at MW-23D and MW-23S during the 2018-2019 monitoring period. Prior to operation of the Collection Trench, downgradient well MW-11R was routinely below this lower limit. The pH returned to values within the Class I boundaries in April 2015 and has remained within limits (Figure 4-5). Time series plots of pH at MW-23D and MW-23S are shown in Figure 5-5.
- Total Dissolved Solids (TDS): TDS exceeded the Class I standard of 1,200 mg/L at upper zone monitoring well MW-8 during five of the eight sampling events. This well also has the highest concentrations of boron and sulfate measured in groundwater (Figure 4-6). There was also one exceedance at wells MW-23D and MW-23S in 2019 (Figure 5-6). Although TDS concentrations at upper zone monitoring well MW-11R have been below the Class I standard since operation of the Collection Trench began in April 2015, during the fourth quarter of 2019, the sulfate concentration was higher than the Class I standard (Figure 5-4).

Electronic Filing: Received, Clerk's Office 09/28/2020

Other Parameters

Concentrations of beryllium, cadmium, and nickel were elevated above the Class I standard (0.004 mg/L, 0.005 mg/L, and 0.1 mg/L respectively) in background monitoring well MW-23S during the fourth quarter of 2019. Time series plots for these parameters at MW-23S are shown in Figures 5-7 to 5-9.

2.3 Statistical Analyses

Analytical data were evaluated for trends following a three-step procedure:

1. Test for outliers using the Grubbs Outlier test.
2. Determine Sen's estimate of slope.
3. Perform a Mann-Kendall trend analysis for any cases (monitoring well/constituent) with a positive slope.

2.3.1 Outlier Analysis

The Grubbs outlier test determines whether or not there is statistical evidence that an extreme high or low observation does not fit the remaining data. The test methodology and results are listed in Appendix C1 and summarized in Table 2-3. The Grubbs test, like all statistical tests, provides statistical evidence of potential outliers, but cannot be used alone to determine whether or not a value is a true outlier that should be excluded from future statistical analysis. Corroborating evidence needed to exclude values includes a very high value relative to all other values for a particular monitoring well/parameter case—which suggests a discrete data reporting or analytical error, or numerous values from a single sample event that are higher than all other sample events for that parameter—which indicates potential laboratory bias. Absent corroborating evidence, the flagged values are considered true but extreme values in the data set. No results were eliminated from statistical analysis due to the Grubbs outlier evaluation.

2.3.2 Sen's Estimate of Slope

Sen's estimate of slope is a non-parametric estimator of trend. It is the median of all slopes between all possible unique pairs of individual data points in the time period being analyzed. The slopes represent the rate of change of the measured parameter, with the y-axis being the parameter value and the x-axis being calendar time. The method is robust, and fairly insensitive to the presence of a small fraction of outliers and non-detect data values. The test methodology and results are listed in Appendix C2 and summarized in Table 2-4.

Data collected in 2018-2019 show 25 cases with positive slopes, 16 cases with negative slopes, and 233 cases with no slope (Table 2-5). The 25 cases with positive slopes were tested using the Mann Kendall test to determine if the positive slopes represented statistically significant increasing trends.

2.3.3 Mann-Kendall Trend Analysis

The Mann-Kendall test is a non-parametric, two-sided test to determine whether or not a dataset has a statistically significant increasing or decreasing trend. The test methodology and results are listed in Appendix C3 and summarized in Table 2-5. Statistically significant increasing trends are flagged in Table 2-4.

Electronic Filing: Received, Clerk's Office 09/28/2020

Thirteen cases with statistically significant increasing trends were identified in the analysis covering samples collected in 2018-2019.

- Boron: Wells with statistically significant increasing trend for boron include MW-23S and MW-115D. Boron concentrations at MW-115D were below Class I standard of 2.0 mg/L and at MW-23S boron concentrations exceeded once (Figure 4-1). Figure 5-1A-B shows time series plots for MW-115D, along with plots for wells that have exceeded the Class I manganese standard at some time since completion of closure activities (MW-6, MW-8, MW-23D, and MW-23S).
- Iron: Statistically significant increasing trend for iron was observed at wells MW-7, MW-11R, MW-14, MW-23D and MW-23S. Iron concentrations at wells MW-7, MW-11R, and MW-14 were below the Class I standard of 5.0 mg/L. Wells MW-23D and MW-23S had one exceedance during fourth quarter of 2019 (Figure 4-2A-B). Figure 5-2A-B shows time series plots for these wells.
- Manganese: MW-7 and MW-115S had a statistically significant increasing trend for manganese. Manganese concentrations at MW-115S exceeded the Class I standard (0.15 mg/L) for all sampling events whereas at MW-7 manganese concentrations were below Class I standard (Figure 4-3A-B). Figure 5-3A-B shows time series plots for MW-7, along with plots for wells that have exceeded the Class I manganese standard at some time since completion of closure activities (MW-6, MW-7D, MW-8, MW-14, MW-23D, MW-23S, MW-115S, and MW-115D).
- Sulfate: MW-115D was the only well with a statistically significant increasing trend for sulfate. Concentrations did not exceed the Class I sulfate standard of 400 mg/L. Figure 5-4A-B shows time series plots for MW-115D, along with plots for wells that have exceeded the Class I sulfate standard at some time since completion of closure activities (MW-7, MW-8, MW-11R, MW-23D, and MW-23S).
- TDS: Statistically significant increasing trend for TDS was only observed at MW-115D; however, the concentrations at this location did not exceed the Class I standard of 1,200 mg/L. Time series plot for MW-115D, along with plots for wells that have exceeded the Class I TDS standard at some time since completion of closure activities (MW-8, MW-11R, MW-23D, and MW-23S) is shown in Figure 5-6.
- Barium: MW-115D was the only well with a statistically significant positive trend for barium. All result at this well for barium were below the Class I standard of 2.0 mg/L. Figure 5-10 shows the time series plot for MW-115D.
- Copper: Copper at well MW-23S showed statistically significant positive trend; however, the concentrations at this location did not exceed the Class I standard of 200 mg/L. Figure 5-11 shows time series plot for this well.

2.4 Site Inspection

The Post-Closure Maintenance Program requires quarterly inspection for the first five years after closure. After five years, the inspection frequency can be reduced to semi-annually provided that semi-annual groundwater monitoring has been approved by Illinois EPA. After five years of semi-annual monitoring, the inspection frequency can be reduced to annually pending approval of annual groundwater monitoring. Discontinuance of Hutsonville site inspections will occur after Illinois EPA approval of the certified Post-Closure Care Report.

Electronic Filing: Received, Clerk's Office 09/28/2020

Some minor gouging in the north terrace ditch was noted in both the March 21 and June 27, 2019 site inspections. Erosion of northwest toe embarkment was also noted in the June 27, 2019 site inspection. Monitoring well MW-7D was found open with J-plug removed during the September 26, 2019 site inspection and inspector closed and secured the well. Erosion of North terrace drainage was noted in December 4, 2019 site inspection. The inspection reports are included in Appendix B.

Electronic Filing: Received, Clerk's Office 09/28/2020

3. EVALUATION OF COMPLIANCE

3.1 Review of Statistically Significant Increasing Trends

The post-closure groundwater monitoring began in January 2013. This report focuses on the eight quarters of groundwater quality data that were collected in 2018-2019. The Sens Estimate of Slope and Mann-Kendall Trend Analysis was performed at the upgradient monitoring wells (MW-23S and MW-23D) as well as at downgradient monitoring wells MW-6, MW-7, MW-7D, MW-8, MW11R, MW-14, MW-115S, MW-115D, and MW-121.

The following thirteen cases with statistically significant increasing trends, sorted by monitoring well location, were identified in the analysis covering samples collected in 2018-2019.

- MW-7: iron, manganese
- MW-11R: iron
- MW-14: iron
- MW-23D: iron
- MW-23S: boron, copper, iron
- MW-115S: manganese
- MW-115D: barium, boron, sulfate, TDS

Of these thirteen cases of statistically significant increasing trends, well locations MW-115S, MW-23D and MW-23S have constituent concentrations that exceed the Class I standard.

Concentrations of manganese at MW-115S exceeded the Class I standard for all sampling events during this reporting period. At background monitoring well MW-23D, concentration of iron was elevated above Class I standard only during the fourth quarter of 2019. Boron and iron concentrations were above Class I standard during the last quarter of 2019 at MW-23S.

Electronic Filing: Received, Clerk's Office 09/28/2020

4. CONCLUSIONS

4.1 Demonstration of Compliance – On Site

Statistical analyses of concentration results for groundwater samples collected in 2018 and 2019 at the Hutsonville Ash Pond D identified thirteen cases of statistically significant increasing trends. The significantly increasing parameters exceeding the Class I standard, manganese at MW-115S, iron at MW-23D and MW-23S, and boron at MW-23S will continue to be evaluated to determine if this trend continues, as well as to determine whether the source is natural or anthropogenic.

MW-11R, located downgradient of the Collection Trench, routinely exceeded the Class I standard for manganese, sulfate, and TDS prior to operation of the Collection Trench. During the fourth quarter of 2019, concentrations of sulfate and TDS exceeded the Class I standard for the first time since the operation of Collection trench began in April 2015. Boron concentrations continued to exceed the Class I standards occasionally after the Collection Trench Operation began. Two instances of boron exceedance were observed at MW-11R during this reporting period. These parameters at MW-11R will continue to be evaluated to determine if this trend continues.

4.2 Demonstration of Compliance – Off Site

At the Hutsonville Site, all wells are considered on-site wells. There are no off-site wells as there is a deed restriction on the neighboring property to the south for groundwater use. Off-site compliance is determined at the downgradient compliance boundary as described in Section 1.3.2 and shown on Table 1-2. Statistically significant increasing trends are present at some Pond D downgradient/compliance wells for the reporting period, however they do not exceed Class I standards.

No action, other than submittal of this report, is required per Section 5.2.3 of the Groundwater Monitoring Plan (Compliance Determination). The Groundwater Monitoring Plan requires a hydrogeologic investigation if a statistically significant increasing trend occurs over a period of two or more consecutive years since closure and it cannot be attributed to a superseding cause.

Electronic Filing: Received, Clerk's Office 09/28/2020

Zinc, dissolved	None	None	None	None	None	None	None	None	None	None	None

Notes:
- "positive", "negative", and "none" describe the slope as calculated using Sen's estimate of slope; slopes that are statistically significant (see below) are indicated by the MK prefix
- MK trend analysis done with non-detects at one half the detection limit.

1 MANAGES 4.1 output displays 0.0 for the median slope; however the direction of the slope was confirmed to be positive by evaluating the data set.

2 MANAGES 4.1 output displays a statistically signficiant positive trend, but further investigation revealed that the designation was due to the reporting limit changes between subsequent sampling events. Therefore, these counts are included into the "none" category in Table 2-5 as there were no trends.

3 MANAGES 4.1 output displays 0.0 for the median slope; however the direction of the slope was confirmed to be negative by evaluating the data set.

- Green shading indicates increasing positive trends that are statistically significant as determined using the Mann-Kendall test at 95% confidence for constituents with maximum concentration **lower** than the Class I groundwater quality standard
- Yellow shading indicates increasing positive trends that are statistically significant as determined using the Mann-Kendall test at 95% confidence for constituents with maximum concentration higher than the Class I groundwater quality standard.

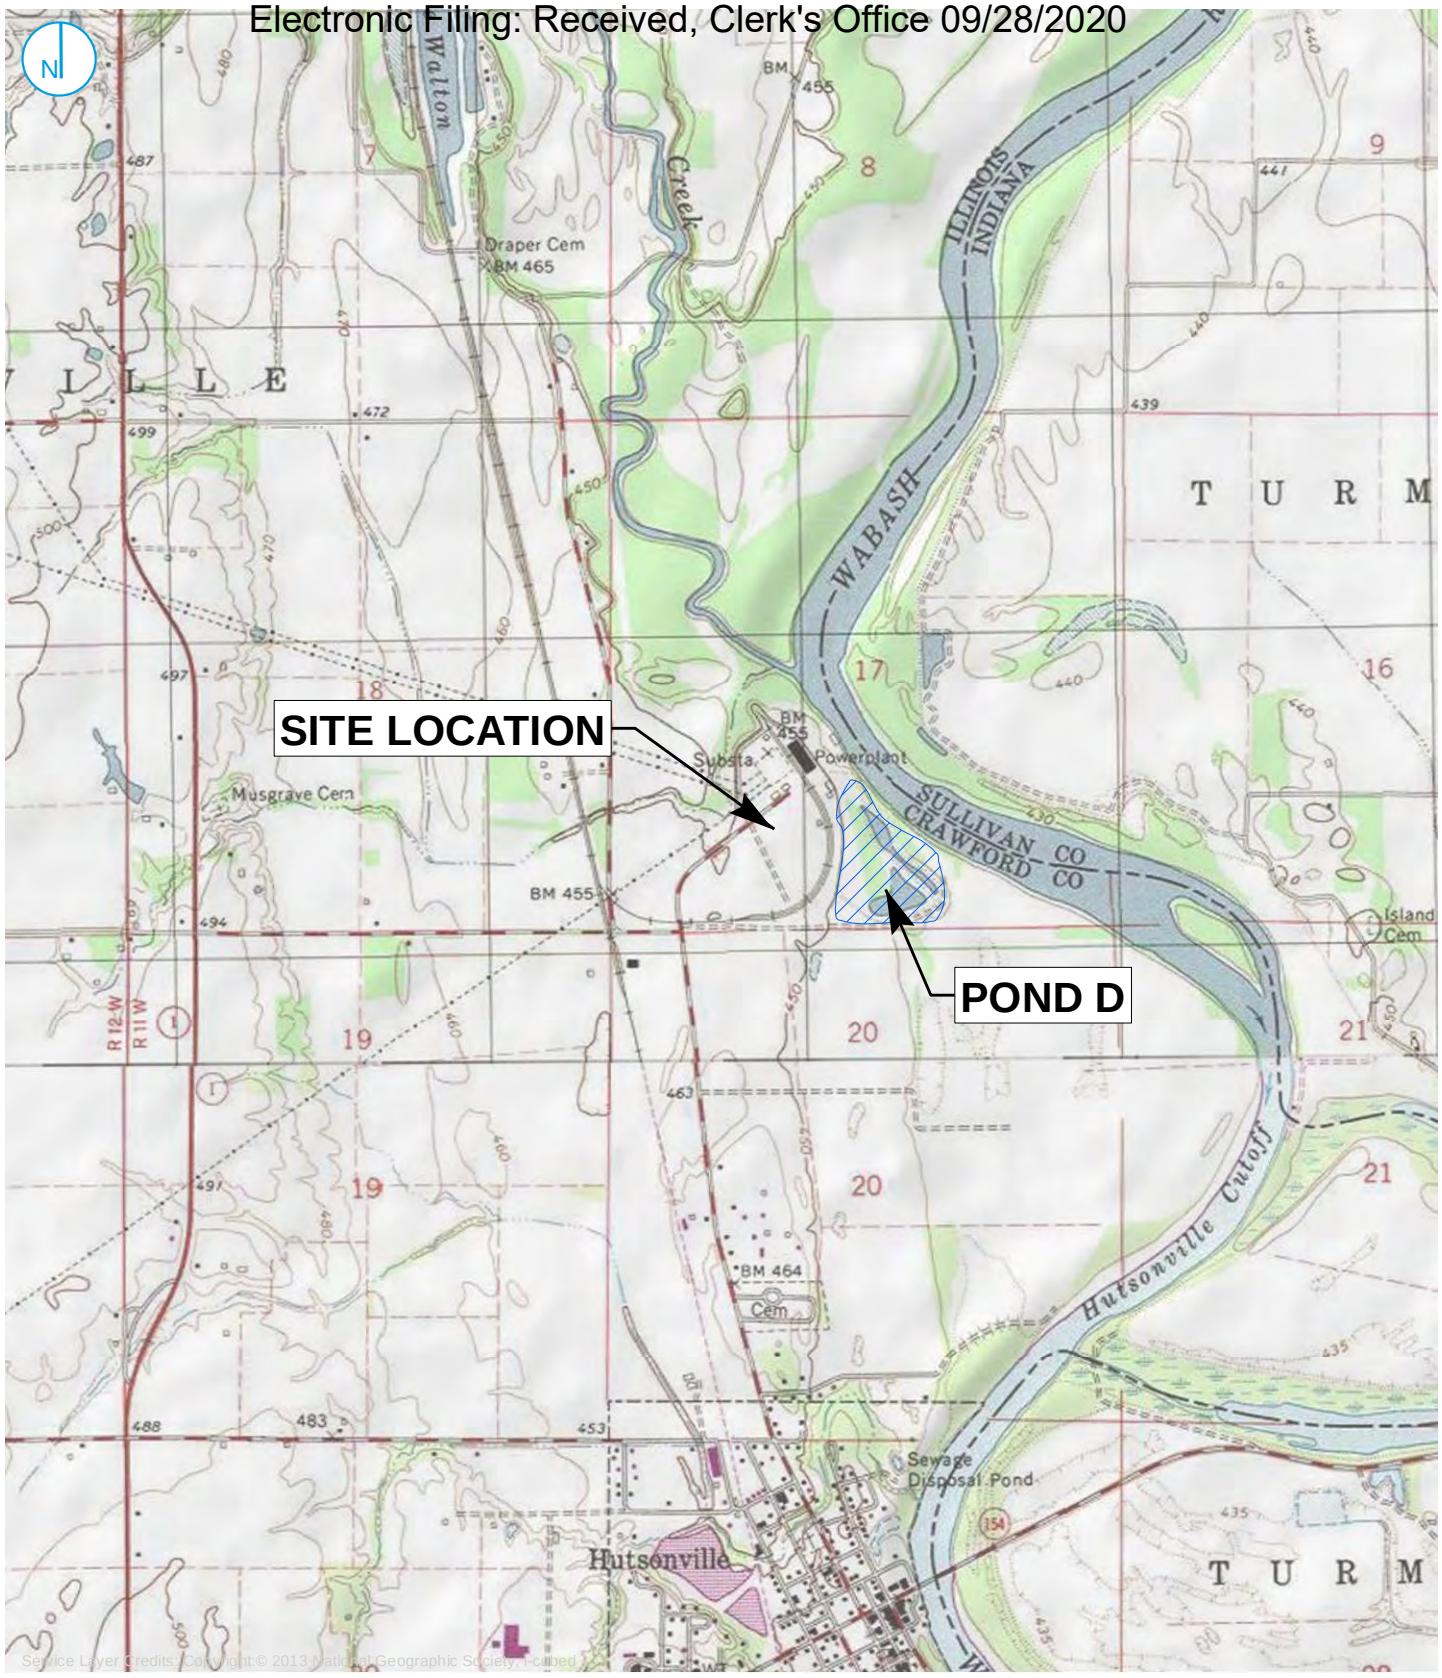

Table 2-5. Summary of Trend Analyses
2019 Annual Report
Former Hutsonville Power Station - Ash Pond D

Time Period	Slope			Statistically Significant Increasing Trends
	Negative	None	Positive	
2013-2014	87	85	68	7
2014-2015	135	57	48	2
2015-2016	113	110	41	1
2016-2017	103	72	41	2
2017-2018	80	133	51	8
2018-2019	16	223	25	13

Notes:
Trends based on data collected during the specified periods.
The number of samples per well location are noted on Table 2-4.

APPENDIX B
SITE INSPECTION REPORTS

Hutsonville Power Station

Ash Pond D Closure Cap - Post-Closure Care Plan

Quarterly Site Inspection Checksheet

Date	**03/21/2019**
Inspector	**HEC**
Temperature	**45 degrees F**
Weather	**Cloudy**

	Item	Condition Code *	Comments
Pond Cap	**Vent Pipes**	GC	
	Drainage Berms	GC	
	Vegetation	GC	
	Erosion	GC	*Some minor gouging in north terrace ditch*
	Liner	GC	
	Water Control Features (rip-rap, paved flumes, etc.)	GC	
	Other	GC	
Embankment	**Vegetation**	GC	
	Liner	GC	
	Erosion	GC	
	Fencing	GC	
	Drainage Channels (rip-rap, paved flumes, etc.)	GC	
	Other	GC	
Groundwater Collection Trench and Discharge System	**Control Panels**	NI	N/A - meters are being read remotely.
	Drainage Sumps / Manholes	NI	N/A - meters are being read remotely.
	Pumps	NI	N/A - meters are being read remotely.
	Groundwater Monitoring Wells	GC	
	Flow Meter Totalizer	GC	N/A - meters are being read remotely.
	Diver-Mate Data Collector (data download)	GC	N/A - meters are being read remotely.
	Other	GC	None

Condition Codes

IM = Item needing immediate maintenance. Remediation/repair should be completed within 1 month.
MM = Item needing minor maintenance and/or repairs within the year.
OB = Condition requires regular observation to ensure that the condition does not become worse.
GC = Good Condition. Working properly.
NE = No evidence of a problem.
NI = Not Inspected. Reason should be stated in comment.

APPENDIX C2
SEN SLOPE AND MANN KENDALL TESTS

Hutsonville Ash Impoundment
Mann-Kendall Trend Analysis

User Supplied Information

Location ID:	**MW115D**	**Parameter Code:**	**00515**
Location Class:	**Downgradient**	**Parameter:**	**Total Dissolved Solids**
Location Type:	**Alluvial Aq.**	**Units:**	**mg/L**
Confidence Level:	**95.00%**		

Date Range: 01/01/2018 to 12/31/2019

Trend Analysis

Trend of the least squares straight line

Slope (fitted to data):	1	mg/L per period
R-Squared error of fit:	1	

Sen's Non-parametric estimate of the slope (two-tailed test)

Median Slope:	1	mg/L per period
Lower Confidence Limit of Slope, M1:	0	mg/L per period
Upper Confidence Limit of Slope, M2+1:	1	mg/L per period

Non-parametric Mann-Kendall Test for Trend

S Statistic:	2
Z test:	2
At the 95.0 % Confidence Level (two-tailed test):	Upward

Hutsonville Ash Impoundment
Mann-Kendall Trend Analysis

User Supplied Information

Location ID:	**MW115D**	**Parameter Code:**	**00618**
Location Class:	**Downgradient**	**Parameter:**	**Nitrate nitrogen, dissolved**
Location Type:	**Alluvial Aq.**	**Units:**	**mg/L**
Confidence Level:	**95.00%**		

Date Range: 01/01/2018 to 12/31/2019

Trend Analysis

Trend of the least squares straight line

Slope (fitted to data):	-0.006	mg/L per period
R-Squared error of fit:	0.431	

Sen's Non-parametric estimate of the slope (two-tailed test)

Median Slope:	-0.003	mg/L per period
Lower Confidence Limit of Slope, M1:	-0.013	mg/L per period
Upper Confidence Limit of Slope, M2+1:	0.000	mg/L per period

Non-parametric Mann-Kendall Test for Trend

S Statistic:	-2.244
Z test:	1.645
At the 95.0 % Confidence Level (two-tailed test):	Downward

10
STATISTICAL ANALYSIS

Stand-Alone Statistical Tests

Statistical Evaluation Report

The Statistical Evaluation Report is comprised of a series of subreports as described below.

User Selections:

- One location.
- Sample date range for data selection.
- Interval length: the length of the averaging period in months (1,2,3,4, or 6).
- One parameter.
- Non-detect processing: multiplier between 0 and 1.
- One-sided confidence $(1-\alpha)$ level – 0.90, 0.95 or 0.99.
- Limit type: used in the statistical overview to determine exceedances.

Mann-Kendall Trend and Seasonal Analysis Tests

The Mann-Kendall test for trend is insensitive to the presence or absence of seasonality. The test is non-parametric and does not assume any type of data distribution. Nonetheless, two forms of the test are provided in MANAGES, one ignoring data seasonality even if it is present, and one considering data seasonality. In the test, the null hypothesis, H_0, is that the Sen trend is zero, and the alternate hypothesis, H_a, is that the trend is non-zero.

In general, the Mann-Kendall test considering seasonality indicates a larger range for allowable Sen estimate of trend when seasonality is actually present than the range indicated by the test performed ignoring seasonality.

In the Mann-Kendall Trend Analysis, available in under the Statistical Evaluation Report and in the Statistical Procedure for Detection Monitoring, and Mann-Kendall Seasonal Analysis, found under the Statistical Evaluation Report, MANAGES first calculates the Sen slope and the upper and lower confidence limits of the Sen slope, and then determines whether the Sen slope is statistically significant. Slope is statistically significant if it is non-zero.

Mann-Kendall Test for Sen Slope Significance – a two-sided, non-parametric method for data sets as small as 10, unless there are many tied (e.g., equal, NDs are treated as tieds) values (Gilbert, 1987; p. 208)	
Indicator Function $\mathrm{sgn}(x_{ij} - x_{jk})$	= 1 if $(x_{ij} - x_{jk}) > 0$ = 0 if $(x_{ij} - x_{jk}) = 0$ = -1 if $(x_{ij} - x_{jk}) < 0$ where $x_{i1}, x_{i2}, \ldots, x_{in}$ are the time ordered data (n_i is total of data in the i-th season).
Mann-Kendall Statistic, S_i	$= \sum_{k=1}^{n_i-1} \sum_{j=k+1}^{n_i} \mathrm{sgn}(x_{ij} - x_{jk})$
Variance of S_i $VAR(S_i)$	$VAR(S_i) =$ $\frac{1}{18}\left\{ n_i(n_i-1)(2n_i+5) - \sum_{p=1}^{g_i} t_{ip}(t_{ip}-1)(2t_{ip}+5) - \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)(2u_{iq}+5) \right\}$ $+ \frac{\sum_{p=1}^{g_i} t_{ip}(t_{ip}-1)(t_{ip}-2) \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)(u_{iq}-2)}{9n_i(n_i-1)(n_i-2)}$ $+ \frac{\sum_{p=1}^{g_i} t_{ip}(t_{ip}-1) \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)}{2n_i(n_i-1)}.$ The variable g_i is the number of tied groups (equal-valued) data in the i-th season, t_{ip} is the number of tied data in the p-th group for the i-th season, h_i is the number of sampling times (or time periods) in the i-th season that contain multiple data, u_{iq} is the number of multiple data in the q-th time period in the i-th season, and n_i is the number of data values in the i-th season.

Test Statistic, Z	If $S' = \sum_{i=1}^{K} S_i$, where K is the number of seasons, then the test statistic Z is computed as: $$Z = \begin{cases} \dfrac{S'-1}{[VAR(S')]^{1/2}} & \text{iff } S' > 0 \\ 0 & \text{iff } S' = 0 \\ \dfrac{S'+1}{[VAR(S')]^{1/2}} & \text{iff } S' < 0 \end{cases}$$ Where "iff" is an acroym meaning: if-and-only-if. A positive Z value means an upward trend and a negative Z value means a negative trend.
Hypothesis Test: H_0 = no trend H_a = trend present This is a two-sided test at the α significance level.	Accept the null hypothesis H_0 of no trend if $\lvert Z \rvert \leq Z_{1-\alpha/2}$ Reject the null hypothesis H_0 if $\lvert Z \rvert > Z_{1-\alpha/2}$ where $Z_{1-\alpha/2}$ is obtained from Table A1 in Gilbert (1987; p. 254).

Kruskal-Wallis Analysis (Test for Seasonality)

To perform the Kruskal-Wallis test for data seasonality, data points are first segmented according to season (Gilbert, 1987). The null hypothesis, H_0, is that all seasons have the same mean value. The alternative hypothesis, H_a ,is that at least one season has a mean larger or smaller than the mean of at least one other season. Montgomery et al. (1987) provide additional information on groundwater data seasonality. This is a two-sided, non-parametric test.

In MANAGES, the Kruskal-Wallis Test for Seasonality is found under Data Review // Non-Parametric Methods // Kruskal-Wallis Analysis. It determines whether the seasonal means for the specified parameter at the specified location are statistically the same.

	or $Z_i \geq SCL$.

Outlier Tests

Outlier tests are useful in detecting inconsistencies of measurement within a data set. An outlier is defined as an observation that appears to deviate markedly from other values of a sample set. There are many possible reasons for the presence of an outlier, including 1) the presence of a true but extreme value from a single population, resulting from random variability inherent in the data; 2) an improper identification of the underlying distribution describing the population from which the sample set comes from; 3) the occurrence of some unknown event(s) such as a spill, creating a mixture of two or more populations; 4) a gross deviation from prescribed sampling procedures or laboratory analysis; 5) a transcription error in the data value or data unit of measurement.

USEPA (1989; p. 8-11) states that the purpose of a test for outliers is to determine whether or not there is statistical evidence that an observation that appears extreme does not fit the distribution of the rest of the data. If an observation is identified as an outlier, then steps need to be taken to determine whether it is the result of an error or a valid extreme observation. If a true error, such as in transcription, dilution, or analytical procedure, can be identified, then the suspect value should be replaced with its corrected value. If the source of the error can be determined but no correction is possible, then the observation is deleted and the reason for deletion is reported along with any statistical analysis. If no source of error can be documented, then it must be assumed that the observation is a true but extreme value of the data set. If this is the case, the outlier observation(s) must not be altered or excluded from any statistical analysis. Identification of an observation as an outlier but with no error documented could be used to suggest resampling to confirm the value (USEPA, 1989; p. 8-13).

The outlier tests provided in MANAGES are based on either the single outlier test of Grubbs (1969), which is used by USEPA (1989; pp. 8-10 to 8-13) or the single outlier test of Dixon (1951, 1953), which is used by USEPA (2000; pp. 4-24) and by ASTM (1998). The outlier tests assume the data come from a normal distribution. Only one outlier, either an extreme low or an extreme high, can be detected during a single analysis of a data set. Additional outliers can be detected by temporarily removing a previously detected outlier from a data set and then repeating the test on the remaining, reduced, data set. During each pass of the outlier test, the sample mean, standard deviation, and sample size used in the test statistics are computed using only the data remaining in the set. The process can be continued until there is either an insufficient amount of data remaining (a minimum of 3 values) or when no additional outliers are found. When using MANAGES, the user will be asked how many outliers are to be checked and it will then automatically perform all of the recursive calls and data reductions with the Grubbs or Dixon routine. When done, a report can be generated that will show each outlier marked with a flag indicating the sequential order in which the outliers were identified.

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Critical values used in the one-sided Grubbs test are taken directly from those in Grubbs and Beck (1972) for sample sizes smaller than 147 observations. Critical values for sample sizes larger than 147 were generated numerically using a Monte Carlo routine, where each sampling event was simulated 100,000 times. Sample sizes ranging from 148 to 5,000 where used and then their resultant test statistic T_n curve fitted at specific significance levels. By this method, it was possible to match Grubbs results to at least four significant digits for corresponding tabulated values.

Critical values used in the one-sided Dixon outlier test are taken directly from tables given in Dixon (1951), Dixon (1953; page 89), and USEPA (2000; p. A-5, Table A-3). The critical values were then curve fitted for every sample size between 3 and 25 as a function of the significance level. By this method, it was possible to match Dixon's results to at least four significant digits for corresponding tabulated values. Note that the Dixon test assumes the data are either normally or lognormally distributed. Hence, sample sizes can only range between 3 and 25, inclusive. Dixon never developed an outlier test for sample sizes larger than 25.

User Selections:

- One or up to 100 locations: a separate test is performed for each location.
- One or up to 100 parameters: a separate test is performed for each parameter.
- Evaluation date range.
- Confidence $(1-\alpha)$ level: 0.90, 0.95 or 0.99.
- Non-detect processing: multiplier between 0 and 1.
- Data transformation option: none and log (base e).
- Number of outliers: one, two, first 5%, first 10%. Selecting any option other than one causes MANAGES to rerun the test, with outliers from prior tests removed, until either no outliers are detected or the specified number of outliers are detected.

Technical Details

Grubbs Outlier Test – The Grubbs outlier test determines whether there is statistical evidence that an observation does not fit the remaining data (USEPA, 1989; p. 8-11). This significance test looks at either the highest or the lowest observation in normal samples.	
The number of observations taken during a specified scoping period; n	*n*

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Mean of the observed data during the scoping period; $\overline{X}$	$\overline{X} = \frac{1}{n}\sum_{i=1}^{n} X_i$ where X_i is the i-th observation.
Standard deviation of observed data; S_x.	$S_x = \sqrt{\frac{1}{(n-1)}\sum_{i=1}^{n}(X_i - \overline{X})^2}$
Test statistics: T_l & T_n	Sort the data into ascending order, then compute the statistics $T_l = (\overline{X} - X_l)/S_x$ $T_n = (X_n - \overline{X})/S_x$ where X_l is the smallest value of the n observations and X_n is the largest value of the n observations.
One-sided test with a (1-α) confidence level that there is a single extreme outlier within the n observations.	Grubbs single, one-sided test of either an extreme low outlier : X_l *is an outlier if* $T_l \geq T_{cr(1-\alpha,n)}$ or an extreme high outlier: X_n *is an outlier if* $T_n \geq T_{cr(1-\alpha,n)}$. The function $T_{cr(1-\alpha,n)}$ is the critical value, given in Grubbs and Beck (1972; Table 1) and USEPA (1989; p. B-11, Table 8) . Note that the critical value assumes that the mean and standard deviation are computed from the sample being tested.

Dixon Outlier Test – The Dixon outlier test determines whether there is statistical evidence that an extreme observation does not fit the remaining data (USEPA, 2000; p. 4-24 and ASTM D6312, 1998). This significance test looks at both the highest and the

lowest observations in a sample data set. However, the routine will only perform the outlier tests if several conditions are first satisfied. For example, the Dixon outlier algorithm checks the distribution of the sample data for both normality and lognormality using the Shapiro-Wilk W-test. The outlier routine will not proceed with a data set if the W-test fails. In addition, the Dixon outlier test is limited to a minimum of 3 and a maximum sample size n of 25 data values.	
The number of observations taken during a specified scoping period; n	Number of observations, n, where $3 \le n \le 25$.
Sorting the sample data	Sort the data into ascending order, with the minimum data value $X_{(1)}$ first and the maximum data value $X_{(n)}$ last. Use the natural log of the data values if data are lognormally distributed, i.e., $X_{(j)} = Ln[X_{(j)}]$.
Goodness-of fit tests	After temporarily excluding either the minimum or maximum value of the data set, the Shapiro-Wilk's W-test is used to determine if the remaining $n-1$ values are normally or lognormally distributed. If not, the Dixon outlier test can't be used.
Test statistic, T_s, for the minimum data value	Compute the T_s test statistic for $X_{(1)}$ as an outlier: $T_s = \frac{X_{(2)} - X_{(1)}}{X_{(n)} - X_{(1)}}$ *for* $3 \le n \le 7$ $T_s = \frac{X_{(2)} - X_{(1)}}{X_{(n-1)} - X_{(1)}}$ *for* $8 \le n \le 10$ $T_s = \frac{X_{(3)} - X_{(1)}}{X_{(n-1)} - X_{(1)}}$ *for* $11 \le n \le 13$ $T_s = \frac{X_{(3)} - X_{(1)}}{X_{(n-2)} - X_{(1)}}$ *for* $14 \le n \le 25.$
Test statistic, T_s, for the maximum data value	Compute the T_s test statistic for $X_{(n)}$ as an outlier:

	$T_s = \frac{X_{(n)} - X_{(n-1)}}{X_{(n)} - X_{(1)}}$ *for* $3 \le n \le 7$ $T_s = \frac{X_{(n)} - X_{(n-1)}}{X_{(n)} - X_{(2)}}$ *for* $8 \le n \le 10$ $T_s = \frac{X_{(n)} - X_{(n-2)}}{X_{(n)} - X_{(2)}}$ *for* $11 \le n \le 13$ $T_s = \frac{X_{(n)} - X_{(n-2)}}{X_{(n)} - X_{(3)}}$ *for* $14 \le n \le 25$.
Critical value T_c	USEPA (2000; p. A-5, Table A-3) lists the critical values of the Dixon test as a function of sample size for a one-sided extreme value test at the significance levels α of 0.1, 0.05, and 0.01.
One-sided test with a (1-α) confidence level that there is a single extreme outlier within the n observations.	Dixon's single, one-sided test for statistical evidence of either an extreme low-valued outlier: $X_{(1)}$ *is an outlier if* $T_s \ge T_c$ or an extreme high-valued outlier: $X_{(n)}$ *is an outlier if* $T_s \ge T_c$. The function T_c is the critical value, given in Dixon (1953; page 89) and USEPA (2000; p. A-5, Table A-3). Note that the critical value assumes that the data are either normally or lognormally distributed.

Other Statistical Calculations Used in MANAGES

Sen Estimate of Slope

The Sen estimate of slope is the median of all slopes between all possible unique pairs of individual data points in the time period being analyzed (Gilbert, 1987). The slopes represent the rate of change of the measured parameter, with the y-axis being the parameter value and the x-axis being calendar days. Sen's estimate of slope is a non-parametric estimator of trend. The method is robust, and fairly insensitive to the presence of a small fraction of outliers and non-detect data values. In contrast, linear regression and other least squares estimators of slope are significantly more sensitive, and more likely to give erroneous slope indications, even when only a few outlier values are present.

When data averaging is not activated, the Sen slope is calculated using individual data points and actual sampling dates. When data averaging is activated, multiple data points within each specified season period are reduced to one data point by arithmetic averaging over each of the season periods. These averaged values are then assigned to the day that corresponds to the middle of that season's period.

The approximate lower and upper confidence limits for the Sen slope can also be calculated using normal theory (Gilbert, 1987). It should be noted that confidence limits for the Sen slope are not necessarily symmetrical about the estimated slope since ranked values of slope are used in the calculation.

MANAGES calculates Sen slope in the Sen Slope Overlay Graph, Statistical Summary reports and in the two Mann-Kendall tests performed under the Statistical Evaluation Report.

Sen's Estimate of Slope – two-sided, non-parametric method that calculates the trend of a single data series. It is less sensitive to outliers and non-detect values than linear regression (Gilbert, 1987; p. 217).	
Slope, Q	$= \frac{x_{i'} - x_i}{i' - i}$ where $X_{i'}$ and x_i are data values at times i' and i, respectively, and where $i'>i$. Typically, i' and i are expressed in units of either days for trend analysis or years for seasonal analysis.
N′	Number of unique data point pairs that can be made for the observations in the data set, for $i'>i$. For n monitoring events, N′ is given as: N′ = n(n-1)/2

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Sen's Slope Estimate	Sen's slope estimator = median slope $= Q_{[(N'+1)/2]}$ if N' is odd $= \frac{1}{2}(Q_{[N'/2]} + Q_{[(N'+2)/2]})$ if N' is even where the Q values have first been ranked from smallest to largest.
$Z_{1-\alpha/2}$	Statistic for the cumulative normal distribution (Gilbert, 1987; p. 254) for the two-sided, α significance level.
Variance estimate of the Mann-Kendall S Statistic, VAR(S)	VAR(S) $= \frac{1}{18}\left[n(n-1)(2n+5) - \sum_{p=1}^{g} t_p(t_p-1)(2t_p+5)\right]$ where g is the number of tied groups, t_p is the number of data in the pth group, and n is the number of data values.
C_α	$= Z_{1-\alpha/2}\sqrt{VAR(S)}$
Sen's Slope , a two-sided test at the α significance level	$M_1 = \frac{(N'-C_\alpha)}{2}$ $M_2 = \frac{(N'+C_\alpha)}{2}$ Lower limit of confidence interval is the M_1-th largest slope, and upper limit of confidence interval is the (M_2+1)-th largest of the N′ ordered slope estimates.

Coefficient of Skewness for Normality

The coefficient of skewness is another measure for data normality (Gilbert, 1987). MANAGES provides the value of the coefficient of skewness in the Statistical Evalueation Report, Statistical Overview. Additional information on data normality is given by Montgomery, et al. (1987).

1. INTRODUCTION

1.1 Background

This 2019 Annual Report has been prepared for AmerenEnergy Medina Valley Cogen, LLC (Ameren) for the Meredosia Power Station (Meredosia, Figure 1-1). Ameren completed closure activities for the Fly Ash Pond and Bottom Ash Pond in accordance with the site-specific closure requirements of Title 35 of the Illinois Administrative Code (IAC) Section 840 in December 2018. Closure activities, which included grading, placement of a high-density polyethylene (HDPE) geomembrane covered with ClosureTurf®/ArmorFill® synthetic turf, and construction of surface water control structures, began in March 2018 and were substantially completed as of December 5, 2018. This is the third annual report for Meredosia since groundwater monitoring was restarted in 2017. Seven rounds of pre-closure groundwater data and four rounds of post-closure data have been collected between June 2017 and December 2019 to satisfy requirements of the Groundwater Monitoring Plan, dated December 14, 2016 (Geotechnology, Inc).

The Groundwater Monitoring Plan, in accordance with 35 IAC 840.114 and 35 IAC 840.116, outlines groundwater monitoring and sampling procedures, establishes the parameters and methods to be used for analyzing the groundwater samples, and describes evaluation methods to assess post-closure groundwater quality and trends to demonstrate compliance with the applicable groundwater standards. The Groundwater Monitoring Program Schedule is provided in Table 1-1.

The current groundwater monitoring network comprises 12 monitoring wells, including five installed in October 2010 (APW-1 through APW-5), four installed in October 2015 (APW-6 through APW-9), and three installed in August 2018 (APW-10 through APW-12). From 2010 to 2012, monitoring wells APW-1 through APW-5 were sampled. Beginning in June 2017 and in accordance with the Groundwater Monitoring Plan, groundwater sampling was restarted and conducted quarterly at monitoring wells APW-1 through APW-9. Beginning in September 2018 and in accordance with the Groundwater Monitoring Plan, monitoring wells APW-10, APW-11, and APW-12 were incorporated into the well network and were sampled quarterly along with wells APW-1 through APW-9. The monitoring wells were installed to define the lateral extent of impacts on site, as well as to assist in future groundwater monitoring of remedial actions. Monitoring well boring and construction logs are included in Appendix A. Locations of all monitoring wells are shown on Figure 1-2. Monitoring well locations, installation dates, construction information, and the groundwater zone they monitor are provided in Table 1-2. Boring logs and construction forms are included in Appendix A. Field and laboratory parameters for evaluating groundwater quality are shown in Table 1-3.

In conjunction with Ameren's request for approval of the Closure Plan, Ameren submitted a Groundwater Management Zone Plan, Fly Ash Bottom Ash Pond, Meredosia Power Station (Geotechnology, Inc., December 2016) and a request to establish the groundwater management zone (GMZ) pursuant to 35 IAC 620.250(a)(2): Ash Ponds Closure, Groundwater Management Zone Application, dated October 17, 2017, which was approved by the Illinois Environmental Protection Agency (IEPA) on November 1, 2017.

Electronic Filing: Received, Clerk's Office 09/28/2020

This annual report includes the following elements:

- Monitoring well boring and installation logs for the 12 currently installed wells, APW-1 through APW-12 (Appendix A)
- A summary of post-closure groundwater monitoring data collected on January 29, 2019; June 4, 2019; August 26, 2019; and December 9, 2019, including data tables (Appendix B)
- Recent Site Inspection Forms (Appendix C)

1.2 Demonstration of Compliance

Compliance will be based on attainment of post-closure groundwater quality that meets the Class I Groundwater Standards, as set forth in 35 IAC 620.410. Groundwater shall be in compliance when concentrations are below the Class I Groundwater Standards and there are no statistically significant increasing trends at the compliance boundary. The trend analysis shall be performed on a minimum of eight consecutive post-closure groundwater samples and use Sen's Estimate of Slope for assessing concentration trends.

Ameren completed closure of the inactive Fly Ash and Bottom Ash Ponds at Meredosia Power Station and the closure project was deemed substantially complete December 5, 2018 in accordance with the Closure Plan (Ameren letter to IEPA dated January 31, 2019). As of the 2019 Annual Report, there are only four rounds of post-closure groundwater data available. Statistical analysis to demonstrate compliance will begin when eight rounds of post-closure data are available. It is anticipated that eight rounds of post-closure data will be available for analysis in the 2020 Annual Report.

Electronic Filing: Received, Clerk's Office 09/28/2020

2. DATA ANALYSIS

2.1 Groundwater Flow

The groundwater elevation contours for each quarterly sampling event shown on Figures 2-1 through 2-4 are based on groundwater measurements collected in 2019 and illustrate groundwater flow. During normal flow conditions, groundwater flow in the upper (shallow) zone is generally northwest and west towards the Illinois River, consistent with past evaluations (Figure 2-1, Figure 2-3 and Figure 2-4). In June 2019, groundwater elevation data was not collected from wells located near the west property boundary (APW-2, APW-3, APW-4, APW-7, APW-9, and APW-12) due to flooding (Figure 2-2). During June 2019 flood conditions, groundwater flow in the southeast corner of Meredosia flowed from APW-11 toward APW-1 in a southeasterly direction, away from the Illinois River.

Consistent with observations during January and December 2018, a minor groundwater inflection was seen at APW-2 during the January and December sampling events in 2019 (Figure 3-1). Groundwater elevation differences between well APW-2 and wells APW-9 and APW-3 ranged from 0.83 to 2.18 feet. APW-2 is screened predominantly in clay while the surrounding wells, including APW-3 and APW-9, are screened mostly in sand, making it likely that APW-2 is slower to react to changes in river elevation.

2.2 Summary of Analytical Data

This annual report presents four rounds of post-closure data collected on January 29, 2019; June 4, 2019; August 26, 2019; and December 9, 2019. Wells APW-2, APW-3, APW-4, APW-7, APW-9, and APW-12 were not sampled during the second quarter sampling event of 2019 due to flooding in the area. Note that total dissolved solids (TDS) was resampled on December 20, 2019 for the fourth quarter sampling event because the original samples were analyzed two days past hold time. All field and laboratory analytical results are tabulated in Appendix B.

As discussed in Section 1.2, and according to the Groundwater Monitoring Plan, eight samples are required to conduct trend analyses for compliance. Since only four rounds of post-closure data are currently available, and an additional four rounds of data are scheduled for collection in 2020, trend analysis will begin in the 2020 Annual Report. According to the Post-Closure Care Plan (Geotechnology, Inc., 2018), two years after the ash ponds have been closed, the groundwater monitoring network will be re-evaluated based on the changes in the groundwater impacts (December 2020).

2.3 Site Inspection

The Post-Closure Maintenance Program requires quarterly inspection for the first five years after closure. After five years, the inspection frequency can be reduced to semi-annually provided that semi-annual groundwater monitoring has been approved by IEPA. After five years of semiannual monitoring, the inspection frequency can be reduced to annually pending approval of annual groundwater monitoring. Discontinuance of site inspections will occur after IEPA approval of the certified Post-Closure Care Report.

Site inspections include assessment of the condition and need for repair of final cover and vegetation, as wells as fencing, monitoring points, and surface water control features. Following completion of closure activities in December 2018, the initial inspection occurred in December 2018 and quarterly inspections were done in 2019. The inspection reports from 2019 are included in Appendix D. Based on these reports, all the components of the closure turf are in good condition.

Electronic Filing: Received, Clerk's Office 09/28/2020

3. CONCLUSIONS

This annual report presents four rounds of post-closure data. The Groundwater Monitoring Plan requires eight consecutive rounds of post-closure data to be collected before statistical analysis of trends can be made for compliance. Once eight rounds of post-closure data have been collected, statistical analysis will be run using all eight samples and used to determine compliance. It is anticipated that eight rounds of post-closure data will be available for analysis in the 2020 Annual Report. No action, other than submittal of this report, is required per Section 5.2 of the Groundwater Monitoring Plan (Compliance Determination).

Electronic Filing: Received, Clerk's Office 09/28/2020

2. Well Use: Monitoring Well Disinfected? No

3. Date Well Completed: Oct 1, 2015 Driller's Estimated Well Yield (gpm): _____

4. Date Permanent Pump Installed: _____ Set at Depth (ft.): _____

5. Pump Capacity (gpm): _____

6. Pitless Adapter Model and Manufacturer: _____ Attachment to Casing: _____

7. Well Cap Type & Manufacturer: _____

8. Pressure Tank Working Cycle (gals.): _____ Captive Air? _____ **9.** Pump System Disinfected: _____

10. Name of Pump Company _____

11. Pump Installer: _____ License # _____

12. _____ Date _____
Licensed Pump Installation Contractor Signature

Illinois Department of Public Health
Division of Environmental Health
525 West Jefferson Street
Springfield, IL 62761

IL 482-0126
Revised 6/09

IMPORTANCE NOTICE: This state agency is requesting disclosure of information that is necessary to accomplish the statutory purpose as outlined under Public Act-0863. Disclosure of this information is Mandatory. This form has been approved by the Forms Management Center.

13. Property Owner: Medina Valley Cogen LLC Well # APW-9

14. Driller: Steven Parker License # _____

15. Name of Drilling Company : Geotechnology, Inc. **16.** Permit Number: _____

Date Issued: _____ **17.** Date Drilling Started Oct 1, 2015

18. Well Site Address: 800 SOUTH WASHINGTON STREET

19. Township Name: _____ Land I.D. # _____

20. Subdivision Name: _____ Lot # _____

21. Location: a. County Moran b. Site Elevation _____ ft. (above msl)

c. Township: _____ Range: _____ Section: _____

d. _____ Quarter of the _____ Quarter of the _____ Quarter

e. GPS: Lat: Degrees 39 Minutes 48 Seconds 57 N

Lon: Degrees -90 Minutes 34 Seconds 14 W

Survey use only

22. Casing and Liner Information

Diameter (in.)	Material, Joint Type	From (ft.)	To (ft.)
2	PVC, threaded	29.3	0

23. Is the well screened? Yes If yes

Diameter (in.)	Length (ft.)	Slot Size (in.)	From (ft.)	To (ft.)
2	10	0.01	29.3	19.3

24. Water from _____ at a depth of (ft.) _____ To (ft.) _____

a. Static water level (ft.) below top of casing _____ which is (in.) above ground _____

b. pumping level is (ft.) _____ pumping (gpm) _____ for (hours) _____

25.

Earth Materials Passed Through	From (ft.)	To (ft.)
FILL: black, silty sand with coal CCR	0	10
Gray SILT - ML	10	12.7
Brown, fine-grained SAND - SP	12.7	18
Brown, medium-grained SAND - SP	18	24
Blind drilled - heaving sands	24	29.3

(Attach 2nd page, if necessary) (If DRY HOLE, fill out log & indicate how hole was sealed)

_____ License # _____
Licensed Water Well Contractor Signature

Electronic Filing: Received, Clerk's Office 09/28/2020

Illinois Environmental Protection Agency **Well Completion Report**

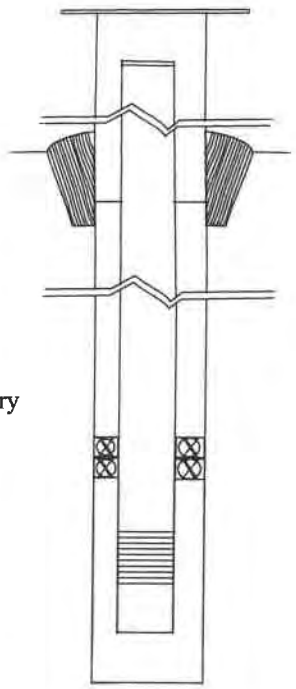
Site Number: _____ County: Morgan

Site Name: Meredosia Power Station Well #: APW-10

State Plane Coordinate: X 2184086.395 Y 1148344.943 (or) Latitude: ___ ___ ___ Longitude: ___ ___ ___ Borehole #: _____

Surveyed by: David Mason & Associates IL Registration #: _____

Drilling Contractor: Geotechnology, Inc. Driller: Thomas Dwyer



Consulting Firm: Geotechnology, Inc. Geologist: Anna Saindon

Drilling Method: Hollow Stem Auger Drilling Fluid (Type): None

Logged By: Jessie Goodwin Date Started: 8/20/2018 Date Finished: 8/20/2018

Report Form Completed By: Jessie Goodwin Date: 12/26/2018

ANNULAR SPACE DETAILS

Type of Surface Seal: Concrete

Type of Annular Sealant: Bentonite Grout Slurry

Installation Method: Tremie

Setting Time: N/A

Type of Bentonite Seal - - Granular, Pellet, Slurry (Choose One)

Installation Method: Gravity

Setting Time: N/A

Type of Sand Pack: Silica

Grain Size: 10-20 Mesh (Sieve Size)

Installation Method: Gravity

Type of Backfill Material: N/A (if applicable)

Installation Method: _____

	Elevations (MSL)*	Depths (BGS)	(.01ft.)
Top of Protective Casing	457.93	-3.83	
Top of Riser Pipe	457.45	-3.35	
Ground Surface	454.10	0.00	
Top of Annular Sealant	453.60	0.50	
Static Water Level (After Completion)	425.99	28.11

APPENDIX C
SITE INSPECTION REPORTS

Inspection Form for Closed Ponds at Ameren Facilities

Projcet Name: Quarterly Ash Pond Cap Inspection

Location: Meredosia Power Plant

System Description: Fly Ash Pond
Bottom Ash Embankment

Engineer/Inspectors: Mike Wagstaff

Inspection Date: 3/29/2019
Temperature: 40's
Weather: cloudy

River Level 436.3'
at Meredosia
Gage 0' = 418.00' MSL
Bottom Ash Pond bottom
is at 430.00' MSL

Owner Representative: n/a

Overall System Rating: Acceptable

System Rating Codes

Acceptable System: Nearly all items or components are rated as GC or NE.

Minimally Acceptable System: One or more items are rated as MM or one or more items are rated as IM or EC and an engineering determination concludes that the IM or EC items would not prevent the system from performing as intended.

Unacceptable System: One or more items are rated as IM or EC and would prevent the system from performing as intended, or a serious deficiency noted in past inspections (which had previously resulted in a minimally acceptable system rating) has not been corrected within the established timeframe, not to exceed two years.

Condition Codes

EC = Emergency Condition. A serious dam safety condition exists that needs immediate action. Emergency measures implemented as instructed by Supervising Engineer, Dam Safety; i.e. pool draw down, work stoppage, or plant stoppage.

IM = Item needing Immediate Maintenance to restore or ensure its safety or integrity. Remediation should be completed within an appropriate timeframe as determined by the Supervising Engineer, Dam Safety.

MM = Item needing Minor Maintenance and/or repairs within the year. The safety or integrity of the item is not yet imperiled.

OB = Condition requires regular Observation to ensure that the condition does not become worse.

GC = Good Condition.

NE = No Evidence of a problem.

NI = Not Inspected. Reason should be stated in comment

Meredosia Power Station
Fly Ash Pond Cap - ClosureTurf
Quarterly Site Inspection Checksheet

Date	3/29/2019
Inspector	Mike Wagstaff
Temperature	40's
Weather	cloudy

	Item	Condition Code *	Comments
Closure Cap	Drainage Ditch/ArmorFill	GC	ArmorFill has not yet been applied to ditches. This work will be done Spring of 2019.
	Sand on Cap	GC	Sand has been applied to 100% of cap and swept into turf for 80% of cap. Remaining sweeping will be done in Spring 2019.
	ClosureTurf	GC	No damage or degradation evident.
	Riprap Outlet Flumes	GC	No vegetation in riprap outlet flumes.
	Other	--	
Embankment	Riprap	GC	Riprap placed during cap construction and is in good condition.
	Vegetation in riprap	GC	No weeds in riprap.
	Vegetation at Toe	GC	Vegetation has been mowed a minimum of 20' from berm toe.
	Debris/Logs	GC	All debris/logs were removed from the berm during closure construction.
	Erosion	GC	None.
	Other	--	

Condition Codes

IM = Item needing Immediate Maintenance. Remediation should be completed within 1 month.
MM = Item needing Minor Maintenance and/or repairs within the year.
OB = Condition requires regular observation to ensure that the condition does not become worse.
GC = Good Condition. Working properly.
NE = No Evidence of a problem.
NI = Not Inspected. Reason should be stated in comment

Bottom Ash Embankment - ClosureTurf
Quarterly Site Inspection Checksheet

Date	3/29/2019
Inspector	Mike Wagstaff
Temperature	40's
Weather	cloudy

	Item	Condition Code *	Comments
Roadway	**Gravel Road**	**GC**	Roadway gravel is compacted and smooth.
	Drainage	**GC**	No drainage problems at this time.
	Other	**GC**	No issues.
Embankment	**Vegetation at Toe**	**GC**	Vegetation has been mowed a minimum of 20' from berm toe.
	ClosureTurf	**GC**	Turf in excellent condition. No signs of wear or damage.
	ArmorFill	**GC**	ArmorFill has been applied and is in good condtion.
	Riprap at Toe	**GC**	No vegetation in riprap.
	Riprap Outlet Flumes	**GC**	Flume at northeast end of berm is in good condition.
	Other	**--**	
Remaining Basin	**Side Slopes**	**GC**	Sedimentation logs are in place, site has been seeded and mulched.
	Bottom	**GC**	Seed has germinated and started growing prior to winter weather.
	Outlet Riprap	**GC**	No weeds in riprap.
	Toe Riprap	**GC**	No weeds in riprap.
	Other	**--**	

Condition Codes

IM = Item needing Immediate Maintenance. Remediation should be completed within 1 month.
MM = Item needing Minor Maintenance and/or repairs within the year.
OB = Condition requires regular observation to ensure that the condition does not become worse.
GC = Good Condition. Working properly.
NE = No Evidence of a problem.
NI = Not Inspected. Reason should be stated in comment

Dear Mr. Buscher,

Re: **2019 Annual Post-Closure Care Report**
Ameren Missouri's Venice Energy Center's Ash Ponds

As required per the approved closure plan, Union Electric Company d/b/a Ameren Missouri is submitting the 2019 Annual Post-Closure Care Report for the Venice Energy Center. This report includes compilation of groundwater monitoring data and trend analysis to demonstrate compliance per Section 5 of the Closure Plan, which was approved by the Agency on May 6, 2011.

Please note that due to the corona virus, our staff does not have the capability to use printing services. We plan to send you hard copies when we are able. Thanks for your understanding as we are trying to limit our staff from potential exposure to this virus.

Please contact me at 314-554-3143 if there are any questions regarding this 2019 Annual Report.

Sincerely,

Julianne Epplin

1. INTRODUCTION

1.1 Background

In May 2011, the Illinois Environmental Protection Agency (IEPA) approved Ameren Missouri's (Ameren) Closure Plan (Natural Resource Technology, Inc. (NRT), 2011) for Venice Power Plant Ash Ponds 2 & 3 and established a Groundwater Management Zone (GMZ) for the site. The Closure Plan included specifications for construction of a cover system over the ash ponds that conformed to the standards for final cover set forth in Illinois Landfill Regulations and a site-specific rulemaking governing closure of an ash pond at The Hutsonville Power Station, owned by an Ameren-affiliated company. See, generally, 35 Illinois Administrative Code (IAC) 840.126 and 35 IAC 811.314. Cover construction was completed in October 2012.

Groundwater quality has been monitored at this site since 1996. The Closure Plan included a summary of the groundwater quality at the site as of 2009 and a revised groundwater monitoring plan that outlined a schedule for monitoring five field and 24 laboratory parameters at 12 monitoring wells (Tables 1-1, 1-2, and 1-3, Figure 1-1). The new monitoring plan was initiated in March 2011 with existing monitoring wells. In accordance with the approved Closure Plan, additional monitoring wells were installed in July 2011. In 2019, IEPA approved a request to change the groundwater monitoring schedule from quarterly to semi-annually and to cease monitoring for beryllium, mercury, and thallium.

This Annual Report is submitted per Section 5.4 of the Closure Plan and includes a ten-year review of the groundwater quality at the site as of 2019 to provide an overview of the effectiveness of the cover system in improving groundwater quality downgradient from the former ponds. This report also includes the following groundwater monitoring plan compliance elements:

- A summary of groundwater monitoring data collected during August 2017 through September 2019. Data collected in 2017 and 2018 were included for completeness because they are used in the statistical analysis of groundwater data. Data tables are included in Appendix A.
- Annual trend analysis results per Section 3.4 of the Closure Plan.
- Groundwater monitoring field data worksheets which note a description of any maintenance or replacement activities performed (Appendix B).
- Final cover site inspection reports and a description of any maintenance activities performed on the cover (Appendix C).

1.2 Groundwater quality overview – 2019

1.2.1 Summary of Cover System Construction and Maintenance

As part of closure activities, Ameren removed all standing surface waters from Ash Ponds 2 & 3 and a geosynthetic cover was constructed to provide a barrier to infiltration and subsequent generation and release of leachate from the ponds (NRT, 2011). The cover system consists of (from bottom up) a 40-mil polyvinyl chloride (PVC) geomembrane; a geocomposite drainage layer constructed of high-density polyethylene geonet encapsulated in geotextile; and a 3-foot thick protective soil layer placed over re-graded ash in the ponds. The geocomposite was provided to drain surface water that infiltrates the protective soil layer. Storm water precipitation

Electronic Filing: Received, Clerk's Office 09/28/2020

is routed away from the cover system toward two low areas at the north and south ends of the cover, then pumped over the levee to the Mississippi River. The cover is graded such that there is no off-site contribution, or run-on, of storm water from areas outside of the ash ponds.

Inspections of the cover system are performed simultaneously with groundwater sampling. Routine maintenance activities are performed at the site, as needed and as soon as practicable after issues are identified, and include recontouring the ground surface, repairing drainage channels, repairing and replacing lining material, revegetating areas, and removing woody vegetation. Maintenance activities can be found in more detail in the Closure Plan (NRT, 2011).

1.2.2 Summary of 2019 Groundwater Quality

Groundwater quality data since completion of pond closure in 2012 were reviewed to assess the overall condition of the groundwater and the performance of the cover system. This review was performed independently from the compliance evaluations required by the Groundwater Monitoring Plan (NRT, 2011), which are focused on specific compliance criteria and proposed mitigation actions. This review is intended as a big-picture view of groundwater quality over time since closure.

The Closure Plan identified boron as the primary indicator constituent for coal ash impacts to groundwater at the site because it is found at relatively high concentrations in coal ash leachate and is mobile in sand and gravel environments similar to the aquifer at Venice. As such, boron was selected for this groundwater quality data review. Boron concentrations over time from closure completion (2012) to the present are presented in Figures 1-2 through 1-7. On the figures, the lines through the concentration data represent the best fit linear regressions for boron concentrations in each well. The regression lines provide a convenient means of evaluating general concentration “trends” over time and are not equivalent to the statistical trends discussed in the groundwater compliance section of this report.

Generally, boron concentrations in most compliance monitoring wells have decreased since 2012 and are currently below Class I Groundwater Standard in **seven** of the ten compliance groundwater monitoring wells (MW-2, MW-2D, MW-3, MW-3D, MW-5, MW-11 and MW-11D). Boron concentrations in three wells (MW-6, MW-6D and MW-10) exhibit slight increases over time at levels above the Class I Groundwater Standard. Note that no statistically-determined increasing trends have been identified for boron for the reporting period. In addition, there are a total of 31 decreasing trends identified of various analytical parameters since completion of closure in 2012, as discussed in Section 3.1 and summarized on Table 3-1.

1.2.3 Conclusion

The decreasing boron concentrations in the majority of compliance monitoring wells across the site is a strong indication that the cover system is functioning to improve overall groundwater quality beneath the ponds. This observation is consistent with the results of groundwater modeling performed in 2010 to simulate changes in groundwater quality resulting from pond closure. Modeling results suggested that boron concentrations in all monitoring wells would stabilize at levels below the Class I Groundwater Standard within 14 to 20 years, with the exception of on-site well MW-6, where boron concentrations were predicted to persist for a longer time period.

Electronic Filing: Received, Clerk's Office 09/28/2020

2. GROUNDWATER MONITORING PLAN COMPLIANCE

2.1 Applicable Groundwater Quality Standards

As described in Section 3.3 of the Closure Plan:

- On site, prior to the completion of the post-closure care period, the applicable groundwater quality standards at the Venice ash ponds are the concentrations as determined by groundwater monitoring, if such concentrations exceed the numeric standards for Class I: Potable Resource Groundwater set forth in 35 IAC 620.410.
- After completion of the post-closure care period, the on-site concentrations of contaminants from the Venice ash ponds as determined by groundwater monitoring, are the applicable groundwater standards if such concentrations exceed the numeric standards for Class I Potable Resource Groundwater set forth in 35 IAC 620.410, and if:
  - To the extent practicable, the exceedance has been minimized and beneficial use, as appropriate for the class of groundwater, has been returned on-site.
  - Any threat to public health or the environment on-site has been minimized.
  - An institutional control prohibiting potable uses of groundwater is placed on the Former Venice Power Plant site in accordance with the Uniform Environmental Covenants Act [765 Illinois Compiled Statutes (ILCS) 122] or an alternative instrument authorized for environmental uses under Illinois law and approved by IEPA is in effect. Existing potable uses of groundwater may be preserved as long as such uses are consistent with human consumption in accordance with accepted water supply principles.

Off-site standards were not proposed because: 1) Ameren did not receive permission from the adjacent property owner to monitor groundwater on that property; 2) the impoundment has been covered, which minimizes exceedances of groundwater quality standards to the extent practical; 3) there are no groundwater receptors in this area; and 4) there is a groundwater restriction ordinance in effect for this area.

2.2 Demonstration of Compliance

As described in Section 3.4 of the Closure Plan:

- Compliance with on-site groundwater quality standards will be achieved when no statistically significant increasing trend that can be attributed to the Venice ash ponds is detected in the concentrations of all constituents monitored at the downgradient boundaries of the Venice site for four consecutive years after changing to an annual monitoring frequency (see Table 1-1).
- If the Sen's non-parametric estimate of slope shows a positive slope at any compliance monitoring well located at the downgradient boundaries of the Venice site GMZ as specified in Table 1-2, or any parameter (Table 1-3) a Mann-Kendall test will be performed at 95 percent confidence to determine whether the positive slope represents a statistically significant increasing trend. Ameren will investigate the cause of a statistically significant increasing trend as described below. If the statistically significant increasing trend occurs during post-closure care, the investigation will include more frequent inspection of the surface of the cover system and evaluation of background concentrations.

Electronic Filing: Received, Clerk's Office 09/28/2020

  - If the investigation attributes a statistically significant increasing trend to a superseding cause, Ameren will notify IEPA in writing, stating the cause of the increasing trend and providing the rationale used in such a determination.
  - If there is no superseding cause for the statistically significant increasing trend and sampling frequency has been reduced to semi-annual or annual sampling, a quarterly sampling schedule will be reestablished. After four consecutive quarterly samples show no statistically significant increasing trend, the frequency of groundwater monitoring will return to either semi-annual or annual, whichever frequency was utilized prior to the return to quarterly sampling.
  - Notifications concerning statistically significant increasing trends and revisions of the sampling frequency will be reported to IEPA in writing within 30 days after making the determinations.
- If a statistically significant increasing trend is observed to continue over a period of two or more consecutive years and there are no superseding causes for the trend, then Ameren will perform the following:
  - A hydrogeologic investigation
  - Additional site investigation, if necessary

Based on the outcome of the investigation above, Ameren may take action to mitigate statistically significant increasing trends. Such actions will be proposed as a modification to the Post-Closure Care Plan within 180 days after completion of the investigation activities described above.

Electronic Filing: Received, Clerk's Office 09/28/2020

3. DATA ANALYSIS

3.1 Groundwater Flow

Groundwater flow contours for the two semi-annual monitoring events which occurred in February 2019 and September 2019 are illustrated in Figures 3-1 and 3-2. Groundwater was encountered at depths between 10 to 30 feet below ground surface (bgs). Groundwater flow in the region is controlled by the Mississippi River, and water levels within the monitoring wells rise and fall with river stage. Groundwater flow in February 2019 and September 2019 was generally from northeast to southwest (toward the Mississippi River) under gradients of 0.03 feet/foot and 0.04 feet/foot. This is the predominant flow pattern during most of the year. During periods of high river stage groundwater flow reversals can occur, with groundwater flowing from northwest to southeast (away from the river).

3.2 Review of Analytical Data

Groundwater samples were collected on August 23, 2017; October 23, 2017; February 12, 2018; May 1, 2018; August 27, 2018; November 5, 2018; February 4, 2019; and September 10, 2019. All field and laboratory analytical results are tabulated in Appendix A. Selected analytes are discussed below.

- Boron was identified as the primary indicator constituent for coal ash impacts to groundwater at the site (see Closure Plan Appendix C). As in past monitoring periods, the highest boron concentrations in 2017-2019 monitoring period were detected in monitoring wells MW-10, MW-11D, and MW-3D (Figure 3-3). MW-10 is located to the north of the covered ash ponds and MW-11D and MW-3D are located to the west of the covered ash ponds; MW-11D and MW-3D are deep wells.
- Chloride is not a coal ash indicator constituent. It is noted here because it has historically had, and continues to have, higher concentrations in background monitoring wells MW-8 and MW-9 than in the compliance monitoring wells (Figure 3-4).
- Sulfate can be an indicator constituent for coal ash; however, there are other anthropogenic sources for elevated sulfate concentrations in groundwater, and sulfate concentrations can decrease in groundwater under strongly reducing conditions. These caveats make sulfate a less reliable indicator for coal ash impacts than boron. As in past monitoring periods, sulfate concentrations at the Venice ash ponds were highest at MW-10 and MW-11D (Figure 3-5) in 2017, 2018, and 2019, where boron concentrations were also highest. However, there are also differences between the sulfate distribution and the boron distribution. For example, MW-6 had boron concentrations greater than 4 milligrams per liter (mg/L), suggesting coal ash impacts, but sulfate concentrations were very low in this monitoring well. Conversely, background monitoring wells MW-8 and MW-9 had low boron concentrations because these wells are not affected by coal ash leachate, yet sulfate concentrations were similar to some of the wells with elevated boron concentrations. Due to these differences, which are consistent with previous monitoring periods, boron appears to be a more reliable indicator of coal ash constituents in groundwater and will, therefore, continue to be used as the primary indicator constituent for Venice Ash Ponds 2 and 3.

Electronic Filing: Received, Clerk's Office 09/28/2020

- Arsenic, boron, iron, lead, manganese, nitrate, sulfate, and total dissolved solids (TDS) exceeded their Class I Groundwater Standards in one or more samples in during the 2017-2019 monitoring period.

3.3 Statistical Analysis

Analytical data were evaluated for trends following a three-step procedure:

- Test for outliers using the Grubbs Outlier test.
- Determine Sen's estimate of slope (Section 3.4 of the Closure Plan).
- Perform a Mann-Kendall trend analysis for any cases (monitoring well/constituent) with a positive slope (Section 3.4 of the Closure Plan).

3.3.1 Outlier Analysis

The Grubbs outlier test determines whether there is statistical evidence of a high or low observation that differs significantly from the other data and provides statistical evidence of potential outliers. The test methodology and results are listed in Appendix D. Outliers identified by the Grubbs outlier test based on the date range of 1996-2019 were eliminated from further statistical analysis.

3.3.2 Sen's Estimate of Slope

Sen's estimate of slope is a non-parametric estimator of trend. It is the median of all slopes between all possible unique pairs of individual data points in the time period being analyzed. The slopes represent the rate of change of the measured parameter, with the y-axis being the parameter value and the x-axis being calendar time. The method is robust, and fairly insensitive to the presence of a small fraction of outliers and non-detect data values. The test methodology and results are listed in Appendix D.

Data collected in within the 2017-2019 monitoring period show 23 cases with positive slopes, 35 cases with negative slopes, and 194 cases with no slope (Table 3-1). The 23 cases with positive slopes were tested using the Mann-Kendall test to determine if the positive slopes represented statistically significant increasing or decreasing trends.

3.3.3 Mann-Kendall Trend Analysis

The Mann-Kendall test is a non-parametric, one-tailed test to determine whether a dataset has a statistically significant increasing or decreasing trend. The test methodology and results are listed in Appendix D. Increasing trends are identified in Table 3-2.

The Mann-Kendall test detected three cases of increasing trends in the 2017-2019 dataset, compared to two cases in the previous monitoring period. One of the three cases of increasing trends during the 2017-2019 monitoring period had concentrations exceeding its respective Class I Groundwater Quality Standard and two cases were below the Class I Groundwater Quality Standard. The three increasing trends identified in the 2017-2019 dataset were:

- Manganese: MW-10
- Nitrate Nitrogen: MW-11
- TDS: MW-3D

Electronic Filing: Received, Clerk's Office 09/28/2020

There were no repeat cases of increasing trends from the 2017-2018 monitoring period to the 2017-2019 monitoring period.

None of the cases were indicative of potential release from Ash Ponds 2 and 3 and the trends associated with the 2017-2019 data set are discussed further in Section 4.

3.4 Groundwater Monitoring System Maintenance and Inspection

The monitoring wells are inspected during each sampling event. Groundwater monitoring field data worksheets which contain inspection records for 2017, 2018, and 2019 are included in Appendix B. Monitoring wells MW-11 and MW-11D were redeveloped and repairs were made to their protective covers and surface completions in September and October 2017. Repair documentation is also included in Appendix B.

3.5 Cover Inspection and Maintenance

Fly Ash Pond Final Cover Inspection Reports (Appendix C) are shared with the Venice plant by Ameren upon completion. The plant responds promptly to correct issues as they are reported. No maintenance activities were required or performed on the ash pond cover system in 2017. The South drain appeared to not be draining properly in March of 2018. The South drain was then repaired and observed to be functioning normally in September of 2018.

In the June 2019 cover inspection report, it was noted that the top of the fence near the barbed wire needed minor repair at both pump stations and that more gravel was needed on the South Pump Station to help prevent erosional damage. The fence was repaired at both pump stations and additional gravel was placed at the South Pump Station in one area September of 2019. The September 2019 cover inspection report noted that additional gravel was needed at two locations at the South Pump Station to help prevent further erosion. The December 2019 cover inspection report noted the additional gravel was added to the two locations and ongoing temporary construction related to the removal and replacement of the Cahokia-Rockford Transmission Line Structure 161. The construction activities include removing the existing steel lattice tower, drilling and pouring the new concrete foundation, and installing the new steel monopole as described in a letter written by Ameren to the IEPA dated August 20, 2019 (Appendix C). The temporary construction disturbed the soil profile, impacted vegetation, and required piercing the membrane and sealing the cover against the foundation using a boot design. The December 2019 report noted that the affected area will have to be reseeded. Planned repair documentation for the Cahokia-Rockford Transmission Line Structure 161 is also included in Appendix C.

Electronic Filing: Received, Clerk's Office 09/28/2020

4. EVALUATION OF COMPLIANCE

4.1 Review of Increasing Trends Within the GMZ

The increasing trends are grouped by parameter and graphed along with concentrations in background wells (MW-8 and MW-9), in Figures 4-1 through 4-3.

4.1.1 Manganese: MW-10

An increasing trend for manganese above the Class I Groundwater Standard occurred at compliance monitoring well MW-10 (Figure 4-1). This is the first occurrence of such a trend at MW-10; increasing trends of manganese have been observed for MW-5 in 2016 and MW-11 in 2017. The solubility of manganese in groundwater is sensitive to redox conditions and concentrations often change due to natural variation, as evidenced by the sporadic increasing trends observed at various monitoring wells in the past. Since MW-10 does not have increasing boron or sulfate trends, the increasing trend for manganese does not indicate that a release from the ponds has occurred.

4.1.2 Nitrate Nitrogen: MW-11

An increasing trend below the Class I Groundwater Standard for nitrate nitrogen occurred at compliance monitoring well MW-11. Increasing trends for nitrate nitrogen have not been observed at the site since 2014, when such trends were noted at wells MW-2D, MW-3D, MW-8 and MW-11D. During this monitoring period, well MW-11 had higher concentrations of nitrate nitrogen than background monitoring wells MW-8 and MW-9, where concentrations are generally stable (Figure 4-2). Elevated nitrate nitrogen concentrations are usually indicative of contamination from fertilizers, sewage, ammonia, or leaking from septic tanks rather than ash leachate.

4.1.3 Total Dissolved Solids: MW-3D

An increasing trend for TDS with concentrations below the Class I Groundwater Quality Standard occurred at compliance monitoring well MW-3D during the 2017-2019 monitoring period (Figure 4-3). Such increasing trends of TDS have been observed intermittently at MW-6D and MW-9 during previous monitoring periods. TDS is a non-specific measure of dissolved concentrations in groundwater. Detectable concentrations ranging from 500 mg/L to 740 mg/L were observed in MW-3D, however there were no increasing trends of this parameter at MW-3D in past monitoring events.

Electronic Filing: Received, Clerk's Office 09/28/2020

5. CONCLUSIONS

Statistical analyses of analytical results for groundwater samples collected in 2017, 2018 and 2019 at the Venice Ash Ponds identified increasing concentration trends for three parameters, none of which is indicative of a release from the ponds. The three cases of increasing trends in the 2017-2019 dataset were:

- Manganese: MW-10
- Nitrate Nitrogen: MW-11
- TDS: MW-3D

This represents a small increase from the two increasing trends identified during the previous monitoring period (2017 – 2018).

As discussed in Section 3, the three cases of increases are not indicative of potential releases from the ash ponds.

- One increasing trend was for manganese at MW-10. Manganese is geochemically dependent on local redox conditions and MW-10 does not have increasing boron or sulfate trends, thus the increasing trend for manganese does not indicate that a release from the ponds has occurred.
- One increasing trend for nitrate nitrogen at well MW-11 does not indicate a release has occurred because elevated nitrate nitrogen concentrations are usually indicative of contamination from fertilizers, sewage, ammonia, or leaking from septic tanks rather than ash leachate.
- One increasing trend for TDS was observed at MW-3D. The TDS concentrations at MW-3D are lower than those detected in both background monitoring well MW-8 and MW-9 and the absence of increasing trends of this parameter at MW-3D in past monitoring events suggests that the TDS trend is not indicative of a release from the ash ponds.

Based on the increasing trends for manganese at well MW-10, nitrate nitrogen at well MW-11, and TDS at MW-3D, and in compliance with Section 3.4 of the Closure Plan, the semi-annual sampling schedule will be continued.

No additional action is required per section 3.4.2 of the Closure Plan (Demonstration of Compliance):

- Monitoring had been reduced to a semi-annual frequency in 2019; a continuation of semi-annual sampling is recommended.

No additional action is required per Section 3.5 of the Closure Plan (Proposed Mitigation Actions) because none of the increasing trends have been observed to continue over a period of two or more consecutive years. Further hydrogeologic and site investigation is not prescribed at this time.

Electronic Filing: Received, Clerk's Office 09/28/2020

[O: RAB 3/20/2020, C: MIK 3/20/2020]

Notes:
- "+" indicates that the Sen's non-parametric estimate of the median slope is positive.
- "-" indicates that the Sen's non-parametric estimate of the median slope is negative.
- Statistically significant positive/negative slopes are hereby referred to as increasing/decreasing trends.
- Mann Kendall Trend analysis done with non-detects at one half the detection limit.
- The most recent eight sampling events were used for analysis; date range for this analysis is 8/1/2017-12/31/2019
- Green shading indicates increasing trends as determined using the Mann-Kendall test at 95% confidence for constituents with maximum concentration lower than the Class I groundwater quality standard.
- Yellow shading indicates increasing trends as determined using the Mann-Kendall test at 95% confidence for constituents with maximum concentration higher than the Class I groundwater quality standard.

2012	15	-
2013	14	-
2014	6	-
2015	1	-
2016	20	-
2017	10	-
2018	2	-
2019	3	31

[O: RAB 3/2/2020, C: MIK 3/2/2020, U: RAB 3/20/2020, C: MIK 3/20/2020]

Notes:
Calculations of long term trends began in 2019
Short term trends were calculated on the basis of eight consecutive sampling events.
Long terms trends were calculated with data since completion of closure in 2012.

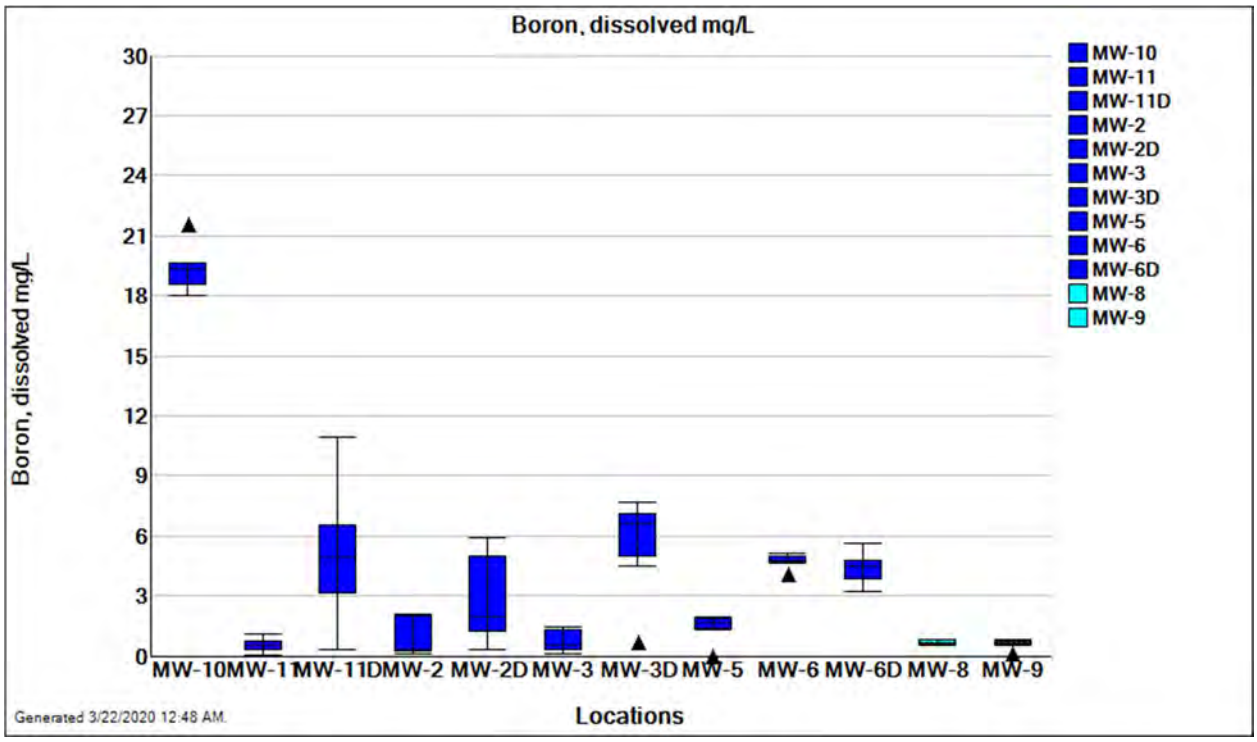

Figure 3-3. Box-whisker plot showing the distribution of boron concentrations by monitoring well for data collected during August 2017 through September 2019.

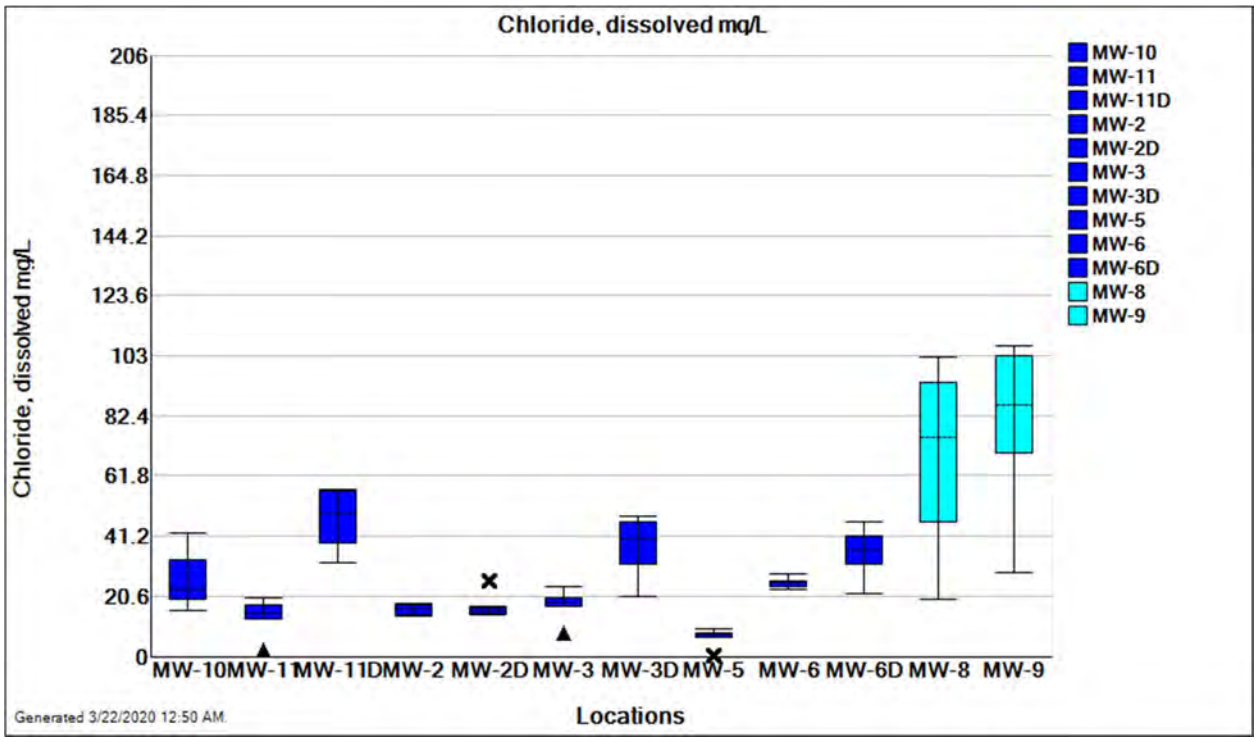

Figure 3-4. Box-whisker plot showing the distribution of chloride concentrations by monitoring well for data collected during August 2017 through September 2019. Background monitoring wells MW-8 and MW-9 had relatively high chloride concentrations.

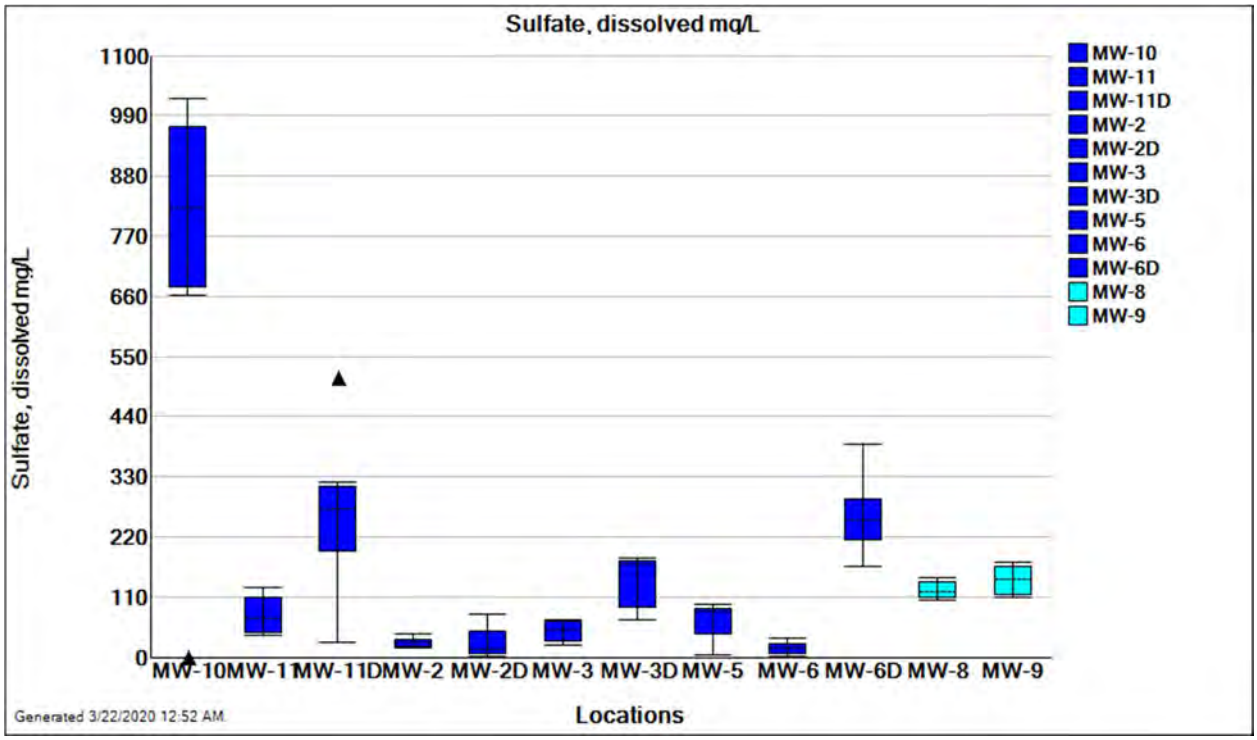

Figure 3-5. Box-whisker plot showing distribution of sulfate concentrations by monitoring well for data collected during August 2017 through September 2019. Similar to boron, the highest sulfate concentrations occurred in MW-10 and MW-11D; however, this plot is dissimilar to the boron plot because background monitoring wells MW-8 and MW-9 had similar or higher sulfate concentrations than MW-11, MW-2, MW-2D, MW-3, MW-3D, MW-5, and MW-6.

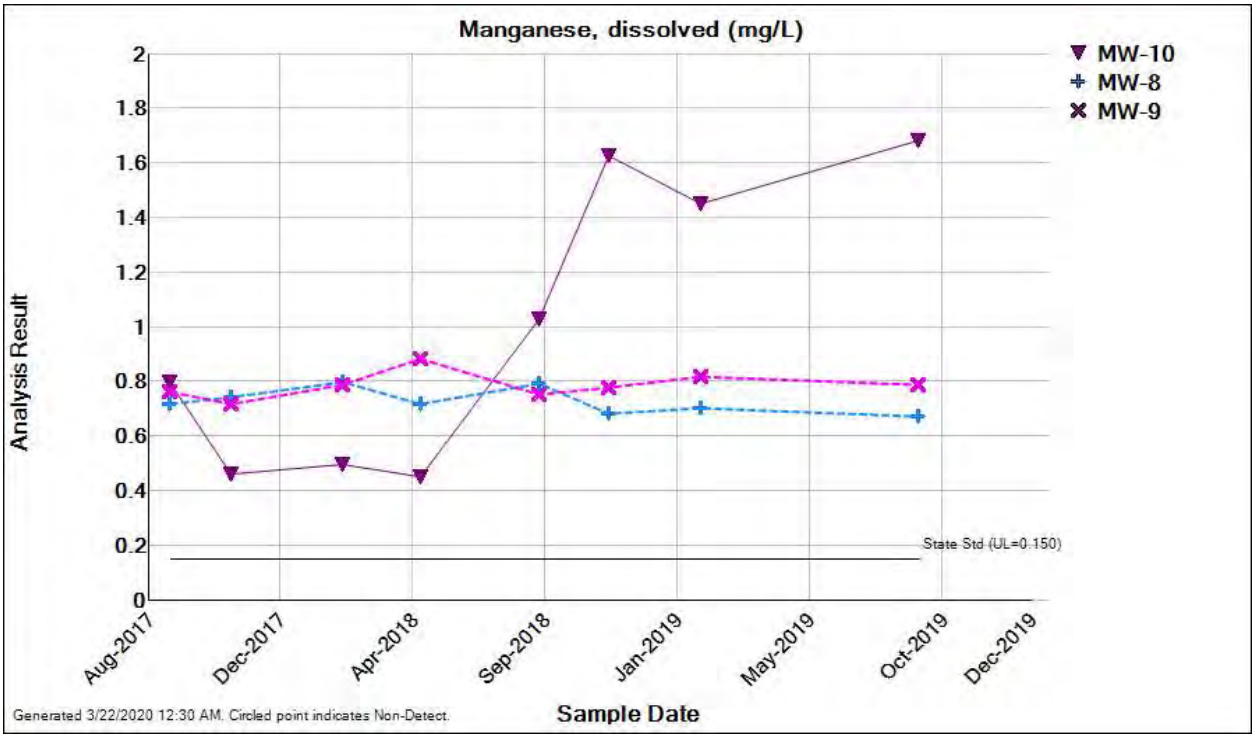

Figure 4-1. Increasing trends for manganese at compliance well MW-10 compared to background wells M-8 and MW-9. The Class I Groundwater Standard is not applicable within the GMZ and is shown for reference only.

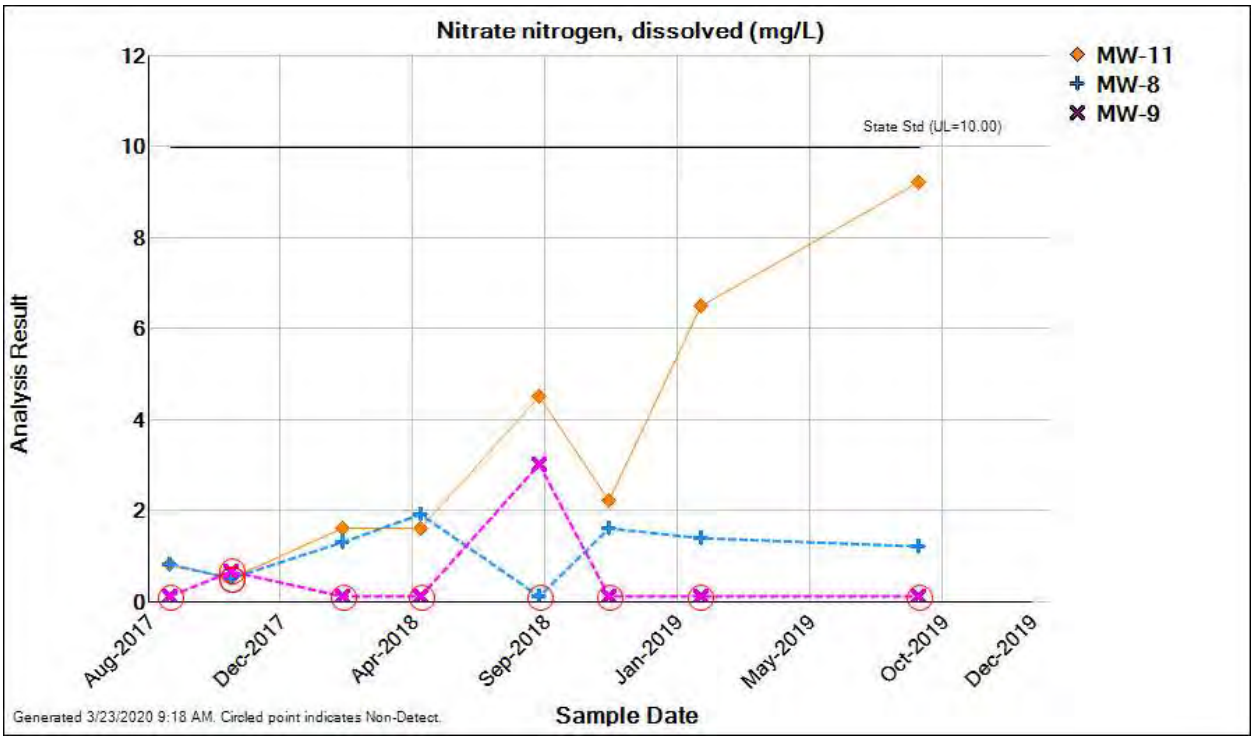

Figure 4-2. Increasing trends for nitrate nitrogen at compliance well MW-11 compared to background wells M-8 and MW-9. The Class I Groundwater Standard is not applicable within the GMZ and is shown for reference only. Red circles indicate values below the detection limit.

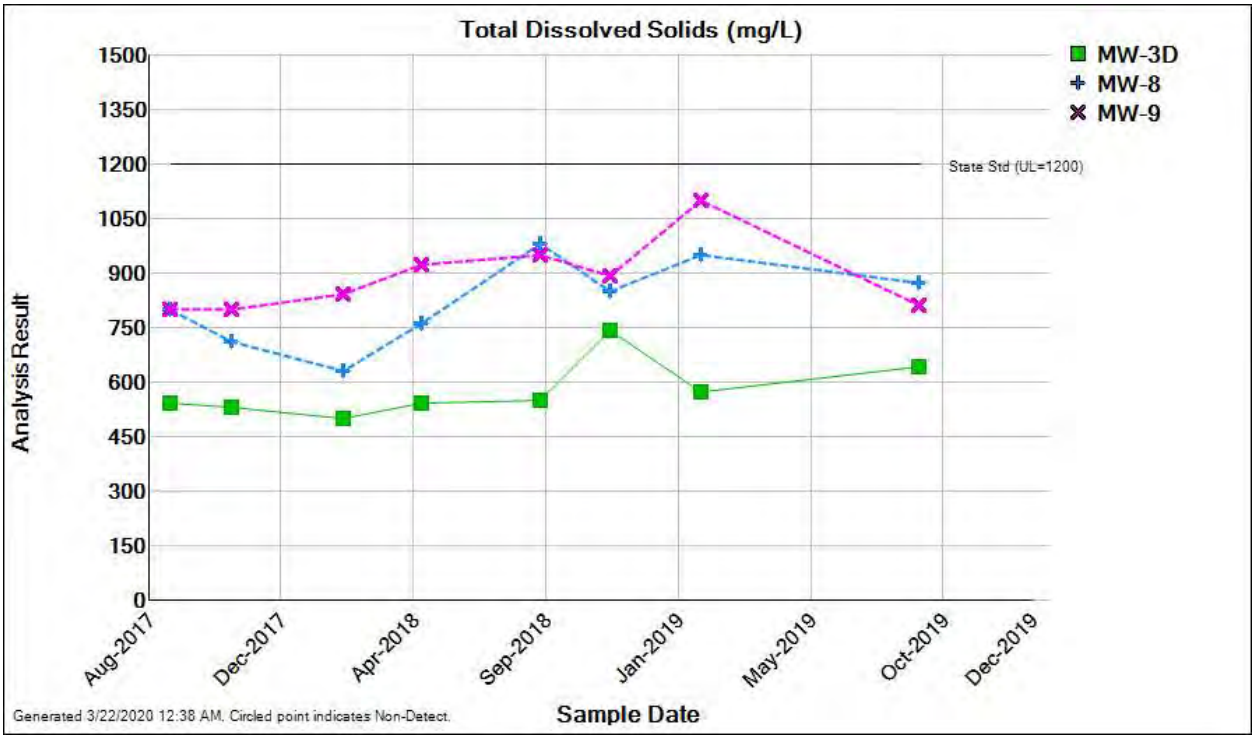

Figure 4-3. Increasing trends for total dissolved solids at compliance well MW-3D compared to background wells M-8 and MW-9. The Class I Groundwater Standard is not applicable within the GMZ and is shown for reference only.

Ameren Services

RE: MONITORING WELL REPAIRS AT THE VENICE ENERGY CENTER, MADISON COUNTY, ILLINOIS

Dear Mr. Giesmann,

Golder Associates Inc. (Golder) is pleased to present Ameren Services (Ameren) with this letter detailing the well re-development and surface completion repairs for monitoring wells MW-11 and MW-11D at the Venice Energy Center (VEC) in Madison County, Illinois. This letter contains the well development forms (Attachment A) and a photo log (Attachment B).

For the well re-development, Golder used an inertial pump with a surge block ring to surge and purge the wells and a stainless steel bailer to surge and remove sediment from the bottom of the wells. Development was deemed completed when field parameters (pH, specific conductivity, and temperature) were within 10 percent difference for three consecutive measurements and turbidity of the water was below 10 Nephelometric Turbidity Unit (NTU).

For the well protective cover repair, Golder subcontracted Bulldog Drilling to provide a crew to remove the damaged surface completion and install new protective covers. Well repair activities were done under the direct supervision of a Golder Engineer. After removing the damaged covers, new protective covers were installed in concrete to a depth of 2.5 feet below ground surface. New gasketed steel lids and protective covers were installed. A high visibility flag and fiberglass pole were installed with the surface completion for each well. A 3M Passive Electronic Marker System (EMS) XR/iD ball marker was placed between the two wells at coordinates 2446742.2 feet East, 14049907.0 feet North (Illinois State Plane West) at a depth of 44 inches below ground surface.

Golder appreciates this opportunity to provide hydrogeological and engineering support services to Ameren. If you have any questions or comments regarding the information provided please call our office at (636) 724-9191.

APPENDIX C
FINAL COVER SITE INSPECTION REPORTS
2017-2019 MONITORING PERIOD

Ameren Missouri

Fly Ash Pond Final Cover Site Inspection

Facility Name: Venice Energy Center Inspection Date: 09/01/2017

Facility Address: 701 Main Street, Venice, IL 62090

Inspection Conditions: Cloudy 70 degrees

SECURITY & ACCESS	YES	NO	N/A	Comments
1. Is access controlled?	✓			
2. Are "No Trespassing" signs posted?			✓	
3. Is there evidence of trespassing?		✓		
COVER & VEGETATION				
4. Is cover in acceptable condition?	✓			
5. Is vegetation in acceptable condition?	✓			
6. Is there any woody species of plant growing (i.e., trees and shrubs greater than 18")?		✓		
7. Is there any area with more than 100 square feet of failed or eroded vegetation?		✓		
8. Is there any erosion or sloughing of embankment slopes?		✓		
DRAINAGE				
9. Are appropriate temporary runoff controls in place?	✓			
10. Are there any rills, gullies, or crevices that are 6" or deeper?		✓		
11. Are drainage channels in acceptable condition?	✓			
12. Are there any low areas or depressions that could facilitate the ponding of water for extended periods of time?		✓		
GEO-MEMBRANE				
13. Is there any exposed flexible membrane?		✓		
14. If so is the flexible membrane damaged?			✓	
PUMP STATION				
15. Are the pump station inlets free of debris?	✓			
16. Are there any structural deficiencies at the pump station?		✓		

N/A = Not Applicable

Springfield, Illinois 62794-9276

Re: Ameren Missouri – Venice Energy Center
Venice Power Station Ash Pond 2 and 3 Post Closure Care Project
Structure 161 Replacement

Dear Mr. Buscher,

Ameren Missouri (Ameren) plans to remove and replace the Cahokia-Roxford Transmission Line Structure 161, which is currently located within the capped Venice Ash Basin. The existing steel lattice tower will be replaced with a steel monopole in order to increase ground clearance as part of Ameren's response plan to the North American Electric Reliability Corporation's (NERC) Alert FAC-008 to meet the National Electrical Safety Code (NESC) requirements and to meet anticipated tie-in requirements for the proposed new Gateway Substation. In November 2019, Ameren plans to drill and pour the new concrete foundation and the actual steel monopole will be installed in spring 2020. The existing steel lattice tower is a four legged steel H-pile foundation and will be cut off just above the final cover and pipe boot, leaving the final cover untouched. See Figures 1 and 2 below.

The replacement of Structure 161 within the capped Venice Ash Basin will damage the final cover. Attached are drawings showing the monopole foundation and penetration details. Replacement of the structure will require piercing the geomembrane and sealing the cap against the foundation using a pipe boot design. Photographs of the repair will be documented as described below.

According to Section 2.1, Final Cover Maintenance in the Post Closure Care Plan prepared by Aquaterra in November 2012, Ameren plans to repair any tears, rips, punctures or other damage to the flexible membrane. Any incidental damage to the cover system from heavy equipment used in construction will also be repaired.

Figure 1: Existing steel lattice Structure 161. Ameren plans to replace this structure with a steel monopole.

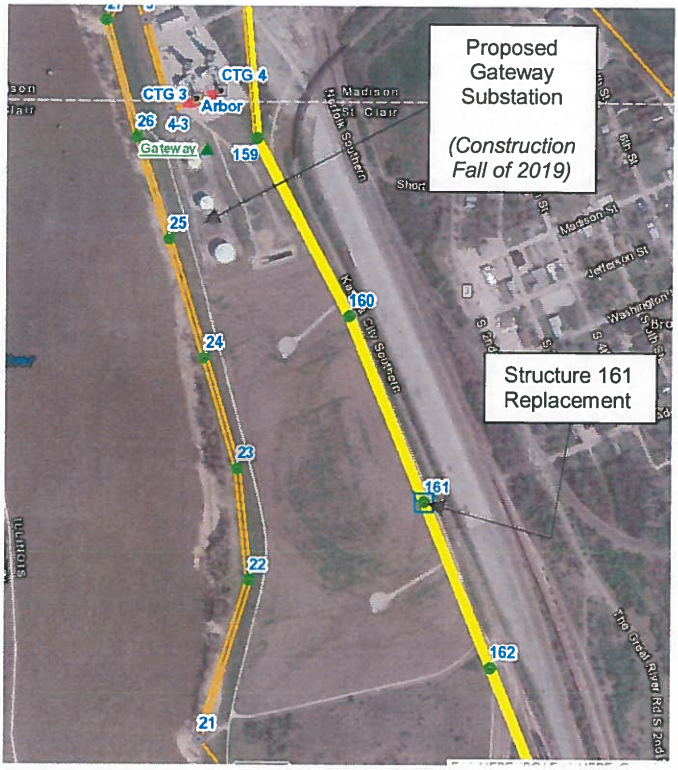

Figure 2: Location of Structure 161 within the sealed Venice Ash Basin. The structure replacement is anticipated to damage the final cover at this location. Any damage to the final cover will be repaired per the Post Closure Care Plan.

Any areas needing repair will be documented on the quarterly inspection forms. Also, any repairs to the final cover will be documented in the annual report, and the report will include the type of repair, surface area repaired, repair methods and materials, and photographic documentation of the repaired area(s).

I recently discussed these plans with Mr. Lynn Dunaway of your staff. Please contact me at 314.554.3143 if there are any questions or concerns regarding the structure replacement.

Sincerely,

Julianne Epplin

NOTES:
1. ALL WORK TO BE DONE IN ACCORDANCE WITH LATEST REVISION OF AMEREN SPECIFICATION TX-1160.
2. CONCRETE TO REACH A MINIMUM COMPRESSIVE STRENGTH OF f'_c = 4500 PSI @ 28 DAYS.
3. YIELD STRENGTH OF REINFORCING TO BE fy=60,000 psi (fy=60,000 psi FOR TIES).
4. REINFORCING STEEL IS EQUALLY SPACED UNLESS OTHERWISE NOTED.
5. ALL TIE LAPS (3B BAR DIAMETER MINIMUM) SHALL BE 180 DEGREES APART ALONG THE LENGTH OF THE PIERS.
6. AS A MINIMUM, ALL TIES SHALL BE TIED OFF TO ALTERNATING REINFORCING BARS.
7. PROVIDE A ¾" CHAMFER ON ALL EXPOSED EDGES.
8. REINFORCING CAGES SHALL BE PROVIDED A MINIMUM OF 1'-6" LONGER THAN THEORETICALLY REQUIRED, UNLESS OTHERWISE NOTED. EXTRA LENGTH OF THE CAGE SHALL BE SUPPLIED WITH TIES AT THE "T1" TIE SPACING. THESE EXTRA TIES ARE INCLUDED IN THE FOUNDATION SUMMARY TABLE.
9. IF ROCK IS ENCOUNTERED AT A DIFFERENT ELEVATION THAN NOTED (± 1'), DRILLING SHALL STOP AND A STRUCTURAL ENGINEER FROM AMEREN SHALL BE CONTACTED FOR FURTHER GUIDANCE.
10. MECHANICAL SPLICES TO BE LOCATED 2' OR GREATER BELOW ANCHOR BOLT CAGE.
11. CORRUGATED METAL PIPE MAY BE USED AS PERMANENT CASING FOR THE UPPER SECTION PIER. A FLOWABLE MATERIAL SHALL BE PLACED BETWEEN THE SOIL AND THE CORRUGATED METAL PIPE. HOWEVER, CORRUGATED METAL PIPE SHALL BE CUT OFF AT GROUND LEVEL AND REMOVABLE CIRCULAR SMOOTH STEEL FORMS SHALL BE USED TO FORM THE PIER PROJECTION. THE USE OF PERMANENT CASING SHALL BE LIMITED TO 10' BELOW GRADE.
12. IF PROJECTION FORM IS LARGER THAN DESIGN PIER DIAMETER BY MORE THAN 1'-0", CONTACT AMEREN ENGINEER FOR INSTRUCTIONS ON EXTRA REINFORCEMENT REQUIREMENTS.
13. ALL CONCRETE POURS SHALL BE MONOLITHIC. USE THE CONSTRUCTION KEY DETAIL ONLY WHEN A COLD JOINT IS UNAVOIDABLE DUE TO AN EMERGENCY.

STATISTICAL ANALYSIS

Stand-Alone Statistical Tests

Statistical Evaluation Report

The Statistical Evaluation Report is comprised of a series of subreports as described below.

User Selections:

- One location.
- Sample date range for data selection.
- Interval length: the length of the averaging period in months (1,2,3,4, or 6).
- One parameter.
- Non-detect processing: multiplier between 0 and 1.
- One-sided confidence $(1-\alpha)$ level – 0.90, 0.95 or 0.99.
- Limit type: used in the statistical overview to determine exceedances.

Mann-Kendall Trend and Seasonal Analysis Tests

The Mann-Kendall test for trend is insensitive to the presence or absence of seasonality. The test is non-parametric and does not assume any type of data distribution. Nonetheless, two forms of the test are provided in MANAGES, one ignoring data seasonality even if it is present, and one considering data seasonality. In the test, the null hypothesis, H_0, is that the Sen trend is zero, and the alternate hypothesis, H_a, is that the trend is non-zero.

In general, the Mann-Kendall test considering seasonality indicates a larger range for allowable Sen estimate of trend when seasonality is actually present than the range indicated by the test performed ignoring seasonality.

In the Mann-Kendall Trend Analysis, available in under the Statistical Evaluation Report and in the Statistical Procedure for Detection Monitoring, and Mann-Kendall Seasonal Analysis, found under the Statistical Evaluation Report, MANAGES first calculates the Sen slope and the upper and lower confidence limits of the Sen slope, and then determines whether the Sen slope is statistically significant. Slope is statistically significant if it is non-zero.

Mann-Kendall Test for Sen Slope Significance – a two-sided, non-parametric method for data sets as small as 10, unless there are many tied (e.g., equal, NDs are treated as tieds) values (Gilbert, 1987; p. 208)	
Indicator Function $\mathrm{sgn}(x_{ij} - x_{jk})$	= 1 if $(x_{ij} - x_{jk}) > 0$ = 0 if $(x_{ij} - x_{jk}) = 0$ = -1 if $(x_{ij} - x_{jk}) < 0$ where $x_{i1}, x_{i2}, \ldots, x_{in}$ are the time ordered data (n_i is total of data in the i-th season).
Mann-Kendall Statistic, S_i	$= \sum_{k=1}^{n_i-1} \sum_{j=k+1}^{n_i} \mathrm{sgn}(x_{ij} - x_{jk})$
Variance of S_i $VAR(S_i)$	$VAR(S_i) =$ $\frac{1}{18}\left\{ n_i(n_i-1)(2n_i+5) - \sum_{p=1}^{g_i} t_{ip}(t_{ip}-1)(2t_{ip}+5) - \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)(2u_{iq}+5) \right\}$ $+ \frac{\sum_{p=1}^{g_i} t_{ip}(t_{ip}-1)(t_{ip}-2) \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)(u_{iq}-2)}{9n_i(n_i-1)(n_i-2)}$ $+ \frac{\sum_{p=1}^{g_i} t_{ip}(t_{ip}-1) \sum_{q=1}^{h_i} u_{iq}(u_{iq}-1)}{2n_i(n_i-1)}.$ The variable g_i is the number of tied groups (equal-valued) data in the i-th season, t_{ip} is the number of tied data in the p-th group for the i-th season, h_i is the number of sampling times (or time periods) in the i-th season that contain multiple data, u_{iq} is the number of multiple data in the q-th time period in the i-th season, and n_i is the number of data values in the i-th season.

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Test Statistic, Z	If $S' = \sum_{i=1}^{K} S_i$, where K is the number of seasons, then the test statistic Z is computed as: $$Z = \begin{cases} \dfrac{S'-1}{[VAR(S')]^{1/2}} & \text{iff } S' > 0 \\ 0 & \text{iff } S' = 0 \\ \dfrac{S'+1}{[VAR(S')]^{1/2}} & \text{iff } S' < 0 \end{cases}$$ Where "iff" is an acroym meaning: if-and-only-if. A positive Z value means an upward trend and a negative Z value means a negative trend.
Hypothesis Test: H_0 = no trend H_a = trend present This is a two-sided test at the α significance level.	Accept the null hypothesis H_0 of no trend if $\lvert Z \rvert \leq Z_{1-\alpha/2}$ Reject the null hypothesis H_0 if $\lvert Z \rvert > Z_{1-\alpha/2}$ where $Z_{1-\alpha/2}$ is obtained from Table A1 in Gilbert (1987; p. 254).

Kruskal-Wallis Analysis (Test for Seasonality)

To perform the Kruskal-Wallis test for data seasonality, data points are first segmented according to season (Gilbert, 1987). The null hypothesis, H_0, is that all seasons have the same mean value. The alternative hypothesis, H_a ,is that at least one season has a mean larger or smaller than the mean of at least one other season. Montgomery et al. (1987) provide additional information on groundwater data seasonality. This is a two-sided, non-parametric test.

In MANAGES, the Kruskal-Wallis Test for Seasonality is found under Data Review // Non-Parametric Methods // Kruskal-Wallis Analysis. It determines whether the seasonal means for the specified parameter at the specified location are statistically the same.

EPRI Proprietary Licensed Material

	or $Z_i \geq SCL$.

Outlier Tests

Outlier tests are useful in detecting inconsistencies of measurement within a data set. An outlier is defined as an observation that appears to deviate markedly from other values of a sample set. There are many possible reasons for the presence of an outlier, including 1) the presence of a true but extreme value from a single population, resulting from random variability inherent in the data; 2) an improper identification of the underlying distribution describing the population from which the sample set comes from; 3) the occurrence of some unknown event(s) such as a spill, creating a mixture of two or more populations; 4) a gross deviation from prescribed sampling procedures or laboratory analysis; 5) a transcription error in the data value or data unit of measurement.

USEPA (1989; p. 8-11) states that the purpose of a test for outliers is to determine whether or not there is statistical evidence that an observation that appears extreme does not fit the distribution of the rest of the data. If an observation is identified as an outlier, then steps need to be taken to determine whether it is the result of an error or a valid extreme observation. If a true error, such as in transcription, dilution, or analytical procedure, can be identified, then the suspect value should be replaced with its corrected value. If the source of the error can be determined but no correction is possible, then the observation is deleted and the reason for deletion is reported along with any statistical analysis. If no source of error can be documented, then it must be assumed that the observation is a true but extreme value of the data set. If this is the case, the outlier observation(s) must not be altered or excluded from any statistical analysis. Identification of an observation as an outlier but with no error documented could be used to suggest resampling to confirm the value (USEPA, 1989; p. 8-13).

The outlier tests provided in MANAGES are based on either the single outlier test of Grubbs (1969), which is used by USEPA (1989; pp. 8-10 to 8-13) or the single outlier test of Dixon (1951, 1953), which is used by USEPA (2000; pp. 4-24) and by ASTM (1998). The outlier tests assume the data come from a normal distribution. Only one outlier, either an extreme low or an extreme high, can be detected during a single analysis of a data set. Additional outliers can be detected by temporarily removing a previously detected outlier from a data set and then repeating the test on the remaining, reduced, data set. During each pass of the outlier test, the sample mean, standard deviation, and sample size used in the test statistics are computed using only the data remaining in the set. The process can be continued until there is either an insufficient amount of data remaining (a minimum of 3 values) or when no additional outliers are found. When using MANAGES, the user will be asked how many outliers are to be checked and it will then automatically perform all of the recursive calls and data reductions with the Grubbs or Dixon routine. When done, a report can be generated that will show each outlier marked with a flag indicating the sequential order in which the outliers were identified.

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Critical values used in the one-sided Grubbs test are taken directly from those in Grubbs and Beck (1972) for sample sizes smaller than 147 observations. Critical values for sample sizes larger than 147 were generated numerically using a Monte Carlo routine, where each sampling event was simulated 100,000 times. Sample sizes ranging from 148 to 5,000 where used and then their resultant test statistic T_n curve fitted at specific significance levels. By this method, it was possible to match Grubbs results to at least four significant digits for corresponding tabulated values.

Critical values used in the one-sided Dixon outlier test are taken directly from tables given in Dixon (1951), Dixon (1953; page 89), and USEPA (2000; p. A-5, Table A-3). The critical values were then curve fitted for every sample size between 3 and 25 as a function of the significance level. By this method, it was possible to match Dixon's results to at least four significant digits for corresponding tabulated values. Note that the Dixon test assumes the data are either normally or lognormally distributed. Hence, sample sizes can only range between 3 and 25, inclusive. Dixon never developed an outlier test for sample sizes larger than 25.

User Selections:

- One or up to 100 locations: a separate test is performed for each location.
- One or up to 100 parameters: a separate test is performed for each parameter.
- Evaluation date range.
- Confidence $(1-\alpha)$ level: 0.90, 0.95 or 0.99.
- Non-detect processing: multiplier between 0 and 1.
- Data transformation option: none and log (base e).
- Number of outliers: one, two, first 5%, first 10%. Selecting any option other than one causes MANAGES to rerun the test, with outliers from prior tests removed, until either no outliers are detected or the specified number of outliers are detected.

Technical Details

Grubbs Outlier Test – The Grubbs outlier test determines whether there is statistical evidence that an observation does not fit the remaining data (USEPA, 1989; p. 8-11). This significance test looks at either the highest or the lowest observation in normal samples.	
The number of observations taken during a specified scoping period; n	*n*

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Mean of the observed data during the scoping period; $\overline{X}$	$\overline{X} = \frac{1}{n}\sum_{i=1}^{n} X_i$ where X_i is the i-th observation.
Standard deviation of observed data; S_x.	$S_x = \sqrt{\frac{1}{(n-1)}\sum_{i=1}^{n}(X_i - \overline{X})^2}$
Test statistics: T_l & T_n	Sort the data into ascending order, then compute the statistics $T_l = (\overline{X} - X_l)/S_x$ $T_n = (X_n - \overline{X})/S_x$ where X_l is the smallest value of the n observations and X_n is the largest value of the n observations.
One-sided test with a (1-α) confidence level that there is a single extreme outlier within the n observations.	Grubbs single, one-sided test of either an extreme low outlier : X_l *is an outlier if* $T_l \geq T_{cr(1-\alpha,n)}$ or an extreme high outlier: X_n *is an outlier if* $T_n \geq T_{cr(1-\alpha,n)}$. The function $T_{cr(1-\alpha,n)}$ is the critical value, given in Grubbs and Beck (1972; Table 1) and USEPA (1989; p. B-11, Table 8) . Note that the critical value assumes that the mean and standard deviation are computed from the sample being tested.

Dixon Outlier Test – The Dixon outlier test determines whether there is statistical evidence that an extreme observation does not fit the remaining data (USEPA, 2000; p. 4-24 and ASTM D6312, 1998). This significance test looks at both the highest and the

lowest observations in a sample data set. However, the routine will only perform the outlier tests if several conditions are first satisfied. For example, the Dixon outlier algorithm checks the distribution of the sample data for both normality and lognormality using the Shapiro-Wilk W-test. The outlier routine will not proceed with a data set if the W-test fails. In addition, the Dixon outlier test is limited to a minimum of 3 and a maximum sample size n of 25 data values.	
The number of observations taken during a specified scoping period; n	Number of observations, n, where $3 \le n \le 25$.
Sorting the sample data	Sort the data into ascending order, with the minimum data value $X_{(1)}$ first and the maximum data value $X_{(n)}$ last. Use the natural log of the data values if data are lognormally distributed, i.e., $X_{(j)} = Ln[X_{(j)}]$.
Goodness-of fit tests	After temporarily excluding either the minimum or maximum value of the data set, the Shapiro-Wilk's W-test is used to determine if the remaining $n-1$ values are normally or lognormally distributed. If not, the Dixon outlier test can't be used.
Test statistic, T_s, for the minimum data value	Compute the T_s test statistic for $X_{(1)}$ as an outlier: $T_s = \frac{X_{(2)} - X_{(1)}}{X_{(n)} - X_{(1)}}$ *for* $3 \le n \le 7$ $T_s = \frac{X_{(2)} - X_{(1)}}{X_{(n-1)} - X_{(1)}}$ *for* $8 \le n \le 10$ $T_s = \frac{X_{(3)} - X_{(1)}}{X_{(n-1)} - X_{(1)}}$ *for* $11 \le n \le 13$ $T_s = \frac{X_{(3)} - X_{(1)}}{X_{(n-2)} - X_{(1)}}$ *for* $14 \le n \le 25.$
Test statistic, T_s, for the maximum data value	Compute the T_s test statistic for $X_{(n)}$ as an outlier:

	$T_s = \frac{X_{(n)} - X_{(n-1)}}{X_{(n)} - X_{(1)}}$ *for* $3 \le n \le 7$ $T_s = \frac{X_{(n)} - X_{(n-1)}}{X_{(n)} - X_{(2)}}$ *for* $8 \le n \le 10$ $T_s = \frac{X_{(n)} - X_{(n-2)}}{X_{(n)} - X_{(2)}}$ *for* $11 \le n \le 13$ $T_s = \frac{X_{(n)} - X_{(n-2)}}{X_{(n)} - X_{(3)}}$ *for* $14 \le n \le 25$.
Critical value T_c	USEPA (2000; p. A-5, Table A-3) lists the critical values of the Dixon test as a function of sample size for a one-sided extreme value test at the significance levels α of 0.1, 0.05, and 0.01.
One-sided test with a (1-α) confidence level that there is a single extreme outlier within the n observations.	Dixon's single, one-sided test for statistical evidence of either an extreme low-valued outlier: $X_{(1)}$ *is an outlier if* $T_s \ge T_c$ or an extreme high-valued outlier: $X_{(n)}$ *is an outlier if* $T_s \ge T_c$. The function T_c is the critical value, given in Dixon (1953; page 89) and USEPA (2000; p. A-5, Table A-3). Note that the critical value assumes that the data are either normally or lognormally distributed.

Other Statistical Calculations Used in MANAGES

Sen Estimate of Slope

The Sen estimate of slope is the median of all slopes between all possible unique pairs of individual data points in the time period being analyzed (Gilbert, 1987). The slopes represent the rate of change of the measured parameter, with the y-axis being the parameter value and the x-axis being calendar days. Sen's estimate of slope is a non-parametric estimator of trend. The method is robust, and fairly insensitive to the presence of a small fraction of outliers and non-detect data values. In contrast, linear regression and other least squares estimators of slope are significantly more sensitive, and more likely to give erroneous slope indications, even when only a few outlier values are present.

When data averaging is not activated, the Sen slope is calculated using individual data points and actual sampling dates. When data averaging is activated, multiple data points within each specified season period are reduced to one data point by arithmetic averaging over each of the season periods. These averaged values are then assigned to the day that corresponds to the middle of that season's period.

The approximate lower and upper confidence limits for the Sen slope can also be calculated using normal theory (Gilbert, 1987). It should be noted that confidence limits for the Sen slope are not necessarily symmetrical about the estimated slope since ranked values of slope are used in the calculation.

MANAGES calculates Sen slope in the Sen Slope Overlay Graph, Statistical Summary reports and in the two Mann-Kendall tests performed under the Statistical Evaluation Report.

Sen's Estimate of Slope – two-sided, non-parametric method that calculates the trend of a single data series. It is less sensitive to outliers and non-detect values than linear regression (Gilbert, 1987; p. 217).	
Slope, Q	$= \frac{x_{i'} - x_i}{i' - i}$ where $X_{i'}$ and x_i are data values at times i' and i, respectively, and where $i'>i$. Typically, i' and i are expressed in units of either days for trend analysis or years for seasonal analysis.
N′	Number of unique data point pairs that can be made for the observations in the data set, for $i'>i$. For n monitoring events, N′ is given as: N′ = n(n-1)/2

Electronic Filing: Received, Clerk's Office 09/28/2020
EPRI Proprietary Licensed Material

Sen's Slope Estimate	Sen's slope estimator = median slope $= Q_{[(N'+1)/2]}$ if N' is odd $= \frac{1}{2}(Q_{[N'/2]} + Q_{[(N'+2)/2]})$ if N' is even where the Q values have first been ranked from smallest to largest.
$Z_{1-\alpha/2}$	Statistic for the cumulative normal distribution (Gilbert, 1987; p. 254) for the two-sided, α significance level.
Variance estimate of the Mann-Kendall S Statistic, VAR(S)	VAR(S) $= \frac{1}{18}\left[n(n-1)(2n+5) - \sum_{p=1}^{g} t_p(t_p-1)(2t_p+5)\right]$ where g is the number of tied groups, t_p is the number of data in the pth group, and n is the number of data values.
C_α	$= Z_{1-\alpha/2}\sqrt{VAR(S)}$
Sen's Slope , a two-sided test at the α significance level	$M_1 = \frac{(N'-C_\alpha)}{2}$ $M_2 = \frac{(N'+C_\alpha)}{2}$ Lower limit of confidence interval is the M_1-th largest slope, and upper limit of confidence interval is the (M_2+1)-th largest of the N′ ordered slope estimates.

Coefficient of Skewness for Normality

The coefficient of skewness is another measure for data normality (Gilbert, 1987). MANAGES provides the value of the coefficient of skewness in the Statistical Evalueation Report, Statistical Overview. Additional information on data normality is given by Montgomery, et al. (1987).

GEOTECHNOLOGY INC
FROM THE GROUND UP

September 20, 2017

Mr. Paul Mauer
Illinois Department of Natural Resources
Office of Water Resources
One Natural Resources Way, 2nd Floor
Springfield, Illinois 62702-1271

Re: Permit Status Change Request
Fly Ash Pond and Closed Ash Pond
Meredosia Power Station
Meredosia, Illinois
Geotechnology, Inc. Project No. J024917.03

Dear Mr. Mauer:

Geotechnology, Inc. (Geotechnology), on behalf of Ameren Missouri, is requesting a permit change status at the referenced site to de-classify the embankments at the Fly Ash Pond and Closed Ash Pond as abandoned dams. A liquefaction analysis performed by Geotechnology is included as an attachment and summarized herein with additional information as discussed in our April 21, 2017 phone call.

The energy center site consists of the decommissioned Meredosia Power Station in Meredosia, Illinois. The Closed Ash Pond does not have an engineered bottom liner and has a soil cap of unknown thickness. The Fly Ash Pond does not have an engineered bottom liner and is scheduled be graded and capped in 2017-2018 construction seasons. The designed cap utilizes ClosureTurf, which is a geosynthetic system that meets the Subtitle D technical requirements and has been tentatively approved by the IEPA for installation.

The embankments at the capped Fly Ash Pond and Closed Ash Pond are currently not Illinois Department of Natural Resources – Office of Water Resources (IDNR) permitted dams. Upon modification of the dams, they would fall under the jurisdiction of IDNR. Based on conversations with IDNR, the following guidelines[1] summarize required documentation for consideration to abandoned a dams:

[1] GUIDELINES FOR PREPARATION OF APPLICATIONS FOR PERMITS FROM: *Illinois Department of Natural Resources, Office of Water Resources, Illinois Department of Natural Resources, Office of Mines and Minerals;* AND FOR REVIEW AND APPROVAL FROM: *United States Department of Labor, Mine Safety and Health Administration, Illinois Environmental Protection Agency;* FOR THE DESIGN, CONSTRUCTION MAINTENANCE AND INSPECTION OF DAMS AND IMPOUNDMENTS AT UNDERGROUND AND SURFACE COAL MINES IN ILLINOIS; *July 2004*

1. Classify the existing condition of the impounded material with respect to its fluid nature;

2. Analyze the liquefaction potential of the impounded material and the related stability of the containing dam;

3. Design the final surface configuration for the impoundment to preclude the potential for re-saturation of the impounded material, especially from any surface water impounding characteristics and the erosion potential of the surface material; and

4. Establish a follow-up inspection schedule to ensure the proposed plans have been effective and include record drawings of any closure modifications.

Each of these IDNR requested items are addressed below:

1. Geotechnology performed liquefaction analysis of the impounded material within Fly Ash Pond and Closed Ash Pond. The complete report is attached for your reference.

   In summary, six – approximately 25 feet deep cone penetration test (CPT) soundings were performed in the Closed Ash Pond and eight- approximately 25 feet CPT soundings were performed in the Fly Ash Pond. Direct push samples from the impounded ash were collected to a depth of approximately 24 feet in the Closed Ash Pond and approximately 24 feet in the Fly Ash Pond.

   The CPT data indicates interbedded layers of material that respond to CPT advancement similar to clay, silty clay, silty sand, and sand in the Fly Ash Pond and interbedded layers of sand and silty sand in the Closed Ash Pond. The interbedded nature of the CPT data interpretation is to be expected in an uncontrolled waste product such as fly ash. The laboratory testing indicates the sampled material in the Fly Ash Pond was fine grained in nature having approximately 98 and 99 percent passing the #200 sieve. The sampled material in the Closed Ash Pond indicates the material is coarser in nature with approximately 4 percent passing the #200 sieve.

   Geotechnology analyzed the CPT data for liquefaction potential and dynamic (post liquefaction) settlement utilizing a design PGA of 0.08g and an earthquake magnitude of 7.5. The analysis incorporated the results of the laboratory tests to refine the fines content within the soundings.

   Based on the liquefaction results there were not potentially liquefiable layers identified within the impounded ash.

2. See response for item 1 for the analysis of the liquefaction potential of the impounded material.

   The stability of the embankments for the Fly Ash Pond was analyzed by Geotechnology prior to the design of the ash pond capping project and approved by the IEPA in 2017 as a stable configuration that does not allow ponding of storm water. The Closed Ash Pond was reported closed with a soil cap in the 1970s.

© 2017 Geotechnology, Inc.

3. The final surface configuration for the impoundments were designed to prevent re-saturation of the impounded material by using a cap system. The Closed Ash Pond uses a soil cap that is graded to drain to a storm water collection system. The Fly Ash Pond cap system is a ClosureTurf cap which includes a HDPE geomembrane (supergripnet), geotextile, turf, sand infill, and a storm water collection system. This cap system is scheduled to be constructed in 2018. Surface grades were designed to prevent ponding of storm water and reduce erosion potential of the surface material. The Fly Ash Pond design was submitted and approved by the IEPA in 2017.

4. As part of the ash pond closure process, a post-closure plan was prepared that includes an inspection schedule of the ash pond caps and the storm water collection systems. The post-closure plan was submitted and approved by the IEPA in 2017.

Based on this additional information, Geotechnology requests, on behalf of Ameren Missouri, that the embankments at Fly Ash Pond and Closed Ash Pond be de-classified and removed from regulatory jurisdiction.

SECTION I – PROJECT INFORMATION

AUTHORIZATION

Our services were authorized by the issuance of Ameren Energy PO 793018, dated June 6, 2017 to Geotechnology, Inc.

PURPOSE AND SCOPE OF SERVICES

The purpose of our services was to evaluate the liquefaction potential of the impounded material in the Fly Ash Pond and the Closed Ash Pond at the Meredosia Site. Briefly, services consisted of site reconnaissance, performing fourteen Cone Penetrometer Test (CPT) soundings, two direct push borings, engineering analyses, and preparation of this report. Important information prepared by The Geoprofessional Business Association (GBA) for studies of this type is presented in Appendix A for your review.

PROJECT AND SITE DESCRIPTION

The project site is at the decommissioned Meredosia Power Station in Meredosia, Illinois. Ameren is proposing to declassify the Fly Ash Pond and the Closed Ash Pond in accordance with guidelines issued by the Illinois Department of Natural Resources – Office of Water Resources (IDNR-OWR). We understand that the Closed Ash Pond does not have a bottom liner and has a soil cap of unknown thickness. The Fly Ash Pond does not have a bottom liner and is scheduled be graded and capped in 2018 construction seasons. The designed cap utilizes ClosureTurf, which is a geosynthetic system that meets the Subtitle D technical requirements and has been approved by the IEPA for installation.

SECTION II - FIELD EXPLORATION AND LABORATORY TESTING

Geotechnology performed fourteen seismic CPT soundings, designated as C-01 through C-08 (Fly Ash Pond) and O-01 through O-06 (Closed Ash Pond). The CPT sounding locations were selected and located in the field by a representative from Geotechnology. The CPT soundings were advanced by Geotechnology, using a 20-ton, track-mounted Vertek direct-push rig. The soundings were advanced to termination depths of approximately 25 feet below land surface (bls) in both the Fly Ash Pond and the Closed Ash Pond. Direct push samples from the impounded ash were collected to a depth of approximately 24 feet in each pond.

Geotechnology performed CPT testing in general accordance with ASTM D5778. The data were collected using a 15-square-centimeter end area, tri-axial geophone, seismic

piezometric cone with a saturated, porous filter ring at the u_2 pore pressure location (i.e., behind the tip). The cone was advanced to the predetermined termination depth or cone refusal at a rate of approximately 20 +/- 5 millimeters per second. The cone resistance, sleeve friction, pore pressure, shear strength, normalized soil behavior type (SBTn), and standard penetration test (SPT) N60 values are presented in Appendix B. Seismic cone penetration tests (SCPT) were performed in each sounding at approximately 3-foot depth intervals to collect shear wave velocity data. Shear wave velocity measurements versus depth at these locations are presented in Appendix C. The fines content was determined on select direct push samples using the percent passing the #200 sieve test and the results are included in Appendix D.

An engineer from Geotechnology observed the CPT data collection process. Unless noted on the CPT logs, the lines designating the changes between various strata represent approximate boundaries. The stratification given on the CPT logs, or described herein, is for use by Geotechnology in its analyses and should not be used as the basis of design or construction cost estimates without Geotechnology's written approval.

The CPT soundings and related information depict subsurface conditions only at the specific locations and times where the soundings were conducted. The passage of time could result in changes in conditions, interpreted to exist, at the locations where CPT was conducted.

SECTION III – SUBSURFACE CONDITIONS

STRATIGRAPHY

We understand the stratigraphy within the ash ponds consists of fly ash to depths of approximately 25 feet in the Fly Ash Pond and approximately 25 feet in the Closed Ash Pond. The CPT data indicates interbedded layers of material that respond to CPT advancement similar to clay, silty clay, silty sand, and sand in the Fly Ash Pond and interbedded layers of sand and silty sand in the Closed Ash Pond. The interbedded nature of the CPT data interpretation is to be expected in an uncontrolled waste product such as fly ash. The laboratory testing indicates the sampled material in the Fly Ash Pond was fine grained in nature having approximately 98 and 99 percent passing the #200 sieve. The sampled material in the Closed Ash Pond indicates the material is coarser in nature with approximately 4 percent passing the #200 sieve.

GROUNDWATER

We understand that the groundwater within the ash ponds is typically perched in nature. Based on the CPT data, groundwater (i.e.,hydrostatic pressure) in the Fly Ash Pond appears to range from depths of approximately 15 to 17 feet below the ground surface. In the Closed Ash Pond, the groundwater (i.e., hydrostatic pressure) appears to range from depths of approximately 26 to 29 feet below the ground surface. Groundwater levels might vary over time due to the effects of seasonal variation in precipitation, recharge, stage of the Illinois River, or other factors not evident at the time of exploration.

SECTION IV – LIQUEFACTION ANALYSIS

Geotechnology analyzed the CPT data for liquefaction potential and dynamic (post-liquefaction) settlement using the CLiq software. CLiq utilizes the analysis method published by Idriss and Boulanger in 2008 and updated in 2014. Based on ASCE 7-10, a design PGA of 0.08g and an earthquake magnitude of 7.5 where used in this analysis. The analysis incorporated the results of the laboratory tests to refine the fines content within the soundings. Based on the liquefaction analysis, it does not appear that the ash ponds have potentially liquefiable layers, i.e. where the calculated factor of safety (F.O.S) is less than 1.0, under the analyzed seismic loading. Liquefaction analysis results for each CPT sounding to the depths pushed are presented in Appendix E.

Geotechnology, Inc. performed seismic and static stability analysis of the embankments and impounded ash. This stability analysis was submitted to the Illinois Department of Natural Resources (IDNR) and approved in 2017. The Closed Ash Pond was reported closed with a soil cap in the 1970s.

Liquefaction Potential Index (LPI[1]) indices are all less than 0, which indicates a **very low risk of liquefaction**. LPI attempts to predict the potential of liquefaction to cause damage to surface features and provide a measure of the severity of liquefaction and has a scale of 0 to 20. *For reference an LPI of 0 indicates a very low liquefaction risk and a LPI of less than 5 indicates a low risk of liquefaction*.

The fluidity of the impounded material was also considered. The elevated or perched groundwater conditions suggest that some level of saturation of the impounded material is possible, especially if the Illinois River is at flood stage. The fines content determined from laboratory testing indicates the impounded material will behave similarly to silts and clays. As such, when saturated, the impounded material would potentially be less fluid than a similarly placed sand material.

SECTION V – CONCLUSIONS

Based on the results of the liquefaction analysis and the seismic and static stability analysis performed by Geotechnology, Inc., it is Geotechnology's opinion that there is a very low risk of surface manifestation of liquefaction or damage to the Fly Ash Pond and Closed Ash Pond embankments during a seismic event.

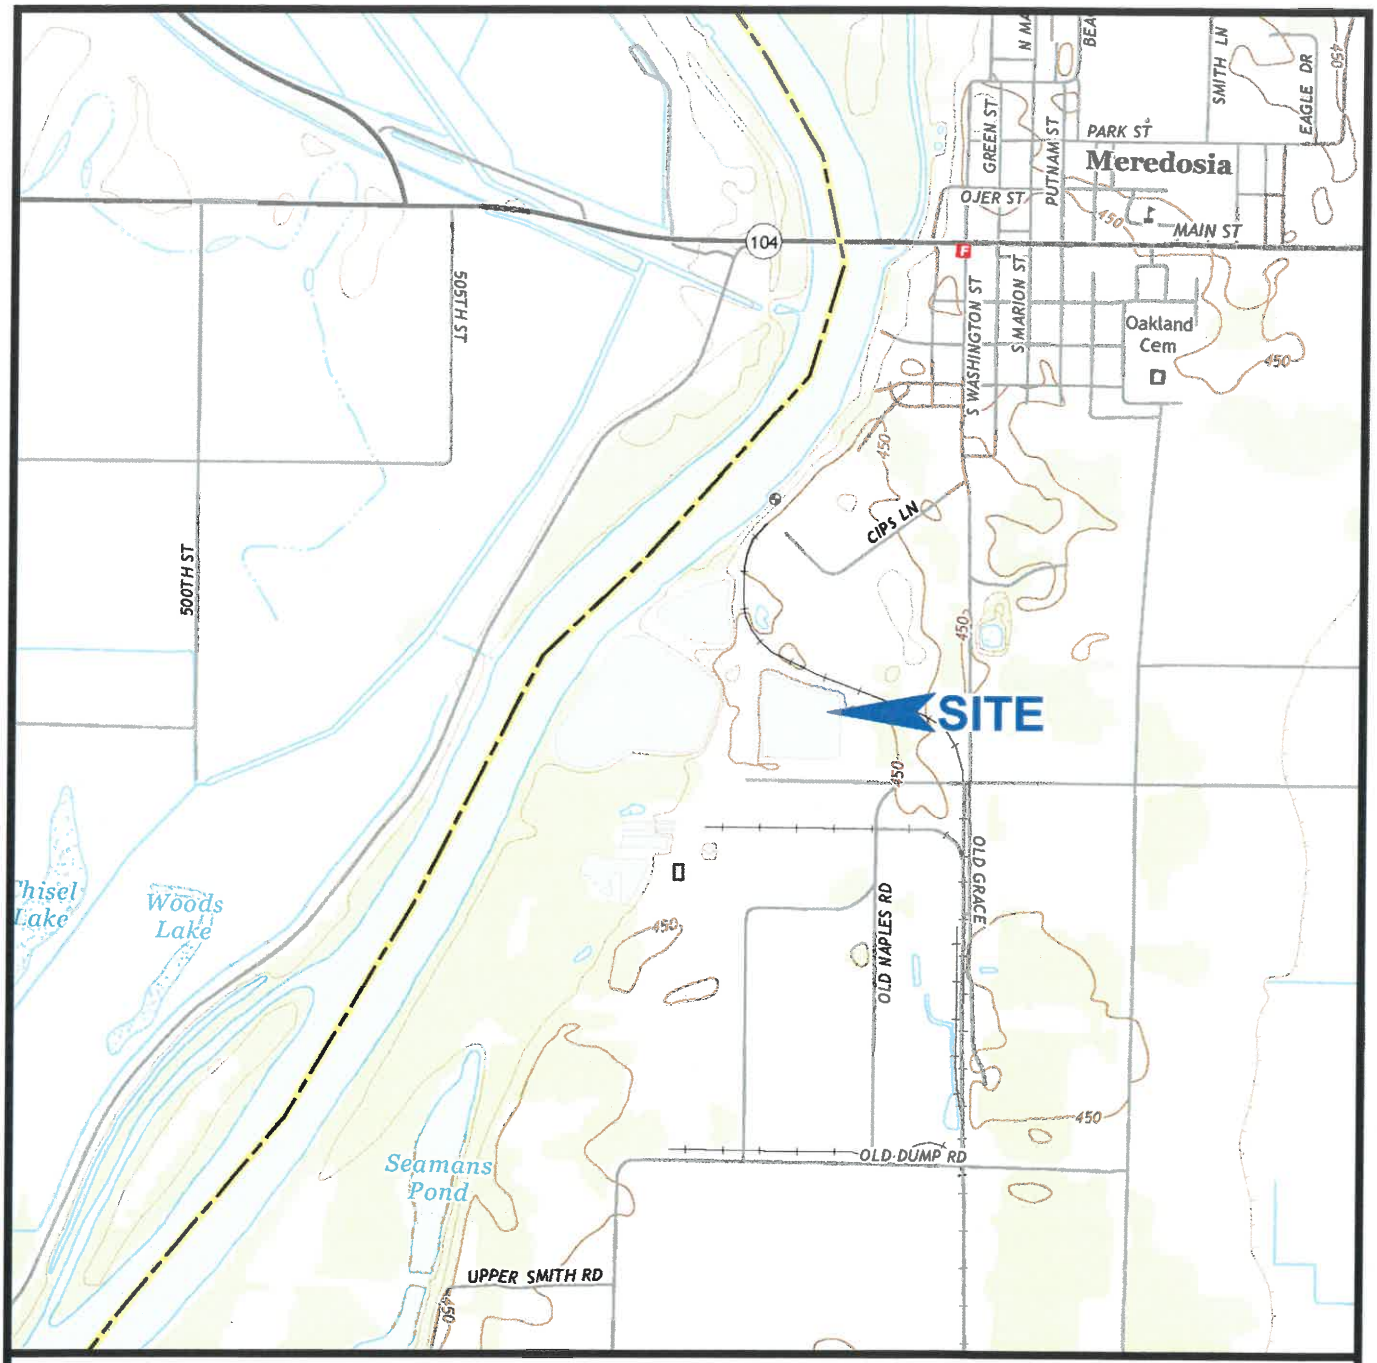
SECTION VI - LIMITATIONS OF REPORT

This report has been prepared on behalf of, and for the exclusive use of, the client for specific application to the named project as described herein. If this report is provided to other parties, it should be provided in its entirety with all supplementary information. In addition, the client should make it clear that the information is provided for factual data only, and not as a warranty of subsurface conditions presented in this report.

Geotechnology has attempted to conduct the services reported herein in a manner consistent with that level of care and skill ordinarily exercised by members of the profession currently practicing in the same locality and under similar conditions. The recommendations and conclusions contained in this report are professional opinions. The report is not a bidding document and should not be used for that purpose.



Our scope of service for this phase of the project did not include any environmental assessment or investigation for the presence or absence of wetlands or hazardous or toxic materials in the soil, surface water, groundwater, or air, on or below or around this site. Any statements in this report or on the boring logs regarding odors noted or unusual or suspicious items or conditions observed are strictly for the information of our client. Our scope of service did not include an assessment of the effects of flooding and erosion of creeks or rivers adjacent to or on the project site.

The analyses, conclusions, and recommendations contained in this report are based on the data obtained from the subsurface exploration. The field exploration methods used indicate subsurface conditions only at the specific locations where samples were obtained, only at the time they were obtained, and only to the depths penetrated. Consequently, subsurface conditions may vary gradually, abruptly, and/or nonlinearly between sample locations and/or intervals.

The conclusions or recommendations presented in this report should not be used without Geotechnology's review and assessment if the nature, design, or location of the facilities is changed, if there is a substantial lapse in time between the submittal of this report and the start of work at the site, or if there is a substantial interruption or delay during work at the site. If changes are contemplated or delays occur, Geotechnology must be allowed to review them to assess their impact on the findings, conclusions, and/or design recommendations given in this report. Geotechnology will not be responsible for any claims, damages, or liability associated with any other party's interpretations of the subsurface data or with reuse of the subsurface data or engineering analyses in this report.

The recommendations included in this report have been based in part on assumptions about variations in site stratigraphy that may be evaluated further during earthwork and foundation construction. Geotechnology should be retained to perform construction observation and continue its geotechnical engineering service using observational methods. Geotechnology cannot assume liability for the adequacy of its recommendations when they are used in the field without Geotechnology being retained to observe construction.

"Important Information about This Geotechnical-Engineering Report" published by the Geotechnical Business Council (GBC) of the Geoprofessional Business Association (GBA) is included as Appendix A. That document discusses some other limitations, as well as ways to manage risk associated with subsurface conditions.

APPENDIX A

IMPORTANT INFORMATION ABOUT YOUR GEOTECHNICAL-ENGINEERING REPORT

Electronic Filing: Received, Clerk's Office 09/28/2020

Important Information about This

Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

Geotechnical Services Are Performed for Specific Purposes, Persons, and Projects

Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical-engineering study conducted for a civil engineer may not fulfill the needs of a constructor — a construction contractor — or even another civil engineer. Because each geotechnical- engineering study is unique, each geotechnical-engineering report is unique, prepared *solely* for the client. No one except you should rely on this geotechnical-engineering report without first conferring with the geotechnical engineer who prepared it. *And no one — not even you* — should apply this report for any purpose or project except the one originally contemplated.

Read the Full Report

Serious problems have occurred because those relying on a geotechnical-engineering report did not read it all. Do not rely on an executive summary. Do not read selected elements only.

Geotechnical Engineers Base Each Report on a Unique Set of Project-Specific Factors

Geotechnical engineers consider many unique, project-specific factors when establishing the scope of a study. Typical factors include: the client's goals, objectives, and risk-management preferences; the general nature of the structure involved, its size, and configuration; the location of the structure on the site; and other planned or existing site improvements, such as access roads, parking lots, and underground utilities. Unless the geotechnical engineer who conducted the study specifically indicates otherwise, do not rely on a geotechnical-engineering report that was:

- not prepared for you;
- not prepared for your project;
- not prepared for the specific site explored; or
- completed before important project changes were made.

Typical changes that can erode the reliability of an existing geotechnical-engineering report include those that affect:

- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light-industrial plant to a refrigerated warehouse;
- the elevation, configuration, location, orientation, or weight of the proposed structure;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project changes—even minor ones—and request an assessment of their impact. *Geotechnical engineers cannot accept responsibility or liability for problems that occur because their reports do not consider developments of which they were not informed.*

Subsurface Conditions Can Change

A geotechnical-engineering report is based on conditions that existed at the time the geotechnical engineer performed the study. *Do not rely on a geotechnical-engineering report whose adequacy may have been affected by*: the passage of time; man-made events, such as construction on or adjacent to the site; or natural events, such as floods, droughts, earthquakes, or groundwater fluctuations. *Contact the geotechnical engineer before applying this report to determine if it is still reliable.* A minor amount of additional testing or analysis could prevent major problems.

Most Geotechnical Findings Are Professional Opinions

Site exploration identifies subsurface conditions only at those points where subsurface tests are conducted or samples are taken. Geotechnical engineers review field and laboratory data and then apply their professional judgment to render an opinion about subsurface conditions throughout the site. Actual subsurface conditions may differ — sometimes significantly — from those indicated in your report. Retaining the geotechnical engineer who developed your report to provide geotechnical-construction observation is the most effective method of managing the risks associated with unanticipated conditions.

A Report's Recommendations Are Not Final

Do not overrely on the confirmation-dependent recommendations included in your report. *Confirmation-dependent recommendations are not final,* because geotechnical engineers develop them principally from judgment and opinion. Geotechnical engineers can finalize their recommendations *only* by observing actual subsurface conditions revealed during construction. *The geotechnical engineer who developed your report cannot assume responsibility or liability for the report's confirmation-dependent recommendations if that engineer does not perform the geotechnical-construction observation required to confirm the recommendations' applicability.*

A Geotechnical-Engineering Report Is Subject to Misinterpretation

Other design-team members' misinterpretation of geotechnical-engineering reports has resulted in costly

Electronic Filing: Received, Clerk's Office 09/28/2020

problems. Confront that risk by having your geotechnical engineer confer with appropriate members of the design team after submitting the report. Also retain your geotechnical engineer to review pertinent elements of the design team's plans and specifications. Constructors can also misinterpret a geotechnical-engineering report. Confront that risk by having your geotechnical engineer participate in prebid and preconstruction conferences, and by providing geotechnical construction observation.

Do Not Redraw the Engineer's Logs

Geotechnical engineers prepare final boring and testing logs based upon their interpretation of field logs and laboratory data. To prevent errors or omissions, the logs included in a geotechnical-engineering report should *never* be redrawn for inclusion in architectural or other design drawings. Only photographic or electronic reproduction is acceptable, *but recognize that separating logs from the report can elevate risk.*

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can make constructors liable for unanticipated subsurface conditions by limiting what they provide for bid preparation. To help prevent costly problems, give constructors the complete geotechnical-engineering report, *but* preface it with a clearly written letter of transmittal. In that letter, advise constructors that the report was not prepared for purposes of bid development and that the report's accuracy is limited; encourage them to confer with the geotechnical engineer who prepared the report (a modest fee may be required) and/or to conduct additional study to obtain the specific types of information they need or prefer. A prebid conference can also be valuable. *Be sure constructors have sufficient time* to perform additional study. Only then might you be in a position to give constructors the best information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions.

Read Responsibility Provisions Closely

Some clients, design professionals, and constructors fail to recognize that geotechnical engineering is far less exact than other engineering disciplines. This lack of understanding has created unrealistic expectations that have led to disappointments, claims, and disputes. To help reduce the risk of such outcomes, geotechnical engineers commonly include a variety of explanatory provisions in their reports. Sometimes labeled "limitations," many of these provisions indicate where geotechnical engineers' responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Environmental Concerns Are Not Covered

The equipment, techniques, and personnel used to perform an *environmental* study differ significantly from those used to perform a *geotechnical* study. For that reason, a geotechnical-engineering report does not usually relate any environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated environmental problems have led to numerous project failures.* If you have not yet obtained your own environmental information, ask your geotechnical consultant for risk-management guidance. *Do not rely on an environmental report prepared for someone else.*

Obtain Professional Assistance To Deal with Mold

Diverse strategies can be applied during building design, construction, operation, and maintenance to prevent significant amounts of mold from growing on indoor surfaces. To be effective, all such strategies should be devised for the *express purpose* of mold prevention, integrated into a comprehensive plan, and executed with diligent oversight by a professional mold-prevention consultant. Because just a small amount of water or moisture can lead to the development of severe mold infestations, many mold- prevention strategies focus on keeping building surfaces dry. While groundwater, water infiltration, and similar issues may have been addressed as part of the geotechnical- engineering study whose findings are conveyed in this report, the geotechnical engineer in charge of this project is not a mold prevention consultant; *none of the services performed in connection with the geotechnical engineer's study were designed or conducted for the purpose of mold prevention. Proper implementation of the recommendations conveyed in this report will not of itself be sufficient to prevent mold from growing in or on the structure involved.*

Rely, on Your GBC-Member Geotechnical Engineer for Additional Assistance

Membership in the Geotechnical Business Council of the Geoprofessional Business Association exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project. Confer with you GBC-Member geotechnical engineer for more information.

SUBJECT: Meredosia Power Station Ash Pond Dams
Permit DS2017058 – IL50707, IL50708 and IL50709

Mr. Matthew Frerking
AmerenEnergy Medina Valley Cogen LLC
11149 Lindberg Business Ct.
St. Louis, MO 63123

Dear Mr. Frerking:

We are in receipt of your March 11, 2019 submittal of as-built drawings for the referenced permit. Our review indicates the work was completed in accordance with the permit. The construction portion of that permit is considered complete.

Subsequent to issuance of the permit you submitted a report by Geotechnology Inc. of the Geotechnical Exploration and Liquefaction Analysis for the Fly Ash Pond and the Closed Fly Ash Pond at the site. The fly ash pond was partially modified under the referenced permit. The conclusion of the report is that the material placed in each impoundment is no longer able to act as a fluid.

As a result of the physical modifications and considering the conclusion of the investigation the status of the impoundments is:

Bottom Ash Pond – IL50707 – A portion of the embankment has been removed. The structure is no longer capable of impoundment and does not meet the definition of a dam under the Part 3702 rules.

Fly Ash Pond – IL50708 – The investigation shows that the material within the structure is no longer capable of acting as a fluid. By definition, the structure is no longer intended to provide impoundment and is not considered to be a dam.

Old Ash Pond – IL50709 - The investigation shows that the material within the structure is no longer capable of acting as a fluid. By definition, the structure is no longer intended to provide impoundment and is not considered to be a dam.

MD 2019 COR LTR 0003

As of this date, there are no structures at the Meredosia Power Station which are jurisdictional under the Part 3702 rules. No further reporting will be required and access by Department staff for inspection of the structures is no longer required. Should the Fly Ash Pond or Old Ash Pond be modified such that they are again able to impound water or other fluid material, the Department will again exercise jurisdiction under the Part 3702 rules.

Any questions or concerns may be directed to gina.kramer@illinois.gov or (217) 785-1661.

Sincerely,

Gina S. Kramer

Gina S. Kramer, P.E.
Dam Safety Engineer
