(VIA ELECTRONIC MAIL)

(SEE PERSONS ON ATTACHED SERVICE LIST)

PLEASE TAKE NOTICE that I have today electronically filed with the Office of the Clerk of the Illinois Pollution Control Board **ENTRY OF APPEARANCE OF MICHAEL MURPHY, ENTRY OF APPEARANCE OF LADONNA DRIVER, ENTRY OF APPEARANCE OF MELISSA BROWN, and PETITION FOR REVIEW OF DENIAL OF PSD PERMIT WITH INTEGRATED PROCESSING**, copies of which are hereby served upon you.

Respectfully submitted,

UNITED STATES STEEL CORPORATION,

By:/s/ *Michael P. Murphy*
One of Its Attorneys

Dated: June 12, 2024

PETITION FOR REVIEW OF DENIAL OF PSD PERMIT WITH INTEGRATED PROCESSING

Petitioner, United States Steel Corporation ("U. S. Steel"), by its attorneys, pursuant to Sections 40.3(a)(1), 40.2(a), and 40(a) and (d) of the Illinois Environmental Protection Act ("Act") (415 ILCS 5/40(a), 40(d), 40.2(a) and 40.3(a)(1)), and 35 Ill. Admin. Code 105.600—105.614, 105.300 – 105.304, and 105.200 – 105.214, petitions the Illinois Pollution Control Board ("Board") for a hearing to contest the decision of the Illinois Environmental Protection Agency ("Illinois EPA" or "Agency") to deny U. S. Steel's application for revision of its construction permit/Prevention of Significant Deterioration (PSD) approval that contains a request for Integrated Processing. In support thereof, Petitioner states as follows:

1. On May 8, 2024, Illinois EPA issued its Denial of an Application for Revisions to a Construction Permit/PSD Approval. SR 0001 – 0091. Illinois EPA's grounds for denial of the Application place U. S. Steel in the impossible position to demonstrate somehow that no violations would have existed for a period of approximately 30 years – including about ten of those years in which U. S. Steel did not even own or operate the facility. U. S. Steel cannot attest to the National Steel operations and emissions; nor is it required to do so as U. S. Steel acquired certain assets of the National Steel Granite City facility on May 20, 2003, pursuant to an Order issued by the United

States Bankruptcy Court for the Northern District of Illinois, Eastern Division (Case Nos. 02-08697 – 02-08738). SR 1309 – 1394.

2. The Agency expects U. S. Steel to somehow show that not only every operating scenario would have complied with all regulations, but also none of the regulations over 30 years would have been violated. U. S. Steel is essentially tasked with the impossible burden to demonstrate compliance with all operating scenarios and all PSD provisions over the nearly 30 years – both of which have significantly evolved over the last three decades. This is not only impossible, but it also is not required; and requiring such a demonstration is contrary to the Clean Air Act and supporting law as explained below.

I. BACKGROUND

A. The Agency's Final Decision

3. On May 8, 2024, Illinois EPA issued its Denial of an Application for Revisions to a Construction Permit/PSD Approval. With this Petition, U. S. Steel has provided a Supporting Record (cited as "SR"), SR 0001 — 2501, along with a Table of Contents for the Supporting Record. The denial is included in the Supporting Record at pages SR 0001 – 0091. The Agency's Notification of Denial of Application is also included at SR 0092 – 0094. 35 Ill. Adm. Code 105.608(b)(1).

4. U. S. Steel submits this Petition pursuant to Section 40.3 of the Act, which provides that if the Agency refuses to grant a PSD permit, "the applicant may, within 35 days after final permit action, petition for a hearing before the Board to contest the decision of the Agency." 415 ILCS 5/40.3(a)(1). U. S. Steel also submits this Petition pursuant to Section 105.604(a) and Part 105 Subpart F of the Board's regulations as the Agency refused to grant the PSD permit. 35 Ill. Adm. Code 105.604(a); 35 Ill. Adm. Code Part 105, Subpart F.

5. Because the application for revision of the construction permit/PSD approval at issue in this Petition included a request for Integrated Processing of revisions to Petitioner's Clean Air Act Permit Program ("CAAPP") permit, this Petition is also submitted pursuant to Section 40.2 of the Act, which provides that if the Agency refuses to grant a CAAPP Permit, "the applicant . . . may, within 35 days after final permit action, petition for a hearing before the Board to contest the decision of the Agency." 415 ILCS 5/40.2(a). U. S. Steel also submits this Petition pursuant to Section 105.302 and Part 105 Subpart C of the Board's regulations. 35 Ill. Adm. Code 105.302; 35 Ill. Adm. Code Part 105, Subpart C.

6. Additionally, because the application for revision of the construction permit/PSD approval, and the Agency's denial, addressed general construction permit requirements, this Petition is also submitted pursuant to Sections 40(a) of the Act. Section 40(a)(1) of the Act provides for submitting a petition for hearing of the Agency's refusal to grant a permit under Section 39 of the Act. 415 ILCS 5/40(a)(1). Furthermore, while U.S. Steel did not apply for a permit under 35 Ill. Adm. Code Part 203, because Illinois EPA's denial of the Application addressed Nonattainment New Source Review issues, U.S. Steel is also filing this Petition pursuant to Sections 40(a) and (d) of the Act to be inclusive of all of the Agency's purported bases for denial. Section 40(d) of the Act provides, in reviewing the denial of Nonattainment New Source Review permit,[1] "the decision of the Board shall be based exclusively on the record before the Agency including the record of the hearing, if any, unless the parties agree to supplement the record." 415 ILCS 5/40(d). As such, U. S. Steel submits this Petition pursuant to Section 105.204 and Subpart B of Part 105 of the Board's regulations. 35 Ill. Adm. Code 105.204; 35 Ill. Adm. Code Part 105, Subpart B.

[1] As stated above, U. S. Steel did not apply for a Nonattainment New Source Review Permit. However, Illinois EPA's denial of the Application include bases for denial based on Nonattainment New Source Review issues.

B. Background on the Project and Permit

7. U. S. Steel owns and operates an integrated iron and steel manufacturing facility in Granite City, Madison County, Illinois (ID # 119813AAI) ("Granite City Works" or "Facility"). SR 0608. The prior owner of this facility was National Steel Corporation. SR 0608. U. S. Steel acquired certain assets of the National Steel Granite City facility on May 20, 2003 pursuant to an Order issued by the United States Bankruptcy Court for the Northern District of Illinois, Eastern Division (Case Nos. 02-08697 – 02-08738). SR 0608; SR 1309 – 1394.

8. The Facility is an integrated steel mill employing raw material handling, processing, and preparation; iron production; steel production; steel finishing; and boilers and other ancillary operations. SR 0609. In 1996, National Steel Corporation produced metallurgical coke in a by-product coke plant. SR 0609. Once U. S. Steel acquired the assets of the Facility, U. S. Steel continued to operate the by-product coke plant until 2015 at which time it was permanently idled. SR 0609. For information purposes, in November 2023, the steel and ironmaking production facilities, including, among other emission units, the blast furnaces and basic oxygen furnace operations, at Granite City Works, were indefinitely idled due to market demands and corporate operating needs which is not uncommon in the integrated iron and steel industry. The plant currently continues to process slabs to produce hot-rolled, cold-rolled and coated sheets. While certain emission units are indefinitely idled ("indefinitely" - because a date certain cannot be provided that the operations will resume because it is dependent upon many factors, including market demand, etc.), the assets continue to be maintained and preserved. In addition, these emission units remain permitted and in the facility's air emissions inventories.

9. On January 25, 1996, prior to U. S. Steel acquiring certain assets of National Steel Corporation, the Agency issued Construction Permit No. 95010001, which also serves as a

Prevention of Significant Deterioration ("PSD") approval, to National Steel Corporation. SR 1278 – 1308; SR 0608. Construction Permit No. 95010001 ("Permit") authorized increases in the allowable production rate of iron and steel at the Granite City facility (the "1996 Project" or "Project"). SR 0608; SR 1278 — 1308.

10. At the time of the Project in 1996, the Permit authorized National Steel Corporation to increase throughput and fuel use at the Facility, including as follows: (i) limits on production of hot metal from the two blast furnaces were increased; (ii) limits on production of liquid steel from the two BOFs were increased; (iii) limits on the use of blast furnace gas ("BFG") at the units in which BFG was burned (i.e., Boilers 1 – 12, blast furnace stoves, BFG flare #1, and ladle drying preheaters) were increased; and (iv) already-effective limits on the use of natural gas at the Project-affected units in which natural gas could be burned (i.e., Boilers 1 – 12, blast furnace stoves, BFG flare #1, and ladle drying preheaters) remained in effect. SR 0611; SR 1278 – 1308.

11. At the time the Permit was initially issued, the Granite City area was designated nonattainment for the ozone and particulate matter with aerodynamic diameter of 10 micrometers or less ("PM_{10}") national ambient air quality standards ("NAAQS"). SR 0608. The area was designated attainment or unclassifiable for all other NAAQS criteria pollutants. SR 0608. Consequently, the Permit included limitations on emissions sufficient to ensure that the Project did not trigger applicability of the Illinois Nonattainment New Source Review ("NNSR") program, also known as Major Stationary Sources Construction and Modification ("MSSCM"), codified at 35 Ill. Adm. Code Part 203 for oxides of nitrogen ("NOx") and volatile organic material ("VOM") (both as precursors for ozone) and PM_{10} and did not trigger PSD permitting requirements for particulate matter ("PM"), nitrogen dioxide ("NO_2"), or lead. SR 0608 – 0609; SR 1278 – 1308. The net emission increases for PM, PM_{10}, NOx, and VOM, including contemporaneous changes,

were below the applicable significant emission rates for these pollutants. SR 0611 – 0612; SR 1278 – 1308. For lead, the project emissions increase was below the significant emission rate. *Id*. For SO_2 and CO, the Project resulted in net emission increases that were greater than the significant emission rates. *Id*. As such, the Project was a major modification for SO_2 and CO and the PSD requirements for these pollutants were addressed by National Steel Corporation in the initial application submitted in 1995 and by Illinois EPA in issuing Permit 95010001. *Id.*; SR 1942 – 2173.

12. The Permit has been revised several times. On June 6, 1997, the Agency addressed the 1996 Permit in an Operating Permit issued to National Steel Corporation. SR 2220 – SR 2249. On January 6, 1999, the Operating Permit was revised. SR 2250 – SR 2284. In the 1999 revision, the Agency increased the limits to National Steel Corporation on the use of natural gas at the Project-affected units in which natural gas could be burned (i.e., Boilers 1 – 12, blast furnace stoves, BFG flare #1, and ladle drying preheaters) and the associated limits on emissions from these units were increased. SR 2250 – SR 2284. The most recent revision was made on December 17, 2012, when the Permit was revised to accommodate a proposed improvement to the air pollution control systems serving the Basic Oxygen Furnace ("BOF") Shop Operations at the facility (the addition of a fabric filter baghouse and associated capture system to improve control of particulate matter emissions). SR 0608; SR 1249 – 1277. Subsequent to issuance of the December 2012 permit, the new controls and improvements were constructed and operated.

13. Requirements of the Permit are also incorporated in the Clean Air Act Permit Program ("CAAPP") Permit for the facility that was issued on March 4, 2013 (Permit No. 96030056 or "CAAPP Permit"). SR 0608; SR 1610 – SR 1941. U. S. Steel timely appealed some

of the conditions of the CAAPP Permit. Petition for Review, *United States Steel Corporation v. Illinois EPA*, PCB 13-53 (April 8, 2013).

14. In 2014, U. S. Steel conducted emissions testing and discovered that the NOx and VOM emissions from two BOFs, in which steel is produced, were higher than is allowed by the Permit. This is because the original permit application submitted by National Steel Corporation understated both the pre-project and post-project NOx and VOM emissions of the BOFs; and the erroneous emission limits in the Permit were based on inaccurate information in the original application submitted by National Steel Corporation. SR 0453.

15. On February 28, 2020, U. S. Steel submitted an Application for Revisions to the Construction Permit/Prevention of Significant Deterioration (PSD) Approval for the 1996 Expansion of the Granite City Works. SR 0961 – 1248; SR 2285. The Application was received by Illinois EPA on March 2, 2020. SR 2285 – 2286; SR 0076; SR 0092; SR 0095.

16. On October 3, 2022, U. S. Steel submitted a supplement to the Application for Revisions to the Construction Permit/Prevention of Significant Deterioration (PSD) Approval for the 1996 Expansion of the Granite City Works. SR 0601. This submission was a supplement to the March 2020 application submitted to Illinois EPA. As such, throughout this Petition, the March 2020 application and the October 2022 supplement are collectively referred to as "the Application."

17. U. S. Steel requested in the Application several revisions to the Permit to address correction of emission data for several emissions units involved in the 1996 Project, as addressed in further detail below. SR 0608.

18. Certain emission limits in the Permit that were considered by Illinois EPA in making NNSR and PSD non-applicability determinations for the 1996 Project were the subject of

revisions requested by U. S. Steel in the Application. SR 0609. The revisions requested by U. S. Steel were necessary to correct prior determinations made by National Steel Corporation and to ensure the continued non-applicability of the NNSR program for ozone precursors and PM_{10}, and the continued non-applicability of the PSD program for emissions of PM and NO_2, to the Project. SR 0609. The Application includes revised Project emission increase calculations, discussion of compliance requirements in support of those non-applicability determinations, and updated net emissions increase analyses. SR 0609. It was U. S. Steel's intent and understanding that the requested changes in the Application would resolve the CAAPP Permit appeal filed by U. S. Steel. SR 0609.

19. The primary changes requested by U. S. Steel in the Application relating to CO emissions are: (i) increases in the permitted emissions from burning of BFG and natural gas; and (ii) inclusion of provisions to address CO emissions from the blast furnace casthouse. SR 0612; SR 0601 – 0958; SR 0961 – 1248. The emission limits established in Permit 95010001 were based on information in the initial 1995 Application submitted by National Steel Corporation, which in turn was based on published emission factors and other literature information. SR 0612. However, actual emissions testing data generated since the initial 1995 application was submitted, as well as updated literature information, indicating that corrections to the emission factors and corresponding limits are necessary and appropriate. SR 0612; SR 0601 – 0958. Because such revisions were not necessitated by or associated with any changes to emission units subsequent to the Project, the changes would be revisions to the original Permit based on better emissions information. SR 0612. The Application also requested revisions with respect to certain other permit terms to clarify compliance demonstration requirements and to improve operational flexibility. SR 0612.

20. In the Application, U. S. Steel also requested clarifications to the names of certain emission units and control devices in the Permit to more accurately reflect their functions within the process, as well as changes to the groupings of emission units. SR 0613; SR 0601 – 0958.

21. As to PM, PM_{10}, NOx, and VOM emissions from Project-affected emission units, in the Application, U. S. Steel requested that certain conditions of the Permit addressing individual emissions units or points, including both limits on annual emissions and provisions addressing emission factors, be removed or revised. SR 0613; SR 0601 – 0958. Permit 95010001 includes a number of emission limitations and other permit conditions that are not explicitly or expressly required by any regulation. SR 0613. Such emission limitations and permit conditions were included in the Permit to restrict the potential to emit of certain operations at the Facility and thereby memorialize non-applicability determinations under the PSD and NNSR permitting programs with respect to these pollutants. SR 0613; SR 1278 – 1308. Additionally, as to PM and PM_{10}, U. S. Steel requested minor revisions in the Application to the emission caps both to accommodate the revised grouping of material handling operations referenced above and to reflect updated emissions information. SR 0613; SR 0601 – 0958. For NOx and VOM, in the Application, U. S. Steel requested increases in permitted emissions from the BOF Shop Operations based upon updated emissions information that are not related to any post-1996 changes at the Facility, i.e., both baseline and post project emissions from BOF Shop Operations require correction. *Id*. In the Application, U. S. Steel also requested revision/elimination of gaseous fuel usage limits for Project-affected combustion units due to the 2015 shut down of the by-product coke oven batteries, which eliminated the ability to use coke oven gas ("COG"), and the retirement of ten of the twelve boilers that existed at the mill at the time of the Project in 1996. SR 0614; SR 0601 – 0958.

22. Furthermore, in the Application, U. S. Steel presented updated net emissions increase calculations for PM, PM_{10}, NOx, and VOM. SR 0614. Unlike the initial application submitted by National Steel Corporation in 1995, the updated calculations in the Application address all emissions from fuel burning units affected by the Project, including emissions from the burning of COG. SR 0614. As demonstrated by the updated calculations, the revisions requested by U. S. Steel in the Application will not trigger after-the-fact PSD or NNSR permitting for emissions of such pollutants under the source obligation provisions because the Project will not become a major modification for such pollutants solely by virtue of the requested changes in the Application. SR 0614 – 0615.

23. In the Application, U. S. Steel also requested the elimination of fugitive dust requirements relating to certain road segments which are not under the control of U. S. Steel and are therefore not a part of the stationary source that is the subject of the Permit. SR 0615; SR 0601 – 0958; SR 0961 – 1248. Furthermore, U. S. Steel did not acquire these segments under the Bankruptcy Order; and U. S. Steel does not and has never owned these road segments nor had control over the segments. *See* SR 0615 (". . . pollutant-emitting activities at these properties are not a part of the Granite City Works stationary source."); *see* SR 1309 - 1394.

24. The Application also included a request for Integrated Processing of revisions to Petitioner's CAAPP Permit. SR 0609. In the Application, U. S. Steel requested that Illinois EPA process the revisions to Permit 95010001 in accordance with the Integrated Processing procedures and issue the revised permit utilizing procedures and compliance requirements that are substantially equivalent to those utilized for issuance of a CAAPP permit, including a public notice period for the revised permit. SR 0609 (citing to 35 Ill. Adm. Code 270.302(e)). It was U. S. Steel's intention that the CAAPP Permit would be modified by means of the administrative

amendments process to address the revisions that would be made to the applicable requirements in Permit 95010001. SR 0609.

25. As referenced above, U. S. Steel did not propose any physical changes in conjunction with the requested revisions to Permit 95010001. SR 0609; SR 0601 – 0958; SR 0961 – 1248.

C. Petitioner's Participation in Public Comment Process

26. In July 2023, the Agency issued a Notice of Intent to Deny (SR 0571) and Draft Denial of an Application for Revisions to a Construction Permit/PSD Approval and sought public comment. SR 0522. After an extension of the comment period (SR 0520), on September 11, 2023, U. S. Steel submitted a Comment Letter to the Agency in response to the Agency's Draft Notice of Intent to Deny Application for Revision to Construction Permit/PSD Approval. SR 0480 — 0519.

27. In December 2023, the Agency issued a Notice of Intent to Deny (SR 0450) and Revised Draft Denial of an Application for Revisions to a Construction Permit/PSD Approval and sought public comment. SR 0359. On January 8, 2024, U. S. Steel submitted additional comments. SR 0320 - 0358.

28. U. S. Steel participated in the Agency public comment process by submitting the above-referenced written comments. 35 Ill. Adm. Code 105.608(b)(2). As shown below, all issues proposed for review were raised during the public comment process. 415 ILCS 5/40.3(a)(2)(ii); 35 Ill. Adm. Code 105.608(b)(4).

D. The Agency's Denial of the Permit

29. On May 8, 2024, Illinois EPA issued its Denial of an Application for Revisions to a Construction Permit/PSD Approval ("Denial Letter"). SR 0001- 0091. In the Denial Letter, the

Agency stated that the "permit application is DENIED because, if a revision to Permit 95010001 were issued as requested by this application, it might violate various Sections of the Illinois Environmental Protection Act (Act) and various provisions in Illinois' regulation pursuant to the Act." SR 0001.

30. The Denial Letter included Attachment 1, a Listing of Denial Points which discussed the specific Sections of the Act and the specific provisions of the Illinois Administrative Code that the Agency claims may not be met if Permit 95010001 were to be revised as requested, as well as a description of the information the Agency claims the Permit Application did not provide, and the specific reasons why Illinois EPA claims the Act might be violated if a revised permit were issued as requested. *Id.* The Denial Letter also had two appendices: Appendix A, which listed and discussed the various sections of the Act that are cited in Attachment 1 as the statutory basis for the Denial Letter; and Appendix B, which listed and discussed the various provisions in Subtitle B of Title 35 of the Illinois Administrative Code that are cited in Attachment 1 as the regulatory basis for the Denial Letter. SR 0001 – 0002.

31. On May 8, 2024, the Agency also issued its Responsiveness Summary for Comments on the Proposed Denial of an Application from United States Steel Corporation – Granite City Works for Revisions to a Construction Permit/PSD Approval Issued for a Production Increase Project at its Iron and Steel Mill in Granite City. SR 0095 — 0319.

E. <u>Petitioner is Aggrieved by the Agency's Denial of the Permit</u>

32. U. S. Steel's Application and the requested revisions to the Permit were denied by the Agency. SR 0001 – 0091. As explained above, in the Application, U. S. Steel requested revisions of the Permit based on updated information. The initial permitting of the Project was completed back in 1996 in an action between Illinois EPA and National Steel Corporation; and U.

S. Steel was never involved in the process. SR 1278 – 1308; SR 1942 – 2173. The initial permitting of the Project in 1996 was based on emissions information that now is in clear need of being updated and/or corrected based on recent test data and literature review. Such revisions are necessary for U. S. Steel to comply with correct limitations and requirements that are well grounded in science and law for its operations going forward. U. S. Steel has been aggrieved by the denial and its interests have been adversely affected by the permit denial. 415 ILCS 5/40.3(a)(2)(i); 35 Ill. Adm. Code 105.608(b)(3).

II. ISSUES PROPOSED FOR REVIEW

A. Standard of Review and Burden of Proof

33. When a construction permit is required by regulation, "the applicant shall apply to the Agency for such permit and *it shall be the duty of the Agency to issue such a permit* upon proof by the applicant that the facility … will not cause a violation of this Act or of regulations hereunder." 415 ILCS 5/39(a) (emphasis added). Therefore, the question before the Board is whether the information submitted by U. S. Steel in the Application sufficiently proves that issuing the requested permit will not cause a violation of the Act and Board regulations. *KCBX Terminals Co. v. IEPA*, PCB 14-110 (June 19, 2014), 2014 WL 2871721, at *44; *Alton Packaging Corp. v. Pollution Control Bd.*, 162 Ill. App. 3d 731, 737 (5th Dist. 1987).

34. In appeals of final Agency decisions under Section 40 of the Act, "the burden of proof shall be on the petitioner." 415 ILCS 5/40/(a)(1); 35 Ill. Adm. Code 105.112(a). "It is well settled that the Agency's denial letter frames the issues in a permit appeal before the Board." *KCBX*, 2014 WL 2871721, at *45. Accordingly, the petitioner has the burden to show that "it is entitled to a permit and that the Agency's reasons for denial are either insufficient or improper" or that the reasons, regulatory bases, and statutory bases for denial are inadequate to support denial.

ESG Watts, Inc. v. Pollution Control Bd., 286 Ill. App. 3d 325, 331 (3rd Dist. 1997); *KCBX*, 2014 WL 2871721, at *45.

35. The Act and Board regulations separately address review of PSD permits under Section 40.3 of the Act. 415 ILCS 5/40.3; 35 Ill. Adm. Code 105.608. In addition to discussing the Agency's final decision, participation in the public comment process, and how the petitioner is aggrieved (all discussed above), the petition must include:

- The issues proposed for review, citing to a specific permit term or condition when applicable and to the Agency record where those issues were raised, citing to any relevant page numbers in the public comments submitted to the Agency and attaching this public comment to the petition (or explaining why the issues were not required to be raised during the public comment process); and

- An explanation why the Agency's previous response to the issues proposed for review was (A) clearly erroneous; or (B) an exercise of discretion or an important policy consideration that the Board should, in its discretion, review.

415 ILCS 5/40.3(a)(2); 35 Ill. Adm. Code 105.608(b). "Any PSD permit issued by the Agency must be upheld by the Board if the technical decisions contained in the permit reflect considered judgment by the Agency." 35 Ill. Adm. Code 105.614. "Only where the record demonstrates that the permitting authority duly considered the issues raised in the comments and that the approach ultimately adopted by the permitting authority is rational, in light of all the information in the record, will the Board defer to the permitting authority's expertise." *In re: ConocoPhillips Co.*, 13 E.A.D. 768 (June 2, 2008), 2008 WL 2324133, at *15.

B. Discussion of Issues Proposed for Review and Explanation as to Why the Agency's Denial was Improper and its Previous Responses were Clearly Erroneous or an Exercise of Discretion or Important Policy Consideration that the Board Should, in its Discretion, Review

36. U. S. Steel is petitioning for review the entire permit denial, including each and every "Denial Point" identified by the Agency in its May 8, 2024 Denial Letter. The issues proposed for review are found in the Agency's May 8, 2024 Denial Letter. SR 0001 – 0091.

37. Each Denial Point identified by the Agency in its Denial Letter will be addressed in turn along with discussion of the issues underlying each point. U. S. Steel's comments and the Agency's responses to them will also be addressed for each Denial Point.

38. No violation of the Act or rules under the Act will occur if the Agency issues the requested Permit and the reasons set forth by Illinois EPA for denial of the Permit fail to demonstrate that issuing the permit would result in a violation of the Act or Board regulations. Therefore, the Agency had a duty to issue the Permit under Section 39(a) of the Act. The Agency's reasons for denial are insufficient and improper, and the reasons, statutory bases, and regulatory bases are inadequate to support denial. Further, the Agency's responses to the issues raised by U. S. Steel were either: (a) clearly erroneous considering the facts and the law; or (b) involved an exercise of discretion by the Agency that the Board, in its discretion, should review; or (c) involved an important policy consideration that the Board should, in its discretion, review. The issues sought to be reviewed are not "technical decisions" that "reflect considered judgment by the Agency" but rather are issues that involve the Agency's incorrect interpretation or application of the law, the Agency's discretionary decisions that were improper that the Board should review and reverse, or the Agency's application of important policy considerations to its decisions which the Board should review and reconsider.

39. In sum, as demonstrated below, and as will be further developed at hearing, the Agency's Denial Points are technically and legally flawed, its rationale is erroneous, its discretionary decisions in denying the Permit were improper, its claimed reasons and legal bases for denial were insufficient, improper, and inadequate, the Agency's decision was not rational in light of all the information in the record, and legal and policy considerations support finding that the Agency should have granted the Permit instead of denying it. Accordingly, U. S. Steel seeks review and reversal of each Denial Point claimed by the Agency and all issues raised under each Denial Point.

i. <u>Denial Point 1: The revised netting analysis for the Project for NOx does not fulfill relevant requirements of New Source Review ("NSR") for such analyses</u>

40. The Agency's first Denial Point claims that the Application[2] does not demonstrate that the Project would still not be a major modification for NOx emissions for purposes of NSR with the increases in NOx emissions that are requested to address errors in the initial permitting of the Project and the revised netting analysis included in the Application does not fulfill relevant requirements of NSR. SR 0003; *see* SR 0003 – 008; *see* SR 0161 – 0209.

41. According to the Agency, "the application requests an increase in the permitted NO_X emissions of the basic oxygen furnaces (BOFs) of more than 200 tons/year"; the "netting analysis for NO_x in the application . . . cannot be relied upon to show that the increases in permitted NOx emissions would not result in the Project being a major modification"; the "revised NSR applicability analysis is flawed as, contrary to applicable rules, it relies upon decreases in NOx emissions from actions that were neither contemporaneous with the Project nor creditable as they were not required

[2] Throughout the Denial Letter, the Agency refers to the 2022 supplement submittal separately from the 2020 application submittal and takes the position that the 2022 submittal was a revised application. However, as explained throughout this Petition, the 2022 submittal was a supplement to the 2020 application. U. S. Steel therefore refers to the 2020 and 2022 submittals collectively as the "Application" that is the subject of this Petition.

by Permit 95010001"; "[t]hese decreases resulted from the later shutdowns of ten older boilers at the facility and the much later shutdown of the two by-product recovery coke oven batteries at the facility, as coke oven gas (COG) ceased to be available for use in Project-affected fuel burning units"; and the "incongruous conclusion of the revised NSR applicability analysis is that the Project was accompanied by an overall decrease in the NOx emissions of Project-affected fuel burning units rather than an increase in NOx emissions as would be expected from an increase in production of iron by the blast furnaces." *Id.*

42. The Agency concluded that because the Project "would become a major modification for NOx with the requested increase in permitted NOx emissions, the Project would become subject to Nonattainment New Source Review (NaNSR) (35 IAC Part 203, Major Stationary Sources Construction and Modification (MSSCAM)) for NOx," and "would also become subject to Prevention of Significant Deterioration or PSD (35 IAC Part 204) for NOx." SR 0004. The Agency argued that, the Application, however, "does not address the substantive requirements of MSSCAM or PSD for a major modification, much less show that these requirements are fulfilled," "does not show that for the Project-affected emissions units for which the Lowest Achievable Emission Rate (LAER) and Best Available Control Technology (BACT) should have originally been required for NOx, LAER and BACT are present as required, respectively, by MSSCAM and PSD," "does not address the requirement of MSSCAM that a major project be accompanied by emission offsets to counterbalance the increase in emissions of the nonattainment pollutant from the project" (for NOx), and "does not include an analysis for the impact of the project on NO2 air quality, as required by PSD." *Id.*

43. Therefore, the Agency contends, "Section 9.1(d) of the Act and the substantive requirements of 35 IAC Part 203 and Part 204 for a major modification (the requirements for LAER,

BACT and emission offsets for NOx and an air quality impact analysis for NO2) would be violated if a revision to Permit 95010001 were issued that increased the permitted NOx emissions of the Project as requested by the 2022 application." *Id.* According to the Agency, "[t]his is because the revised NSR applicability analysis for the Project for NOx improperly relies upon decreases in NOx emissions that are neither contemporaneous nor creditable to claim that the Project would continue to not be a major modification for NOx with the increases in permitted NOx emissions that are being requested." *Id.*

44. In the Agency's "Discussion" regarding Denial Point 1, the Agency explains its position that the Permit Application was denied because it "requests that the Project be permitted for additional NOx emissions but does not show that the Project would still not be a major modification for NOx if the permit were revised as requested. As the Project would become a major modification for NOx with the requested revisions to Permit 95010001, the 2022 application must show for NOx that the relevant substantive requirements of PSD and NaNSR are fulfilled for the Project." SR 0005. Illinois EPA found that "[i]t would not be appropriate for a revised permit to be issued with increases in permitted NOx emissions as requested by the current application if this application does not also show that the applicable substantive requirements of PSD and NaNSR would be met for the Project for NOx." *Id.*

45. In discussing the netting analysis, the Agency acknowledged that, in the Application, U. S. Steel requested increases in NOx emissions for certain equipment but these increases "would be accompanied by decreases in the NOx emissions of certain other units" and "[w]ith these accompanying decreases, the net increase in NOx emissions from the Project with the requested revised permit would continue to not be significant." SR 0005. The Agency claimed, however, that U.S. Steel's "netting analysis for NOx in the 2022 application cannot be relied upon

for issuance of a revised permit for the Project as requested by U.S. Steel" because the Application "does not include relevant information showing that additional decreases in NOx emissions that would now be proposed to be relied upon would be contemporaneous and creditable for permitting of the Project" as required by 35 IAC 204.550 and 203.208. SR 0006.

46. The Agency further contended that a "revised permit cannot be issued for the Project that relies upon 'post-project' emissions decreases, which occurred after the Project, to show that the Project with the requested increases in NOx emissions of the furnaces, should still not be considered a major modification." *Id.* The Agency noted that "changes that are unrelated to the Project have occurred at certain fuel burning units after the initial issuance of" the Permit and U. S. Steel in the Permit Application "proposes to rely upon the decreases in NOx emissions due to these changes, which decreases were not and could not have been relied upon by the original permit for the Project." *Id.*

47. Illinois EPA's position is that the Application relies on emission decreases that are not contemporaneous. SR 0006. The Application "indicates baseline NOx emissions of 131.8 and 123.2 tons/year from the use of blast furnace gas (BFG) and natural gas, respectively, in Boilers 1 through 12," the twelve boilers at the source in 1996 that were addressed by the Permit. SR 0006 — 0007. Boilers 1 through 10 were shut down in 2009 and the Agency argues that the Permit Application "does not show that NOx emissions of these ten boilers, as existed in the period prior to 2009, were considered in the 'future' NOx emissions with the Project of at most 706 tons/year from the Project-affected fuel burning units." *Id.* at 0007. Boilers 11 and 12 continue in operation but flue gas recirculation systems have been installed on these boilers (to control NOx emissions) pursuant to Construction Permit 10080022, issued in January 2011, but the Agency claims that the Permit Application "does not show that the revised netting analysis for NOx does not rely on the

lower NOx emissions from Boilers 11 and 12 that are now being achieved with the new control systems, rather than their NOx emissions as previously existed with the Project in the period before these control systems were installed." *Id.*

48. The Agency also noted that the Application "indicates baseline NOx emissions of 461 tons/year from use of coke oven gas (COG) in the blast furnace stoves and Boilers 11 and 12" but in 2015, the two by-product recovery coke oven batteries at the Granite City Works were shut down. *Id.* "COG ceased to be available for use in the stoves or Boilers 11 and 12" but it "was available for use in the stoves and these boilers in 1996." *Id.* The Agency therefore claimed that the Application "does not show that the revised netting analysis for NOx would not rely upon decreases in the NOx emissions of the stoves and boilers due to the elimination of COG, which did not occur until 2015." *Id.*

49. Illinois EPA then claimed that "for purposes of applicability of NSR, the NOx emissions allowed from the Project in 1996 that would be permitted with the requested revisions to the permit *could be* substantially higher than indicated in the 2022 application." SR 0008 (emphasis added). The Agency further claimed that "it must be assumed that the 'future NOx emissions' indicated in the 2022 application reflect maximum actual NOx emissions beginning in 2023, with the requested revisions to Permit 95010001. The application does not suggest that these future NOx emissions are the emissions that should have been allowed by the permit back in 1996 when the permit was issued and the Project commenced." *Id.*

50. The Agency contends that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), and 39(a)*, and 35 Ill. Adm. Code 201.160(a), 203.201, 203.203(b), 203.208**, 203.301, 203.302,

204.550**, 204.810, 204.1100(c), 204.1110, and 204.1130.[3] SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides, in part, that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations. 415 ILCS 5/39(a); SR 0078 – SR 0079. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.201 of the Board's regulations provides that, for a project that is major for a pollutant in a nonattainment area for that pollutant, an entity must comply with the substantive requirements of Part 203. 35 Ill. Adm. Code 203.201; SR 0084. Section 203.203(b) of the Board's regulations provides that applications for construction permits must contain sufficient information to demonstrate compliance with Part 201 and the requirements of Part 203, including Subpart C of Part 203. 35 Ill. Adm. Code 203.203(b); SR 0084.

51. Section 203.208 of the Board's regulations provide the steps to determine whether an increase or decrease in emissions in available for purposes of determining a net emissions increase; such steps provide, in part, that a decrease in actual emissions is creditable to the extent that it is federally enforceable at and after the time that actual construction on the particular change begins, and that an increase or decrease in actual emissions is contemporaneous only if it occurs

[3] Throughout the Agency's Denial Letter, the Agency cites to provisions of the Act and Board's regulations using asterisks. SR 0001 – 0091. The Agency explains the use of the asterisks in Appendices A and B to the Denial Letter. *Id*. In this Petition, when discussing the claims made in the Denial Letter, and when responding to those claims, U. S. Steel is including the asterisks as used by the Agency in the Denial Letter.

between the date that an increase from a particular change occurs and the date five years before a timely and complete application is submitted for the particular change. 35 Ill. Adm. Code 203.208; SR 0085 – 0086. Section 203.301 provides the definition of lowest achievable emission rate ("LAER"). 35 Ill. Adm. Code 203.301; SR 0086. Section 203.302 provides an owner or operator of a new major source or major modification shall provide emission offsets equal to or greater than the allowable emissions from the source or net increase in emissions from the modification sufficient to allow Illinois EPA to determine that the source or modification will not interfere with reasonable further progress. 35 Ill. Adm. Code 203.302; SR 0086 – 0087. Section 204.550 of the Board's regulations provides the definition of "net emissions increase" and provides, in part, that an increase or decrease in actual emissions is contemporaneous with the increase from the particular change only if it occurs between the date five years before construction on the particular change commences and the date that the increase from the change occurs; and a decrease in actual emissions is creditable only to the extent that it is enforceable as a practical matter at and after the time that actual construction on the particular change begins. 35 Ill. Adm. Code 204.550; SR 0088 – 0089.

52. Section 204.810 of the Board's regulations provide, in part, that a PSD permit application must include, if a determination of BACT is required, a detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that BACT would be applied. 35 Ill. Adm. Code 204.810; SR 0089. Section 204.1100(c) of the Board's regulations provides that a major modification must apply BACT for each regulated NSR pollutant for which it would result in a significant net emissions increase at the source. 35 Ill. Adm. Code 204.1100(c); SR 0090. Section 204.1110 of the Board's regulations provides that the owner or operator of a proposed

source or modification must demonstrate that allowable emission increases from the proposed source or modification, "in conjunction with all other applicable emission increases or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of: a) Any NAAQS in any air quality control region . . . ." 35 Ill. Adm. Code 204.1110; SR 0090. Section 204.1130 of the Board's regulations provide, in summary, that a permit applicant for a project that is considered major for pollutant(s) for purposes of PSD address that ambient air quality in the area that the proposed project would affect for such pollutant(s). 35 Ill. Adm. Code 204.1130; SR 0090 – 0091.

53. The issues raised by Denial Point 1 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0491 – 0494; SR 0330 – 0335.

54. As explained in the comments, in its evaluation, Illinois EPA improperly considers emissions and emissions increases that were authorized by Illinois EPA at the time Permit 95010001 was issued to National Steel Corporation but will not occur in the future. SR 0030; SR 0491. The NOx emissions increase from the Project authorized by Illinois EPA prior to U. S. Steel's ownership (when National Steel Corporation owned and operated the facility) is greater than that with the revisions proposed by U. S. Steel. *Id*. Illinois EPA is attempting to shift to U. S. Steel a burden that is not U. S. Steel's. SR 0331. U. S. Steel has demonstrated in the Application that the Project would not become a major modification solely by virtue of the changes and other requested revisions. SR 0331; SR 0491. U. S. Steel has no obligation to show that the actual or potential NOx emissions of the units in the period from 1996 to the present have not exceeded the emission rates currently proposed by U. S. Steel. SR 0331.

55. Illinois EPA's position and demands place U. S. Steel in the impossible position to show that no violations would have existed for a period of 30 years – including about ten of those years in which U. S. Steel did not even own or operate the facility nor can it attest to the National Steel emissions. The Agency expects U. S. Steel to somehow show that not only every operating scenario complied with all regulations, but also that none of the regulations over 30 years would have been violated. U. S. Steel is essentially tasked with the impossible burden to demonstrate compliance with all operating scenarios and all PSD provisions over the nearly 30 years – both of which have significantly evolved over the last three decades.

56. The Agency's position regarding U. S. Steel's obligations with respect to PSD and NNSR as to NOx emissions is contrary to the law. SR 0331. In *U. S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677 (N.D. Ill. 2011), the Court held that, where a facility should have been subject to BACT and other substantive requirements of the major NSR permitting programs due to modifications implemented by a prior owner, the Act does not obligate a subsequent owner to come into compliance with those requirements. *U.S. v. Midwest Generation* involved an enforcement action under the Clean Air Act for injunctive relief and civil penalties against the owner and operator of coal-fired power plants. *Id*. at 679. The power plants were originally owned by Commonwealth Edison Co. ("ComEd"), then sold to Edison Mission Energy, Inc. ("EME"), who then transferred control to Midwest Generation. *Id*. at 680.

57. Prior to selling the plants to EME, it was alleged that ComEd modified five of its power plants between 1994 and 1999 but did not obtain permits for the modifications. *Id*. at 645. After the modifications, Commonwealth Edison sold the plants to Midwest Generation. *Id.* at 646. No one challenged the modifications until 2009, 10 years after they were completed. *Id*. The court held that any PSD claim accrued, and the statute of limitations began to run, in 1999, because the

violation would be "complete when construction commences without a permit." *Id.* at 646-47. Accordingly, any claims based on PSD violations for failing to obtain a permit were barred by the statute of limitations. *Id.* Moreover, the court held that "[t]oday's emissions cannot be called unlawful just because of acts that occurred more than five years before the suit began. Once the statute of limitations expired, Commonwealth Edison was entitled to proceed as if it possessed all required construction permits" because "enduring consequences of acts that precede the statute of limitations are not independently wrongful." *Id.*at 648.

58. *Midwest Generation* involved failure to obtain any construction permits, including PSD permits, for projects that required both. In contrast, National Steel obtained a construction permit, which permit constituted a PSD approval for two pollutants, but did not obtain PSD approval with respect to NO_X emissions. The alleged failure to obtain PSD approval with respect to NO_X emissions is essentially identical; the *Midwest Generation* principles apply to this case. This is because when the Permit was issued in 1996, Illinois did not have its own PSD program, but rather had been delegated authority by USEPA to implement and enforce the federal PSD program. *See In Re: West Suburban Recycling and Energy Center, L.P.*, 1996 WL 780306, at *3. Permits "issued by states acting with delegated authority are considered EPA-issued permits." *In Re: Christian County Generation, LLC,* 13 E.A.D. 449, 2008 WL 281839, at *11 n. 1 (E.P.A. Jan. 28, 2008). Thus, where Illinois EPA "acts as EPA's delegate in implementing" a federal program in Illinois, the permit "is considered an EPA-issued permit for purposes of federal law." *Id.* Under federal law, with respect to PSD claims, the Clean Air Act "does not provide its own statute of limitations. Therefore, the general, five-year, federal statute of limitations applies." *U.S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677, 691 (N.D. Ill. 2011).

59. In relation to the BACT requirements, the court in *Midwest Generation* explained that "[t]here is no obligation to apply 'best available control technology' in the abstract.'" *Id.* at 690. BACT requirements are not freestanding but are imposed in the pre-construction permit process. *Id.* The court explained that "[i]n the absence of such a permit, they do not exist." *Id.*

60. While the *Midwest Generation* case addressed the issues of continuing PSD violations in an enforcement context, the court's discussion of PSD and BACT requirements is relevant to the permitting context. Here, National Steel obtained a permit in 1996, but it contained certain incorrect emissions information and limits. Those errors were discovered and dealt with appropriately by U. S. Steel in applying to correct the emissions information and limits. The time for Illinois EPA to seek fulfillment of the regulatory consequences of the prior incorrect emissions information and limits has long since passed. Since National Steel could never be found liable for those errors even if it continued to own the facility, U. S. Steel likewise cannot be subject to punishment for the consequences of the incorrect permit limits. Given that Midwest Generation was not liable in the enforcement context for its predecessor's failure to get a required permit at all,[4] certainly U. S. Steel, which inherited a facially valid permit from its predecessor, should not suffer based on purported failure by the predecessor to get (and Illinois EPA to issue) the correct permit. Furthermore, the issues raised and actions demanded of U. S. Steel now were never raised when National Steel applied for the Permit in 1995. *See, generally* SR 1942 – 2173.

61. Illinois EPA's position in this matter, while not in the enforcement context, essentially holds U. S. Steel liable for National Steel's conduct. The Agency disregards *Midwest Generation* and attempts to circumvent its limitations imposed by that decision. U. S. Steel's

[4] Subsequent to the *Midwest Generation* decisions, the Agency has issued several construction permits to Midwest Generation for the same emissions units that were the subject of the decisions, and those permits authorized operation of the modified units without imposing BACT or other major NSR obligations. SR 0331 n. 16.

Application merely seeks to correct the incorrect emissions limits and move forward in light of the current status of the facility. Moreover, Illinois EPA takes the position that permit terms and conditions that the Agency itself issued (which it could only do upon a finding that no violation would occur) cannot be relied upon even where no change is requested to those terms and conditions. The Agency's position is one that places an unlawful, impracticable, if not impossible, burden on U. S. Steel. Furthermore, the burden that the Agency is placing on U. S. Steel is not only contrary to *Midwest Generation*, but inconsistent with the Order issued by the United States Bankruptcy Court for the Northern District of Illinois (Case Nos. 02-08697 – 02-08738). *See*, *generally* SR 1309 – 1394.

62. Instead of appropriately considering the situation in a prospective, forward-looking, and realistic manner that reflects the current conditions and future operations at the Facility, and accepting the provisions of the Permit that U. S. Steel does not seek to change, Illinois EPA takes the position that U. S. Steel must assess the details of operating scenarios that may have existed nearly 30 years ago when the Permit was issued and before U. S. Steel's ownership. Illinois EPA's position is based on retrospectively looking back to the time the Permit was issued in 1996 and revised in 1998 and speculating about what operations may have been like at that time instead of concentrating on what the actual consequences of its permitting decision would be in a practical sense. In addition, U. S. Steel cannot speak to or verify on how National Steel operated nor can it attest to its emissions.

63. This is also true of the concerns raised by Illinois EPA pursuant to the non-attainment area portion of the New Source Review program in 35 Ill. Admin. Code 203 (NNSR). Illinois has had its own program under Part 203 for a long time, and the statute of limitations situation is not the same as in the PSD context. However, the reality of Illinois EPA's position in

the Part 203 context is that it would be impossible for U. S. Steel to meet Illinois EPA's demands. Illinois EPA cites Section 203.302 for emissions offsets, requiring an owner or operator of a major modification to provide emission offsets equal to or greater than the allowable emissions from the net increase in emissions from the modification. There are regulatory requirements for determining emission offsets, including Sections 203.302 and 203.303. One of those requirements is that emission offsets must be effective prior to start-up of the modified source. It is not clear how U. S. Steel could be expected to obtain such emission offsets now, for a project that started up decades ago. Thus, the Agency appears to instill an impossibility in its permit denial. If the Board agrees with the Agency's approach, U. S. Steel may never be able to obtain a corrected permit. This cannot be a rational result.

64. U. S. Steel explained as follows in its written comment:

> Under the PSD and NNSR programs as in effect at the time of the Production Increase Project, where the project involved changes to existing emissions units that are so significant that the emissions unit was deemed not to have begun normal operation, the post-change actual emissions of that unit are assumed equal to its potential to emit. 40 CFR § 52.21(b)(21). The major modification applicability test was therefore based on a comparison of the pre-project actual emissions and the post-project potential to emit of the emissions unit or group of units. 40 CFR §§ 52.21(b)(2)-(3). An emissions unit's potential to emit is its maximum capacity to emit a pollutant under its physical and operational design. 40 CFR § 52.21(b)(4). Limitations on the capacity to emit a pollutant are treated as part of the design of an emissions unit or group of units if the limitation or the effect it would have on emissions is legally enforceable and enforceable as a practical matter. Where the potential to emit of a unit or group of units is governed by enforceable limitations rather than by the unrestricted physical capacity of that unit or those units, and where those limitations were necessary to a determination that a project was not a major modification, the term "synthetic minor" is commonly used to describe the project and the associated limitations.

SR 0331 – 0332.

65. The source obligation provisions effectively require updated PSD and NNSR applicability analysis in situations where the permit applicant proposes to relax a synthetic minor

limitation in a permit. SR 0332. Applicability analyses performed to determine whether the source obligation provisions apply are prospective, not retrospective as Illinois EPA claims. *Id.* U. S. Steel's prospective calculation of potential NOx emissions from specific fuel combustion units affected by the Project include zero emissions from Boilers 1 – 10 (which no longer exist); does not include the greater NOx emission rates of Boilers 11 and 12 prior to required retrofit of flue gas recirculation in those boilers; and includes zero emission from combustion of coke oven gas as fuel (since coke oven gas is no longer available). *Id.* The Application demonstrates that the Project will not become a major modification solely due to the requested relaxations. *Id.*

66. As demonstrated by the Application, NOx emissions associated with a facility configuration that is no longer authorized, or that are under a counterfactual hypothetical, are immaterial to the source obligation demonstration. SR 0333. The Application reflects the prospective reality for the fuel combustion units at the facility. *Id.*

67. Further, Illinois EPA argues, as to Project emission increases and net emission increases, that additional decreases in NOx emissions that U. S. Steel proposes to rely upon are not contemporaneous and otherwise creditable as required by the NSR regulations. SR 0333. However, the Agency's analysis includes separate calculations of increases and decreases based on specific fuels and changes in fuels, which is inconsistent with the PSD and NNSR rule requirements. *Id.* For certain Project-affected fuel combustion units, the change in actual NOx emissions is properly calculated as the total post-project actual NOx emissions (regardless of the fuel or fuels being burned to generate those emissions) minus the total pre-project actual NOx emissions (regardless of the fuel or fuels that were burned to generate those emissions). SR 0333; SR 0601 – 0958. Further, it was appropriate to include the emission changes at the certain Project-affected fuel combustion units in the updated calculation of the NOx emissions increase from the

Project as calculated in the Application. SR 0334; SR 0601 – 0958. Emissions changes at these emission units must be included in the calculation of the emissions increase that will occur as a result of the project, under the first clause in the definition of the term "net emissions increase." SR 0333 – 0334. Lastly, as explained in written comments, "even if the contribution of the certain fuel combustion units affected by the Production Increase Project were properly considered as among the other decreases under the second clause of the definition rather than a contribution to the emissions increase from the project under the first clause of the definition, it is not relied upon for the non-applicability determination." SR 0334. The net NOx emissions increase from the Project as presented in the Application is -237.3 tons per year; even if the decrease of 250.3 tons per year as calculated by the Agency is omitted from the calculation, the net emissions increase is 13 tons per year, which is less than the significant level of 40 tons per year and demonstrates that the Project would not become a major modification solely by virtue of the relaxations requested by U. S. Steel. SR 0334 – 0335.

68. The updated NOx emission increase calculations presented in the Application fully conform to and satisfy the source obligation provisions of the PSD and NNSR rules. SR 0335. Because the Project would not become a major modification with respect to NOx emissions solely by virtue of the requested relaxations, the substantive requirements of PSD and NNSR programs are not required elements of the Application. SR 0335.

69. As noted above, U. S. Steel advocates that the PSD Program is forward-looking and prospective. Illinois EPA, on the other hand, claims that "the PSD program is not actually forward looking." SR 0114. The Agency's position is again contrary to the law. One purpose of the PSD program is "to assure that any decision to permit increased air pollution in any area to which this section applies is made only after careful evaluation of all the *consequences* of such a

decision." 42 U.S.C. § 7470(5) (emphasis added). Therefore, "the PSD program is forward-looking," and the "PSD requirements are forward-looking." *United States v. Louisiana Generating, LLC,* 929 F. Supp. 2d 591, 593 (M.D. La. 2012); *United States v. EME Homer City Generation L.P.*, 823 F. Supp. 2d 274, 281 (W.D. Pa. 2011), *aff'd*, 727 F.3d 274 (3d Cir. 2013). Therefore, Illinois EPA's position that the PSD Program is not forward looking is without merit.

70. The Agency claimed that the Bombardier letter by USEPA supported its position. SR 0183 – 0184; SR 0308 – 0311. Bombardier involved a higher threshold for major source/modification due to a change in the area designation. SR 0183 – 0184. Here, however, U. S. Steel is not seeking a change in the major source/modification threshold. It is simply updating the emissions information to show that the original major modification threshold is not exceeded, and U. S. Steel's netting analysis demonstrates that this was not a major modification. Accordingly, the Bombardier letter does not support the Agency's position.

71. The Agency also claimed that the PSE & G Determination supported its position. SR 0184 – 0185; SR 0312 – 0315. PSE & G states that any relaxation of an established limit that would make the project "major" would at that point in time make PSD applicable. SR 0314. Here, however, the updated emissions information provided in the application does not make the project major. Thus, the PSE & G Determination does not support the Agency's position.

72. The Agency presented its own NO_X netting analysis in the Responsiveness Summary. SR 0300 – 0306. This analysis included one simple and glaring error; mere correction of that error makes clear that the Project would not become a major modification with respect to NO_X emissions as a result of the revisions requested in the Application. The Agency's analysis shows that the net NO_X emissions increase is less than the significant level of 40 tons per year, provided that the future total NO_X emissions from the affected fuel-burning units are less than

983.2 tons per year. *Id*. The Agency provided a speculative and strained analysis suggesting that the total future NO_X emissions from the affected fuel-burning units might reasonably be assumed to exceed this value. This speculation is preposterous. In the Application submitted in March 2020, U. S. Steel proposed to accept a NO_X emission cap of 632.5 tons per year over the affected fuel-burning units. SR 0961 – 1248. In the Supplement submitted in October 2022, at the direction of the Agency, U. S. Steel proposed no enforceable emission cap because such cap would be superfluous: (i) The currently effective emission cap of 706 tons per year covering all affected fuel-burning units in Permit No. 95010001 significantly overstates the maximum anticipated NOx emissions from these units; and (ii) Any future total NO_X emission rate from these units less than 956 tons per year, including any rate in the range 706 tons per year to 956 tons per year, will result in a calculated net NO_X emissions increase of 13.1 tons per year. SR 0601 – 0958. (In other words, for any such value, the "p" variable in the Agency's speculative analysis is zero.) The Agency is aware that future total NO_X emissions from the affected fuel-burning units will be less than 983.2 tons per year. SR 0119 – 0120, fn. 21 (". . .the Application requests future permitted annual NO_X emissions for the . . . Project-affected fuel burning units of . . .706 tons/year . . ."). If, contrary to the direction given to U. S. Steel by the Agency in 2022, the Agency determined that it was necessary to impose an enforceable limit on total NO_X emissions from the affected fuel-burning units, the appropriate path forward was for the Agency to exercise its discretion and authority to impose such limit, not to deny the Application merely because U. S. Steel had not proposed such a limit in its Application. 35 Ill. Adm. Code Section 201.156 ("The Agency may impose such conditions in a construction permit as may be necessary to accomplish the purposes of the Act, and as are not inconsistent with the regulations promulgated by the Board thereunder.").

73. Based on all the above, the provisions of the Act and Board regulations referenced

by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel. The Project would not become a major modification with respect to NOx emissions, so the substantive requirements of PSD and NNSR programs are not required elements of the Application.

74. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

ii. Denial Point 2: The determination of baseline NOx emissions in the revised netting analysis cannot be independently confirmed

75. The Agency's second Denial Point claims that the determination of baseline NOx emissions in the revised netting analysis cannot be independently confirmed. SR 0009; *see* SR 0009 – 0012; *see* SR 0209 – 0218.

76. The Agency stated that the Permit Application "does not include data and information supporting the determinations of baseline NOx emissions for certain emissions units in the revised NSR applicability analysis for NOx." SR. 0009. The Agency contended that the revised NSR applicability analysis not only sought increases in permitted NOx emissions of the blast furnace casthouse and BOFs to correct errors in the original application for the Production Increase Project, but also now addressed NOx emissions from burning coke oven gas ("COG") in Project-affected units, which the Illinois EPA did not require be addressed in 1996. *Id.* With respect to continuous casting operations, the Agency stated that the analysis took a different approach with use of natural gas and associated NOx emissions. *Id.* Finally, the Agency contended that the revised NSR applicability analysis did not reflect a reevaluation of the NOx

emission factor used for ladle preheaters and, for these units, an emissions factor for use of natural gas in boilers continues to be used, which the Agency claims "likely is not appropriate for the simpler burner systems in preheaters." *Id.*

77. Illinois EPA took the position that because of claimed "deficiencies in the data and information" provided for the baseline NOx emissions of fuel burning units, "the revised NSR applicability analysis cannot be relied upon," and the analysis "cannot serve as proof that the Production Increase Project would not become a major modification for NOx under NSR with the increases in permitted NOx emissions" that were requested. SR 0009. The Agency stated that "[l]ikely or possible deficiencies in the emission data in the revised NSR applicability analysis for NOx in the application need to be resolved or corrected before any revised version of" the Permit could be issued based on the revised NSR applicability analysis. *Id.*

78. In the Agency's "Discussion" regarding Denial Point 2, the Agency asserts that the Permit Application "does not show that all Project-affected fuel burning units have been addressed" and, for "units that are addressed, the application does not show that appropriate emission factors and operating data have been used to estimate emissions." SR 0010. Given that "specific concerns exist with the determination of baseline NOx emissions for certain emission units," the Agency claimed that "concerns exist with the determination of the overall baseline NOx emissions for the Project." *Id.* The discussion included the baseline usage of COG, the emission factor for use of COG in Boilers 11 and 12, the emission factor for use of natural gas in ladle preheaters, and emissions from use of natural gas on the continuous casting lines. SR 0010 – 0012.

79. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d) and 39(a)*, and 35 Ill. Adm. Code 201.152**, 201.152*** and 201.160(a). Section 9(a) of the Act

contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – SR 0079. Section 201.152 of the Board's regulations provide, in part, that construction permit applications must include information regarding the quantities and types of raw materials to be used in the emission source or air pollution equipment, and must include information concerning the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083.

80. The issues raised by Denial Point 2 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0494 – 0497; SR 0336 – 0339.

81. As explained in the written comments, Illinois EPA's claim that U. S. Steel did not provide sufficient information for the PSD/NNSR non-applicability determination is without merit. SR 0336. With respect to the baseline usage of COG, the permit application includes extensive discussion of the use of coke oven gas as fuel during the pre-project baseline period. *Id.* The Agency's position was, in part, based on the fact that "National Steel did not provide data for

usage of COG." SR 0210. As discussed above, however, U. S. Steel cannot be liable for National Steel's conduct; and this is a question that Illinois EPA should have requested from National Steel – not U. S. Steel. U. S. Steel cannot attest to the accuracy or veracity to National Steel's submittals and emissions nor is it required to do so.

82. With respect to the emission factor for use of COG in Boilers 11 and 12, the emission factor listed in the Permit Application was "a scrivener's error" and the factor used is actually based on emission testing performed at Boiler 12, which was discussed with Illinois EPA. SR 0336 - 0337. As to the emission factor for use of natural gas in ladle preheaters, this emission factor "has been used consistently for all purposes pertaining to the permitting of the Production Increase Project and has been both accepted and prescribed by Illinois EPA for that purpose." SR 0337. Given that Illinois EPA repeatedly accepted and relied upon this emission factor for calculating NO_X emissions from combustion of natural gas in ladle preheaters in numerous permitting actions over the course of nearly thirty years, no further justification was needed. *Id.* USEPA regularly accepts the use of emission factors from one source to apply to another type of source using the same fuel. For example, in the IIS MACT RTR, USEPA allowed U. S. Steel to test a boiler burning BFG to develop emission factors for blast furnace stoves using the same fuel. Cross utilization of emission factors across different types of units is commonly accepted by USEPA. *See* SR 2502 – 2512. Furthermore, a ladle preheater cannot be tested and there are no published emission factors for ladle preheaters.

83. Concerning emissions from use of natural gas on the continuous casting lines, because "there is no NOx formation from the continuous casting operation other than from combustion of natural gas" and "all natural gas consumption in the continuous casting operation is accounted for elsewhere, U. S. Steel did not account for any additional pre-project actual NO_X

emissions from the continuous casting operation." *Id.* U. S. Steel further clarified in its comments, however, that "emissions associated with natural gas combustion in this operation were properly accounted for both in pre-project baseline and the post project emission for the project affected units." SR 0037 — 0039.

84. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel. Again, the Application shows that the Project would not become a major modification.

85. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. Additionally, the Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Moreover, this is an important policy consideration that the Board should review and reverse Illinois EPA's decision.

iii. Denial Point 3: The Application lacks information for the actual NOx emissions of Project-affected fuel burning units (lack of information relevant to netting)

86. The Agency's third Denial Point claims that the Permit Application lacks information for the actual NOx emissions of project-affected fuel burning units, specifically, that the revised netting analysis for NOx does not show that the value for the maximum future NOx emissions from certain fuel burning units (706 tons/year), in aggregate, is appropriate. SR 0013.

87. The Agency contended that the Permit Application "does not show that 706 tons/year represents the post-project NOx emissions of these units as could have been addressed when Permit 95010001 was originally issued in 1996 if emissions from burning of COG in these units when operating at the levels of iron and steel production that were permitted had been considered." SR 0013. Further, according to the Agency, the Permit Application "also does not

show that the actual NOx emissions of the subject units in the period from 1996 to the present have not exceeded 706 tons/year." *Id.* The Agency's position is that U. S. Steel needed to "show that a value for future NOx emissions of the subject units of 706 tons/year does not really represent 'future' emissions beginning at the present time" because, otherwise, "the value for future NOx emissions in the application improperly takes credit for reductions in the NOx emissions of the Production Increase Project (Project) that were not originally part of the Project." *Id.*

88. Illinois EPA concluded that although only two of 12 boilers that were in operation in 1996 remain in operation currently, "it is not appropriate to only address the potential NOx emissions of the two boilers that now remain," and although COG is no longer being produced due to shutdown of other units, "when revaluating applicability of NSR for the Project for NOx with the increases in permitted emissions now requested, it is not appropriate to evaluate the NOx emissions of the units that formerly used COG as they now exist and to ignore the fact that in 1996 these units did use COG and their potential NOx emissions were higher." *Id.* The Agency stated that the "difficulty is that the revised NSR applicability analysis for NOx in the 2022 application attempts to rely on this 'post-project' reduction in the NOx emissions of these units to make up for the increases in permitted NOx emissions of the blast furnace casthouse and BOFs that are requested." SR 0014. Therefore, Illinois EPA claims it would have been improper to issue a revised permit "that reflects current circumstances for the subject units if this reflects NOx emissions that are lower than could have properly been allowed in 1996." *Id.*

89. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: Sections 9(a), 9.1(d), 39(a)*, 39(a)** and 39(a)***, and 35 IAC 201.152***, 201.160(a), 203.123, 203.128, 203.208*, 204.400, 204.550* and 204.560. Section 9(a) of the Act contains the general prohibition against air

pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.152 of the Board's regulations provide, in part, that construction permit applications must include information regarding the quantities and types of raw materials to be used in the emission source or air pollution equipment, and must include information concerning the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083; SR 0087 – 0088. Section 203.128 and Section 204.560 of the Board's regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; SR 0089. Section 203.208 and Section 204.550 of the Board's regulations provide the definition of Net Emissions Determination including the process to show a project would not be a major modification. SR 0084; SR 0088.

90. The issues raised by Denial Point 3 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0494 – 0497, SR 508; SR 0336 – 0339, SR 0350.

91. As explained in the written comments, the Permit Application provided a basis for the proposed maximum future NOx emissions of 706 tons per year from certain fuel combustion units. SR 0339. The Permit Application did not request a change in the maximum NOx emissions from the fuel combustion units; instead, U. S. Steel requested continued use of the limit of 706 tons of NOx emissions from the fuel combustion units that had been in place in the existing permit since 1999. *Id.* As discussed above, the Agency should accept its previously issued permit terms that U. S. Steel does not seek to change.

92. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

93. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. Additionally, the Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Moreover, this is an important policy consideration in which the Board should review and reverse the Illinois EPA's determination.

iii(a). <u>Denial Point 3A: The Application lacks information for the actual NOx emissions of Project-affected fuel burning units (lack of supporting information)</u>

94. The Agency's Denial Point 3A claims that the Permit Application lacks supporting information regarding the amount of maximum future NOx emissions from certain fuel burning units, 706 tons/year. SR 0015.

95. The Agency argues that the Permit Application does not list specific units whose NOx emissions are being addressed and describe the nature of the various units relative to the emissions of NOx from burning fuel. *Id.* Illinois EPA states that data was not provided for the maximum annual amounts of fuels burned. Moreover, the Agency states that data was not provided "for the emission factors used to calculate annual emissions, the sources or basis of those factors, and why those factors should be considered representative of the NOx emissions of the various types of units that are being addressed." *Id.* The Agency contended that without this information, the Permit Application "does not include information that is necessary to allow the Illinois EPA to rely upon the future maximum NOx emissions of the subject units, presumably the fuel burning units affected by the Production Increase Project, being no more than the stated amount, or issue a revised permit that limits NOx emissions to the stated amount." *Id.*

96. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: Sections 9(a), 9.1(d), 39(a)*, and 39(a)**, and 35 IAC 201.152**, 201.152***, 201.160(a), 203.123, 203.128, 204.400, and 204.560. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include

information regarding the quantities and types of raw materials to be used in the emission source or air pollution equipment, and must include information concerning the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083, 0087. Section 203.128 and Section 204.560 of the Board's regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; 0089.

97. The Agency did not include Denial Point 3A in its Initial Draft Denial Letter. SR 0016. The issues raised by Denial Point 3A were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0494 – 0497 and 0507 – 0509; SR 0336 – SR 0339 and 0349 – 0351.

98. As explained in the written comments, the Permit Application provided a basis for the proposed maximum future NOx emissions of 706 tons per year from certain fuel combustion units. SR 0339. The Permit Application did not request a change in the maximum NOx emissions from the fuel combustion units; instead, U. S. Steel requested continued use of the limit of 706 tons of NOx emissions from the fuel combustion units that had been in place in the existing permit since 1999. *Id.* As discussed above, the Agency has no basis to not accept its previously issued permit terms that U. S. Steel does not seek to change.

99. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

100. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that U. S. Steel could not rely upon an existing emission limit which had already been approved by the Agency involves a discretionary decision and an important policy consideration that the Board should review and reverse.

iv. Denial Point 4: For the basic oxygen furnaces, the 2022 Application does not address the potential for uncaptured emissions of NOx, VOM, and CO through the roof monitor of these furnaces

101. The Agency's fourth Denial Point claims that the Permit Application does not include information regarding uncaptured emissions of NOx, VOM, and CO for the BOFs that occur through the room monitor on the building in which the BOFs are located, the BOF shop. SR 0017.

102. Illinois EPA stated that stack testing of the control systems for the particulate system for the BOFs and the baghouse installed in the last 10 years. SR 0017. The Agency claimed that "[t]hese control systems may capture most of the emissions of the BOFs, achieving overall capture efficiencies that engineering design suggests may approach 100 percent." *Id.* The Agency claimed that the Application, however, "does not contain technical or engineering information showing that all emissions of the BOFs are now being captured and no emissions occur through the roof monitor or other openings in the BOF shop." *Id.* The Agency concluded that "[a]bsent information addressing uncaptured emissions of NOx, VOM and CO from the

BOFs, the 2022 application would not provide complete information about the emissions of the BOFs." *Id.*

103. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, and 39(a)**, and 35 Ill. Adm. Code 201.152***, and 201.160(a). Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include information regarding the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083.

104. The issues raised by Denial Point 4 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0497 — 0498; SR 0339 — 0340.

105. As explained in the written comments, contrary to the Agency's position, the Permit Application "does not reflect an assumption that there are zero uncaptured emissions" from the

basic oxygen furnaces but instead reflects the conclusion that, "if there are any such uncaptured emissions, those emissions are fugitive emissions and are not quantifiable." SR 0339 – 0340. "Fugitive emissions are counted for purposes of PSD and NNSR applicability determinations only to the extent that such emissions are quantifiable." SR 0340. Illinois EPA's speculation regarding possible fugitive emissions from the basic oxygen furnaces is not a sufficient basis to determine that the emissions actually exist and are quantifiable. *Id.* U. S. Steel should not be held accountable for inclusion of such emissions when the Agency did not consider these emissions when issuing the Permit to National Steel in 1996. Moreover, the "primary mechanism for formation of particulate matter during charging and tapping is the oxidation of molten metal" and this "formation mechanism cannot be expected to result in the formation of NOX or VOM." *Id.*

106. The Agency contended that U. S. Steel did not address this Denial Point with respect to uncaptured emissions of CO through the roof monitor, but then conceded that U. S. Steel addressed this issue in a different comment. SR 0221 fn. 149. Indeed, U. S. Steel specifically noted that the Agency previously presumed that there are no CO emissions from this emission point, and "U. S. Steel did not request any changes to existing permit terms relating to this emission point." SR 0326. Thus, U. S. Steel had no reason to believe that the Agency had reconsidered its prior determination relating to CO emissions from the roof monitor. *Id.*

107. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

108. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial.

Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

v. Denial Point 5: The emission inventory for the source used in the air quality analysis for CO omits certain CO emissions

109. The Agency's fifth Denial Point claims that the Air Quality Modeling Report, which provides the Source Impact Analysis, in the Application is deficient because it does not address certain CO emissions of units that are at, or were at, the facility. SR 0023; *see* SR 0023 – 0025; *see* SR 0131 – 0144.

110. The Project permitted under Permit 95010001 was a major modification under PSD because it involved physical and operational changes that would result in a significant net increase in emissions of CO. SR 0486; SR 0325; SR 0601 – 0958. As to the PSD permit application that National Steel Corporation submitted for the Project in 1995, Illinois EPA determined that the application included all necessary information, including the air quality impact analysis, and granted PSD approval for the project in conjunction with issuance of the permit. *Id*. The Application that is the issue of this Petition includes corrective updates to some of the emissions data relied upon by Illinois EPA in issuing Permit 95010001 in 1996. *Id*. As explained in the Application, recent information suggests that some of the emission data relied upon by the Agency in issuing the Permit in 1996 are not representative. SR 0325. U. S. Steel and the Agency agreed that corrective updates to these data and to CO air quality impact analysis are appropriate. *Id*. The Application includes an updated analysis.

111. However, in the Denial Letter, the Agency contended that the air quality analysis does not address: (i) uncaptured CO emission of the blast furnace casthouse and the basic oxygen furnaces (emissions that occur from roof monitors and other openings); and (2) CO emissions of the two by-product recovery coke oven batteries that were in operation in 1996. SR 0023 – 0026.

112. The Agency claimed that, by not addressing these emissions, the source impact analysis does not fully address the impact of the Project on ambient air quality for CO, both with increases in permitted CO emissions as now requested and as would have been determined in 1996 is the Project had been permitted for more CO emissions as is now being requested. *Id.* The Agency also contends that the source impact analysis does not explain why the CO emissions of certain units need not be considered. SR 0023.

113. As to the uncaptured emissions from the casthouse on the blast furnaces, the Agency contended that the analysis does not address these uncaptured emissions. SR 0024. The Agency stated that the Application indicates potential CO emissions of 13.6 tons/year from the roof monitor on the casthouse on the blast furnaces and that these uncaptured CO emissions must be addressed in the air quality analysis. SR 0024.

114. As to the uncaptured emissions from the basic oxygen furnaces, the Agency contended that the analysis does not address these uncaptured emissions. SR 0024. The Agency states that the Application also does not explain why uncaptured emissions would not be present since the Application does not show 100% capture of emissions from furnaces by the control systems. *Id*.

115. As to the by-product coke oven batteries, the Agency contended that the Application did not explain why the analysis should not consider the CO emission of the former by-product coke oven batteries. SR 0024. The Agency stated that the "analysis does not address CO ambient air quality with the Project as would have been predicted by the original air quality analysis for the Project if it had addressed the additional CO emissions now being requested for the Project." SR 0023.

116. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, and 39(a)**, and 35 Ill. Adm. Code 201.152***, 201.160(a), 204.330, 204.1110, and 204.1130. SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include information concerning the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 204.330 of the Board's regulations provides the definition of "complete." 35 Ill. Adm. Code 204.330; SR 0087. Section 204.1110 of the Board's regulations provides that the owner or operator of a proposed source or modification must demonstrate that allowable emission increases from the proposed source or modification, "in conjunction with all other applicable emission increases or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of: a) Any NAAQS in any air quality control region . . . ." 35 Ill. Adm. Code 204.1110; SR 0090. Section 204.1130 of the Board's regulations provide,

in summary, that a permit applicant for a project that is considered major for pollutant(s) for purposes of PSD address that ambient air quality in the area that the proposed project would affect for such pollutant(s). 35 Ill. Adm. Code 204.1130; SR 0090 – 0091.

117. The issues raised by Denial Point 5 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0386 – 0487; SR 0325 – 0327.

118. The Act or Board regulations do not require that a request for revision of a PSD approval include any of the information listed by the Agency. SR 0326. As such, none of the concerns raised by the Agency are deficiencies warranting denial of the permit application. *Id.*

119. Relating to the possibility of CO emissions from the BOF shop roof monitor, the Agency's prior determination that the Project would not cause or contribute to a violation of the CO NAAQS was based on the Agency's assumption that there were no CO emissions from the basic oxygen furnace shop roof monitor. SR 0326. U. S. Steel is not requesting in the Application any changes to the existing permit terms relating to this emission point. *Id.*; *see* SR 0601 – 0958. The Agency did not request that the updated analysis include any emissions from this emission point. *Id.* As explained by the Agency, "[i]t is well established that an air quality impact analysis required under the PSD program must be based on accurate information for the emissions of relevant units for their emissions of the pollutant whose impacts are being analyzed." SR 0134. It was reasonable for U. S. Steel to conclude that its updated CO air quality impacts analysis, which addressed revisions to the CO emission rates only for those emission points where both U. S. Steel and Illinois EPA agreed that National Steel's modeled rates should be corrected, was sufficient for the purpose of requesting revisions to the permitted CO emission from certain combustion units

burning blast furnace gas and/or natural gas and affected by the Project. *Id*. U.S. Steel should not be held accountable for such an issue that was not previously raised by Illinois EPA.

120. In relation to the historical CO emissions from the by-product coke oven batteries operated by National Steel Corporation at the time Permit 95010001 was issued in 1996, it is unclear whether the Agency's contentions relate to the demonstration the Agency approved in 1996 or the current Application. *Id*. If the concerns relate to the demonstration approved in 1996, those emissions were indeed included. *Id*.; SR 2287 – 2286 (Table 5-8); *see, generally* SR 1278 – 1308. If the concerns relate to the demonstration in the current Application, U. S. Steel is not requesting PSD approval for CO emissions from by-product coke oven batteries. *Id*.; *see* SR 0601 – SR 0958. The requested PSD approval is forward-looking – it is based on the applicable regulations and other circumstances as they exist or will exist at the time of permit issuance. SR 0327, fn. 4 (citing 42 U. S.C. 7410(k); *United States v. EME Homer City Generation, L.P.*, 727 F. 3d 274 (3d Cir. 2013)). As such, there is no basis for considering emissions under such scenario in evaluation whether a requested change will cause or contribute to a violation of any NAAQS. *Id*.

121. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

122. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial.

v(a). <u>Denial Point 5A: Issues with the background air quality used in the air quality analysis the emission inventory for the source</u>

123. The Agency's Denial Point 5A claims that, as related to baseline ambient air quality for CO, the Air Quality Modeling Report, which includes the air quality analysis, included in the

Application is deficient in that it does not address baseline ambient air quality as existed at the time that the Project was initially permitted or as it presently exists. SR 0026; *see* SR 0026 – SR 0027; SR 0131 – SR 0144.

124. The Agency stated that the value for background air quality from ambient monitoring conducted in 2016 – 2018 that is used in the analysis is not representative of air quality in the period before the Project was initially permitted or air quality at the present time. R 0026. The Agency contended that the Application did not justify use of the background value that is not representative of the period when the Project was initially permitted. *Id.* The Agency stated that, even if that can be justified, the Application did not explain why it is appropriate to use a background value taken from ambient monitoring conducted over five years ago. *Id.*

125. The Agency contended that it would not be proper to rely on the results if the Air Quality Modeling Report to issue a revised Permit that would provide for increases in permitted CO emissions as requested. *Id.*

126. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, and 39(a)**, and 35 Ill. Adm. Code 201.160(a), 204.330, 204.1110, and 204.1130. SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.160(a) of the Board's regulations provides that no

construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 204.330 of the Board's regulations provides the definition of "complete." 35 Ill. Adm. Code 204.330; SR 0087. Section 204.1110 of the Board's regulations provides that the owner or operator of a proposed source or modification must demonstrate that allowable emission increases from the proposed source or modification, "in conjunction with all other applicable emission increases or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of: a) Any NAAQS in any air quality control region . . . ." 35 Ill. Adm. Code 204.1110; SR 0090. Section 204.1130 of the Board's regulations provides, in summary, that a permit applicant for a project that is considered major for pollutant(s) for purposes of PSD address that ambient air quality in the area that the proposed project would affect for such pollutant(s). 35 Ill. Adm. Code 204.1130; SR 0090 – 0091.

127. The issues raised by Denial Point 5A were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0324; SR 0485.

128. In relation to the Agency's concerns regarding the use of background CO concentration data from 2016 – 2018, such data was the most current quality-assured data available at the time of U. S. Steel's submittal of the Application in March 2020. *Id*. Use of such data was approved by Illinois EPA following its review of U. S. Steel's dispersion modeling protocol in February 2020. *Id*.

129. While the 2016 – 2018 background CO concentration data is less current now than it was at the time of the Application submittal, currentness of air quality data is one aspect of the permit application review process that is ensured by compliance with the procedural requirements

relating to timely processing of permit applications. SR 0327; SR 0487. These requirements include Section 201.158 of the Board's regulations, which provides that a permit application shall be deemed to have been filed 30 days after submittal if Illinois EPA has not notified the applicant that it is incomplete. 35 Ill. Adm. Code 201.158; SR 0327 fn. 5; SR 0487 fn. 4. Additionally, the Clean Air Act requires that final action on a PSD permit application be taken no later than one year after filing. 42 U. S.C. 7475(c); SR 0327 fn. 5; SR 0487 fn. 4. Furthermore, it would be impracticable, if not impossible, to compile all of the required data to perform the analyses from 30 years ago.

130. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

131. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial.

vi. Denial Point 6: Scope of proposed group emission limits

132. The Agency's sixth Denial Point claims that the Permit Application does not show that proposed collections of emission units for "group limits" of annual emissions of particulate, NOx, and VOM are appropriate. SR 0028.

133. The Agency stated that the Permit Application did not "propose limitations that would only apply to the annual emissions of particulate of the casthouse for the two blast furnaces" or to the "annual particulate emissions of the two BOFs" which are "principal emission units at the Granite City Works." SR 00028. Further, according to the Agency, the Permit Application does not show that it would be unreasonable for the casthouse and BOFs to continue to have

limitations for annual emissions of particulate that are directly enforceable, independent of emissions of the other, lesser units. *Id.*

134. The Agency concluded that if a revision to the Permit "were issued without limits that independently apply to the emissions of the blast furnaces casthouse and to the emissions of the two BOFs," then the Permit Application "would not show the limits on annual emissions established in such revised permit would serve to restrict the emissions of the casthouse and the two BOFs as a practical matter." SR 0028.

135. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, and 39(a)**, and 35 Ill. Adm. Code 201.160(a), 203.123, 203.128, 204.400, and 204.560. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083; 0087 – 0088. Section 203.128 and Section 204.560 of the Board's

regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; SR 0089.

136. The issues raised by Denial Point 6 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0499 – 0500; SR 0341 – 0342.

137. As U. S. Steel discussed in its comments, the Application proposes that PM, PM_{10}, NO_X, and VOM emissions be subject to annual emission caps covering groups of related emissions units and emission points. SR 0341. With respect to the blast furnace operations and the BOF shop, "the proposed groupings include emission points with significant emissions, such as the BOF electrostatic precipitator stack, and minor emission points such as the iron spout baghouse stack." *Id.* Further, the Application proposed approaches that would make these emissions limits enforceable as a practical matter. *Id.* The fact that there may be alternative potentially suitable groupings of emissions units is not a valid basis for denial. SR 0342. Further, other permits in Region V have allowed groupings of emissions units in a manner similar to that proposed by U. S. Steel. *See* SR 0150; SR 0621 (citing and linking to Severstal permit); *see also* Permit to Install 182-05C issued to Severstal Dearborn Inc., p. 5, 65-68 (discussion grouping of emission units in Severstal permit).[5]

138. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

139. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial.

[5] Publicly available at https://www.deq.state.mi.us/aps/downloads/permits/finpticon/2005/182-05C.pdf.

Additionally, the Agency's decision involved a discretionary determination that the Board should review and reverse.

vii. Denial Point 7: Inadequate justification for elimination or revision of current limits for Project-affected fuel burning limits

140. The Agency's seventh Denial Point claimed that the Permit Application did not contain information supporting revisions to the Permit to revise or eliminate existing limitations for usage of fuels by Project-affected fuel burning units. SR 0034.

141. The Agency claimed that the Application "does not quantitatively demonstrate that this would not result in an increase in the potential emissions of the subject units." SR 0034. Further, the Agency stated that the existing Permit did not limit the usage of COG because that usage "was not quantitatively addressed in 1996 during the initial permitting of the Production Increase Project." *Id.* In addition, the shutdown of two coke oven batteries in 2015 and resulting decrease in COG usage also resulted in more natural gas to be used in other units such as blast furnace stoves. *Id.* The Agency's position is that the Permit Application did not include the information necessary for it to set values for revised limitations that would be appropriate. *Id.* Consequently, the Agency contended that the Permit Application contained insufficient information to eliminate the limitations in the current Permit for usage of fuel by Project-affected fuel burning units. *Id.*

142. Illinois EPA confirmed that "the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant" but nonetheless other limits for fuel usage and emissions may be appropriate, including addressing fuel burning units other than the Project-affected units. SR 0034 — 0035. While the "limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation," the Agency claimed new fuel usage limits may be needed for certain units, such as the four slab reheat furnaces affected by the

elimination of COG, and the cogeneration boiler which began operation several years before the by-product coke oven batteries at the facility were shutdown." SR 0035.

143. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, and 39(a)**, and 35 Ill. Adm. Code 201.160(a), 203.123, 203.128, 204.400, and 204.560. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083; 0087 – 0088. Section 203.128 and Section 204.560 of the Board's regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; SR 0089.

144. The issues raised by Denial Point 7 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0508 – 0509; SR 0350 – 0351.

145. As U. S. Steel discussed in its comments, it initially specifically requested "enforceable emission caps for emissions of NOx and other pollutants from the fuel combustion units affected by the Production Increase Project and provided emission calculations supporting these proposed emission caps." SR 0350. Illinois EPA then informally and correctly noted that "enforceable emission caps are superfluous and unnecessary where the maximum potential emissions of the affected unit or units is less than or equal to the emission caps under consideration." *Id.* Based on this position, the Permit Application did not include an express request for enforceable emission caps for the affected fuel combustion units. *Id.* As to the claim that fuel burning units other than Project-affected units need to be addressed, such as the slab reheat furnaces and cogeneration boiler, limits on these units would not be appropriate because these emissions units were not among the units affected by the Production Increase Project and are therefore irrelevant. *Id.* at 0350—0351.

146. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

147. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

viii. Denial Point 8: The application does not show that emission factors that are proposed as prescribed factors for certain units would be representative

148. The Agency's eighth Denial Point claims that the Permit Application does not include information justifying the future use of "prescribed emissions factors" for certain units for

the purpose of determining compliance with the requested revised limitations for the emissions of the project. SR 0036.

149. Illinois EPA contended that U. S. Steel did not show "that the proposed factors should be considered representative, accurate and appropriate." SR 0036. For example, the Agency claimed that the Permit Application did not include an explanation for the proposed prescribed emissions factors for the uncaptured emissions of particulate of the BOFs, which are lower than the factors used for baseline emissions. *Id.* The Agency agreed that this was "generally reasonable" in light of improvements that have been made to improve "capture and control of the particulate emissions of the BOFs and should lower uncaptured emissions." *Id.* Nonetheless, the Agency argued, the Permit Application did not explain how the proposed emissions factors were developed and did not address practices for control of particulate emissions of the BOFs that would accompany the proposed factors. *Id.* The Agency concluded that the Permit Application "does not show that the proposed prescribed factors would appropriately be relied upon for the purpose of enforceably limiting the future emissions of the emission units and emission points for which they are proposed." *Id.*

150. The Agency identified three separate emissions units in this Denial Point for which it claimed U. S. Steel did not provide support for prescribed emissions factors or show that they are representative: (1) the roof monitor on the basic oxygen furnace shop (uncaptured emissions from the furnaces); (2) the caster mold, slab cutoff, and slab ripping processes on the continuous casting lines; and (3) the Mag-Lime Silo. SR 0038 — 0040.

151. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)* 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code

201.160(a), 203.123, 203.128, 204.400, and 204.560. SR 0036. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – SR 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation

of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083; SR 0087 – 0088. Section 203.128 and Section 204.560 of the Board's regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; SR 0089.

152. The issues raised by Denial Point 8 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0504 – 0507; SR 0346 – 0349.

153. As discussed in U. S. Steel's comments, the Application includes all required supporting information regarding the emission factors and, in fact, provide more extensive information "than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996." SR 0347. With respect to the roof monitor on the basic oxygen furnace shop (uncaptured emissions from the furnaces), Illinois EPA acknowledged that the emission factors proposed by U. S. Steel were representative of the current configuration, but then incorrectly claimed that the emissions factors should reflect particulate emissions in 1996, which are not relevant here because "these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time." SR 0349. As stated elsewhere, U. S. Steel cannot determine all operating scenarios and emissions under National Steel's ownership, nor is U. S. Steel required to do so. *See, e.g., Midwest Generation* and the Order issued by the United States Bankruptcy Court for the Northern District of Illinois, Eastern Division (Case Nos. 02-08697 – 02-08738), as discussed *supra*. *See* SR 1309

– 1394. With respect to the caster mold, slab ripping, and slab ripping processes on the continuous casting lines, no further justification was required because the "PM/PM10 emission factors for the continuous casting operation at Granite City Works have been consistently prescribed by Illinois EPA for this purpose for many years." SR 0347. With respect to the Mag-Lime Silo, U. S. Steel voluntarily proposed that emissions be subject to limits where it had no obligation to do so, and provided all required information. SR 0348.

154. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

155. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

ix. Denial Point 9: For the roof monitor of the casthouse, the Application does not show that the methodology that is proposed to be prescribed for the determination of NOx and VOM emissions would be representative

156. The Agency's ninth Denial Point claims that the Permit Application did not include information justifying the use of the requested "prescribed emission determination methodology" for the uncaptured NOx and VOM emissions of the blast furnace casthouse. SR 0041.

157. The Agency claimed that the Permit Application "does not include information showing that the proposed methodology should be considered representative, accurate and appropriate." SR 0041. The Agency argued that it was not shown "that changes in the levels of captured NOx and VOM emissions, as measured by emission testing, would be due to actual changes in the overall level of NOx emissions from the casthouse rather than other causes," such

as changes in operations, the existence of the baghouse control systems, or variation in results of emission testing. *Id.* The Agency concluded that the Permit Application "does not show that the proposed prescribed methodology would appropriately be relied upon for the purpose of addressing the future uncaptured NOx and VOM emissions of the blast furnace casthouse." *Id.*

158. The Agency further stated that the proposed emission calculation methodology assumed capture efficient of 95 percent but the Permit Application did not show that the proposed methodology would result in "emission rates for the roof monitor that would be representative." SR 0042. This is because, the Agency contended, that the resulting emission rates would be directly related to the measured emissions of the main baghouse of the casthouse, which could fluctuate if the capture efficiency is lower during testing. *Id.* Thus, the Agency argued, "unlike specific emission rates for NOx and VOM that would be prescribed in a revised permit, the 'proposed methodology' would not address the NOx and VOM emissions from the roof monitor in a way that can reasonably be considered to be representative on an ongoing basis." *Id.*

159. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v), and 35 Ill. Adm. Code 201.160(a), 203.123, 203.128, 204.400, and 204.560. SR 0042. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose

reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083; SR 0087 - 0088. Section 203.128 and Section 204.560 of the Board's regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; SR 0089.

160. The issues raised by Denial Point 9 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0501; SR 0343.

161. As discussed in the written comments, U. S. Steel agrees that the issue that actual capture efficiency of less than 95% would not be reflected in the calculation methodology proposed by U. S. Steel "exists as a theoretical matter." SR 0343. This scenario, however, "is effectively prohibited, as operation of the blast furnace casthouse capture system is subject to stringent requirements under 40 CFR part 63, subpart FFFFF, particularly § 63.7790(b)." *Id.* Indeed, USEPA used 95% capture and control efficiency from blast furnace casthouse fugitives in its residual risk and technology review of the Integrated Iron and Steel MACT rule. *See* 89 Fed. Reg. 23294 (April 3, 2024); USEPA Docket EPA-HQ-OAR-2002-0083, "Technology Review for the Integrated Iron and Steel NESHAP - (Update) Final Rule (03/01/2020)."[6] Accordingly, the proposed approach is an appropriate compliance demonstration method for inclusion in the revised construction permit and Illinois EPA should have allowed it in its discretion. *Id.*

162. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

163. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

[6] Publicly available at https://www.regulations.gov/document/EPA-HQ-OAR-2002-0083-1085.

x. Denial Point 10: The Application does not include necessary support for the emission factors that are proposed as prescribed factors for certain units

164. The Agency's tenth Denial Point claims that the Permit Application does not include information justifying the future use of the proposed "prescribed emission factors" for the purpose of determining compliance with the requested revised limitations for the emissions of the Project-affected units. SR 0043.

165. The Agency claimed that although "the proposed factors are derived from emissions factors developed by USEPA," the Application did not include information showing that the factors should be considered representative, accurate and appropriate. SR 0043. The Agency identified three separate emission units in this Denial Point for which it claimed U. S. Steel did not provide support for emissions factors: (1) the blast furnace casthouse roof monitor; (2) the slag pits; and (3) the iron pellet screen. SR 0044. The Agency concluded that the Permit Application "does not show that the proposed prescribed factors would appropriately be relied upon for the purpose of enforceably limiting the future emissions of the emission units and emission points for which they are proposed." *Id.*

166. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v), and 35 Ill. Adm. Code 201.160(a), 203.123, 203.128, 204.400, and 204.560. SR 0044. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not

cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – SR 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. Section 203.123 and Section 204.400 of the Board's regulations provide the definition of "Federally Enforceable" including that emissions limitations are enforceable as a practical matter. SR 0083; SR 0087 – 0088. Section 203.128 and Section 204.560 of the Board's regulations provide the definition of "potential to emit" including that emissions are practically enforceable. SR 0083; SR 0089.

167. The issues raised by Denial Point 10 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0501 – 0506; SR 0343 — 0348.

168. With respect to the blast furnace casthouse roof monitor, U. S. Steel explained that the proposed emissions factors were derived from the pre-control PM emission factor for iron published by U.S. EPA and based on data published by U.S. EPA. SR 0343 —0344. Further, more extensive information regarding the emission factors was provided in the Permit Application than was provided prior to issuance of the Permit in 1996. SR 0344. Additionally, the assumption of 95% capture efficiency for the blast furnace casthouse has been consistently applied by Illinois EPA for many years. *Id.* U. S. Steel initially proposed PM and PM_{10} emission factors of 0.031 lb per ton of iron and 0.0155 lb per ton of iron, respectively, which "have been prescribed by Illinois EPA for this purpose for decades." *Id.* Illinois EPA informally commented that "these historically assumed emission factors are slightly higher than the values that would result from correctly calculating the emission factors using Illinois EPA's historic assumptions" and suggested that U. S. Steel use the revised and corrected emission factors, which were used in the Permit Application. *Id.* In light of Illinois EPA's repeated acceptance of and reliance on the assumption of 95% capture efficiency in numerous permitting actions over a period of nearly thirty years, and in light U. S. Steel's implementation of the informal suggestion by Illinois EPA to correct the emission factor calculations no further justification was needed. *Id.*

169. With respect to the slag pits, the emission factor proposed by U. S. Steel "has been consistently applied by Illinois EPA for decades" and the summary of the derivation of that factor in the Permit Application was merely a paraphrasing of Illinois EPA's description. SR 0346. In light of Illinois EPA's repeated acceptance of and reliance on this emission factor in numerous

permitting actions over a period of nearly thirty years, no further justification was needed. *Id.* As to the iron pellet screen, the Permit Application explained that the proposed emission factor was derived from the PM_{10} emission factor published by U. S. EPA for crushed stone screening, and the PM emission factor was based on an assumed 95% capture efficiency. SR 0347.

170. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

171. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

xi. Denial Point 11: The determination of particulate emissions from handling of coke, iron pellets and limestone are not supported and cannot be confirmed

172. The Agency's eleventh Denial Point claims that the Permit Application did not provide supporting information for the baseline emissions from handling coke, iron pellets, and limestone. SR 0045.

173. The Agency argued that the Permit Application did not "explicitly list the various units whose emissions are being addressed and describe the nature of the various units relative to their emissions of PM and PM-10." SR 0045. Illinois EPA asserted that data was not provided for the annual amounts of various materials that were handled by these units or for "the emission factors used to calculate annual emissions, the sources or basis of those factors, and why those factors should be considered representative of the emissions of the various types of units being addressed." *Id.* The Agency concluded that the "issuance of a revised permit with limitations for

the future emissions of these units that are practically enforceable necessarily requires that the application include supporting information." *Id.*

174. The Agency further stated that as to baseline particulate emissions, "the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be independently confirmed." SR 0045. The Agency contended that the Permit Application did not provide support for "corrected" determinations of baseline particulate emissions, according to the Agency, because it did not provide "detailed calculations for the emissions from handling each material." SR 0045 - 0046. Illinois EPA further noted that the Permit Application did "not include information for particulate emissions from handling of coke, iron pellets and limestone" but emissions information is needed for the period of operation before the coke oven batteries were shut down in 2015 and "to address handling of coke before U. S. Steel constructed the conveyor system to receive coke directly from the heat recovery coke production facility built by Gateway." SR 0046.

175. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, and 35 Ill. Adm. Code 201.152* and 201.160(a). SR 0045. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past

compliance history. 415 ILCS 5/39(a); SR 0078 – SR 0079. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include information concerning processes to which the emission unit or air pollution control equipment is related. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083.

176. The issues raised by Denial Point 11 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0498 – 0499; SR 0340 – 0341.

177. As discussed in U. S. Steel's comments, the Permit Application included all required information. SR 0341. Further, Illinois EPA's characterization of these baseline emission rates as "corrected" is erroneous because these "are the values presented in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. U. S. Steel made no change to these values and is not in possession of information that would allow such change." *Id.* "In light of Illinois EPA's acceptance of and reliance on these values during that prior permitting action," no further justification was needed. *Id.*

178. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

179. Therefore, the Agency's final decision to deny the Application based upon this

Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

xii. Denial Point 12: The requested changes to the grouping of units in the permit for consistency with the groupings of units in the CAAPP Permit would not address all differences in the groupings of units

180. The Agency's twelfth Denial Point claimed that the requests in the Permit Application to change the grouping of units to be consistent with the CAAPP Permit were inappropriate. SR 0047.

181. The Agency explained that, in the Application, U. S. Steel requested changes to the Permit because the areas or sections of the CAAPP permit in which certain emission units are addressed are not the same as those in the Permit. SR 0047. Most significantly, in the Permit, "discrete material handling and processing operations are addressed with the units with which they are associated" but in the CAAPP Permit, the operations are addressed in a separate section of the permit. *Id.* The Agency conceded that "it is reasonable" for the Permit to be revised so that the placement of units is the same as their placement in the CAAPP Permit, but the Agency had several concerns about the changes proposed to the Permit to accomplish this. *Id.* The Agency concluded that the Permit Application did not request all revisions that would be appropriate to the Permit and the CAAPP Permit because for "certain units, the application would not address differences in where the units are addressed by the two permits and the related emission standards and requirements that may apply to those units" and, as to the naming of units, the requested change was "improper as well as unnecessary." SR 0048. According to the Agency, if the Permit were revised with the placement of units in the permit shifted as requested in the Application, Integrated

Processing would be precluded because the revision of the Permit would allow discrepancies or errors in the provisions for certain units in the current CAAPP permit to be perpetuated by the amendments to the CAAPP permit." *Id.*

182. Illinois EPA identified three separate issues for this Denial Point: (1) requested changes for the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)"; (2) the absence of a request for revisions for the "Deslagging Station and Material HS"; and (3) the absence of any requests for changes for "Ladle Drying/Preheating." SR 0048 — 0051.

183. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v), and 35 Ill. Adm. Code 201.152 and 201.160(a). SR 0047. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable

requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include information concerning processes to which the emission unit or air pollution control equipment is related. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083.

184. The issues raised by Denial Point 12 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0510 - 0513; SR 0352 - 0354

185. With respect to requested changes for the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)," U. S. Steel explained that, regardless of naming convention, this item was properly characterized as an emission point, not an emissions unit. SR 0352. The only condition in the Permit that applies to this emission point "is a particulate matter emission limit of 12.8 tons per year, which applies solely to the emission point and not separately to 'the equipment or activities that generate emissions.'" *Id.* Any uncaptured emissions from that equipment or activities are routed to atmosphere through the Basic Oxygen Furnace Shop Roof Monitor, and those emissions are subject to the separate emission limits for the item referenced as

"BOF Roof Monitor." *Id.* This is consistent with the overall structure of the Permit, which was issued by Illinois EPA many years prior to U. S. Steel's ownership, and in which the emission limits for non-fugitive emissions are applicable to emission points (e.g., "Casthouse Baghouse," "Iron Spout Baghouse," "BOF ESP Stack") rather than emissions units. *Id.* A similar change to the item naming was effected by Illinois EPA in 2013 when issuing the CAAPP permit, where the Agency referred to this emission point (the item to which the emission limit of 12.8 tons per year is applicable) as "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)." SR 0353. Notably, the "list of the equipment and activities that would be covered by this new term" (i.e., Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility) is exactly the same as the list of the equipment and activities that are currently covered by the term "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" in the Permit and by the term "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)" in the CAAPP permit. *Id.* Thus, U. S. Steel requested only discrete changes to the Permit, "none of which related to reconfiguring the equipment and activities venting to this emission point." *Id.*

186. With respect to the absence of a request for revisions for the "Deslagging Station and Material HS," contrary to the Agency's claim, U. S. Steel did request a non-substantive change to the "Deslagging Station and Material HS" by indicating in the Permit Application that this item should be renamed as "Baghouse 1 for Material Handling." SR 0353. This request was made because: (1) renaming this item based on the emission point rather than the emitting activity is more consistent with the naming convention generally used in the Permit; and (2) the historical naming of this item is misleading because this baghouse does not serve to control emissions from any slag removal operation (the steel slag removal station is not served by any capture system or baghouse). *Id.* This requested renaming is consistent with Attachment 3 of the CAAPP Permit,

which refers to this item as "Baghouse #1." *Id.* at 0354. Moreover, contrary to the Agency's claim, U. S. Steel has not claimed that the slag removal station should not appropriately be categorized as slag skimming nor that it should not be addressed with the other slag skimming operations in the basic oxygen furnace shop. *Id.*

187. As to the absence of any requests for changes for "Ladle Drying/Preheating," U. S. Steel denies that there was any requirement "to maintain consistency with the approach to these units in the CAAPP permit" as claimed by the Agency. SR 0354.

188. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

189. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision that the Board should review and reverse.

xiii. Denial Point 13: The 2022 Application does not request revisions to permit 95010001 and, indirectly, to the CAAPP Permit that would also be necessary as this Application requests that the revised permit prescribe emission factors for certain units

190. The Agency's thirteenth Denial Point claims that because the Permit Application requests establishment of prescribe emission factors for certain units, U. S. Steel also needed to request certain revisions to the Permit to ensure consistency with the CAAPP Permit. SR 0052.

191. The Agency argued that the Permit Application did not request that the revision to the Permit add conditions describing how compliance with annual emission limitations is to be determined. *Id.* If it were not stayed, Condition 5.13 of the CAAPP Permit would address the general procedures for how compliance with limitations on annual emissions set by the Permit is

to be determined, and that condition would generally require that compliance with limitations on annual emission be determined using "appropriate emission factors." *Id.* The condition, however, does not address or provide for use of prescribed factors or methodology to determine compliance with limitations on annual emissions, as is being requested by the Permit Application. *Id.* The Agency concluded that if a revised version of the Permit were issued that provided for use of prescribed emission factors and methodology without conditions describing how compliance with limitations for annual emissions in the Permit is to be determined, then the limitations on annual emissions in the revised permit would not be enforceable as a practical matter. *Id.* CAAPP Condition 5.13 cannot be relied upon because, in addition to being stayed, it only provides for use of appropriate emission factors and does not provide for the use of prescribed emissions factors or prescribed emission determination methodologies. *Id.* Further, with no request for conditions addressing how compliance with limitations on annual emissions is to be determined, the Agency contended that the Application does not show that the criteria for Integrated Processing are met. *Id.*at 0052 – 0053. "That is, the 2022 application would not show that the request for a revised permit would provide for compliance requirements substantially equivalent to those provided for by the CAAPP since the application does not request that the revised permit include requirements substantially equivalent to those that would have been provided by CAAPP Condition 5.13 if it were not stayed." *Id.*

192. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code 201.160(a). SR 0052. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to

issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant, upon becoming aware of a failure to submit relevant facts or upon submittal of incorrect information, shall submit supplementary facts or correct information. 415 ILCS 5/39.5(5)(i); SR 0079 – 0080. Section 39.5(7)(a) of the Act provides that CAAPP permits shall contain limitations and conditions and terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) provides that the Agency shall issue a CAAPP permit if all conditions are met, including that the Agency has received a complete application. 415 ILCS 5/39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment," which includes a permit revision that incorporates into the CAAPP permit the requirements "from preconstruction review permits provided the program meets procedural and compliance requirements substantially equivalent to those contained in this Section." 415 ILCS 5/39.5(13)(10)(c)(v); SR 0081. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083.

193. The issues raised by Denial Point 13 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0510; SR 0351 – 0352.

194. As discussed by U. S. Steel, the Agency's position is incorrect because U. S. Steel requested that the Permit be subject to "integrated processing," which requires Illinois EPA to process the Permit Application and draft the Permit using a program that "meets procedural and compliance requirements substantially equivalent to those" imposed in the CAAPP program. SR 0351. "Although this request was stated generally, and the permit application did not specify with precision the monitoring and recordkeeping requirements to be imposed in the revised construction permit and the amended CAAPP permit, that approach is appropriate." *Id.* It is the Agency's responsibility under the Act to draft monitoring and recordkeeping requirements in permits. Further, the request for integrated processing inherently requested that Illinois EPA include in the Permit the minimum elements of the CAAPP permit, including provisions to assure compliance with emission limits, and to remove or revise conflicting or redundant permit terms. *Id.* at 0352.

195. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

196. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's decision involved a discretionary decision and an important policy consideration that the Board should review and reverse.

xiv. Denial Point 14: The 2022 Application does not address the amendment to the CAAPP Permit authorized by Construction Permit 11050006, as is relevant for the requested integrated processing of the revision to Permit 95010001

197. The Agency's fourteenth Denial Point claims that the Application was not accompanied by a request or application for an administrative amendment to incorporate changes

to the CAAPP Permit 96030056 that are authorized by Construction Permit 11050006 issued on April 1, 2013. SR 0054; *see* SR 0054 – 0056; *see* SR 0274 – 0277.

198. Specifically, the Agency contended that the Application does not identify the version of the CAAPP permit for the facility that would be eligible for administrative amendment pursuant to Integrated Processing. *Id*. The Agency states that this is relevant because Illinois EPA has already issued a construction permit with Integrated Processing to U. S. Steel – Construction Permit 11050006 (issued on April 1, 2013). SR 0055.

199. The Agency stated that Construction Permit 11050006 addresses the baghouse control system installed on the basic oxygen furnaces to improve control of the particulate emissions of the furnaces from charging and tapping. SR 0054. The Agency contended that "[c]ertain work practices that were required by Permit 95010001 for control of particulate emissions of the furnaces with only an ESP system conflicted with the use of the baghouse system or would no longer be appropriate when emissions were also controlled with the new system. To address the fact that these work practices were also present in the CAAPP permit for the facility, Construction Permit 11050006 was subject to Integrated Processing and allowed certain changes to be made to the CAAPP permit by administrative amendment." SR 0055.

200. The Agency stated that U. S. Steel has not initiated a revision to the CAAPP permit to incorporate the changes by submitting an application for administrative amendment of the CAAPP permit. *Id*. The Agency cites to Section 39.5(13)(a) of the Act, which provides that the Agency "shall take final action on a request for an administrative permit amendment within 60 days after the receipt of the request." SR 0055 – 0056 (citing to 415 ILCS 39.5(13)(a)). The Agency stated that, absent the administrative amendment, the Application effectively requests that Illinois EPA reissue a CAAPP permit that contains provisions that are no longer accurate as related

to the basic oxygen furnaces. *Id.* Additionally, the Agency argued that, as to Integrated Processing, there are effectively two version of the CAAPP Permit – one is the CAAPP Permit currently in effect and the other is an amended version of the CAAPP Permit that would take effect if and when U. S. Steel submits its application for administrative amendment. SR 0275.[7]

201. The Agency also stated that, absent a formal request to initiate the administrative amendment of the CAAPP Permit contemplated by Construction Permit 11050006, the Application can only request Integrated Processing to allow administrative amendments of the current CAAPP Permit. SR 0055 – 0056.

202. The issues raised by Denial Point 14 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0513 – 0514; SR 0355.

203. The Application includes all required information relating to identification of the CAAPP Permit to be administratively amended following Integrated Processing of the Construction Permit Application. SR 0355; SR 0513.

204. Neither the Act nor the Board's regulations require an application for a construction permit, even one with a request for Integrated Processing, to specify the version of the CAAPP permit for the facility that should be amended. SR 0355; SR 0513. It is the Agency's responsibility to make revisions and amendments to CAAPP permits in conformance with applicable rules and laws. *Id.*

205. Regarding incorporating the provisions of Construction Permit 11050006 into the facility's CAAPP Permit, U. S. Steel submitted an application to renew its CAAPP Permit in November 2013. SR 0355. In the 2013 application, U. S. Steel expressly requested that Illinois

[7] The Agency also contended that drafting the revisions to the Permit as requested must be done so that the amendments to the CAAPP Permit that it authorizes can take place seamlessly. SR 0275. While U. S. Steel acknowledges the Agency's discussion on the need for forethought and advance planning in preparing a revised version of the Permit (SR 0275), this discussion does not stand as a basis to deny the Permit.

EPA incorporate the conditions of Construction Permit 11050006 into the CAAPP Permit and also noted that the BOF process described in the CAAPP Permit needs to be updated as to Condition 7.5 with regard to the new secondary baghouse added as part of the Emission Reduction Project. SR 0355; SR 0513 – 0514. Such application as deemed completed by operation of law pursuant to 39.5(5)(f) of the Act. SR 0355; see 415 ILCS 5/39.5(5)(f) ("Unless the Agency notifies the applicant of incompleteness, within 60 days of receipt of the CAAPP application, the application shall be deemed complete."). The Agency retains the authority to request additional information in conjunction with a CAAPP permit application but has not done so. *Id*. (citing to 415 ILCS 5/39.5(g) which states: "If after the determination of completeness the Agency finds that additional information is necessary to evaluate or take final action on the CAAPP application, the Agency may request in writing such information from the source with a reasonable deadline for response.").

206. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, 39(a)**, and 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code 201.160(a). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section

201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. However, as explained above, neither the Act nor the Board's regulations require an application for a construction permit, even one with a request for Integrated Processing, to specify the version of the CAAPP permit for the facility that should be amended. SR 0355; SR 0513. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. However, as explained above, the Application includes all required information relating to identification of the CAAPP Permit to be administratively amended following Integrated Processing of the Construction Permit Application. SR 0355; SR 0513.

207. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

208. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that an applicant for a construction permit revision with Integrated Processing must specify the version of the CAAPP permit for the facility that should be amended involves an important policy consideration that the Board should review and reverse.

xv. Denial Point 15: The 2022 Application would not clarify the relationship between fugitive dust control measures required by Permit 95010001 and measures required by 35 IAC 212 Subpart K

209. The Agency's fifteenth Denial Point claims that, as "related to practices to reduce emissions of fugitive dust from roadways, parking areas and open areas at the Granite City Works and certain public roadways near this facility, the 2022 application does not propose revisions to clarify the interplay between the associated recordkeeping and reporting that are required by Permit 95010001 and the associated recordkeeping and reporting that are required by Board rules." SR 0057; *see* SR 0057 – 0059; *see* SR 0277 – 0279.

210. The Agency contended that, for roadways, parking areas and other open areas, the amended CAAPP permit would not clearly delineate the standards for opacity of emissions pursuant to the Board rules that apply to the different categories of emission units. SR 0057 – 0058. The Agency also contended that an amended CAAPP as requested would perpetuate errors in the current CAAPP Permit regarding applicability of Board rules because it is the Agency's position that the requirements of 35 Ill. Adm. Code 212.316 should not be applied to public roadways. *Id.*

211. Specifically, the Agency claimed that, except for Condition 25, Permit 95010001 does not address the Board's rules for control of fugitive dust emissions. SR 0057. Additionally, the Agency stated that, while the CAAPP Permit addresses requirements for control of fugitive dust, it is unclear whether the requirements for recordkeeping and reporting in 35 Ill. Adm. Code 212.316(g) are applicable for the public roadways for which specific measures to reduce emissions of fugitive dust are required by the Permit. *Id.* The Agency cited Condition 7.13.9(a) of the CAAPP Permit, which contains the requirement for Section 212.316(g) without further elaboration on whether public roads are subject to such a requirement. *Id.* The Agency contended that, via Condition 5.3.2(c)(ii) addressing the overall source conditions and applying the requirements in Sections 212.309, 212.310, and 212.312, the CAAPP permit indirectly indicates that the requirements of Section 212.316(g) also apply to the subject public roadways. *Id.* The Agency contended that the Permit does not currently deal with regulatory requirements for fugitive dust and, as such, an issue exists because Integrated Processing of a revision of the Permit requires that the compliance procedures in the revised permit be consistent with those required by the CAAPP permit. SR 0058 – 0059.

212. The Agency stated that the Application does not make clear the relationship between the requirements established by the permit as to fugitive dust in Conditions 23, 24, 26, 27, 28, 29, and 30 of the Permit and state regulatory requirements for fugitive emissions in Part 212 Subpart K. SR 0058. The example that the Agency provided is Condition 29 requires daily recordkeeping for the implementation of required measures for on-site dust control, but does not address the relationship between these records and the recordkeeping required by Section 212.316(g)(2). *Id.*

213. The issues raised by Denial Point 15 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0514; SR 0355 – 0356.

214. The Agency contends that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, 39(a)**, and 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code 201.160(a). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received

additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – SR 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083.

215. However, an application for a construction permit, even one with a request for Integrated Processing, is not required to specify the relationship between exiting permit terms and applicable rule requirements. SR 0355; SR 0514. It is Illinois EPA's responsibility to draft a permit with conditions that the Agency judges to be suitable and appropriate and in conformance with applicable rules and laws. Therefore, this Denial Point cannot be a basis for denial of the Application. *Id.*

216. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

217. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that an applicant for a construction permit revision with Integrated Processing must specify the relationship between existing permit terms and applicable rule requirements involves an important policy consideration that the Board should review and reverse.

xvi. Denial Point 16: The 2022 Application does not address changes to the CAAPP Permit that are needed due to revisions to 40 CFR 63 Subpart FFFFF as could be expedited by integrated processing of Permit 95010001

218. The Agency's sixteenth Denial Point claims that the Application does not address or identify changes to Permit 95010001, or by means of Integrated Processing changes to CAAPP Permit 96030056, that are appropriate as a result of certain revisions to the Iron and Steel National Emission Standards for Hazardous Air Pollutions ("NESHAP"), 40 CFR 63 Subpart FFFFF. SR 0060; *see* SR 0060 – 0061; *see* SR 0280 – 0283.

219. The Agency stated that the revisions to the Iron and Steel NESHAP, which took effect in January 2022, provide that the emissions standards under the NESHAP apply at all times (i.e., removing start up, shutdown, and malfunction exemption provisions). SR 0060.

220. The Agency contended that the provisions of the Iron and Steel NESHAP are "relevant to Permit 95010001 as it directly or indirectly relies on these rules for the compliance procedures that accompany the permit limitations for the particulate emissions of the NESHAP-subject units, as needed to make those limitations enforceable as a practical matter." *Id.* Specifically, the Agency stated:

> For the BOFs, Permit 95010001 directly relies on 40 CFR 63 Subpart FFFFF as Condition 9 refers to applicable provisions of 40 CFR 63 Subpart FFFFF for the work practices, opacity limits, operational limits, emission testing, operational monitoring, recordkeeping and reporting that are required. For the blast furnace casthouse and units other than the BOFs that are subject to 40 CFR 63 Subpart FFFFF, the applicable compliance provisions of this NESHAP are currently indirectly relied upon as those requirements are addressed in the CAAPP permit for the facility. (For the BOFs, the CAAPP permit also addresses the applicable compliance procedures of 40 CFR 63 Subpart FFFFF.)

Id.

221. The Agency's position is that, absent recognition of these recent revisions in the Application, the version of CAAPP Permit 96030056 that would be authorized by means of

Integrated Processing could continue to reflect the historic version of the Iron and Steel NESHAP. *Id*.

222. The issues raised by Denial Point 16 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0514 – 0515; SR 0356.

223. Illinois EPA may adjust CAAPP permit terms to assure compliance with all applicable requirements. *See* 415 ILCS 5/39.5(15)(a)(iv); SR 0356; SR 0515.

224. Further, the applicable requirements of the Iron and Steel NESHAP as currently codified are legally enforceable, and the monitoring, testing, recordkeeping, and work practice requirements provide a sound technical basis for demonstration of compliance with the particulate matter emission limits. SR 0356; SR 0515; 85 Fed. Reg. 42074 (July 13, 2020). This is so regardless of whether Illinois EPA adjusts the CAAPP Permit to assure compliance with all regulatory requirements. *Id*. Moreover, the recent NESHAP Subpart FFFFF revisions are not related to the Project and, thus, U. S. Steel was under no obligation to address them in the Application.

225. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code 201.160(a). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – SR 0079. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate

the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. As to these provisions, U. S. Steel is not required by the Act or regulations to include suggested bases upon which Illinois EPA may revise the facility's CAAPP Permit. SR 0356; SR 0515. As such, neither the Act nor Board regulations would be violated if the revised Permit was issued as required as to this point. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. As to these provisions, as explained above, Illinois EPA may revise a CAAPP permit to assure compliance with all applicable requirements. *See* 415 ILCS 5/39.5(15)(a)(iv); SR 0356; SR 0515.

226. Moreover, the Agency contends that this Denial Point is not based on a deficiency in Permit 96030056 in that the Application does not show that the Project-affected emissions units that are subject to NESHAP Subpart FFFFF would be required to comply with the current

requirements of the Subpart FFFFF rules, rather than with the provisions of Permit 95030056. SR 0281 – 0282. The Agency further states that the Application does not request revisions to the Permit or administrative amendments to the CAAPP Permit by means of Integrated Processing that would provide that the Project-affected units subject to NESHAP Subpart FFFFF must comply with the current requirements of the federal regulations. *Id.* U. S. Steel does not disagree with Illinois EPA's observation regarding the relevance of the NESHAP requirements. SR 0515. However, the Application was submitted by U. S. Steel for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NNSR applicability evaluations relating to the Project implemented by National Steel Corporation. U. S. Steel did not intend for the Application to address changes that are not directly relevant to this purpose, and neither is U. S. Steel obligated to address all potential unrelated changes. SR 0357; SR 0515 – 0516.

227. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

228. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that an applicant for a construction permit revision with Integrated Processing must include suggested bases upon which the Agency might reopen the facility's CAAPP permit involves an important policy consideration that the Board should review and reverse.

xii. Denial Point 17: The 2022 Application does not address changes to the CAAPP Permit that have resulted from shutdown of emission units, as is relevant for the requested integrated processing of the revision to Permit 95010001

229. The Agency's seventeenth Denial Point claims that the Application "does not identify or address changes to the CAAPP Permit for the facility (Permit 96030056) that result from the permanent shutdown of certain emission units at the facility" as a revision to Permit 05010001 to be issued with Integrated Processing. SR 0062; see SR 0062 – 0064; SR 0283 – 0285.

230. The Agency contended that U. S. Steel did not take other action to initiate issuance of a revision to CAAPP Permit 96030056 that would remove provisions concerning emission units that are now permanently shutdown, such as the two by-product coke oven batteries that were permanently shut down in 2015. SR 0062.

231. The Agency's position is that, because the Application did not include the information or take other appropriate action as identified above, the Application does not include the necessary information to enable a revision to Permit 95010001 to be issued with Integrated Processing because the Application would not show that such a revision to Permit 95010001 would meet the criteria for Integrated Processing. SR 0062.

232. The Agency stated that the Application "would not show that the revisions to Permit 95010001 would provide for procedural and compliance requirements to Permit 96030056 that are substantially equivalent to those provided for by the CAAPP. The application would not support subsequent amendment of Permit 96030056 by means of Integrated Processing that would remove provisions for units that are now shutdown." SR 0062. The Agency contended that Integrated Processing of a construction permit allows only for subsequent amendments to a CAAPP permit as provided for by the construction permit and that the Agency does not have authority to revise a

CAAPP permit to remove provisions for units that are now shut down but are not otherwise the subject of the construction permit. *Id.*

233. The Agency claimed that, while the Application states that the by-product coke ovens at the facility have been shut down, the Application needs to separately address the consequences for the current CAAPP permit (in addition to the shutdown of coal and coke handling operations, the coke by-product plant, the handling of coke by-products, possibly certain wastewater treatment processes, and the use of coke oven gas). *Id.*

234. The issues raised by Denial Point 17 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0515 – 0516; SR 0356 – 0357.

235. Neither the Act nor the Board's regulations require an application for a construction permit revision, even one for which Integrated Processing is requested, to request changes to the CAAPP permit other than those directly resulting from the requested revisions of the underlying construction permit. SR 0357; SR 0515. It is the Agency's responsibility to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws. *Id.*

236. The Application was submitted by U. S. Steel for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NNSR applicability evaluations relating to the Project implemented by National Steel Corporation. U. S. Steel did not intend for the Application to address changes that are not directly relevant to this purpose. SR 0357; SR 0515 – 0516.

237. Additionally, the application to renew the CAAPP permit was submitted in November 2013, and that application was deemed complete pursuant to Section 39.5(5)(f) of the

Act. *Id.* The Agency has not requested additional information in conjunction with the CAAPP permit application. *Id.*

238. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 39(a)*, 39(a)**, and 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code 201.160(a). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. As to these provisions, neither the Act nor the Board's regulations require an application for a construction permit revision, even one for which Integrated Processing is requested, to request changes to the CAAPP permit other than those directly resulting from the requested revisions of the underlying construction permit. As such, there would be no violation of the Act or regulations if the revised Permit was issued as requested. SR 0357; SR 0515. Section 39.5(5)(i) of the Act provides that an applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in an application for a CAAPP permit shall, upon becoming aware of such failure or incorrect

submittal, submit supplementary facts or correct information. 415 ILCS 39.5(5)(i); SR 0079. Section 39.5(7)(a) of the Act provides that all CAAPP permits must contain limitations and conditions and other enforceable terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) of the Act provides that the Agency shall issue a CAAPP permit, modification, or renewal if all the referenced conditions are met, including that the Agency has received a complete application and, if necessary, has requested and received additional information. 415 ILCS 39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment." 415 ILCS 5/39.5(13)(c)(v); SR 0081. The Application was submitted by U. S. Steel for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NNSR applicability evaluations relating to the Project implemented by National Steel Corporation. SR 0357; SR 0515 – 0516.

239. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

240. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that an applicant for a construction permit revision with Integrated Processing must address changes to the facility's CAAPP permit other than those directly resulting from the requested revisions of the underlying construction permit involves an important policy consideration that the Board should review and reverse.

xiii. Denial Point 18: The evaluation of Best Available Control Technology ("BACT") in the 2022 Application for CO is not sufficient and does not adequately support U. S. Steel's proposal for BACT

241. The Agency's eighteenth Denial Point claims that the Application addresses BACT for CO from the casthouse; but the BACT evaluation is not sufficient because it does not show that BACT, other than add-on control devices, were considered. SR 0065; *see* SR 0065 – 0068; *see* SR 0144 – 0157. The Agency also contended, for the blast furnace stoves, the Application does not include supporting information, such as diagrams and cost data, to support the claim that it is not feasible to conduct emission testing. SR 0065. For both, the Agency contends that the Application does not include descriptions or documentation for the investigations that were conducted into available options for CO control. SR 0065. The Agency claimed therefore that the Application cannot be relied upon to conclude that BACT is utilized for CO for the casthouse and blast furnace stoves or for the Agency to set appropriate requirements as BACT for CO in revising the Permit. SR 0065.

242. As to the CO emission from the casthouse, the Agency stated that the Application only identifies add-on control options and does not identify other process-related control options, such as work practices, or explain why process-related control options are not available. SR 0066. The Agency contended that a determination of BACT must consider options to control or reduce emissions of an emission unit besides add-on control devices. SR 0066 (citing to 42 U. S.C. 7479(3)).

243. As to the CO emissions from the blast furnace stoves, the Agency stated that information such as diagrams and cost are necessary if the BACT for CO is not a numerical standard. SR 0065. The Application proposed that BACT reflect certain good combustion practices for CO. SR 0067. The Agency argued that additional support is needed to support the

claim that measurement or testing of emissions of the blast furnace stoves is infeasible. SR 0067 – 0068.

244. As for the lack of documentary support for the review of available control options, the Agency contended that this is appropriate and necessary for both the casthouse and stoves because BACT determinations for the CO emissions of blast furnace casthouses and blast furnace stoves are uncommon. SR 0067; SR 0067, fn. 77. The Agency stated that BACT evaluations commonly include copies of information from the RBLC that is potentially relevant and further explanation is also provided if some information is not considerable applicable to the units at issue. SR 0067.

245. The issues raised by Denial Point 18 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0487 – 0490; SR 0327 – 0330.

246. The Application includes estimates of the CO emissions from the casthouse and the blast furnace stoves and includes a detailed description of the systems of continuous emission reduction that U. S. Steel proposed to control these emissions in accordance with 35 Ill. Adm. Code 204.810(a)(3). SR 0488; SR 0327; SR 0601 – 0958. However, as described above, the Agency contends that the Application does not include other information necessary to determine that BACT would be applied. As explained below, U. S. Steel has met any BACT obligations in relation to CO emissions from the casthouse and blast furnace stoves.

247. First, as to the CO emissions from the blast furnace casthouse, U. S. Steel was not required to include a BACT analysis as to these emissions in its Application. SR 0328; SR 0488 – 0489. U. S. Steel voluntarily provided a proposed BACT analysis for these emissions at the request of Illinois EPA. *Id.* U. S. Steel was under no obligation to do so because the Application

does not request any changes to its current permits relating to CO emissions from the casthouse. SR 0488; SR 0328; SR 0601 - 0958. "There is no obligation to apply [BACT] in the abstract." *U. S., et al. v. Midwest Generation, LLC, et al*., 781 F. Supp. 2d 677, 690 (N.D. Ill. 2011). BACT requirements are not freestanding but are imposed in the pre-construction permit process. *Id*. The Northern District of Illinois explained that "[i]n the absence of such a permit, they do not exist." *Id.* As such, U. S. Steel's obligations are limited to those requests addressed in the Application.

248. Additionally, as to the CO emissions from the blast furnace casthouse, the only control options identified by U. S. Steel for potential consideration in a BACT determination by the Agency are add-on air pollution control equipment options (installation and use of a capture system and some type of incinerator). SR 0488; SR 0327; SR 0601 – 0958. U. S. Steel conducted a literature search, which did not identify any process-related control option for CO emissions from blast furnace casthouses. SR 0488; SR 0327. As such, U. S. Steel is not required to explain why process-related control options are not available because the literature did not identify any. *Id*.

249. Moreover, the Agency is familiar with the chemical reaction that is forced to occur in the casthouse as an inherent part of the ironmaking process and the Agency did not submit a request for additional information to U. S. Steel. SR 0488; SR 0327 (citing to the Agency's Statement of Basis for the 2013 revised CAAPP permit, wherein the Agency explains the ironmaking process); SR 1396 – 1401. U .S. Steel did not receive a request from the Agency for specific additional information and, as such, U. S. Steel could not know that it needed to explain that partial combustion of coke inevitably yields CO as a reaction product. SR 0328; SR 0488.

250. Additionally, U. S. Steel did not attach documentary support for why process-related control options are not available because its literature search did not identify any process-

related control options available. SR 0327 – 0328; SR 0488 – 0489. U. S. Steel is not required by 35 Ill. Adm. Code 204.810(a)(3) to attach documentation that contain no pertinent information. *Id*.

251. As to the CO emissions from the blast furnace stoves, in the 1995 permit application, National Steel Corporation proposed that BACT for CO emissions for the blast furnace stoves is maintenance of good combustion practices. SR 0489; SR 0328; SR 1942 – 2173; *see* SR 2174 – 2219. As described in the Application, this determination is consistent with the PSD requirement that a permit prescribe work practices to satisfy the BACT requirement where the permitting authority "determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible." SR 0489; SR 0328 (citing to 35 Ill. Adm. Code 204.280); SR 0601 – 0958; SR 1942 – 2173. When issuing permits in 1996 and 2013, Illinois EPA reviewed this BACT proposal and agreed with it. SR 0489; SR 0328; SR 1278 – 1308; SR 2179; *see, generally* SR 1395 - 1442.

252. U. S. Steel explained in detail in the Application why numeric emissions limits were not proposed, explaining that direct measurement of emissions by use of USEPA reference methods, is not feasible for the fuel emission units at issue. SR 0489; SR 0329; SR 0601 - 0958. U. S. Steel detailed the lack of sampling port in the stack and challenges to installing a sampling port. *Id*. The cited statutory and regulatory provisions do not require more specific information. SR 0329 – 0330; SR 0490.

253. Additionally, the information included in the Application is more detailed than the information in the application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA in issuing Permit No. 95010001 in 1996. SR 0490; SR 0330.

254. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9(b)(2), 9.1(d), 39(a)*, 39(a)**, and 39(a)***, and 35 Ill. Adm. Code 201.152*, 201.152***, 201.160(a), 204.280, 204.330, 204.810, 204.820, and 204.1100(c). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9(b)(2) of the Act provides the prohibition against violating conditions that are imposed by air permits. 415 ILCS 5/9(b)(2); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include information concerning processes to which the emission unit or air pollution control equipment is related, and the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. As to these provisions, there will be no violations of the Act or Board regulations if the Permit is issued as requested because, as explained above, U. S. Steel has met any BACT obligations in relation to CO emissions from the casthouse and blast

furnace stoves. Section 204.280 of the Board's regulations provides the definition of "Best Available Control Technology." 35 Ill. Adm. Code 204.280; SR 0087. Section 204.330 of the Board's regulations provides the definition of "complete." 35 Ill. Adm. Code 204.330; SR 0087. Section 204.810 of the Board's regulations provides, in part, that a PSD permit application must include, if a determination of BACT is required, a detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that BACT would be applied. 35 Ill. Adm. Code 204.810; SR 0089. As explained above, these items were included in the Application – the necessary information was included and addressed. Section 204.820 of the Board's regulations provides that "[a]ny owner or operator who constructs or operates a source or modification not in accordance with the application submitted under this Part or with the terms of any approval to construct . . . shall be subject to appropriate enforcement action." 35 Ill. Adm. Code 204.820; SR 0089. Section 204.1100(c) of the Board's regulations provides that a major modification must apply BACT for each regulated NSR pollutant for which it would result in a significant net emissions increase at the source. 35 Ill. Adm. Code 204.1100(c); SR 0090. As explained above, U. S. Steel has met any BACT obligations in relation to CO emissions from the casthouse and blast furnace stoves.

255. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

256. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial.

xix. Denial Point 19: The Application does not address BACT for SO_2 and CO from use of coke oven gas (COG) in the blast furnace stoves

257. The Agency's nineteenth Denial Point claims that the Application "does not include demonstrations of BACT for sulfur dioxide (SO_2) and CO from the burning of coke oven gas (COG) in Project-affected fuel burning units." SR 0069; *see* SR 0069 – 0070; *see* SR 0144 and SR 0157 – 0160. The Agency states that, absent such information, the Application does not allow a revision to the Permit to be issued for the Project that considers baseline emissions from burning COG. SR 0069.

258. The Agency contended that, because the Application addresses SO_2 and CO emissions from the use of coke oven gas as fuel in the blast furnace stoves, the Application must also address BACT for SO_2 and CO as applied to use of coke oven gas as fuel in the stoves since SO_2 and CO are pollutants for which the Project is a major modification subject to PSD. SR 0069 – 0070.

259. The Agency stated that, "[i]f emissions from burning of COG are to be relied upon for the issuance of a revised permit, the 2022 application must also address the BACT requirements of PSD for the SO_2 and CO emissions from use of COG, as would have been applicable in 1996, when the Project commenced . . . . PSD would be violated if a revised permit were issued for the Project based on revised NSR applicability analyses that considered use of COG, as contained in the 2022 application, absent demonstrations that the Project utilized BACT for emissions of SO_2 and CO from use of COG." SR 0069.

260. The Agency argued that, because the Application does not address BACT as explained above, the Application does not demonstrate that prior to February 2015 (when the by-product recovery coke oven batteries were shutdown and coke oven gas ceased to be available),

BACT was being utilized for the SO_2 and CO emissions from the use of coke oven gas in the blast furnace stoves. SR 0070.

261. Additionally, the Agency stated that the Application does not state that it was no longer necessary to address CO emission from the use of coke oven gas as of February 2015 since coke oven gas was no longer available. SR 0070.

262. The issues raised by Denial Point 19 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0490 – 0491; SR 0030.

263. The deficiency alleged by the Agency relates to a historical issue – emissions from the burning of COG, which was only available when the by-product recovery coke batteries were in operation prior to their shutdown in 2015. SR 0330; SR 0490 – 0491. The Agency asserted that the Application must address BACT for this historical issue since the Application addresses emissions from burning of coke oven gas. *See* SR 0069.

264. However, U. S. Steel is under no statutory or regulatory obligation to address such historical issues in the Application. *See* SR 0330; *see* SR 0490 – 0491. A source owner's obligations with respect to BACT are limited to those imposed in a PSD permit. *See U. S., et al. v. Midwest Generation, LLC, et al*., 781 F. Supp. 2d 677 (N.D. Ill. 2011); s*ee U. S., et al. v. Midwest Generation, LLC, et al*., 694 F. Supp. 2d. 999 (N.D. Ill. 2010). In relation to the BACT requirements, the Court explained that "[t]here is no obligation to apply 'best available control technology' in the abstract.'" *U. S., et al. v. Midwest Generation, LLC, et al*., 781 F. Supp. 2d 677, 690 (N.D. Ill. 2011). BACT requirements are not freestanding but are imposed in the pre-construction permit process. *Id*. The Court explained that "[i]n the absence of such a permit, they do not exist." *Id.* As discussed above, while the case addressed the issues of continuing PSD

violations in an enforcement context, the Court's discussion of PSD and BACT requirements is relevant to the permitting context.

265. Here, U. S. Steel's BACT obligations are limited to those exiting operations addressed in the Application. SR 0330; SR 0490 – 0491. U. S. Steel is not required to address BACT obligations for an operation that is no longer in use at the facility, i.e., burning of COG. *Id*.

266. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9.1(d), 39(a)*, 39(a)**, and 35 Ill. Adm. Code 201.152*, 201.152***, 201.160(a), 204.280, 204.330, 204.810, and 204.1100(c). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides, in part, that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; and the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act. 415 ILCS 5/39(a); SR 0078 – SR 0079. Section 201.152 of the Board's regulations provides, in part, that construction permit applications must include information concerning processes to which the emission unit or air pollution control equipment is related, and the nature, points of emissions, and quantities of emissions (uncontrolled and controlled) at the source. 35 Ill. Adm. Code 201.152; SR 0082. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations.

35 Ill. Adm. Code 201.160(a); SR 0083. Section 204.280 of the Board's regulations provides the definition of "Best Available Control Technology." 35 Ill. Adm. Code 204.280; SR 0087. Section 204.330 of the Board's regulations provides the definition of "complete." 35 Ill. Adm. Code 204.330; SR 0087. Section 204.810 of the Board's regulations provides, in part, that a PSD permit application must include, if a determination of BACT is required, a detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that BACT would be applied. 35 Ill. Adm. Code 204.810; SR 0089. Section 204.1100(c) of the Board's regulations provides that a major modification must apply BACT for each regulated NSR pollutant for which it would result in a significant net emissions increase at the source. 35 Ill. Adm. Code 204.1100(c); SR 0090. As explained above, U. S. Steel's BACT obligations are limited to those exiting operations addressed in the Application. SR 0330; SR 0490 – 0491. U. S. Steel is not required to address BACT obligations for an operation that is no longer in use at the facility, i.e., burning of COG. *Id*. Therefore, issuance of the revised Permit as requested would not result in violations of the Act or regulations or result in air pollution. A determination of BACT was not required for the burning of COG since that is no longer available.

267. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

268. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that an applicant must address BACT for an operation that no longer exists at the facility involves an important policy consideration that the Board should review and reverse.

xx. Denial Point 20: As related to SO_2 emissions from the use of BFG, the 2022 Application is inconsistent with a pending 2008 application

269. The Agency's twentieth Denial Point claims that, "[a]s related to emissions of sulfur dioxide (SO2) from burning blast furnace gas (BFG), the 2022 application is inconsistent with and conflicts with an earlier application for revisions to Permit 95010001 that was received on February 8, 2008 (the '2008 application')." SR 0071; *see* SR 0072; see SR 0128 – 0131.

270. The 2008 application, which was an application for revisions to Permit 95010001, requested increases in the SO_2 emissions from burning of BFG. SR 0071; SR 1443 – 1580. The Agency claimed that the Application did not reference the 2008 application or explain if the revisions to Permit 95010001 requested by the 2008 application as it relates to SO_2 emissions from burning of BFG are still needed. SR 0071 – 0072. The Agency also stated that the Application does not address the 2008 application to explain why the revisions to the Permit requested by the 2008 application are no longer needed. *Id.*

271. The Agency noted that U. S. Steel has not requested withdrawal of the 2008 application and notes that U. S. Steel's approach taken in the Application to SO_2 emissions from burning BFG is different than the approach taken for NOx, VOM, and particulate. SR 0071 – SR 0072.

272. Specifically, the Agency pointed to the 2008 application in which U. S. Steel requested an increase in the SO_2 emission factor limit for BFG from 6.65 to 16.00 pounds/million cubic feet of gas burned, but states that the Application does not request a change for this emission factor limit. SR 0072. The Agency stated that the Application does not show that the revisions to the SO_2 emission limits requested in the 2008 application were in fact not needed at that time. *See* SR 0072.

273. The Agency argued that, absent resolving the conflict between the 2008 application and Application, the Application should not be considered to show compliance with the SO_2 emission limits for burning BFG currently in Permit 95010001. SR 0071 – 0072.

274. The issues raised by Denial Point 20 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0324 – 0325; SR 0485 – 0486.

275. As explained in the comments, the Agency has not acted on the application submitted in 2008. SR 0485; SR 0324; *see* SR 1443 – 1580. U. S. Steel submitted the 2008 application in accordance with a Consent Order between U. S. Steel and Illinois. *See* SR 1581 – 1609 (*State of Illinois v. United States Steel Corporation*, No. 05-CH-750, Third Judicial Circuit (Madison County)); SR 0324 – 0325; SR 0485; *see* SR 1443 – 1580.

276. The 2008 application was based on limited information that was available to U. S. Steel at the time of submittal. SR 0485; SR 0324; SR 1443 – 1580. However, information subsequently gathered by U. S. Steel supports that, when averaged over the year, the emission factor limit in existing Permit 95010001 is appropriate. SR 0485; SR 0324.[8]

277. The Agency noted that U. S. Steel has not withdrawn the 2008 application; however, U. S. Steel cannot withdraw the 2008 application at this time but would do so following issuance of the revised Permit and termination of the Consent Order. SR 0485; SR 0324. Nevertheless, this point cannot be a basis for denial of the Application. SR 0330; SR 0490 – 0491.

278. Furthermore, the Application did not need to show compliance with SO_2 emission limits for burning BFG currently in Permit 95010001 because the Application did not request any changes to the SO_2 emission limits. SR 0325. The Application also did not include demonstrations

[8] It is noteworthy that this topic was discussed with Illinois EPA as the 2020 Application submittal was pending and the Agency did not object to this development at the time. SR 0325; SR 0485.

of compliance with any of the numerous emission limits that apply to the Facility and are unrelated to the present Application. SR 0325. There is no statutory or regulatory obligation requiring that an application for a construction permit include compliance demonstrations for emission limits that are unrelated to the application. SR 0325.

279. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 9(b)(2), 9.1(d), 39(a)*, 39(a)**, 39(a)***, and 35 Ill. Adm. Code 201.160(a). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 9(b)(2) of the Act provides the prohibition against violating conditions that are imposed by air permits. 415 ILCS 5/9(b)(2); SR 0078. Section 9.1(d) of the Act provides the prohibition against violations of Section 165 (PSD) and Section 173 (NNSR) of the Clean Air Act. 415 ILCS 5/9.1(d); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. As explained above, information subsequently gathered by U. S. Steel supports that, when averaged over the year, the emission factor limit at issue here in existing Permit 95010001 is appropriate and, therefore, the increase requested in the 2008 application is no longer needed. As such, because the Facility is in

compliance with the emission factor limit in existing Permit 95010001, there is no potential for air pollution, or violation of the Act or regulations.

280. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

281. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that a construction permit application must address compliance demonstrations for emission limits that are unrelated to the application, involves an important policy consideration that the Board should review and reverse.

xxi. Denial Point 21: As related to emission limits for SO_2, lead and CO, the 2022 Application is inconsistent with pending Board appeals

282. The Agency's twenty-first Denial Point claims that, "[f]or various processes, the 2022 application does not request or propose appropriate changes to the current emission factor limits in Permit 95010001 for SO_2, lead and CO to resolve pending permit appeals (PCB 2013-52 and PCB 2013-62)." SR 0073; *see* SR 0073 – 0075; *see* SR 0125 – 0127.

283. The Agency explained that Permit 95010001 sets emission factor limits for the blast furnace casthouse and the slag pits for SO_2, for the BOF for lead and CO; and for desulfurization and reladling for lead. SR 0073. The Agency contended that the Application "does not indicate that the inclusion of the current emission factor limits in a revised permit is not expected to result in another appeal as to these limits are now considered to be acceptable." SR 0073.

284. Additionally for the BOF for CO, the Agency contended that the Application does not indicate that "the current limit would still be acceptable if it applied in aggregate to the CO emissions from the stack of the ESP and the stack of the baghouse. . . ." SR 0073. The Agency

also claimed that, because the Application does not request that these limits be revised to address all stack emissions of the BOF, that the Application effectively requests a relaxation of the current limits. SR 0075.

285. The Agency argued that, as such, the Application is not consistent with the two permit appeals (PCB 13-53 and PCB 13-62) currently pending at the Board. SR 0075.

286. The Agency also noted that U. S. Steel has not amended the appeals so that they no longer address the emission factor limits that are set for SO_2, CO, and lead, and that the Application does not include an explanation as to why these emission factor limits are no longer considered to be objectionable. SR 0075.

287. The issues raised by Denial Point 21 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0324; SR 0485.

288. As explained in the written comments, there is no regulatory or statutory authority, or authority arising from a Board order, to support the Agency's position that the Application must be consistent with and address the issues in the pending permit appeals. SR 0324; SR 0485. The absence of addressing issues in the pending permit appeals in the Application is not a ground for denial of the Application. *Id.* While it is logical for the Agency to inquire about contested provisions in pending appeals that may appear to be absent in the Application, the absence of such discussion is not a ground for denying the Application. SR 0324; SR 0485.[9]

289. It was U. S. Steel's understanding, based on conversations with the Agency, that once the revised permit was issued, the pending permit appeals could be dismissed. *Id.*

[9] It is noteworthy that, in its numerous discussions with the Agency on the Application, the Agency did not mention prior to the draft denial that it was the Agency's position that U. S. Steel must address individually in its permit application all items that are currently under appeal. SR 0324; SR 0485.

290. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), and 39.5(13)(c)(v) and 35 Ill. Adm. Code 201.160(a). SR 0073. Section 9(a) of the Act contains the general prohibition against air pollution. 415 ILCS 5/9(a); SR 0078. Section 39(a) of the Act provides that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations; the Agency may impose such other conditions as may be necessary to accomplish the purposes of the Act; and the Agency may impose reasonable conditions in a permit specifically relating to an applicant's past compliance history. 415 ILCS 5/39(a); SR 0078 – 0079. Section 39.5(5)(i) of the Act provides that an applicant, upon becoming aware of a failure to submit relevant facts or upon submittal of incorrect information, shall submit supplementary facts or correct information. 415 ILCS 5/39.5(5)(i); SR 0079 – SR 0080. Section 39.5(7)(a) of the Act provides that CAAPP permits shall contain limitations and conditions and terms which are or will be required to accomplish the purposes and provisions of the Act and to assure compliance with all applicable requirements. 415 ILCS 5/39.5(7)(a); SR 0080. Section 39.5(10)(a)(iv) provides that the Agency shall issue a CAAPP permit if all conditions are met, including that the Agency has received a complete application. 415 ILCS 5/39.5(10)(a)(iv); SR 0080 – 0081. Section 39.5(13)(c)(v) of the Act provides the definition of "administrative amendment," which includes a permit revision that incorporates into the CAAPP permit the requirements "from preconstruction review permits provided the program meets procedural and compliance requirements substantially equivalent to those contained in this Section." 415 ILCS 5/39.5(13)(10)(c)(v); SR 0081. Section 201.160(a) of the Board's regulations provides that no construction permit shall be issued unless the applicant submits proof that the emission unit or air pollution control equipment will be

constructed or modified to operate so as not to cause a violation of the Act or Title V, Subtitle B, Chapter I of the Board's regulations. 35 Ill. Adm. Code 201.160(a); SR 0083. However, as explained above, there is no obligation under the cited statutory and regulatory provisions to address in a construction permit application consistency with issues in the pending permit appeals. SR 0324; SR 0485.

291. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

292. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial.

xxii. Denial Point 22: The 2022 Application does not include a signed certification for the accuracy and completeness of the Application

293. The Agency's twenty-second Denial Point claims that the Application, as submitted on October 7, 2022, did not include a certification for the truth, accuracy and completeness of the application. SR 0076; *see* SR 0076 – 0077; *see* SR 0122 – 0125.

294. In the Application as submitted on October 7, 2022, U. S. Steel included a copy of an earlier certification dated February 25, 2022 that was submitted with the application submitted in March 2020. SR 0076.

295. The Agency contended that the copy of the prior certification "cannot serve as the required certification." SR 0076. The Agency claimed that the 2022 Application replaces the prior 2020 Application because the 2022 Application is a revision of the 2020 Application and U. S. Steel intended as such by stating in the cover letter that, "'Due to the nature of revisions throughout this application, the Illinois EPA should refer to this application for permit processing.'" SR 0076 – 0077.

296. The Agency stated that the "2022 application replaced the prior 2020 application" and, therefore, the "2022 application must include a new certification for its truth, accuracy and completeness." SR 0076 – 0077.

297. Additionally, in its September 11, 2023 written comment responding to the Agency's Initial Draft Denial Letter, U. S. Steel attached a certification dated September 8, 2023. SR 0076; SR 0484; SR 0517 – 0519.

298. The Agency argued that this later-submitted certification was not sufficient to correct the prior omission because it was an attachment to comments and not submitted as a supplement to the 2022 Application. SR 0076. Moreover, the Agency pointed out that an errata sheet, or something similar, did not accompany the certification that "corrected erroneous information in the application as either identified by the Illinois EPA in the Initial Draft Denial or identified by U. S. Steel when developing its response to the Initial Draft Denial." SR 0076. The Agency claimed that, as such, even if submitted as a supplement, the certification's "truthfulness and validity would be questionable" and "absent an appropriate certification the Application is deficient." SR 0076.

299. The issues raised by Denial Point 22 were discussed by U. S. Steel in its September 11, 2023 and January 8, 2024 written comments to the draft denials. SR 0322 – 0324; SR 0483 – 0485.

300. As explained in its comments, the "2022 application" referenced by the Agency in the draft denials is a construction permit application submitted on March 2, 2020. SR 0323; SR 0484. The Application as submitted on March 2, 2020 included a completed 199-CAAPP form. SR 0323; SR 0484; SR 1038 – 1041. This form included the following certification language, which was signed and dated by U. S. Steel:

> I certify under penalty of law that, based on information and belief formed after reasonable inquiry, the statements and information contained in this application are true, accurate and complete and that I am a responsible official for the source, as defined by Section 39.5(1) of the Environmental Protection Act.

SR 1041.

301. The Application materials submitted in October 2022 constituted a supplement to the Application submitted on March 2, 2020. In the transmittal letter to the October 2022 Supplement, U. S. Steel explained that it and the Agency had been in discussions regarding the 2020 Application and that U. S. Steel "has updated the permit application to reflect those discussions. Due to the nature of the discussions throughout the application, the Illinois EPA should refer to this application revision for processing." SR 0601; SR 0120 – 0121. The Agency argued that this language supports the Agency's position. SR 0120 – 0121. While the cover letter to the October 2022 Supplement stated that the Agency should refer to that application for processing given the extent of the revisions to the March 2020 Application, U. S. Steel did not intend for the October 2022 Supplement to replace the March 2020 Application. *See* SR 0323; SR 0484. In the cover letter for the October 2022 Supplement, for purpose of administrative convenience only, U. S. Steel suggested that Illinois EPA refer to the Supplement rather than to the initial submittal in March 2020 because, as requested by Illinois EPA following review of the 2020 Application submittal, the sections of the Application were reordered. SR 0323; SR 0484; SR 0601. Additionally, in response to the Agency's point that the 2022 Supplement included previously submitted application forms, U. S. Steel did this for administrative convenience. *See* SR 0121; SR 0323; SR 0484.[10]

[10] It is noteworthy that the Agency did not request U. S. Steel to submit a certification for the Supplement prior to issuing its draft denial letter. SR 0485.

302. The Agency argued that the 2022 Supplement differs significantly from the March 2020 Application and that the October 2022 Supplement addressed revisions to the Permit without the need to refer to the 2020 Application submittal. SR 0119 – 0120. U. S. Steel acknowledges that the 2022 Supplement differs from the 2020 Application in certain aspects, however neither the Act nor Board regulations requires the Supplement to be treated as a revised or separate application due to this fact.[11] The language in U. S. Steel's cover letter is clear that the October 2022 Supplement is a supplement and addresses revisions to the March 2020 Application. SR 0601.

303. Furthermore, the cited Act and Board regulatory provisions only state that a certification is required for each permit application, but do not expressly require a separate certification for each supplement to a permit application. *See* 415 ILCS 5/39.5(5)(e); *see* 35 Ill. Adm. Code 270.401(f); SR 0323; SR 0484.

304. Additionally, as noted by the Agency, without waiving any rights or defenses, U. S. Steel submitted a new certification along with its September 11, 2023 written comment to the Agency's Initial Draft Denial Letter. SR 0517 – SR 0519; SR 0484; SR 0324. The certification signed and dated by U. S. Steel certified to the truth, accuracy and completeness of the Application supplement that was submitted in October 2022. SR 0517 – 0519; SR 0484; SR 0324. The Agency argues that attaching the certification to U. S. Steel's comment letter was not submitting the certification as a supplement to the application (SR 0076); however, U. S. Steel made clear in its comment letter to the Agency that U. S. Steel was providing a new certification as requested by

[11] The Agency also contended that it is not denying the Application because the 2022 submittal was not accompanied by an application fee due to revisions to applications in response to a notification that the earlier application was incomplete not requiring a separate fee under Section 9.12 of the Act. SR 0026, fn. 22. However, Section 9.12 of the Act also does not require a separate application fee for supplements to an earlier application.

the Agency and clearly intended for the new certification to become a part of the permit record. SR 0484; SR 0324.[12]

305. Therefore, a certification for the October 2022 supplement was submitted prior to the final permit application denial. SR 0517 – 0519; SR 0484; SR 0324.

306. The Agency contended that the following Act and Board regulatory provisions may be violated as to this Denial Point if a revised permit were granted: 415 ILCS 5/39(a)* and 39.5(5)(e) and 35 Ill. Adm. Code 270.401(f). SR 0076. Section 39(a) of the Act provides, in part, that it is the duty of Illinois EPA to issue a permit upon proof by the applicant that the facility or equipment will not cause a violation of the Act or regulations. 415 ILCS 5/39(a); SR 0078. As explained above and further below, there is no requirement that each supplement to an application contain a certification. A certification was included in the March 2020 Application within the 199-CAAPP Form. SR 1038 – 1041. Additionally, even if the Agency's interpretation is correct that a certification for each supplement to an application is required, a certification was submitted for the October 2022 Supplement along with U. S. Steel's September 11, 2023 comment letter. SR 0484 and 0517 – 0519; SR 0324. As such, issuance of the revised Permit as requested will not cause a violation of the Act or regulations based on this Denial Point. Section 39.5(5)(e) of the Act provides that each submitted CAAPP permit application shall be certified for truth, accuracy, and completeness by a responsible official. 415 ILCS 5/39.5(5)(e); SR 0079. Section 270.401(f) of the Board's regulations provides that a CAAPP permit application shall contain a certification by a responsible official that the statements and information in the application are true, accurate, and complete based on information and belief formed by the responsible official after reasonable

[12] The Agency also stated that the September 2023 comment letter acknowledges an error in the 2022 submittal and, therefore, the comment letter contradicted the certification. SR 0124. The error the Agency referenced is a scrivener's error (SR 0124, fn. 27); the comment letter clearly acknowledges this error and, taken as a whole with the certification attachment, appropriately acknowledges the error.

inquiry. 35 Ill. Adm. Code 270.401(f); SR 0091. The provisions of Section 39.5(5)(e) of the Act and Section 270.401(f) of the Board's regulations do not specify that each supplement to a CAAPP permit application must contain a certification. A certification was included in the March 2020 Application within the 199-CAAPP Form. SR 1038 – 1041. Additionally, even if the Agency's interpretation is correct that a certification for each supplement to an application is required, a certification was submitted for the October 2022 Supplement along with U. S. Steel's September 11, 2023 comment letter. SR 0484 and 0517 – 0519; SR 0324.

307. As such, the provisions of the Act and Board regulations referenced by the Agency will not be violated if a revised permit were granted as requested by U. S. Steel.

308. Therefore, the Agency's final decision to deny the Application based upon this Denial Point was clearly erroneous considering the facts and the law. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. Additionally, the Agency's position that a lack of certification accompanying a supplement to a permit application calls into question the entire application involves an important policy consideration that the Board should review and reverse.

III. CONCLUSION

309. As explained above, the Agency's final decision to deny the Application was clearly erroneous considering the facts and the law; involved an exercise of discretion by the Agency that the Board, in its discretion, should review; and involved important policy considerations that the Board should, in its discretion, review and reverse.

310. The Agency's reasons, statutory bases, and regulatory bases are insufficient, improper, and inadequate to support denial. The Agency's final decision is not supported by the record and is not rational in light of all in the information in the record.

311. U. S. Steel therefore respectfully requests that the Board grant review of the Agency's final decision to deny the Application and a schedule a hearing in this matter to review such final action. U. S. Steel requests that the Board enter an order finding that the Agency's final decision was clearly erroneous, was not supported by the record, was not supported by the Act or Board regulations, and involved important policy issues that the Board resolves in favor of the Petitioner.

WHEREFORE, for the reasons set forth above, Petitioner, UNITED STATES STEEL CORPORATION petitions the Illinois Pollution Control Board for a hearing on the Illinois EPA's final action to deny the Application, and requests that the Illinois Pollution Control Board find that Illinois EPA's final decision was improper, remand the matter to the Agency, and instruct the Agency to issue the Permit as requested in the Application.

Respectfully submitted,

UNITED STATES STEEL CORPORATION,
Petitioner,

Dated: June 12, 2024

DENIAL OF AN APPLICATION FOR REVISIONS TO A CONSTRUCTION PERMIT/PSD APPROVAL[1]

May 8, 2024

U.S. Steel Granite City
Attn: Krista Armentrout – Environmental Manager
1951 State Street
Granite City, Illinois 62040

Permit/Application No.: 95010001 I. D. No.: 119813AAI
Date Permit Originally Issued: January 25, 1996
Date Application for Revisions Received: October 7, 2022
Subject of Permit: Production Increase
Location: Granite City Works, Southeastern Granite City

The Illinois EPA has reviewed your above referenced application for revisions to the above-referenced construction permit/Prevention of Significant Deterioration (PSD) approval (Permit 95010001) issued for the above referenced project. The permit application is DENIED because, if a revision to Permit 95010001 were issued as requested by this application, it might violate various Sections of the Illinois Environmental Protection Act (Act) and various p*rovisions* in Illinois' regulation pursuant to the Act. The Sections of the Act that might be violated include Sections 9(a), 9(b)(2), 9.1(d), 39(a), 39.5(5)(e), 39.5(7)(a), 39.5(5)(i), 39.5(10)(a)(iv) and 39.5(13)(c)(v). The provisions of the relevant Illinois regulations, i.e., Subtitle B of Title 35 of the Illinois Administrative Code (IAC), that might be violated include 35 IAC 201.152, 201.160(a), 203.123, 203.128, 203.201,. 203.203(b), 203.208, 203.301, 203.302, 204.280, 204.330, 204.400, 204.550, 204.560. 204.810, 204.1100(c), 204,1110, 204.1130 and 270.401(f).

The specific Sections of the Act and the specific provisions of the Illinois Administrative Code that may not be met if Permit 95010001 were to be revised as requested by this application are detailed in the Listing of Denial Points, Attachment 1 of this permit denial. For each Denial Point, Attachment 1 also describes the information that this application did not provide and the specific reasons why the Act and might be violated if a revised permit were issued as requested, with accompanying explanation and discussion.

This permit denial has two appendices. Appendix A lists the various sections of the Act that are cited in Attachment 1 as the statutory basis for this denial letter, with description and, in some cases, general explanation why the section might be violated if Permit 95010001 were to be revised as requested by this application. Appendix B lists the various provisions in

[1] In this application, US Steel requests that the revision of Permit 95010001 be processed with "Integrated Processing," as is provided for by Sections 39.5(13)(a) and (c)(v) of the Act. Integrated Processing would allow changes to the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, as would be set forth in the revised permit, to subsequently be made by means of an Administrative Amendment of the CAAPP permit.

Subtitle B of Title 35 of the Illinois Administrative Code that are cited in Attachment 1 as the regulatory basis for this denial letter, with description and, in some cases, general explanation why the provision might be violated if Permit 95010001 were to be revised as requested by this application.

Before taking action to deny the above-referenced application, the Illinois EPA held two public comment periods on drafts of proposed denial letters, an Initial Draft Denial Letter and a Revised Draft Denial Letter, in accordance with 35 IAC Part 252, as provided for by 35 IAC 252.105(b).

If you have any questions on the denial of this denial, please call Jason Schnepp or Minesh Patel at 217/785-1705.

U.S. Steel Granite City (I. D. No. 119813AAI)
Permit/Application No. 95010001
Application Received on October 7, 2022 for Revisions to the Permit

ATTACHMENT 1: LISTING OF DENIAL POINTS

1. THE REVISED NETTING ANALYSIS FOR THE PROJECT FOR NITROGEN OXIDES (NOx) DOES NOT FULFILL RELEVANT REQUIREMENTS OF NEW SOURCE REVIEW (NSR) FOR SUCH ANALYSES

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d) and 39(a)*. (Note: The significance of asterisks that accompany certain Sections of the Act is explained in Appendix A.)

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 Illinois Administrative Code (IAC) 201.160(a), 203.201, 203.203(b), 203.208**, 203.301, 203.302, 204.550**, 204.810, 204.1100(c), 204.1110 and 204.1130. (Note: The significance of asterisks that accompany certain provisions of the Illinois Administrative Code is explained in Appendix B.)

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not show that the Production Increase Project (Project) would still not be a major modification for emissions of nitrogen oxides (NOx) for purposes of New Source Review (NSR) with the increases in NOx emissions that are requested to address errors in the initial permitting of the Project. In particular, the application requests an increase in the permitted NOX emissions of the basic oxygen furnaces (BOFs) of more than 200 tons/year. The netting analysis for NOx in the application, which addresses the Project with the requested increases in NOx emissions, is flawed so cannot be relied upon to show that the increases in permitted NOx emissions would not result in the Project being a major modification. The revised NSR applicability analysis is flawed as, contrary to applicable rules, it relies upon decreases in NOx emissions from actions that were neither contemporaneous with the Project nor creditable as they were not required by Permit 95010001. These decreases resulted from the later shutdowns of ten older boilers at the facility and the much later shutdown of the two by-product recovery coke oven batteries at the facility, as coke oven gas (COG) ceased to be available for use in Project-affected fuel burning units. The incongruous conclusion of the revised NSR applicability analysis is that the Project was accompanied by an overall decrease in the NOx emissions of Project-affected fuel burning units rather than an increase in NOx emissions as would be expected from an increase in production of iron by the blast furnaces.

As the Project would become a major modification for NOx with the requested increase in permitted NOx emissions, the Project would become subject to Nonattainment New Source Review (NaNSR) (35 IAC Part 203, Major Stationary Sources Construction and Modification (MSSCAM)) for NOx. NOx is regulated as a precursor to the formation of ozone in the atmosphere and, in 1996, the Granite City Works was in an area designated nonattainment for ozone air quality. (This area is still nonattainment for ozone.) As the Project would become a major modification for NOx with the requested increase in permitted NOx emissions, the Project would also become subject to Prevention of Significant Deterioration or PSD (35 IAC Part 204) for NOx. NOx is also regulated as a precursor to the formation of nitrogen dioxide (NO_2) in the atmosphere and, in 1996, the facility was in an area designated attainment or unclassified for NO_2 air quality. (This area is still attainment or unclassified for NO_2.) However, as related to the NOx emissions of the Project as now requested by the 2022 application, the application does not address the substantive requirements of MSSCAM or PSD for a major modification, much less show that these requirements are fulfilled. The application does not show that for the Project-affected emissions units for which the Lowest Achievable Emission Rate (LAER) and Best Available Control Technology (BACT) should have originally been required for NOx, LAER and BACT are present as required, respectively. by MSSCAM and PSD. For NOx, the application also does not address the requirement of MSSCAM that a major project be accompanied by emission offsets to counterbalance the increase in emissions of the nonattainment pollutant from the project. The application also does not include an analysis for the impact of the project on NO_2 air quality, as required by PSD.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Section 9.1(d) of the Act and the substantive requirements of 35 IAC Part 203 and Part 204 for a major modification (the requirements for LAER, BACT and emission offsets for NOx and an air quality impact analysis for NO_2) would be violated if a revision to Permit 95010001 were issued that increased the permitted NOx emissions of the Project as requested by the 2022 application. This is because the revised NSR applicability analysis for the Project for NOx improperly relies upon decreases in NOx emissions that are neither contemporaneous nor creditable to claim that the Project would continue to not be a major modification for NOx with the increases in permitted NOx emissions that are being requested.

Discussion

Overview

For NOx emissions, the 2022 application for revisions to the Construction Permit 95010001 for the Production Increase Project (Project)[1] does not address or show fulfillment of the substantive requirements of the Prevention of Significant Deterioration (PSD) and Nonattainment New

[1] Permit 95010001 was initially issued in January 1996 for a "Production Increase" at the Granites City Works. It provides for increases in the allowable production rates of iron from 2,372,500 to 3,165,000 tons per year and of steel from 2,774,000 to 3,580,000 tons per year. This permit was preceded by Construction Permit 9209014, a permit for increases in production issued in September 1992. That permit provided for increases in the permitted production rate on a monthly average basis for iron from 5,600 to 6,500 tons per day (equivalent to production of 2,372,500 tons per year) and for steel from 6,900 to 7,600 tons per day (equivalent to production of 2,774,000 tons per year).

Source Review (NaNSR) programs related to impacts on air quality, i.e., air quality analysis for impacts on NO_2 air quality per 35 IAC 204.1130 and emission offsets for NOx per 35 IAC 203.302. For the blast furnaces and blast furnace stoves, i.e., the emission units that underwent physical modifications with the Project, the 2022 application also does not show fulfillment of the BACT and LAER requirements, respectively of PSD (35 IAC 204.1100) and NaNSR (35 IAC 203.301) for NOx emissions.[2, 3] This showing is necessary because Permit 95010001 is currently based on the net increase in NOx emissions from the Project not being significant so that the Project is not a major modification for NOx.[4] The 2022 application requests that the Project be permitted for additional NOx emissions but does not show that the Project would still not be a major modification for NOx if the permit were revised as requested. As the Project would become a major modification for NOx with the requested revisions to Permit 95010001, the 2022 application must show for NOx that the relevant substantive requirements of PSD and NaNSR are fulfilled for the Project. It would not be appropriate for a revised permit to be issued with increases in permitted NOx emissions as requested by the current application if this application does not also show that the applicable substantive requirements of PSD and NaNSR would be met for the Project for NOx.

In this regard, the 2022 application requests that the permitted NOx emissions of the casthouse on the blast furnaces and the basic oxygen furnaces be increased by 19.4 and 220.2 tons/year, respectively, for an overall increase of 239.6 tons/year. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.)[5] The revised netting analysis for the Project for NOx in the 2022 application suggests that this increase would be accompanied by decreases in the NOx emissions of certain other units. With these accompanying decreases, the net increase in NOx emissions from the Project with the requested revised permit would continue to not be significant.[6] The requested increase in the permitted NOx emissions of the blast furnaces and

[2] The basic oxygen furnaces, at which the largest increase in permitted NOx emissions is requested, were not physically modified and would not become subject to requirements for BACT or LAER for NOx even if the Project were a major modification.

[3] The 2022 application also does not include an analysis of alternatives. This analysis would have been required to be included in the original application for the Project if it had been recognized in 1996 that the Project was a major modification for NOx. It is beyond the scope of the revisions of Permit 95010001 that are now requested to address the fact that such an analysis was not originally part of the construction permit application for the Project.

[4] Under the PSD program, the significant emission rate for NOx is 40 tons/year; under NaNSR, since Granite City is not in an area that is classified as serious, severe or extreme nonattainment for ozone air quality, the significant emissions rate for NOx is also 40 tons/year. An increase in NOx emissions or, if the source elects to evaluate the net increase in emissions, a net increase in NOx emissions from a project that is equal to or greater than this rate is considered significant. (35 IAC 204.660 and 35 IAC 203.209.)

[5] In the 2022 application, the increases in the NOx emissions of the blast and basic oxygen furnaces reflect proposed corrections to baseline emissions, as well as increases in the permitted emissions with the project. For the blast furnaces, the application indicates that baseline NOx emissions should be lowered from 15.6 to 4.6 tons/year. For the basic oxygen furnaces, baseline NOx emissions should be raised from 46.94 to 179.8 tons/year. (2022 application, Table 6-5, “Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units.”)

[6] When a netting analysis that showed a project would not be a major modification is found to have understated emissions of certain new or modified emission units, the next step is usually to examine

basic oxygen furnaces, 239.6 ton/year combined, would not result in the Project becoming a major modification for NOx. For this purpose, the 2022 application indicates that the overall decrease in NOx emissions from Project-affected fuel burning units would now be 250.3 tons/year, comparing their revised baseline NOx emissions of 956.3 tons/year and future NOx emissions of 706 tons/year. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) However, the 2022 application does not identify the specific decreases in NOx emissions that occurred at different groups of Project-affected fuel burning units. Instead, the 2022 application simply indicates that the future NOx emissions of the Project-affected fuel burning units, overall, would not exceed 706.0 tons/year.

This netting analysis for NOx in the 2022 application cannot be relied upon for issuance of a revised permit for the Project as requested by US Steel. The application does not include relevant information showing that additional decreases in NOx emissions that would now be proposed to be relied upon would be contemporaneous and creditable for permitting of the Project. For emission decreases to be relied on for the purpose of a netting analysis, 35 IAC 204.550 and 203.208 provide that the decreases must be contemporaneous and creditable. This necessitates information for how the additional decreases in NOx emissions addressed in the revised netting analysis for NOx were created and how the amounts of the decrease were quantified. Most significantly, the 2022 application does not show that certain decreases in NOx emissions that it would rely upon should be considered contemporaneous with the Project. A revised permit cannot be issued for the Project that relies upon “post-project” emissions decreases, which occurred after the Project, to show that the Project with the requested increases in NOx emissions of the furnaces, should still not be considered a major modification. This is critical because changes that are unrelated to the Project have occurred at certain fuel burning units after the initial issuance of Permit 95010001. The 2022 application proposes to rely upon the decreases in NOx emissions due to these changes, which decreases were not and could not have been relied upon by the original permit for the Project. These decreases in emissions would be relied upon by the revised netting analysis as the analysis does not account for and exclude the emissions decreases from these changes from the analysis. (In addition, as will be addressed separately below, the 2022 application does not include appropriate support for certain units for the quantification of NOx emissions in the revised netting analysis.)

Application Relies on Emission Decreases That Are Not Contemporaneous

As related to the requirement of the NSR rules that decreases in emissions relied upon for netting be contemporaneous, the 2022 application indicates baseline NOx emissions of 131.8 and 123.2 tons/year from the use of blast furnace gas (BFG) and natural gas, respectively, in Boilers 1

whether the project should still not be considered a major modification. The revised netting analysis for this purpose may consider adjustments such as reductions in the permitted emissions of other new or modified units involved in the project. It may also consider additional emission decreases that were not relied upon by the original netting analysis but could have been as they are contemporaneous and creditable. As this reexamination of a project shows that it still would not be considered a major modification with appropriate adjustments to the netting analysis, an appropriately revised construction permit may be issued that is based on the project continuing to not be a major modification.

through 12. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) Boilers 1 through 12 are the twelve boilers at the source in 1996 that were addressed by Permit 95010001. Ten of these boilers, Boilers 1 through 10, were shut down in 2009.[7] The 2022 application does not show that NOx emissions of these ten boilers, as existed in the period prior to 2009, were considered in the "future" NOx emissions with the Project of at most 706 tons/year from the Project-affected fuel burning units. In addition, with regard to Boilers 11 and 12, the two remaining old boilers at the source that continue in operation, flue gas recirculation systems have been installed on these boilers pursuant to Construction Permit 10080022, issued in January 2011. These systems were installed to control NOx emissions to facilitate compliance with 35 IAC 217.164. The 2022 application does not show that the revised netting analysis for NOx does not rely on the lower NOx emissions from Boilers 11 and 12 that are now being achieved with the new control systems, rather than their NOx emissions as previously existed with the Project in the period before these control systems were installed.

The application also indicates baseline NOx emissions of 461 tons/year from use of coke oven gas (COG) in the blast furnace stoves and Boilers 11 and 12.[8] In 2015, US Steel shut down the two by-product recovery coke oven batteries at the Granite City Works. COG ceased to be available for use in the stoves or Boilers 11 and 12. However, COG was available for use in the stoves and these boilers in 1996. As related to the Project, the 2022 application does not show that the revised netting analysis for NOx would not rely upon decreases in the NOx emissions of the stoves and boilers due to the elimination of COG, which did not occur until 2015.[9]

---

[7] The shutdown of Boilers 1 through 10 was required by Condition 2.6(a) of Construction Permit 06070023, which was originally issued in January 2008. This permit addresses construction of a cogeneration boiler at the facility that would be designed to produce both high-pressure steam to generate electricity and lower pressure process steam. This boiler has been constructed and is in operation. The permitting of this new boiler relied upon contemporaneous decreases in NOx emissions from several actions, most notably, a decrease of 558.9 tons/year from addition of low NOx burners to four reheat furnaces. The permitting of the new cogeneration boiler also relied on a 33.41 tons/year decrease in NOx emissions from the shutdown of Boilers 1 through 10 as this eliminated use of natural gas by these boilers. The related application for emissions decreases that were contemporaneous with the new boiler did not rely on any decreases in the NOx emissions of these boilers from use of COG and BFG. This is because "…the boilers shutdowns will not result in any change in the amount of BFG and COG combusted at the Facility." (Application 06070022, Section 3.3.1. "Boilers 1 through 10 Shutdown Emission Calculations," p. 3-7.) The reliance of Permit 06070023 on emission decreases from the shutdown of these boilers is a further impediment to reliance on these decreases in a revised netting analysis for the Project.

[8] For Project-affected boilers, the 2022 application indicates that baseline NOx emissions from usage of COG are addressed only for Boilers 11 and 12. (2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units.") This is likely erroneous since the application for Permit 06070022 indicates that Boilers 1 through 10 also had the ability to use COG.

[9] The 2022 application does reflect increased use of natural gas by Project-affected fuel burning units. The application explains that with the shutdown of the by-product coke oven batteries, COG is no longer available and more natural gas may need to be used (e.g., 2022 application, Section 6.3, Post-Project NOx Emissions Limitations"). Permit 95010001 currently limits annual use of natural gas by the Project-affected fuel burning units to 1,346 million cubic feet. The revised netting analyses in the 2022

In summary, for purposes of applicability of NSR, the NOx emissions allowed from the Project in 1996 that would be permitted with the requested revisions to the permit could be substantially higher than indicated in the 2022 application.[10] This application does not show that this would not be the case such that the Project would not become a major modification for NOx with the requested increases in the permitted emissions of the blast furnaces and the basic oxygen furnaces. The timing of actions that have resulted in decreases in NOx emissions of fuel burning units after 1996 is critical when considering applicability of NSR to the Project with the requested revisions to Permit 95010001. As the decreases in NOx emissions from certain actions cannot be considered or would be smaller, the net increase in NOx emissions of the Project would be greater. In this regard, it must be assumed that the "future NOx emissions" indicated in the 2022 application reflect maximum actual NOx emissions beginning in 2023, with the requested revisions to Permit 95010001. The application does not suggest that these future NOx emissions are the emissions that should have been allowed by the permit back in 1996 when the permit was issued and the Project commenced.[11]

---

application are based on a post-project annual natural gas usage of up to 1,980 million cubic feet (e.g., Tables 5-7, 6-6 and 7-3).

The decreases in NOx emissions that resulted from the shutdown of the coke oven batteries and elimination of COG in 2015 are contemporaneous with any increases in NOx emissions due to the accompanying use of more natural gas. However, these emissions decreases are not contemporaneous relative to the Project, which was undertaken in 1996. In addition, an application for revisions to Permit 95010001 is not an appropriate venue to address the use of more natural gas due to the shutdown of the coke oven batteries. The Project involved increases in production of iron and steel. The Project-affected fuel burning units do not include four slab furnaces that also used COG and now must use more natural gas. Lastly, the consequences of the shutdown of the coke oven batteries on the facility's NOx emissions, including the consequences for the slab reheat furnaces, are the subject of a separate construction permit application, Application 15030001, received March 5, 2015, which application is still pending.

[10] It should be noted that for purposes of applicability of NSR, for the same reasons that the 2022 application understates the net increase in emissions of NOx from Project-affected fuel burning units, the application also understates the increases or net increases in emissions of the Project for purposes of NSR for particulate matter (PM), particulate matter$_{10}$ (PM_{10}) and volatile organic material (VOM), i.e., pollutants other than NOx for which the requested revised permit for the Project would rely upon the increase or net increase in emissions not being significant.

[11] With the requested revisions of Permit 95010001, it is unclear how the "future NOx emissions" of fuel burning units indicated in the 2022 application are NOx emissions that could have been allowed by this permit in 1996. The future NOx emissions of affected fuel burning units indicated in the 2022 application are less than the baseline NOx emissions, i.e., proposed future emissions of 706 tons/year compared to the claimed baseline of 956 tons/year. However, the Project did not include any elements that would lower the NOx emissions of fuel burning units. Rather, the production of more iron and steel would be accompanied by increased utilization of the blast furnace stoves and boilers as more blast air and steam are generally needed for blast furnaces to produce more iron. Accordingly, in 1996, the NOx emissions of fuel burning units allowed by Permit 95010001 must necessarily be more than the baseline emissions, as this permit addresses a project that involves use of more BFG and natural gas by Project-affected fuel burning units. (Use of COG was not expected to be affected by the Project because production of COG was constrained by the design and operation of the existing coke oven batteries, which were not being modified as part of the Project.)

Indeed, the future NOx emissions of the fuel burning units for purposes of any revised netting analysis should be expected to be substantially greater than their baseline emissions. If one assumes that the increases in emissions would be proportional to the permitted increase in iron production, future NOx emissions of the fuel burning units would be expected to increase by roughly 40 percent. If the baseline

2. THE DETERMINATION OF BASELINE NOx EMISSIONS IN THE REVISED NETTING ANALYSIS CANNOT BE INDEPENDENTLY CONFIRMED

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d) and 39(a)*.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152**, 201.152*** and 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include data and information supporting the determinations of baseline NOx emissions for certain emissions units in the revised NSR applicability analysis for NOx. In this regard, it is noteworthy that the revised NSR applicability analysis does more than seek increases in permitted NOx emissions of the blast furnace casthouse and BOFs to correct errors in the original application for the Production Increase Project. As explained in the discussion below, the revised NSR applicability analysis now also addresses NOx emissions from burning coke oven gas (COG) in Project-affected units, which the Illinois EPA did not require be addressed in 1996. For the continuous casting operations, the analysis also takes a different approach to use of natural gas and associated NOx emissions. Lastly, the analysis does not reflect a reevaluation of the NOx emission factor used for ladle preheaters. For these units, an emissions factor for use of natural gas in boilers, which likely is not appropriate for the simpler burner systems in preheaters, continues to be used.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* As there are deficiencies in the data and information that is provided in the 2022 application for the baseline NOx emissions of fuel burning units, the revised NSR applicability analysis cannot be relied upon. Separate from Denial Point 1 concerning reliance on NOx emission decreases that are not contemporaneous and creditable, deficiencies in the emission data presented in this analysis are also a reason why this analysis cannot serve as proof that the Production Increase Project would not become a major modification for NOx under NSR with the increases in permitted NOx emissions that are now being requested. Likely or possible deficiencies in the emission data in the revised NSR applicability analysis for NOx in the application need to be resolved or corrected before any revised version of Permit 95010001 is issued that would be based upon a revised NSR applicability analysis for the Project.

---

emissions of these units should have been 956 tons/year, as indicated in the 2022 application, this suggests future emissions of these units with the Project should be about 1,340 tons/year (956 tons/year x 1.4 = 1,338 ~ 1,340 tons/year). Alternatively, absent any decreases in NOx emissions from the twelve boilers and the discontinuation of COG, and disregarding increased use of natural gas in place of COG, the NOx emissions from the Project-affected fuel burning units for purposes of NSR applicability, as of 1996, would be on the order of 1,420 tons/year (Proposed future emissions of 706 tons/year + 131.8 tons/year attributable to use of BFG by the boilers + 123.2 tons/year attributable to use of natural gas by the boilers + 461 tons/year from the discontinuation of the use of COG in the stoves and Boilers 11 and 12 ~ 1,420 tons/year). If so, the calculated change in NOx emissions from Project-affected fuel burning units for purposes of NSR applicability would be a net increase on the order of 460 tons/year (1,420 – 956 = 464), rather than a net decrease of about 250 tons/year.

Discussion

The new determination of baseline NOx emissions of Project-affected fuel burning units provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not show that all Project-affected fuel burning units have been addressed. For units that are addressed, the application does not show that appropriate emission factors and operating data have been used to estimate emissions. As specific concerns exist with the determination of baseline NOx emissions for certain emission units, as discussed below, concerns exist with the determination of the overall baseline NOx emissions for the Project.

Baseline Usage of Coke Oven Gas (COG)

As already discussed, the use of coke oven gas (COG) in Project-affected fuel burning units is introduced in the 2022 application for revisions to Permit 95010001.[12] This application does not include supporting documentation or explanation for the baseline usage of COG utilized in the revised netting analysis. The annual usage of COG in the blast furnace stoves (374 million cubic feet/year) and in boilers (2,211 million cubic feet/year) is simply presented in the revised netting analysis for NOx. (2022 application, Appendix B - Emission Calculations, USS Granite City - 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis). The indicated usages of COG are not accompanied by any documentation or explanation.

Emission Factor for Use of COG in Boilers 11 and 12:

For COG, the 2022 application utilizes a NOx emission factor for Boilers 11 and 12[13] of 404 pounds/million cubic feet of COG.[14] The application states that this factor is based on emission testing conducted on the stack of A Coke Battery (2022 application, Table 6-4. "NOx Emission Factors for Fuel Burning"). The application does not show that it is appropriate to utilize an

[12] It should be noted that the introduction in the revised netting analysis for the Project of NOx emissions from use of COG in Project-affected fuel burning units is not acknowledged in the section of the 2022 application in which historical production and operating rates are discussed. Section 6.2.1 of the application, "Historical Throughput Rates," states that "The pre-project actual emissions were calculated using the same production and operating rates as the 1995 Application shown in Table 6-3 [Pre-Project Production and Operating Rates for NOx]." This statement is clearly not accurate as the usage of and NOx emissions from COG were not quantified in the 1995 application. Moreover, Table 6-3 does not include information for the historical or baseline usage of COG.

[13] In the 2022 application, there is an inconsistency in the information for the baseline NOx emissions of boilers. In Table 6-5, "Pre-project Actual Emissions and Summary of Changes to Pre-Project NOx Emissions Factors for Affected Emissions Units," baseline NOx emissions of Boilers 1 through 10 do not appear to be addressed since this table shows that baseline emissions are provided for B11 and B12 (Boilers 11 and 12). In Appendix B, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis, baseline NOx emissions appear to be provided for all boilers, as information is shown as being for "boilers."

[14] For the stoves, the revised netting analysis utilizes a lower NOx emission factor of 80 pounds/million cubic feet of COG. The application states that this factor is based on an emission test for which the date is unknown (2022 application, Table 6-4, p. 6-3). As this factor is identical to the NOx emission factor in USEPA's WebFIRE database for burning COG in industrial boilers, this factor can be considered appropriate. (USEPA, Clearinghouse for Inventories & Emission Factors, Emission Factors & AP42, WebFIRE, with search conducted using the term "coke oven gas" in the field under Select options under Source Classification Code. .

emission factor developed from the results of emission testing on the combustion stack of a coke oven battery to calculate emissions of a boiler. There are significant differences between combustion of COG as occurs at coke ovens and combustion of fuel in a boiler. At a fundamental level, a combustion stack emits the products of combustion from the heating of coke ovens to the high temperature needed to convert coal into coke. Regenerative heat exchangers are utilized to efficiently achieve this temperature. Boilers 11 and 12 emit the products of combustion from burning fuel to achieve the temperature needed convert water into process steam.[15]

Emission Factor for Use of Natural Gas in Ladle Preheaters:

For use of natural gas, the 2022 application utilizes a single emission factor for NOx emissions from all Project-affected fuel burning units. This factor, 306 pounds/million cubic feet of natural gas reflects the results of emission testing conducted on Boiler 12 when using natural gas. The application does not show that it is appropriate to utilize this emissions factor for ladle preheaters, which are different types of emissions units than boilers. Moreover, the revised netting analysis for NOx in the application erroneously indicates that the estimated baseline NOx emissions of ladle preheaters were "Revised to use current AP-42 emission factor." (2022 application, Appendix B, Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) The current AP-42 NOx emission factor for small boilers (<100 million Btu/hour heat input) without low NOx burners or flue gas recirculation is only 100 pounds/million cubic feet of natural gas. (USEPA, *Compilation of Air Pollutant Emission Factors*, AP-42, Table 1.4-1.)

Emissions from Use of Natural Gas on the Continuous Casting Lines:

Unlike the original application, the 2022 application does not directly address NOx emissions associated with use of natural gas in continuous casting operations.[16] In this regard, this application states:

> The pre-project actual emissions for the Continuous Caster Mold – Caster #1 and Caster 2 process, as presented by National Steel Corporation in the 1995 Application listed NOx emissions from this operation. USS Granite City evaluated this analysis and determined that there is no NOx formation from this operation. Any NOx emissions from this operation are due to combustion of natural gas and are already accounted for under the gaseous fuel burning activities listed above [Section 6.2.2.1, Fuel Burning Emissions Units

[15] Application 15030001, the pending application for a construction permit for use of more natural gas with the shutdown of the by-product coke oven batteries, utilizes an emission factor for use of COG of 80 pounds/million cubic feet for baseline NOx emissions of Boiler 12. This is the NOx emission factor in FIRE for use of COG in boilers. This factor is much lower than 404 pounds/million cubic feet, the factor for COG used in the 2022 application for the baseline emissions of Boilers 11 and 12.

It should be noted that Application 15030001 does not include a NOx emission factor for Boiler 11 for COG. This is likely because Boiler 11 did not use COG in the baseline period used for Boilers 11 and 12 (January 2013 through December 2014) for the net increase analysis in this application.

[16] As reflected in Permit 95010001, the original permitting of the Project accounted for NOx emissions of 89.5 tons/year from Caster Molds – Casting but did not account for any NOx emissions from Slab Cut-Off and Slab Ripping, for which only particulate emissions were addressed.

Emissions (Revised)]. Therefore, in the revised analysis, NOx emissions are not included from this operation.

2022 application, Section 6.2.2.7, "Continuous Caster Mold Process Emissions (Revised)."

This is problematic for several reasons. First, the 2022 application does not address the NOx emissions of the natural gas-oxygen torches used in the slab cutting and slab ripping processes, which are part of the continuous casting lines.[17] Second, as the application indicates that NOx emissions are present from the mold processes on the casting lines, the application does not show that the same NOx emission factor is appropriate for this use of natural gas as utilized for ladle preheaters or, alternatively, separately account for the NOx emissions from use of natural gas in the casting process. Lastly, the 2022 application does not identify either the caster processes or the torches as units whose use of natural gas and resulting NOx emissions would be addressed with the emissions of other Project-affected fuel burning units (e.g., 2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units").

[17] Alternatively, if NOx is not formed by the torches given they are supplied with oxygen, the application does not confirm that usage of natural gas by the torches was not considered when the baseline NOx emissions from use of natural gas in Project-affected fuel burning units were determined.

3. THE APPLICATION LACKS INFORMATION FOR THE ACTUAL NOx EMISSIONS OF PROJECT-AFFECTED FUEL BURNING UNITS (LACK OF INFORMATION RELEVANT TO NETTING)

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152***, 201.160(a), 203.123, 203.128, 203.208*, 204.400, 204.550* and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The revised Netting Analysis for NOx in the 2022 application does not show that the value for the maximum future NOx emissions from certain fuel burning units, 706 tons/year, in aggregate, is appropriate for purposes of NSR. That is, the 2022 application does not show that 706 tons/year represents the post-project NOx emissions of these units as could have been addressed when Permit 95010001 was originally issued in 1996 if emissions from burning of COG in these units when operating at the levels of iron and steel production that were permitted had been considered. The 2022 application also does not show that the actual NOx emissions of the subject units in the period from 1996 to the present have not exceeded 706 tons/year. In other words, the application does not show that a value for future NOx emissions of the subject units of 706 tons/year does not really represent "future" emissions beginning at the present time. Otherwise, the value for future NOx emissions in the application improperly takes credit for reductions in the NOx emissions of the Production Increase Project (Project) that were not originally part of the Project. When the Project was initially issued in 1996, the NOx emissions from use of blast furnace gas (BFG) and natural gas in 12 boilers at the Granite City Works was addressed. When revaluating applicability of NSR for the Project for NOx with the increases in permitted emissions requested by the application, it is not appropriate to only address the potential NOx emissions of the two boilers that now remain. Although the other ten boilers are now shutdown, they were operating and emitted NOx in 1996. Similarly, in 1996, coke oven gas (COG) was used as a fuel and burned at the facility. With the shutdown of the two by-product recovery coke oven batteries at the facility, COG is no longer being produced. The NOx emissions of the fuel-burning units that formerly burned COG are now lower than they were in 1996 since natural gas is used to make up for the heat input to the units previously provided by COG. (Compared in terms of pounds of NOx per million Btu of fuel heat input, the NOx emissions from use of natural gas as a fuel are generally lower than those from use of COG.) However, when revaluating applicability of NSR for the Project for NOx with the increases in permitted emissions now requested, it is not appropriate to evaluate the NOx emissions of the units that formerly used COG as they now exist and to ignore the fact that in 1996 these units did use COG and their potential NOx emissions were higher. Again, as touched on in Denial Point 1, the difficulty is not that the future NOx emissions of the subject units may be lower compared to

what may have been possible for their permitted NOx emissions in 1996. The difficulty is that the revised NSR applicability analysis for NOx in the 2022 application attempts to rely on this "post-project" reduction in the NOx emissions of these units to make up for the increases in permitted NOx emissions of the blast furnace casthouse and BOFs that are requested.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* It would be improper for the Illinois EPA to issue a revision to Permit 95010001 that is based on the NSR applicability analysis for NOx in the 2022 application that is not consistent with the provisions of the NSR rules governing such analyses. This would be the case if the value/proposed limitation for maximum future NOx emissions of the subject units in the application was relied upon for issuance of a revision to Permit 95010001 and this value/proposed limitation does not reflect the potential emissions from the subject units with the Project, as required by 35 IAC 203.208 and 204.550 In other words, it would be improper for a revised permit to be issued that reflects current circumstances for the subject units if this reflects NOx emissions that are lower than could have properly been allowed in 1996.

Discussion

The 2022 application does not include a demonstration that the actual NOx emissions of Project-affected fuel burning units would not have exceeded the "future amount" or post-project emissions indicated in the revised netting analysis for the Project for NOx since Construction Permit 95010001 was issued if the production of iron and steel by the source was at the levels allowed by this permit.

3A. THE APPLICATION LACKS INFORMATION FOR THE ACTUAL NOx EMISSIONS OF PROJECT-AFFECTED FUEL BURNING UNITS (LACK OF SUPPORTING INFORMATION)

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

!. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*, *201.152****,35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The amount in the 2022 application for the maximum future NOx emissions from certain fuel burning units, 706 tons/year, in aggregate, is not accompanied by supporting information but is simply presented. The application does not explicitly list the various units whose NOx emissions are being addressed and describe the nature of the various units relative to the emissions of NOx from burning fuel in the units. Data is not provided for the maximum annual amounts of fuels burned in these units. Data is also not provided for the emission factors used to calculate annual emissions, the sources or basis of those factors, and why those factors should be considered representative of the NOx emissions of the various types of units that are being addressed.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include information that is necessary to allow the Illinois EPA to rely upon the future maximum NOx emissions of the subject units, presumably the fuel burning units affected by the Production Increase Project, being no more than the stated amount, or issue a revised permit that limits NOx emissions to the stated amount. The missing information is needed so that the Illinois EPA and other interested parties can independently review the methods, data and calculations by which the representation in the 2022 application for maximum future NOx emissions of the subject units was determined. This information is also necessary if the Illinois EPA is to place appropriate conditions in a revised permit requiring US Steel to track the NOx emissions of the subject units, so as to verify that that the future NOx emissions do not exceed the amount stated in the application or other appropriate amount. In this regard, it is significant that the emissions of many of the Project-affected fuel burning units at the facility, i.e., the blast furnace stoves, the BFG gas flares, and various process heaters, cannot be directly determined because these units are not amenable to emission testing.
Note that this denial point addresses the lack of supporting information for the maximum future NOx emissions of the subject units that is stated in the 2022 application. Denial Point 3, above,

addresses the time period that should be reflected in the determination of maximum future emissions for purposes of evaluating applicability of NSR.

(A further discussion is not provided for this denial point, as it was not present in the Initial Draft Denial Letter. Following the close of the public comment period on the Initial Draft Denial Letter, the Illinois EPA realized that the 2022 application is also deficient as the value it provides for future NOx emissions of Project-affected fuel burning units is not accompanied by supporting information.)

4. FOR THE BASIC OXYGEN FURNACES, THE 2022 APPLICATION DOES NOT ADDRESS THE POTENTIAL FOR UNCAPTURED EMISSIONS OF NOx, VOLATILE ORGANIC MATERIAL (VOM) AND CARBON MONOXIDE (CO) THROUGH THE ROOF MONITOR FOR THESE FURNACES

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*** and 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include information for the uncaptured emissions of NOx, volatile organic material (VOM)_ and carbon monoxide (CO) for the BOFs that occur through the roof monitor on the BOF shop, i.e., the building in which the BOFs are located. The existences of emissions of NOx, VOM and CO from the BOFs is well-established from testing of the stacks of the control systems for the particulate emissions of the BOFs. This testing shows emissions now occur through both the older ESP control system for the BOFs and the baghouse that was installed within the last ten years to improve control of particulate emissions from charging and tapping of the BOFs. These control systems may capture most of the emissions of the BOFs, achieving overall capture efficiencies that engineering design suggests may approach 100 percent. However, the 2022 application does not contain technical or engineering information showing that all emissions of the BOFs are now being captured and no emissions occur through the roof monitor or other openings in the BOF shop. Complete capture of the emissions of the BOF is also not required by applicable regulations. For example, under the National Emission Standards for Hazardous Air Pollutants for Integrated Iron and Steel Manufacturing Facilities ("Iron and Steel NESHAP" or "NESHAP"), 40 CFR 63 Subpart FFFFF, Table 1, the opacity of emissions from the roof monitor and other openings in the BOF shop at the facility is only limited to no more than 20 percent, on a 3-minute average.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information addressing uncaptured emissions of NOx, VOM and CO from the BOFs, the 2022 application would not provide complete information about the emissions of the BOFs. For NOx, absent information for these uncaptured emissions, if US Steel were to submit a corrected, revised NSR applicability analysis to show that the Project would not be a major modification for NOx with increases in permitted emissions as requested, that analysis would not be complete. For VOM, for which the 2022 application also requests an increase in permitted emissions, the revised NSR applicability analysis to support such a revision is not complete. For CO, for which revisions to the PSD approval provided by Permit 95010001 are requested for emission units other than the BOFs, the updated air quality impact analysis for

CO required under the PSD rules would not reflect a complete emissions inventory for the existing sources of CO emissions at the Granite City Works.

Discussion

For the basic oxygen furnaces, consistent with the original permitting of the Project, the 2022 application only quantifies stack emissions of NOx, VOM and CO. For these furnaces, the application does not address uncaptured emissions of these pollutants. (For these furnaces, the 2022 application does address uncaptured emissions of particulate and lead[18] for which Permit 95010001 limits emissions of these pollutants from the "BOF [Basic Oxygen Furnace] Roof Monitor," (Permit 95010001, Condition 18 and Table 2, Item 2)).

The revised netting analyses for NOx and VOM in the 2022 application assume that all emissions of these pollutants from the basic oxygen furnaces are now captured. That is, with the installation of the new baghouse control system on the furnaces to improve control of particulate emissions from the charging and tapping processes, all NOx and VOM emissions of these furnaces that originally were not captured and were emitted through the roof monitor now are captured and are emitted through the stack on the baghouse system. For example, as related to emissions of NOx, the application explains,[19, 20]

> At the time of the 1995 Application, the BOF Shop did not include a baghouse to capture secondary emissions. Secondary emissions were released to the atmosphere through the BOF Shop roof monitor. No information was available at the time about the NOx emissions from the BOF Shop roof monitor. Since then, the BOF Shop includes a capture system for secondary emissions that are routed to a baghouse. NOx emissions testing for the BOF Shop

[18] The uncaptured lead emissions of the basic oxygen furnaces are summarily addressed by the 2022 application. In Section 2.2, this application states that changes to the current limits for lead emissions set by Permit 95010001 are not requested. As such, this application acknowledges the current limits for lead emissions in Permit 95010001, including the limits for uncaptured emissions from these furnaces that are emitted through the roof monitor (Permit 95010001 Condition 18 and Table 2, Item 2). Revisions to these limits are not requested.

[19] The 2022 application addresses uncaptured emission of VOM of the basic oxygen furnaces in a similar manner in Part 7 of the application. Refer to the second Section 7.2.2.1 in the application on p. 6-4, "BOF Baghouse – Secondary Emissions (New)."

[20] As reflected in this excerpt, the 2022 application refers to the NOx and VOM emissions of the baghouse system as "secondary emissions." This is inconsistent with the meaning of this term under the NESHAP for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, which only restricts this term to emissions of particulate matter. It is also misleading as it does not distinguish between captured and uncaptured emissions and suggests that capture of these emissions with a baghouse is sufficient to eliminate concerns for the existence of uncaptured emissions.

In this regard, as defined at 40 CFR 63.7852, "*Secondary emissions* mean **particulate matter** emissions (emphasis added) that are not controlled by a primary emissions control system, including emissions that escape from open and closed hoods, lance hole openings, and gaps or tears in the primary emission control system." For secondary emissions, 40 CFR 63 Subpart FFFFF recognizes the existence of both captured or stack emissions and uncaptured emissions, as would occur through a roof monitor. For basic oxygen furnaces, as well as setting emission limits for particulate emissions from primary control systems, this NESHAP also sets separate emission limits for 1) the particulate matter emissions from a control device used for the collection of secondary emissions, and 2) the opacity of secondary emissions that exit any opening in the furnace shop or other building housing a basic oxygen furnace.

> baghouse completed in the 2019-2020 time frame shows an average NOx rate of 0.0075 lb/ton for the BOF Shop Baghouse Stack. USS Granite City added the BOF Shop secondary NOx emission baseline based on the result of the stack test for the BOF Shop Baghouse stack.
>
> 2022 application, Section 6.2.2.6. "BOF Baghouse – Secondary Emissions (New)."

This assumption made by the 2022 application for uncaptured emissions of NOx and VOM of the basic oxygen furnaces, i.e., that all emissions that were formerly uncaptured are now emitted through the baghouse system, is not appropriate. At a fundamental level, the application does not include any support for this assumption. A rigorous analysis for and quantification of the uncaptured emissions of NOx and VOM from these furnaces is warranted as these emissions were overlooked in the original permitting for the Project.[21]

Then, the data for NOx and VOM emissions from the baghouse stack, which is now available from testing of the baghouse, does not support this assumption and, if anything, shows that this assumption is unsound. This is because this testing does not address the level of capture being achieved by the baghouse system. Rather it shows that there are emissions of these pollutants from charging and tapping and, as such, data for the uncaptured emissions of these pollutants is also appropriate. In this regard, the results of emission testing for the NOx and VOM emissions from the new baghouse system on these furnaces, as cited by the application, indicate more than negligible levels of emissions. (2022 application, Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase

[21] In the original permitting of the Project, the uncaptured emissions of NOx and VOM from the basic oxygen furnaces appear to have been considered negligible. This was likely because the emissions of NOx and VOM of the furnaces were all attributed to the refining process, rather than to charging and tapping. During the refining step in a basic oxygen furnace, oxygen is injected into the molten iron charged to a furnace, which removes carbon from the iron by oxidation, converting the iron into steel. The oxidation of the carbon also provides heat to facilitate the melting of the scrap metal that is also charged to the furnace, so molten metal in the appropriate temperature range can be tapped from the furnace.

In 1996, the basic oxygen furnaces were only controlled by the electrostatic precipitator (ESP) system. While the ESP system only reduces or controls emissions of particulate and not emissions of NOx or VOM, the ESP system does capture NOx and VOM from these furnaces. As the capture efficiency for particulate emissions from refining is assumed to be at least 99.9 percent, it was also reasonable to assume that the ESP system also would achieve at least 99 percent capture for NOx and VOM. With these assumptions, i.e., that NOx and VOM are only generated during the refining step and at least 99.9 percent capture of these emissions is achieved by the ESP system, given the limits on emissions of NOx and VOM from the stack of the ESP set by Permit 95010001, i.e., 69.63 and 10.74 tons/year, respectively, the uncaptured emissions of NOx and VOM from these furnaces would have been projected to be no more than 0.07 and 0.01 tons/year, respectively,. (For example, for NOx, 69.63 tons/year ÷ (99.9 ÷ 100.0) x (100.0 – 99.9) ÷ 100.0 = 0.07 tons/year.) For purposes of determining applicability of NSR to the Project. the increases in NOx and VOM emissions of the furnaces with the Project would be less because these calculations for uncaptured emissions address all emissions of the furnaces, both baseline emissions and the increases in emissions from the Project.

Even with the correction to the emission data for the basic oxygen furnaces indicated in the 2022 application, <u>if</u> all NOx and VOM emissions of these furnaces were actually attributable to the refining step, uncaptured NOx and VOM emissions would still be very small. For example, the potential NOx emissions from the stack of the ESP are now shown to be 380.0 tons/year. With capture of at least 99.9 percent of the NOx by the ESP system, the potential uncaptured NOx emissions from these furnaces would still only be an additional 0.38 tons/year.

Analysis and Revised VOM PSD Net Emissions Increase Analysis.) For NOx, the application indicates baseline captured emissions of 179.8 tons/year, of which, based on the measured emissions from the new baghouse system, as much as 5.1 percent, i.e., 9.1 tons/year, would have been uncaptured in 1996; captured VOM emissions are 26.6 tons/year, of which as much as 15.8 percent, i.e., 4.2 tons/year, would have been uncaptured emissions in 1996. However, instead of assuming that all NOx and VOM emissions are now captured, it would not be unreasonable to assume that the new baghouse system improved capture of the emissions from charging and tapping such that the levels of captured emissions from the baghouse stack and the uncaptured emissions through the roof monitor are now identical.[22, 23]

Finally, the assumption that all NOx and VOM emissions of these furnaces is now captured is inconsistent with the approach taken in the 2022 application to the particulate and lead emissions of these furnaces, for which it is assumed that there are uncaptured emissions that still occur through the roof monitor. In particular, the 2022 application requests that the revised permit establish prescribed emission factors for the particulate emissions of the basic oxygen furnaces

[22] It is reasonable to assume that the new baghouse that was installed to improve control of particulate emissions from charging and tapping of the basic oxygen furnaces reduced these emissions to less than half of their previous amounts. For example, the nominal control efficiency for charging and tapping went from 95 percent with only the ESP control system to 97.5 percent with the addition of the baghouse system. With this assumption, the potential NOx and VOM emissions from the baghouse stack from charging and tapping would be estimated to be about the same as the potential uncaptured emissions from charging and tapping that still occur through the roof monitor, with both being about 2.5 percent of the total emissions from the furnaces. The remainder of the NOx and VOM emissions from charging and tapping continue to occur through the ESP stack (95 percent of the total emissions of the furnaces).

[23] With this assumption, the potential NOx emissions of the basic oxygen furnaces with the Project would become 420.4 tons/year, rather than 400.0 tons/year (400.0 tons/year x (100% + 5.1%) ÷ 100% = 420.4 tons/year. The potential VOM emissions of these furnaces with the Project would become 52.1 tons/year, rather than 45.0 tons/year (45.0 tons/year x (100% + 15.8%) ÷ 100% = 52.1 tons/year.

that occur through the roof monitor.[24] For example, for pre-project actual emissions of the roof monitor, Section 5.2.2.7 of the application explains the following, [25]

> Prescribed emissions factors consistent with the approach described in Section 3 [Discussion of Permit Conditions Used to Restrict PTE] are provided herein. USS Granite City is proposing prescribed emission factors for the BOF Shop Roof Monitor for which emissions testing is not feasible.[Footnote 33] For BOF Roof Shop Monitor, use PM emissions factor of 0.0296 lb/ton and filterable PM_{10} emission factor of 0.0198 lb/ton.
>
> Footnote 33: PM and PM_{10} emissions factors are appropriately determined from the results of emission testing per 40 CFR 63 Subpart FFFFF to determine PM and PM_{10} emission rates for the BOF ESP and baghouse, Desulf/Soda Ash and Hot Metal Charging Baghouse, Slag Skimming Baghouse, and Baghouse 2 for Argon Stirring and Ladle Metallurgy.
>
> 2022 application, Section 5.5.2.2. "Prescribed Emission Factors for Certain BOF Shop Operations."

[24] The 2022 application requests that Permit 95010001 be revised to set "prescribed emission factors" for the emissions of certain emissions units or their uncaptured emissions (e.g., the uncaptured particulate emissions of the basic oxygen furnaces, which are also referred to as the emissions through the roof monitor of the basic oxygen furnace shop). For those units or emission points, the prescribed emission factors would effectively replace the provisions currently in Permit 95010001 that address emissions in pounds/ton of input or production or in pounds/hour. For convenience, these provisions in the permit are generally referred to as "emission factor limits." The usage of this term extends to the provisions of the permit that address emission of lead that are in pounds per hour. In this regard, in Permit 95010001, Table 2, these limits for lead emissions are listed under the heading of "Emission Factor," along with the limits in pounds per ton of production for emissions of other pollutants.

Unlike the emission factor limits currently in Permit 95010001, which the Illinois EPA considers to be directly enforceable against US Steel, prescribed emissions factors that would be established in a revision to Permit 95010001 would not be enforceable. Instead, prescribed emission factors would be specific values for emission rates that US Steel would have to use for normal operation when determining compliance with the limits on annual emissions set by the revised permit. The appropriateness of the various prescribed emissions factors that are selected would be a matter that would be considered during the processing of the revisions to Permit 95010001. Given the role of prescribed emission factors in determining compliance with annual emission limits set by the permit, it is expected that prescribed emission factors would only be set for units for which emissions testing is not feasible or is not warranted given the low levels of annual emissions predicted by engineering analysis and calculations. It is also expected that, as it is practical to do so, prescribed emission factors would be conservative, reflecting the maximum rates of emissions that could occur during the routine, compliant operation of emissions units.

[25] For pre-project actual emissions of particulate matter of the basic oxygen furnace through the roof monitor, Section 5.2.2.7 of the 2022 application explains the following,

> The BOF roof monitor actual emissions were calculated using the information from AP-42 Chapter 12.5 and AIRS (Aerometric Information Retrieval System) database. For pre-change actual PM and PM_{10} emissions, National Steel used 90% capture efficiency during the charging and tapping steps and 99% capture efficiency during the refining step for BOP operations. A detailed description of the baseline roof monitor PM and PM_{10} emission factors is provided in Appendix C of the 1995 Application. For the BOF operations, per particle size distribution in AP-42 Table 12.5-2, 67% of PM is PM_{10}. No changes are necessary for this emission factor.
>
> 2022 application, Section 5.2.7.7, BOF Roof Monitor Emissions (No Change)

The fact that there are emissions of NOx and VOM from the basic oxygen furnaces that now occur from the stack of the new baghouse system but were previously not captured and were not originally quantified raises concern that similar circumstances are present for emissions of CO. [26] In this regard, the 2022 application requests various revisions to Permit 95010001 to correct issues that are posed for the original permitting of the Project with respect to CO emissions, but the application does not propose any such revisions for the basic oxygen furnaces or explain why such revisions are not needed.[27]

[26] For the basic oxygen furnaces, uncaptured emissions of CO should generally be expected to be much greater than the uncaptured emissions of NOx or VOM because the permitted stack emissions of CO of these furnaces are much greater. In this regard, Permit 95010001 limits the CO emissions from the stack of the ESP system for these furnaces to 16,097 tons/year. (The 2022 application does not request an increase in this limit.) If only 99.9 percent capture of CO is assumed by the ESP system, the potential uncaptured CO emissions of these furnaces would be 16.1 tons/year. (16,097 tons/year ÷ {99.9 ÷ 100.0} x {100.0 – 99.9} ÷ 100.0 = 16.1 tons/year CO.) Of course, the capture efficiency of the ESP system for CO could be higher than the efficiency for NOx or VOM if CO is only formed during the refining step when oxygen is actually being injected into the furnace and not during the entire refining step. However, one approach to the revision of Permit 95010001 would be to conservatively assume that the capture efficiency of the ESP system for CO is the same as its capture efficiency for particulate.

[27] The application also does not suggest that it would be inappropriate for any revised permit to simply limit the stack emissions of CO from the basic oxygen furnaces, addressing the combined stack emissions of the ESP and the new baghouse, to the current limits for the CO emissions of the furnaces in Permit 95010001, which limits currently apply only to emissions from the stack of the ESP.

5. THE EMISSION INVENTORY FOR THE SOURCE USED IN THE AIR QUALITY ANALYSIS FOR CARBON MONOXIDE (CO) OMITS CERTAIN CO EMISSIONS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152***, 201.160(a), 204.330, 204.1110 and 204.1130.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The "Air Quality Modeling Report," Appendix C of the 2022 application, which provides the "Source Impact Analysis" required under PSD, is deficient because it does not address certain CO emissions of units that are at or were at the Granite City Works. In particular, the uncaptured CO emissions of the blast furnace cast house and the BOFs (i.e., the emissions that occur from the roof monitors and other openings in structures) are not addressed. The CO emissions of the two by-product recovery coke oven batteries formerly at the Granite City Works, which were in operation in 1996, are also not addressed.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* As the source impact analysis in the 2022 application does not address certain CO emissions, it does not fully address the impact of the Production Increase Project, with increases in permitted CO emissions as now requested, on ambient air quality for CO. This analysis also does not address the impact of the Project on CO air quality as would have been determined in 1996 if the Project had been permitted for more CO emissions, as is now being requested by the 2022 application.

Discussion

The results of the analysis of the impacts of the Project on ambient air quality for carbon monoxide (CO) cannot be relied upon because the inventory for the CO emissions of the source with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered. The 2022 application includes an air quality analysis because the Project was originally permitted as a major modification for CO under the Prevention of Significant Deterioration (PSD) program and the application requests revisions to Permit 95010001 to increase the CO emissions for which the Project is permitted.[28] To support

[28] The 2022 application requests that Permit 95010001 be revised to address an additional 25,334 tons/year of CO. This would include emissions of 320 tons/year of CO from the casthouse on the blast furnaces, for which CO was not addressed in the original permitting for the project (2022 application, Section 4.4, p. 4-4) . This would also include an additional 25,014 ton/year from Project-affected fuel burning units, other than Boilers 1 through 10, which are now retired (2022 application, Sections 4.2 and 4.3, pp. 4-2 and 4-3). For the fuel burning units, US Steel has determined that the emission factors for CO

this request, an air quality analysis for CO must be part of the application pursuant to Illinois' PSD rules, 35 IAC 204.1130, Air Quality Analysis, since the request involves revisions to the provisions in Permit 95010001 that involve the Project as it is a major modification for CO under the PSD program.

Uncaptured Emissions from the Casthouse on the Blast Furnaces

The air quality analysis in the 2022 application does not address the uncaptured emissions of the casthouse (2022 application, Appendix C – Air Quality Modeling Report, Table for "US Steel Granite City Volume Source Inputs"). The application indicates potential CO emissions of 13.6 tons/year from the roof monitor on the casthouse on the blast furnaces (2022 application, Section 4.4). These "uncaptured" CO emissions, which are not captured by the baghouse systems on the casthouse, must be addressed in the air quality analysis submitted to support revisions of Permit 95010001 to provide for more CO emissions from the Project.

Uncaptured Emissions from the Basic Oxygen Furnaces

The air quality analysis in the 2022 application does not address uncaptured emissions of the basic oxygen furnaces. (2022 application, Appendix C – Air Quality Modeling Report, Table for "US Steel Granite City Volume Source Inputs.") As discussed earlier, the 2022 application does not address uncaptured emissions from these furnaces. The application also does not explain why uncaptured emissions would not be present as the application does not show 100 percent capture of the emissions of these furnaces by the control systems for emissions of particulate. As there are uncaptured CO emissions from these furnaces, these emissions must also be addressed in the air quality analysis submitted to support revisions of Permit 95010001 to accommodate additional CO emissions from the Project.

By-product Coke Oven Batteries

The 2022 application does not explain why the air quality analysis in the application should not consider the CO emissions of the former by-product coke oven batteries at the source. These batteries were in operation when the Project was originally permitted in 1996 and did not cease operation until 2015. Accordingly, the analysis does not address CO ambient air quality with the Project as would have been predicted by the original air quality analysis for the Project if it had addressed the additional CO emissions now being requested for the Project. On the other hand, the analysis addresses CO emissions of emission units that did not exist in 1996, as this analysis addresses the emissions of the heat recovery coke ovens adjacent to the Granite City Works, which were built and are now operated by Gateway Energy & Coke. [29]

utilized in the original permitting of the Project, particularly the emission factor for blast furnace gas used in the blast furnaces stoves, understated CO emissions.

[29] The modelling in the air quality analysis did address certain newer units, which came into operation after the Project in 1996. In particular, the analysis addressed the CO emissions of the new coke oven batteries adjacent to the Granite City Works that are owned and operated by Gateway Energy & Coke. However, modeling of the CO emissions of new units would only compensate for the CO emissions of existing units if the new batteries were direct, in-kind replacements of the shutdown units, which is not the case. This is not the case. The batteries that were shut down by US Steel were by-product recovery batteries. They recovered chemicals from the off-gas from the coking process (e.g., benzene, toluene and naphthalene, with the gas then used as fuel for heating the coke ovens and in certain other units at the source. Gateway's batteries are heat recovery batteries, in which the off-gas from coking is combusted in

the ovens and the heat is used to make steam and generate electricity. Moreover, the new batteries and the old batteries both operated for a period of several years before US Steel shut down its batteries.

5A. ISSUES WITH THE BACKGROUND AIR QUALITY USED IN THE AIR QUALITY ANALYSIS THE EMISSION INVENTORY FOR THE SOURCE USED IN

(Note: In the Initial Draft Denial, this denial point, Denial Point 5A, was not addressed separately but was instead addressed as part of Denial Point 5. This deficiency is now being addressed separately for ease of understanding. This deficiency relates to the value for background ambient air quality used in the CO air quality analysis rather than deficiencies in the inventory of sources (i.e., the compilation of emissions units and emission data) used in the dispersion modeling in the air quality impact analysis for CO.)

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d) and 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 204.330, 204.1110 and 204.1130.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The "Air Quality Modeling Report," Appendix C of the 2022 application, which also provides the "Air Quality Analysis" required under PSD, is deficient. As related to baseline ambient air quality for CO, this report does not address baseline ambient air quality as existed at the time that the Production Increase Project was initially permitted. It also does not address ambient air quality as it presently exists. Rather, a value for background air quality from ambient monitoring conducted in 2016 through 2018 is used. This does not represent either air quality in the period before the Project was initially permitted or air quality at the present time. While the monitoring station in East St. Louis that was the source for the value selected for background air quality ceased operation in 2019, the Missouri Department of Natural Resources continues to conduct ambient monitoring for CO at a site in St. Louis. (In this regard, the 2022 application, p. 4-5, indicates that "There are many existing ambient CO monitors within the 100 miles of the facility (Figure 4).") The 2022 application does not justify use of a value for background ambient air quality that is not representative of the period when the Project was initially permitted. Then, if this can be justified, the 2022 application does not explain why it is appropriate to use a value for background air quality taken from ambient monitoring conducted over five years ago.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested*: Because of the issues with the value for baseline air quality used in the "Air Quality Modeling Report" in the 2022 application, as discussed above, it would not be proper to rely on the results of this report to issue a revised permit what would provide for increases in permitted CO emissions as requested by the 2022 application.

Discussion

In addition [to the deficiency addressed in Denial Point 5], the air quality analysis in the application uses a value for CO background air quality on an 8-hour average that is based on ambient air quality data collected for a three year period consisting of 2016, 2017 and 2018. As such the value used for background air quality is not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted.[30]

[30] Under the PSD program, the air quality analysis for a project whose modelled maximum impact(s) by itself on air quality for a pollutant are above certain specified concentration(s) or "significant impacts levels" under the PSD program must also consider "background air quality." This accounts for the contribution to ambient air quality of mobile sources (e.g., cars, trucks and buses) and of other sources (e.g., residential and commercial heating), which contribution cannot be determined as part of the computerized dispersion modelling for discrete emission units performed as part of the analysis. The air quality analysis in the 2022 application shows that the maximum air quality impact of the Project with the requested increases in CO emissions would continue to be above the significant impact level for CO on an 8-hour average. (In the original air quality analysis, the Project's impacts were significant for CO on both a 1-hour and an 8-hours average.) The value for background in the current air quality analysis is based on data collected at an ambient air monitoring station in East St. Louis operated by the Illinois EPA. If US Steel shows that the air quality analysis for the revision to Permit 95010001 should address current ambient air quality for CO, the value for background air quality in the analysis should be updated. Since the Illinois EPA discontinued ambient monitoring for CO at its East St. Louis monitoring station in 2020, the new value for background would likely need to be based on data collected at an appropriate monitoring station in Missouri operated by the Missouri Department of Natural Resources.

It should be noted that the values for background used in the original air quality analysis were likely conservative, as they were based on data from a now retired monitoring station in Granite City that was less than a third of a mile from the Granite City Works. Given the location of that station, the ambient air quality data collected at that station may have included the contribution to air quality of units for which modelling was also conducted, so that the original analysis effectively counted the impacts of those units twice. Thus, it is reasonable for the current air quality analysis to use value(s) for background air quality based on data collected at a monitoring station other than the one that was originally used.

6. SCOPE OF PROPOSED GROUP EMISSION LIMITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not show that certain proposed collections of emission units for the "group limits" for annual emissions of particulate, NOx and VOM that are generally requested are appropriate. In this regard, the 2022 application does not propose limitations that would only apply to the annual emissions of particulate of the casthouse for the two blast furnaces. The application also does not propose limitations that would apply only to the annual particulate emissions of the two BOFs. These are principal emission units at the Granite City Works. For the casthouse, the 2022 application does not show that that it would be unreasonable or inappropriate for Permit 95010001 to continue to have limitations for annual emissions of particulate that are directly enforceable independent of emissions of the other, lesser units involved in production of iron (i.e., the charging of the blast furnaces and slag pit operations). (As the application does not indicate any NOx or VOM emissions from these lesser operations, it is unclear whether group limits are actually being requested for blast furnace operations for NOx and VOM.) Similarly, for the BOFs, the 2022 application does not show that it would be unreasonable or inappropriate for Permit 95010001 to continue to have limitations for annual particulate emissions that are directly enforceable independent of the emissions of other, lesser units involved in making steel (i.e., the removal of sulfur from the molten iron, the skimming of the resulting slag from the surface of the iron in the ladle, and the ladle metallurgy operations after the BOFs). (The application does not actually indicate any NOx emissions from these lesser operations; for VOM, the only lesser unit identified with emissions is the skimming of slag.) While the 2022 application points to three construction permits for facilities issued by other permitting authorities as support for the proposition that limitations on annual emissions that apply to both principal units and lesser units are appropriate, the 2022 application does not show that the circumstances of the Granite City Works are such that those other permits should serve as precedents for the requested revisions of Permit 95010001. Variability in utilization or activity was an inherent aspect in the basic design or purpose of those three facilities and led to the approach to the emissions limitations that were set for those facilities. In this regard, one facility involved a fleet of sea-going vessels engaged in exploration for petroleum. The second facility, "the first of its kind," would be developed to make fuel ethanol from processed municipal waste and sewage sludge. (It may also be relevant that the construction permit for this facility, and as well as the permit for a fleet of vessels that would conduct offshore exploration for petroleum, both limited emissions so that the facilities would not be major sources for purposes of NSR.) The third facility was being developed as a peaking power plant, to operate mainly when other

sources of electricity, including wind and solar power, could not fully satisfy the demand for electricity. Moreover, this last permit sets limitations for the annual emissions of a group of identical generating units. As such, this permit does not provide support for setting limitations for a collection of disparate emission units. In summary, the 2022 application does not request revisions to Permit 95010001, that would continue to separately limit the annual particulate emissions of the blast furnace casthouse and the annual emissions of the two BOFs by themselves.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* If a revision to Permit 95010001 were issued without limits that independently apply to the emissions of the blast furnaces casthouse and to the emissions of the two BOFs, the 2022 application would not show the limits on annual emissions established in such revised permit would serve to restrict the emissions of the casthouse and the two BOFs as a practical matter. In this regard, as US Steel is applying for revisions to emission limits that are currently in Permit 95010001, it is obliged in its application to adequately explain and justify the revisions to the current emission limits that it is requesting. The three permits cited by US Steel in the 2022 application do suggest that permit limitations for the annual emissions of emission units that are accompanied by appropriate operational and/or emissions monitoring may now be considered acceptable as being enforceable as a practical matter without associated emission factor limits, i.e., limits on emission of pollutant(s) in pounds per ton of production or throughput, pounds per million Btu fuel heat input or pounds per hour. However, these permits do not show that the stringency of the current limits for the annual emissions of principal emissions units at the Granite City Works, a facility with substantial emissions in an urban area, should generally be relaxed by setting revised limits that would now apply to emissions of both principal unit(s) and other lesser units, as is proposed by the 2022 application.

Discussion

The application does not show that the proposed collections of emission units for the requested group limits for annual emissions of particulate, NOx and VOM are appropriate.[31, 32] In particular, the application does not propose limits that would only apply to the annual emissions of the casthouse on the blast furnaces and to the annual emissions of the two basic oxygen furnaces. These are principal emission units at this facility. It would be reasonable and appropriate for both the annual emissions of the casthouse and the annual emissions of the two basic oxygen furnaces to be directly limited separately from the emissions of any other units. The construction permits issued by permitting authorities in other jurisdictions cited in the application as support for

[31] For PM, PM_{10}, NOx and VOM (i.e., pollutants other than sulfur dioxide (SO_2), carbon monoxide (CO) and lead), the 2022 application requests that the revised permit not include the provisions in Permit 95010001 that the Illinois EPA considers would limit emissions of individual "processes" in pounds/ton of production or throughput and in tons/year. These provisions were set to ensure that the Project would not be a major modification for purposes of New Source Review (NSR). The removal from Permit 95010001 of the "emission factor limits" which limit emissions of various process operations relative to their production or throughput, would facilitate resolution of two permit appeals filed by US Steel with the Illinois Pollution Control Board (PCB), PCB 2013-53 and PCB 2013-62. Both appeals indirectly address the emission factor limits in Permit 95010001. PCB 2013-53 concerns the revised Clean Air Act Permit Program (CAAPP) permit for the facility (Permit 96030056) issued in 2013. US Steel appealed this permit as it repeats the emission factor limits as originally set by Permit 95010001. PCB 2013-62 concerns the construction permit for the addition of the baghouse system to improve control of particulate emissions from charging and tapping of the BOFs, Permit 11050006, as reissued in 2013. For the BOFs, this permit also repeats the emission factors limits for the BOFs set by Permit 95010001. US Steel appealed the subject emission factor limits in these permits because, prior to issuing the revised CAAPP permit for the facility in 2013, the Illinois EPA had explicitly explained that the provisions in the permit containing emission factors were considered to constitute enforceable limits on emissions. This was done in the Illinois EPA's "Statement of Basis for a Planned Revision of the Clean Air Act Permit Program (CAAPP) Permit for: U. S. Steel Corporation, Granite City Works, 20th and State Streets, Granite City, Illinois," of March 2011, pages 20 through 26. That these provisions set enforceable limits was then recognized by the USEPA in the Administrator's subsequent order of December 3, 2012, "In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056," Petition Number V-2011-2, pages 7 through 9).

[32] With regard to the current limits for the annual emissions of PM, PM_{10}, NOx and VOM of individual processes, the 2022 application requests "group limits" for the annual emissions of groups of related emission units. For example, the application requests that the revised permit limit the overall emissions of a group of units that includes the casthouse for the blast furnaces and other, ancillary units involved in production of iron. The permit currently sets separate limits for the emissions of the casthouse, the emissions from charging the blast furnaces, and the emissions from slag pit activities. Unlike the current limits for annual emissions, which apply on a calendar year basis, the proposed new limits for annual emissions would be rolled monthly, restricting emissions over each consecutive 12 month period. The requested limits would theoretically be less stringent than the current limits as US Steel could potentially compensate for any "overage" of emissions by unit(s) in a group of units with lower levels of emissions from other units in the group.

Incidentally, in these appeals, US Steel only challenges the emission factor limits for "processes," such as the casthouse, the basic oxygen furnaces, continuous casting operations, and discrete material handling operations. These appeals do not challenge the emission factor limits for fuel burning units affected by the Project. Those limits do not restrict the emissions of individual units or groups of similar units. Instead, they separately restrict the emissions from use of different fuels, i.e., blast furnace gas, natural gas and oil.

emission limits that apply to groups of emission units do not show that the annual emissions of the casthouse and the basic oxygen furnaces should not both continue to be limited individually.[33]

In this regard, the 2022 application points to USEPA policy and practice concerning how the potential emissions of a source may be restricted (2022 application, Section 3, "Discussion of Permit Conditions used to Restrict PTE [Potential to Emit]). The application shows that USEPA has found that construction permits may be issued that restrict potential emissions by means of limits on annual emissions that are practically enforceable. Accordingly, the current provisions in Permit 95010001 that limit emissions of process units in pounds/ton of production of throughput, which apply on a short-term rather than annual or long-term basis, are not essential to restrict potential emissions. In addition, the application points to several construction permits issued outside of Illinois since 2000 for which the permitting authority determined that annual emission limits that apply to groups of emission units that are practically enforceable were determined to be sufficient to restrict potential emissions without need for accompanying limits that address emissions on a short-term basis.[34, 35] However, the 2022 application does not show that the

[33] In light of the construction permits issued by other permit authorities cited by the application as support for group limits, it would seem acceptable for a revised permit to set group limits for the emissions units or operations that do not qualify as principal units. For example, for the production of iron, a revised permit could set limits for the overall emissions from charging the blast furnaces and the slag pits. Alternatively, limits specifically for the emissions of the casthouse for the blast furnaces and the basic oxygen furnaces, i.e., the principal units at the facility for iron and steel production, could be accompanied by group limits for the overall emissions of these principal units and the other, "non-principal" units in these areas of the facility. For example, limits could be set for both emissions of the casthouse and for the emissions of the casthouse, charging of the blast furnaces, and the slag pits.

[34] The 2022 application, Appendix E - "Copies of EPA Determinations," contains two decisions by the USEPA's Environmental Appeals Board (EAB):

- The 2012 decision of the EAB for an Outer Continental Shelf (OCS) Permit to Construct and Title V Air Quality Operating Permit issued by Region 10 of USEPA to Shell Offshore, Inc. (USEPA, EAB, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2012).
- The 2018 decision of the EAB for a PSD permit issued by the Department of Environmental Quality for Pima County, Arizona, to Tucson Electric Power (USEPA, EAB, *In Re Tucson Electric Power*, PSD Appeal No. 18-02, Order Denying Review, Decided December 3, 2018).

[35] In a footnote, the 2022 application also refers to the USEPA's order responding to a petition to object to a Title V permit issued for a facility in Middletown, New York proposed by Masada (USEPA, Order, May 2, 2001, *In the Matter of Orange Recycling and Ethanol Production Facility, Pencor-Masada Oxynol, LLC*, Permit ID: 3-3309-00101/00001, Issued by the New York State Department of Environmental Conservation, Petition No.: II-2000-07.) As explained by US Steel in the application, in this order, the USEPA upheld the,

> …use of annual emission caps with a rolling cumulative total methodology and rejected petitioners' "concerns that the permit appears to rely on after-the-fact monitoring, rather than engineering practices, test data or vendor guarantees" to establish restrictions on PTE. U. S. EPA based its findings on the fact that "[i]f the source has no room to operate under the PTE emission limiting cap, it must cease operation or face a violation" and that "all PTE limits rely on after the fact monitoring of some kind."
>
> 2022 application, Footnote 11.

specific circumstances of the Project are such that the current limits for annual emission of the principal emission units should be replaced with group limits that apply to the combined emissions of principal emission units and other lesser emission units.[36] The circumstances of the Granite City Works are not the same as those presented by the cited permits. US Steel's Granite City Works is a manufacturing facility at which iron is produced from iron ore in blast furnaces and steel is produced from molten iron and scrap metal in basic oxygen furnaces. The processes that generate emissions at the Granite City Works are different than the oil-fired engines that are generally addressed by the permit for Shell Offshore and the natural gas-fired engines addressed by the permit for Tucson Electric. The permit for Shell Offshore, Inc., addresses a marine drilling unit, the "Kulluk," and an associated fleet of support vessels that may be used during July through November of each year to conduct exploratory drilling operations in areas of the Beaufort Sea north of Alaska. The permit for Tucson Electric Power addressed a new peaking electrical generating facility with ten engine-generating units at Tucson Electric's Irvington Station. The utilization of the individual generating units in the new facility would vary from day to day and season to season as the use of the units would be tied to the inability of other electrical generating facilities to meet the demand for electricity.[37]

---

[36] For the casthouse on the blast furnaces, Permit 95010001 currently sets separate limits for the emissions of various pollutants from the casthouse baghouse (i.e., the main baghouse for the casthouse), the iron spout baghouse, and the roof monitor (uncaptured emissions). If Permit 95010001 were to be revised, it would be reasonable for each pollutant for which emissions are limited, other than CO, for the permit to restrict the overall emissions of the pollutant from the casthouse, rather than to individually limit the stack emissions of each control system and uncaptured emissions. The application also does not suggest that it would be inappropriate for any revised permit to simply limit the stack emissions of CO from the BOFs.

For the basic oxygen furnaces, the current permit separately addresses emissions of particulate and lead from the stack of the ESP and the roof monitor (uncaptured emissions.) For these furnaces, it would also be reasonable in a revised permit to set limits for different pollutants for the overall emissions of the pollutant from these furnaces. In particular, the revised permit would not set limits specifically for the emissions of the new baghouse system that was installed to improve control of particulate emissions from charging and tapping of these furnaces. Instead, the revised permit would address emissions that occur from this baghouse with limits for different pollutants for the overall emissions of these furnaces.

[37] At the Shell Off-Shore and Masada facilities, variability of utilization or operation of different emission units was a consideration in the permitting of these facilities. In its response to comments on the draft permit for Shell Offshore, USEPA Region 10 explains,

> The commenters are correct that EPA guidance does express a general preference for shorter time periods rather than 12-month rolling limits. See 1989 PTE Guidance at 9. As the commenter acknowledges, however, EPA has also recognized that longer rolling limits are appropriate for sources with substantial and unpredictable variations in emissions, as well as for those sources that curtail operation during part of a year on a regular seasonal cycle. Id. at 9 – 10. Such is the case here. Shell's planned exploratory operations are atypical as compared to other sources because emission units consist of multiple engines and generators with variable emission on the Kulluk and a fleet of numerous support vessels. Operations will vary from hour-to-hour, day-to-day month-to-month, and season-to-season based on factors such as the number of wells drilled, the activity being undertaken (drilling mud cellar lines, other drilling activity, or activity that does not involve drilling), the depth of wells drilled, whether emergency engines are being run for testing, and ice conditions. Given the variability in operations, and thus emissions expected from the source, and after considering a full

7. INADEQUATE JUSTIFICATION FOR ELIMINATION OR REVISION OF CURRENT LIMITS FOR PROJECT-AFFECTED FUEL BURNING UNITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

---

range of options for limiting the source's potential to emit, Region 10 determined that it was appropriate to establish longer-term rolling limits.

USEPA, Region 10, "Response for Comments for Outer Continental Shelf Permit to Construct and Title V Air Quality Operating Permit: Conical Drilling Unit Kulluk," October 2011, p. 26.

In the USEPA's order for Masada of April 8, 2002, USEPA observes that,

Masada's operations will have significant fluctuations due [sic] the variability of the processed waste, making an operating parameter-based PTE limit less appropriate. The emissions-based PTE limit discussed below recognizes this fact and provides Masada with operational flexibility accordingly. Moreover, Masada will be measuring its emissions on a real-time basis using CEMS [continuous emissions monitoring systems], obviating the need to limit and monitor operating parameters as a surrogate for emissions.[Footnote 6] Thus the petitioners have not demonstrated that it was inappropriate for the NYSDEC [New York State Department of Environmental Conservation] to restrict Masada's emissions directly, rather than its operation or production.

Although it is generally preferable that PTE limitations be as short-term as possible (e.g., not to exceed one month), EPA guidance [USEPA, "Guidance on Limiting Potential to Emit in New Source Permitting," June 13, 1989] also allows permits to be written with longer term limits if they are rolled (meaning recalculated periodically with updated data) on a frequent basis (e.g., daily or monthly). The 1989 guidance recognizes that such longer rolling limits may be appropriate for sources with 'substantial and unpredictable annual variation in production." 1989 Guidance at 9.

Footnote 6. This is consistent with prior EPA practice in appropriate circumstances. See e.g., Memorandum entitled "3M Tape Manufacturing Division Plant, St. Paul, Minnesota," from John Rasnic to David Kee, dated July 14, 1992 ("a federally enforceable emission limit may be used …to limit the potential to emit as long as a continuous emissions monitor (CEM) or an acceptable alternative is used."); and Memorandum entitled "Policy Determination on Limiting Potential to Emit for Koch Refining Company Clean Fuels Project," from John Rasnic to David Kee, dated March 13, 1992 ("Use of an emission limit to restrict potential to emit …is acceptable provided that emissions can be and are required to be readily determined or calculated.")

USEPA, Order, April 8, 2002, "*In the Matter of Orange Recycling and Ethanol Production Facility, Pencor-Masada Oxynol, LLC*, Permit ID: 3-3309-00101/00003, Issued by the New York State Department of Environmental Conservation," Petition No.: II-2001-05, p. 6)

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency*: The 2022 application does not include information that would support revisions to Permit 95010001 to revise or eliminate current limitations for usage of fuels by the Project-affected fuel burning units, as is requested by the application. With regard to the elimination of the current limitations, the 2022 application does not quantitatively demonstrate that this would not result in an increase in the potential emissions of the subject units. This is of particular concern as Permit 9501001 does not limit the usage of COG, which was not quantitatively addressed in 1996 during the initial permitting of the Production Increase Project. Moreover, with the shutdown in 2015 of the two by-product recovery coke oven batteries at the facility, more natural gas must now be used as fuel in certain subject units (e.g., the blast furnace stoves), to replace the COG that was previously used. With regard to the revisions of the current limitations, the 2022 application does not include information that would be necessary for the Illinois EPA to set values for revised limitations that would be appropriate. As discussed above in Denial Point 3A, the 2022 application does not include the data and calculations underlying the representations in the 2022 application for future maximum emission of the Project-affected fuel burning units. This data would include the maximum usages of fuels as would be needed for the Illinois EPA to appropriately set revised limitations for future usages of fuel.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would eliminate or revise the current limitations in Permit 95010001 for the usage of fuel by Project-affected fuel burning units.

Discussion

The justification provided in the 2022 application for revisions to Permit 95010001 to eliminate or revise limits on usage of fuel and, presumably, emissions by Project-affected fuel burning units is not adequate. Although this application indicates that the revised permit should not contain the limits for usage of natural gas and BFG currently set by Permit 95010001, it does not propose any new limits in their place.

> USS Granite City is also requesting revision/elimination of gaseous fuel usage limits for project-affected combustion units. In 2015, USS Granite City shutdown its by-product coke oven batteries. This eliminated the ability to use coke oven gas ("COG") as a fuel at the mill. In addition, ten of the twelve boilers at the time of the Project in 1996 have been retired. These actions have greatly reduced the emissions from fuel combustion in project-affected emissions units and obviate the need to preserve limits to restrict PTE of the remaining units.
>
> 2022 application, Section 2.2.3, p. 2-4.

This rationale is deficient because it does not consider that the 2022 application also requests that the revised permit address an increase in the usage of natural gas at the facility as a consequence of the shutdown of the by-product coke oven batteries. While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed

above,[38] this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the 2022 application does not show that new limits for fuel usage and emissions would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shutdown. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown.

[38] It is noteworthy that the 2022 application does not address what an appropriate limit for usage of COG would have been in Permit 95010001 if the permit had originally addressed use of COG by Project-affected fuel burning units. In the absence of such information, it is unclear how the shutdown of the two by-product coke ovens at the facility and elimination of COG led to decreases in NOx emissions relative to the limits for NOx emissions of fuel-burning units set by Permit 95010001.

8. THE APPLICATION DOES NOT SHOW THAT EMISSION FACTORS THAT ARE PROPOSED AS PRESCRIBED FACTORS FOR CERTAIN UNITS WOULD BE REPRESENTATIVE

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* Relative to the revisions to Permit 95010001 that are requested to establish certain "prescribed emission factors," the 2022 application does not include information justifying the future use of such proposed factors for the purpose of determining compliance with the revised limitations for the emissions of the project that are requested. In particular, the 2022 application does not include information showing that the proposed factors should be considered representative, accurate and appropriate. For example, for the uncaptured emissions of particulate of the BOFs, which occur through the roof monitor and, possibly, other openings in the BOF shop building, the application does not include any explanation for the emission factors that are proposed as prescribed emission factors. These factors are lower than the factors that were used for the calculations in the application for the baseline emissions of uncaptured particulate from the BOFs. This is generally reasonable as improvements have been made that have improved capture and control of the particulate emissions of the BOFs and should lower uncaptured emissions. Notably, a baghouse control system has been installed to improve control of emissions from charging and tapping the BOFs. However, the 2022 application does not explain how the proposed prescribed factors were developed. It also does not lay out the practices for control of particulate emissions of the BOFs that would accompany the proposed factors.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would determine future emissions of the subject emission units and emission points based on the factors proposed in the 2022 application. The 2022 application does not show that the proposed prescribed factors would appropriately be relied upon for the purpose of enforceably limiting the future emissions of the emission units and emission points for which they are proposed.

Discussion

To calculate baseline emissions of certain emission units for which emission testing is not feasible or practical, the 2022 application necessarily relies on use of emission factors that are

not based on source-specific emissions testing. Likewise, for the ongoing determination of the emissions of these units, the application requests that revised Permit 95010001 "prescribe" or specify the emission factors that are to be used. As explained in the 2022 application, where a permit relies on a limit on annual emissions or an "annual emission cap" to restrict potential emissions, USEPA policy and precedent provide that:

> Where the permit prescribes an emission factor to be used in conjunction with operational data in demonstrating compliance [with an annual emission cap], the permitting authority should describe the basis for its determination that the emission factor is representative.
>
> 2022 application, Section 3, p. 3

This summary of relevant USEPA policy in the 2022 application is consistent with the statements made by the EAB and the Administrator of USEPA in various orders responding to petitions that request it object to Title V permits or, in Illinois, CAAPP permits), issued by a permitting authority. In its decision in *Shell Offshore, Inc.*, the EAB also considered the use of prescribed emission factors in the permit that was appealed. The EAB did not object to this practice. It found that the use of prescribed emission factors may be appropriate for a permit to prescribe use of specific emission factors published by USEPA in its *Compilation of Air Pollutant Emission Factors* (AP-42) for certain emission units for the purpose of determining emissions for purposes of compliance with annual emission limits set by the permit.[39]

> The Region explained in the record its rationale, based on the Region's technical expertise and applied in certain limited circumstances, for supplementing source-specific emission factors derived for most of the emission units or groups of emission units with either AP-42 emission factors, or factors derived from source test data Shell submitted to the Region in support of two separate, previously OCS [Outer Continental Shelf] PSD permits authorizing Shell to conduct exploratory activities in the Chukchi and Beaufort Seas using the *Discover* drillship.
>
> USEPA, Environmental Appeals Board, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2013.

For US Steel, Granite City Works, the USEPA specifically addressed the use of emission factors for determining compliance with emission limits in an order of December 3, 2012. Note that relative to prescribed emission factors, the USEPA's finding, as is provided below, should be considered *dicta*. This is because the permit that was the subject of the appeal did not provide for use of prescribed emission factors. In addition, as the order addresses the possibility of using of

[39] The EAB did observe that it is preferable that compliance with emission limits set by a permit be determined using source-specific emission factors, as would be developed by emissions testing required by the permit. The EAB did not address prescribed emission factors from sources other than AP-42 since the permit that was appealed only prescribed use of emission factor from AP-42. Given the general nature and limited scope of AP-42, the EAB's decision should not be interpreted to preclude use of emissions factors from source other than AP-42. There are emission units and pollutants for which use of prescribed emissions is appropriate for which emission factors are not present in AP-42 or better emission factors are available from other sources.

prescribed emission factors in terms of the actions that the Illinois EPA would need to take when issuing a permit that prescribed emission factors, the order serves to identify the underlying information that a source must provide in an application if it seeks a permit that would provide for use of prescribed emission factors is sought. The Illinois EPA would then be responsible for assuring that the emission factors that are prescribed would be appropriate and sufficient for compliance or noncompliance with the associated emission limits to be reasonably determined.[40,]

> …IEPA [Illinois EPA] must include in the permit itself the monitoring methodology for determining compliance with these limits [emission factor limits and annual emission limits]. If using emission factors, IEPA must propose the actual emission factors in the permit or supporting permit record, and provide supporting documentation for the accuracy and appropriateness of these emission factors, such as historical source test data or other available information. If source test data are not readily available for a specific emission unit, as IEPA asserts, other sources of emission factors (including published literature and material and energy balances) must be reviewed and cited for acceptable emission factors before issuing the permit.
>
> USEPA, Order Responding to Petitioner's Request that the Administrator Object to Issuance of State Operating Permit, Petition Number V-2011-2, *In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056*, Petition Number V-2011-2, dated December 3, 2012, p. 12.

<u>Roof Monitor on the Basic Oxygen Furnace Shop – Particulate Emissions:</u>
The 2022 application does not include support for the particulate emission factors that are proposed as prescribed factors for the roof monitor on the basic oxygen furnace shop (i.e., the uncaptured emissions from these furnaces). The application does include support for the <u>baseline</u>

[40] In an order concerning a Title V permit issued by the Texas Commission on Environmental Quality (TCEQ), the Administrator of USEPA stated the following when addressing the use of emission factors in the permit:

> …Moreover, the justification provided by a permittee in a permit application should not substitute for the judgment of the permitting authority (TCEQ) with responsibility for ensuring that a Title V permit contains sufficient monitoring to ensure compliance. If TCEQ wishes to adopt and incorporate an applicant's technical justification for specific monitoring into the current Title V permit record, it must, at minimum, identify specifically where such a justification is to be found (just as it would be required to do it if [sic]wished to incorporate by reference a requirement located elsewhere.)
>
> USEPA, Administrator, Order Responding to Petition Requesting Objection to the Issuance of Title V Operating Permit, Petition No. VI-2017-6, *In the Matter of BP Amoco Chemical Company, Texas City Chemical Plant, Galveston County, Texas, Permit No. 01513*, dated July 20, 2021, p. 18.

particulate emission rates for the roof monitor on the basic oxygen furnace shop.[41, 42] However, the permitting of the Project in 1996 relied upon various changes that were made to improve capture and control of emissions of particulate from the basic oxygen furnaces and decrease the uncaptured emissions of particulate. For example, a fourth section was added to the ESP in 1995, increasing the volume of air that it could handle. As such, the baseline particulate emission rates of the Project are not representative of future emissions with the Project. Moreover, the emission factors actually proposed in Section 5.5.2.2 in the 2022 application are lower than emission factor limits now contained in Table 2 of Permit 95010001 for the roof monitor on the basic oxygen furnace shop. For PM, an emission factor of 0.0296 ~~0.01986~~ pounds/ton is proposed as a prescribed factor, compared to the current emission factor limit of 0.0987 pounds/ton; for filterable PM_{10}, an emission factor of 0.0198 0~~.0296~~ pounds/ton is proposed, compared to the current emission factor limit of 0.06614 pounds/ton. The 2022 application does not show that the emission factors for the roof monitor on the basic oxygen furnace shop that are proposed as prescribed emission factors in Section 5.5.2.2 of the application are representative.[43]

Caster Mold, Slab Cutoff/Ripping Processes in Continuous Casting:
For the caster mold, slab ripping and slab ripping processes on the continuous casting lines, prescribed emission factors are proposed in Section 5.5.3 of the 2022 application that are identical to the baseline particulate emission rates for these emission units as generally discussed in Section

[41] The baseline emission rates for the roof monitor are based on emissions factors from AP-42 for uncontrolled emission with application of 90 and 99 percent capture efficiencies for the refining process and the charging and tapping processes, respectively, being provided by the ESP control system on the furnaces in the baseline period before 1996 (2022 application, Section 5.5.2.2). While the application cites to Appendix C in the original application for the Project as support for these values for capture efficiency, this appendix only uses these assumed values of capture efficiency when calculating baseline emission rates for the Project. This appendix does not actually provide technical support for these values for capture efficiency being representative of the levels of capture efficiency that were achieved for particulate emissions of the basic oxygen furnaces in the baseline period for the Project. Appendix C also does not provide support for the higher levels of capture efficiency (95% and 99.9%) that it uses for operation and emissions for the basic oxygen furnaces with the Project.

[42] It should generally be noted that the sections of the 2022 application that provide the explanation or basis for the emission factors used in the application are not the sections in which prescribed emission factors are proposed for certain units. The basis for the different emission factors is typically provided earlier in the application in the sections of the application where baseline emission rates are addressed. For example, the particulate emission rates or factors for the roof monitor on the blast furnace casthouse are discussed in Section 5.2.3.3 (2022 application, p. 5-3); the proposed prescribed emission factors for this emission point, which are the same numerically, are provided later in Section 5.5.1.2 without further discussion (2022 application, p. 5-14 and 5-15).

[43] The emission factors that the 2022 application proposes to be prescribed for particulate emissions from the roof monitor on the basic oxygen furnaces may be appropriate at the present time given the installation of a baghouse control system on these furnaces. Nonetheless, for a revised permit to be issued that prescribes emission factors for emission from the roof monitor, the application must show that those factors are representative with the emission control measures that are required by the permit. It must also be recognized that those prescribed factors would not be representative of emissions before the new baghouse system was installed and operation of this system was required. As such, particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}.

5.2.2.11, 5.2.2.13 and 5.2.2.14 of the application. In these sections, the application explained that these emission factors reflect emission factors from a report prepared by the Illinois EPA in 1991, i.e., "Illinois EPA 1991 EIS PM/PM_{10}." This is not sufficient to show that the emission factors that are proposed as prescribed factors are representative. In this regard, the statement that these factors were taken from a historic report prepared by the Illinois EPA does not show that this report included information showing why these factors should be considered representative and can be prescribed by a revised permit.

Mag-Lime Silo:

For the Mag-Lime Silo, a prescribed emission rate of 0.009 pounds/hour is proposed (2022 application, Section 5.5.4.2). As explained in the application, this unit, which stores the reagent used in desulfurization of iron in the basic oxygen furnace shop, was overlooked in the original permitting of the Project (2022 application, Section 5.4.4 and Footnote 34, p. 5-16 and 5-17). US Steel elected not to address its baseline emissions in the revised netting analyses for PM and PM_{10} because emissions are low, i.e., potential annual emissions less than 0.1 tons. However, the application does not include calculations explaining how US Steel determined that potential particulate emissions of this unit are less than 0.1 tons/year, much less information showing that a prescribed emission rate of 0.009 pounds/hour should be considered representative of the emissions of this unit.[44]

[44] The application also does not explain how US Steel determined that the potential annual particulate emissions of the Mag-Lime Silo are less than 0.1 tons. In this regard, the application does not include calculations that identify any assumptions about operation of this unit or the control of its emissions made by US Steel when calculating the potential emissions of this unit. For example, for particulate matter, was the outlet emission rate of the filter that is part of this unit assumed to be less than the regulatory limit of 0.03 grains per dry standard cubic foot pursuant to 35 IAC 212.308 and 212.313?

9. FOR THE ROOF MONITOR OF THE CASTHOUSE, THE APPLICATION DOES NOT SHOW THAT THE METHODOLOGY THAT IS PROPOSED TO BE PRESCRIBED FOR THE DETERMINATION OF NOx AND VOM EMISSIONS WOULD BE REPRESENTATIVE

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a). 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* Relative to the revision to Permit 95010001 that is requested to establish a certain "prescribed emission determination methodology" for the uncaptured NOx and VOM emissions of the blast furnace casthouse, the 2022 application does not include information justifying the future use of such proposed methodology for the purpose of determining compliance with the revised limitations for the NOx and VOM emissions of the blast furnace casthouse that are requested. In particular, the 2022 application does not include information showing that the proposed methodology should be considered representative, accurate and appropriate. In this regard, the 2022 application does not show that changes in the levels of captured NOx and VOM emissions, as measured by emission testing, would be due to actual changes in the overall level of NOx emissions from the casthouse rather than other causes. For example, changes in the levels of measured NOx or VOM emissions could be due to changes in the manner of operation of either the iron making/tapping processes or the baghouse control systems as they function to capture NOx and VOM emissions. Changes in the levels of measured emissions could also be due to the variation in the results of emission testing that may be present with the applicable reference test methods.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would determine future uncaptured NOx and VOM emissions of the blast furnace casthouse based on the methodology proposed in the 2022 application. The 2022 application does not show that the proposed prescribed methodology would appropriately be relied upon for the purpose of addressing the future uncaptured NOx and VOM emissions of the blast furnace casthouse.

Discussion

For the NOx and VOM emissions of the roof monitor on the casthouse on the blast furnaces (i.e., uncaptured emissions, which do not pass through a control device), the 2022 application proposes a prescribed emission calculation methodology that involves the results of emission testing for the main baghouse for the casthouse and an assumed capture efficiency of 95 percent.[45] For example, for NOx emissions from the roof monitor, the application requests that,

> Prescribed emissions factors consistent with the approach described in Section 3 [Discussion of Permit Conditions Used to Restrict PTE] are provided herein. USS Granite City is proposing a prescribed emissions calculation methodology for NOx emissions from the blast furnace casthouse roof monitor based on application of 95% capture emissions to the NOx stack test result for the blast furnace casthouse baghouse.
>
> 2022 application, Section 6.5.1.2, Prescribed Emission Factors for Blast Furnaces Operations, p 6-9.

The application does not show that the "proposed methodology" would result in NOx and VOM emissions rates for the roof monitor that would be representative. In this regard, the proposed methodology would yield emission rates for the roof monitor that would be related directly to the measured emissions of the main baghouse on the casthouse. However, it would not address the effect of variation in capture efficiency on emissions. That is, with the proposed methodology, if emissions from the baghouse measured by a particular test were "lower," the calculated emission rate of the roof monitor would also be lower. The methodology would not address a situation in which the emissions measured by testing are lower because the capture efficiency of the baghouse system during testing was also lower. In this situation, there would actually be more emissions through the roof monitor. As such, unlike specific emission rates for NOx and VOM that would be prescribed in a revised permit, the "proposed methodology" would not address the NOx and VOM emissions from the roof monitor in a way that can reasonably be considered to be representative on an ongoing basis.[46, 47]

[45] With the proposed methodology, the NOx or VOM emission rate for the uncaptured emissions of the casthouse would be derived from the emission rate of the main baghouse measured by periodic testing using the following formula:

[{Measured rate of the baghouse (lbs/ton) ÷ 0.95} x 0.05] = Calculated rate for the monitor (lbs/ton)

[46] This issue would not be present with an appropriate prescribed emission factor. As such, a factor would not change based on the results of periodic testing, the factor could be reviewed when processing the application to confirm that it was conservatively developed so as to be representative on an ongoing basis.

[47] Section 7.5.1.2 of the 2022 application, which addresses the proposed calculation methodology for the VOM emissions from the roof monitor on the casthouse, erroneously refers to the results of emissions testing of the main baghouse system on the casthouse for NOx rather than testing for VOM.

10. THE APPLICATION DOES NOT INCLUDE NECESSARY SUPPORT FOR THE EMISSION FACTORS THAT ARE PROPOSED AS PRESCRIBED FACTORS FOR CERTAIN UNITS.

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* Relative to the revisions to Permit 95010001 that are requested to establish certain "prescribed emission factors" as specifically proposed by the 2022 application, the application does not include information justifying the future use of such proposed factors for the purpose of determining compliance with the revised limitations for the emissions of the Project-affected units that are requested. In particular, as the proposed factors are derived from emissions factors developed by USEPA, the 2022 application does not include information showing that the factors that were derived and are now proposed should be considered representative, accurate and appropriate. For example, for the blast furnace casthouse, the application proposes a prescribed emission factors for uncaptured emissions of particulate that are based on factors in USEPA's *Compilation of Air Pollutant Emission Factors*, AP-42, and achievement of at least 95 percent capture efficiency by the particulate control systems on the casthouse (i.e., 5 percent of the particulate emission being uncaptured). However, as support for reliance on these systems achieving at least 95 percent capture efficiency, the application only refers to a single memorandum by USEPA staff and a consultant.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include necessary information to allow a revised permit to be proposed for the Project, much less issued, that would determine future emissions of the subject emission units and emission points based on the factors proposed in the application. The application does not show that the proposed prescribed factors would appropriately be relied upon for the purpose of enforceably limiting the future emissions of the emission units and emission points for which they are proposed.

Discussion

The 2022 application does not include relevant supporting information for certain emission factors used in the application, as follows. Absent this information the Illinois EPA cannot assess whether the prescribed emission factors proposed for these units should be considered representative.

Blast Furnace Casthouse Roof Monitor:
The prescribed particulate emission factors proposed for the roof monitor on the blast furnace casthouse (i.e., the uncaptured emissions from the casthouse) are identical to the baseline emission rates. These rates are based on emission factors from AP-42 for uncontrolled emissions with application of a 95 percent capture efficiency for the baghouse control systems on the casthouse. The application only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency (2022 application, Section 5.2.3). Further support is needed for a prescribed emission factor based on achievement of 95 percent capture.

Slag Pits:
For particulate emissions from quenching of slag, the 2022 application does not include a copy of the "EPA assessment" that is the basis of the emission factors and material showing how the selected emission factors were derived from this assessment. For emissions from transfer of slag, the application does not include a copy of the calculations by which the emission factors were developed from the formulas provided in AP-42, Section 13.2.4. The application also does not address whether the emission factors rely on control by the application of water or the presence of residual moisture and, if so, the basis for the assumed levels of control efficiency. (2022 application, Section 5.2.2.5, p 5-4).

Iron Pellet Screen:
For the Iron Pellet Screen, the proposed prescribed emission factor for PM and PM_{10} emissions is identical to the baseline emission rates (2022 application, Section 5.2.2.16). While the emission factor for uncontrolled emissions for screening of crushed stone in Table 11-19.2-2 in AP-42 is identified as the basis of this emission rate, a control efficiency of 85 percent is applied, reducing the factor that is actually used to 15 percent of the cited AP-42 factor. The application does not describe the means by which the particulate emissions of this screen are controlled or reduced to show that 85 percent control of particulate emissions is achieved for the Iron Pellet Screen.[48]
In addition, AP-42 lists two emission factors for screening of crushed stone, one for PM and one for PM_{10}. The emission factor for PM is about three times the factor for PM_{10} (0.025 pounds/ton ÷ 0.0087 pounds/ton = 2.87, ~ 3). The 2022 application does not show that for screening of iron ore pellets, an emission factor that was developed for PM_{10} is directly transferable to PM emissions.

[48] The CAAPP permit, Condition 7.4.2 indicates that the Iron Pellet Screen is not served by emission control equipment.

11. THE DETERMINATIONS OF PARTICULATE EMISSIONS FROM HANDLING OF COKE, IRON PELLETS AND LIMESTONE ARE NOT SUPPORTED AND CANNOT BE CONFIRMED

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*,35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* For handling of coke, iron pellets and limestone, the baseline emissions of particulate matter (PM) and particulate matter-10 (PM-10) provided in the 2022 application are both 17.2 tons/year. The information for baseline emissions from handling these materials is not accompanied by supporting information. The application does not explicitly list the various units whose emissions are being addressed and describe the nature of the various units relative to their emissions of PM and PM-10. Data is not provided for the annual amounts of various materials that were handled by these units. Data is also not provided for the emission factors used to calculate annual emissions, the sources or basis of those factors, and why those factors should be considered representative of the emissions of the various types of units being addressed.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would restrict future PM and PM-10 emissions of the subject units. The issuance of a revised permit with limitations for the future emissions of these units that are practically enforceable necessarily requires that the application include supporting information as discussed above. For example, the Illinois EPA needs information on how baseline emissions were determined to confirm that the baseline emissions were reasonably determined. This information is also needed to determine what limitations on emissions should be set in the revised permit and if the permit should require any specific practices to assure emissions are controlled to levels relied upon in the calculations of baseline emissions. Finally, this information is needed so appropriate permit conditions can be developed setting forth how compliance with the limitations is to be demonstrated.

Discussion

With regard to baseline particulate emissions, the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not provide needed supporting information for the “corrected” determinations of baseline particulate emissions of

these operations as it is not accompanied by detailed calculations for the emissions from handling each material. (2022 application, Table 5-5. "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM Emissions Factors for Affected Emission Units" and Table 5-6, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM_{10} Emissions Factors for Affected Emission Units.")[49]

With regard to emissions with the Project, the 2022 application does not include information for particulate emissions from handling of coke, iron pellets and limestone. Since the by-product coke oven batteries were not shut down until 2015, emission information is needed for handling of coal for the period of operation with the Project before the batteries were shut down. Likewise for coke, emission information is needed to address handling of coke before US Steel constructed the conveyor system to receive coke directly from the heat recovery coke production facility built by Gateway.[50]

[49] Tables 5-5 and 5-6 do refer to "Table F-3 of the 1995 application" for these material handling operations. A copy of this table is provided in Appendix B of the 2022 application. However, this table only appears to address PM_{10} emissions, for which it provides annual emissions in tons/year. This table does not include calculations and background information showing how the annual emissions of PM_{10} were determined. Finally, the data for annual emissions of material handling operations appears to rely on the "PM10 SIP" requiring a 90 percent reduction from uncontrolled emissions without providing any support for this assumption.

[50] As this new system was constructed as part of a different project, i.e., the construction of the Gateway facility, rather than the Production Increase Project, US Steel should not address emissions that are specifically associated with this new system.

12. THE REQUESTED CHANGES TO THE GROUPING OF UNITS IN THE PERMIT FOR CONSISTENCY WITH THE GROUPINGS OF UNITS IN THE CAAPP PERMIT WOULD NOT ADDRESS ALL DIFFERENCES IN THE GROUPINGS OF UNITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152* and 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application requests certain changes to Permit 95010001 because the areas or sections of the CAAPP permit for the Granite City Works, Permit 96030056, in which certain emission units are addressed are not the same as those in Permit 95010001. Most notably, in Permit 95010001, discrete material handling and processing operations are addressed with the units with which they are associated. For example, handling of fluxes and alloy materials for the BOFs is addressed with the provisions of the permit for the BOF Shop. In the CAAPP Permit, handling of fluxes and alloy materials for the BOFs and other discrete material handling and processing operations are addressed in a separate section of the permit (Section 7.1) rather than with Blast Furnace Operations (Section 7.4), the BOF Shop (Section 7.5), or Continuous Casting Operations (Section 7.6). While it is reasonable for Permit 95010001 to be revised so that the placement of units in this permit is the same as their placement in the CAAPP permit, several concerns are posed by the specific changes to Permit 95010001 that are requested to accomplish this. In particular, the 2022 application requests that Permit 95010001 be revised to address the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" with other ancillary operations in the BOF Shop, rather than with the Continuous Casting Operations. This change would be appropriate as these units would be placed with other units that are subject to the Iron and Steel NESHAP, 40 CFR 63 Subpart FFFF, as they are BOF Shop ancillary operations. However, the application also requests that the permit be revised to refer to these units as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." This change would not be appropriate as it would refer to the baghouse serving these units and its emissions rather than to the units themselves and their emissions. The application also does not request any changes to Permit 95010001 for the "Deslagging Station and Material HS [Handling System]." In the CAAPP permit, these units are currently addressed twice, both with the discrete material handling operations (Section 7.1) and with continuous casting operations (Section 7.6). More importantly, the placement of these units in Permit 95010001 should be directed by the emission standards that apply to these units. These units would be appropriately addressed with BOF Shop Operations (Section 7.5) as they entail either a "skimming station" or "ladle metallurgy" for purposes of the Iron and Steel NESHAP. Finally, for "Ladle Drying/Preheating," the application does not request revisions to Permit 95010001 although the CAAPP permit addresses these emission units both with BOF Shop Operations (Section 7.5) and with other Project-affected fuel burning units (Condition 5.6.2(a)(ii)). In Permit 95010001, these units are currently only addressed as Project-affected fuel burning units.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* As related to the location in permits where certain emission units are addressed, the 2022 application does not request all revisions that are known to be appropriate to Permit 95010001, and, by means of Integrated Processing of the revisions to Permit 95010001, are appropriate to the CAAPP permit for the facility. For certain units, the application would not address differences in where the units are addressed by the two permits and the related emission standards and requirements that may apply to those units. As related to the naming of units, the Applicant requests a change that is improper as well as unnecessary. As such, if Permit 95010001 were revised with the placement of units in the permit shifted as requested by the 2022 application, it would preclude Integrated Processing of the revised permit. This is because the revision of Permit 95010001 would otherwise allow discrepancies or errors in the provisions for certain units in the current CAAPP permit, which have now been identified and are within the potential scope of the revisions to Permit 95010001, to be perpetuated by the amendments to the CAAPP permit that would be authorized.

Discussion

As addressed in Section 2.2.2 of the 2022 application, US Steel generally requests changes to the organization of Permit 95010001 because the areas or sections of the CAAPP permit in which certain units are addressed are different than those in Permit 95010001. Most notably, in Permit 95010001, discrete material handling and processing operations are addressed with either the blast furnace operations, operations in the basic oxygen furnace shop or the continuous casting operations, based upon the area with which they were considered to be associated. In the CAAPP permit, these discrete material handling and processing operations are generally addressed in a separate section of the permit, Section 7.1, "Material Handling and Processing Operations." In addition, in the CAAPP permit, the "Argon Stirring Station and Material Handling Tripper" was addressed with units in the basic oxygen furnace shop in Section 7.5 of the CAAPP permit rather than with the continuous casting operations as in Permit 95010001.

While it is reasonable for there to be consistency in the groupings or categorization of emission units in Permit 95010001 and the CAAPP permit, as generally requested by US Steel, several concerns are posed, as discussed below, by the specific changes to Permit 95010001 that have been requested.

Requested Changes for the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)"**:**

As explained in Section 11.1.2 of the 2022 application, US Steel requests that the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" now be addressed in Permit 950100001 with operations in the Basic Oxygen Furnace Shop. The application also requests that this unit be identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." However, the application does not actually identify the specific units that would be addressed by the proposed new term. In this regard, the application is not accompanied by an itemized list of the equipment and activities that would be covered by this new term or a diagram that identifies this equipment and activities. US Steel's request also does not explain how the requested revision to Permit 95010001 would do what has generally been requested as the proposed new

term would refer to a "Material Handling Tripper." As the 2022 application requests changes to terminology in Permit 95010001, the changes should act to better identify the emission units that would be addressed, improving the specificity and clarity of the revised permit.[51, 52]

Absence of A Request for Revisions for the "Deslagging Station and Material HS"**:**
The 2022 application does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS (Handling System).[53] These emission units are currently addressed in Permit 95010001 with continuous casting operations (Permit 95010001, Condition 20 and Table 3). In the CAAPP permit, a "Steel Deslagging Station" is identified as one of the continuous casting operations (CAAPP permit, Condition 7.6.2(a)).[54] The 2022 application does not explain why this steel deslagging operation should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the basic oxygen furnace shop. In this regard, for the argon stirring station, US Steel does explain in Section 11.1.2 of the 2022 application that this station should be addressed with operations in the basic oxygen furnace shop rather than with continuous casting operations. This is because this station is a "BOPF shop ancillary operation" for purpose of the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF (2022 application, Section 11.1.2). US Steel does not explain why the current placement in Permit 95010001 of the steel deslagging station with continuous casting is appropriate and this station should not also be addressed with other BOPF shop ancillary operations. Alternatively, US Steel does not request that this station be addressed with other

[51] For example, the proposed new term would not make clear that the basic oxygen furnace shop actually has two ladle stirring stations and one ladle metallurgy furnace, all served by Baghouse 2.
[52] The requested change to the terminology for these emission unit(s) is also problematic as it would refer to a control device, Baghouse 2, rather than to the equipment or activities that generate emissions. Applied literally, the proposed term would only address captured emissions; it would not address the uncaptured emissions, which elude capture for control by the baghouse.
[53] For example, in Section 5.2, the 2022 application does not identify any updates or revisions to the pre-project actual emissions of the steel deslagging station and associated material handling system. Likewise, Appendix B – Emission Calculations does not identify any changes from the 1996 netting analyses that involve these units (Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis and Revised PM10 PSD Net Emissions Increase Analysis).
[54] The presence of a deslagging station that is physically located in the continuous casting building is indicated in the pending application for renewal of the CAAPP permit. This application indicates that the particulate emissions of this station are controlled.

> Deslagging Station:
> Molten steel from the BOF is transferred directly from the BOFs to the continuous casting building. The first operation carried out in this building is the skimming of slag from the surface of the molten steel. Slag removed by this operation is skimmed into slag pots for disposal. Baghouse #1 is used to control emissions from this process.
>
> CAAPP Renewal Application, Appendix D: Process Descriptions, Section 7.6 Continuous Casting, Deslagging Station, p. D-56.

BOPF shop ancillary operations.[55] Slag skimming is one of the operations that 40 CFR 63.7852 defines as being "Basic oxygen process furnace shop ancillary operations."[56, 57]

For the "Deslagging Station and Material HS," the 2022 application also does not request revisions to Permit 95010001 as the CAAPP permit currently limits particulate emissions of this operation twice, once as a continuous casting operation and again as a material handling operation. In this regard, the CAAPP permit limits the particulate emissions of a "Deslagging Station and associated Material Handling System (Condition 7.6.6(a). As indicated by a reference in this condition, the CAAPP permit also limits emissions of a "Material HS and Deslagging Station" (Condition 7.1.6(b)(i)) in Section 7.1 of the CAAPP permit, where discrete material handling and processing operations are addressed. The 2022 application does not request revisions to Permit 95010001 to facilitate amendment of the CAAPP permit to appropriately address the emissions of this deslagging station and the associated material handling system. In the absence of such revisions, the current CAAPP permit would suggest that the revised netting analyses for particulate should address the emissions of these units twice, once as deslagging and once as material handling. On the other hand, if Permit 95010001 would address emissions of these units in this way, the consolidated emission limits for continuous casting and discrete material handling operations would be inappropriate as emissions of the deslagging station and the associated material handling system would be accounted for twice.[58]

---

[55] The proper categorization of this steel deslagging station is important when considering US Steel's request for consolidation of the emission limits currently set by Permit 95010001. As a general matter, any new, "consolidated" limits set by a revised permit must be developed to apply to sensible groupings of units. The groupings of units should facilitate identification in the revised permit of the regulatory requirements that apply to various units. This is especially true as the consolidated limits would rely on certain applicable regulatory requirements, e.g., the work practices and operational monitoring requirements under 40 CFR 63 CFR Subpart FFFFF, to assure consistent operation of emission units so as to keep short-term emissions at or below the established emission rates for the units.

[56] For this steel deslagging station, there is a potential compliance issue relative to the NESHAP, 40 CFR 63 Subpart FFFFF. The CAAPP permit indicates that the emissions of this station are not controlled (CAAPP permit, Condition 7.6.2). On the other hand, if its emissions are controlled by Baghouse 2, the direct applicability of the NESHAP to this station becomes a minor matter. This is because Baghouse 2 is directly subject to requirements of 40 CFR 63 Subpart FFFFF as it controls emissions from "ladle metallurgy." Ladle metallurgy is defined by 40 CFR 63.7852 as "… a secondary steelmaking process that is performed typically in a ladle after initial refining in a basic oxygen furnace to adjust or amend the chemical and/or mechanical properties of steel. This definition does not include vacuum degassing."

[57] It is also noteworthy that as the steel deslagging station is identified as a continuous casting operation by Permit 95010001, the permit applies 35 IAC 212.458(b)(8), which sets a limit of 5 percent, 6-minute average, for the opacity of emissions from the various continuous casting operations (Permit 95010001, Condition 19). However, Permit 95010001 omits the introductory language for this standard that provides that it does not apply to fugitive emissions. The introductory language is present in the CAAPP permit, which addresses the standards that apply to both fugitive and non-fugitive emissions of continuous casting operations (Permit 96030056, Conditions 7.6.3((b), (b)(ii) and (c)).

[58] If there was not actually a material handling system associated with the steel deslagging station, this could be readily addressed in the application for revisions of Permit 95010001. The application could acknowledge the error in the original application, as reflected in the permit that was issued, accompanied by an accurate diagram for the deslagging station as it existed in 1995 and as it now exists. In this regard,

For “Ladle Drying/Preheating,” Absence of Any Request for Changes**:**
For “Ladle Drying/Preheating,” the 2022 application does not request any changes to Permit 95010001 to maintain consistency with the approach to these units in the CAAPP permit. In Permit 95010001, these emission units are addressed with other Project-affected fuel burning units (Permit 95010001, Table 4, Certain Fuel Combustion Units). In the CAAPP permit, these units are addressed in Section 7.5 as “Basic Oxygen Processes” with other units in the Basic Oxygen Furnace Shop, as well as elsewhere in the permit with other Project-affected fuel burning units (e.g., Conditions 5.6.2((ii) and (iii)). In addition, the CAAPP permit sets a limit for the total NOx emissions of the BOF Shop (Condition 7.5.6(b)). In the absence of appropriate changes to the CAAPP permit, since the ladle drying/preheating takes place in the basic oxygen furnace shop, the limit for the NOx emissions of the basic oxygen furnace shop would apply to the sum of the NOx emissions of the basic oxygen furnaces and the ladle dryers/preheaters.

it is perhaps noteworthy that Permit 95010001 does not identify the material(s) that are handled by the material handling operations associated with the steel deslagging station.

13. THE 2022 APPLICATION DOES NOT REQUEST REVISIONS TO PERMIT 95010001 AND, INDIRECTLY, TO THE CAAPP PERMIT THAT WOULD ALSO BE NECESSARY AS THIS APPLICATION REQUESTS THAT THE REVISED PERMIT PRESCRIBE EMISSION FACTORS FOR CERTAIN UNITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not request that the revision to Permit 95010001 add condition(s) generally setting forth how compliance with annual emission limitations set by Permit 95010001 is to be determined. While revisions are requested to establish certain "prescribed emission factors" and "prescribed emission determination methodology," the application does not request related revisions to Permit 95010001 to generally address the procedures that are to be followed when determining compliance with the limitations on annual emissions set by Permit 95010001. In this regard, it is noteworthy that, if it were not stayed, Condition 5.13 of the CAAPP permit for the Granite City Works, Permit 96030056, would address the general procedures for how compliance with limitations on annual emissions set by Permit 95010001 is to be determined. (That condition is currently stayed following an appeal to the Pollution Control Board, PCB 2013-53.) That condition would generally require that compliance with limitations on annual emission be determined using "appropriate emission factors." However, that condition does not address nor would it provide for use of prescribed factors or methodology to determine compliance with limitations on annual emissions, as is being requested by the 2022 application.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* If a revised version of Permit 95010001 were issued that provided for use of prescribed emission factors and methodology without condition(s) generally setting forth how compliance with limitations for annual emissions in Permit 95010001 is to be determined for emission units which the permit establishes prescribed emission factors and methodology (similar to CAAPP Condition 5.13 as it currently addresses use of appropriate emission factors), the limitations on annual emissions in the revised permit would not be enforceable as a practical matter. In this regard, at this time, CAAPP Condition 5.13, which addresses the use of appropriate emission factors in determining compliance with annual emission limitations, cannot be relied upon for this purpose. As well as currently being stayed, that condition only provides for use of appropriate emission factors. It does not provide for the use of prescribed emissions factors or prescribed emission determination methodologies. Moreover, in the absence of a request in the 2022 application for suitable condition(s) generally addressing how compliance with limitations on annual emissions is to be determined, the

application does not show that the revision to Permit 95010001 that is requested would meet the criteria for Integrated Processing, as the application also specifically requests. That is, the 2022 application would not show that the request for a revised permit would provide for compliance requirements substantially equivalent to those provided for by the CAAPP since the application does not request that the revised permit include requirements substantially equivalent to those that would have been provided by CAAPP Condition 5.13 if it were not stayed.

Discussion

The 2022 application does not request revisions to general provisions in Permit 95010001 that would enable revisions to the CAAPP permit for the Granite City Works, Permit 96030056, to be made by administrative amendment to allow prescribed emission factors to be used to determine ongoing emissions of certain emission units. In this regard, the CAAPP permit currently provides that "appropriate emission factors" shall be used when determining emissions to evaluate compliance with the emission limits for process units set by Permit 95010001. Permit 95010001 does not specify how emissions are to be determined for this purpose, much less specify that, for certain emission units and pollutants, prescribed emission factors are to be used.[59] Accordingly, the procedures to determine compliance with the emission limits set by Permit 95010001 were established in the CAAPP permit for the Granite City Works. This was necessary because the emission limits set by Permit 95010001 are applicable requirements under the CAAPP. The procedures that were established in the current CAAPP permit do not provide for the use of prescribed emission factors. Rather, the CAAPP permit generally requires US Steel to use "appropriate emission factors," i.e., emission factors that do not understate emissions, with the primary responsibility for the appropriateness of the factors that are used placed on US Steel.[60] The CAAPP permit also provides for recordkeeping and reporting by US Steel so that the Illinois EPA and interested parties can know and may review for the emission factors that are being used. However, the 2022 application simply requests revisions to Permit 95010001 to require use of prescribed emission factors for certain units. The application does not address the fact that the CAAPP permit currently does not accommodate the use of prescribed emission factors to calculate emissions but instead requires use of "appropriate emission factors."[61]

[59] Condition 39(a) of Permit 95010001 did require "one-time testing" for various pollutant for certain emission units within 270 days of the date that this permit was initially issued. Additional time was subsequently provided to complete testing for the particulate emissions of a boiler when burning blast furnace gas. Unfortunately, the permit did not require testing of the NOx and VOM emissions of the BOFs. That testing was subsequently required by the CAAPP permit issued for the facility.

[60] This approach is consistent with a basic principle of the Title V permit program, as reflected in the CAAPP, that the responsibility for showing compliance with applicable air pollution control requirements for a facility lies with the source or Permittee for the facility, and not with the permitting authority.

[61] It should also be noted that in PCB 2013-53, the appeal that is pending before the Pollution Control Board for CAAPP permit 96030056, US Steel challenged Condition 5.13, General Procedures for Certain Permit Limits on Emissions. Condition 5.13 is relevant to the requested revisions of Permit 95010001 as it specifies procedures by which compliance is to be generally determined with the emission factor limits and annual emission limits set by Permit 95010001for process units. In addition to not proposing revisions to Permit 95010001 to accommodate use of prescribed emissions factors, the 2022 application does not address related revisions to Condition 5.13 of Permit 96030056 to potentially facilitate resolution of PCB 2013-53 as Condition 5.13 is challenged in this appeal.

14. THE 2022 APPLICATION DOES NOT ADDRESS THE AMENDMENT TO THE CAAPP PERMIT AUTHORIZED BY CONSTRUCTION PERMIT 11050006, AS IS RELEVANT FOR THE REQUESTED INTEGRATED PROCESSING OF THE REVISION TO PERMIT 95010001

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application was not accompanied by an application for an administrative amendment to incorporate changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are authorized by Construction Permit 11050006, issued April 1, 2013. That construction permit addresses the baghouse control system installed on the BOFs to improve control of the particulate emissions of these furnaces from charging and tapping. As that construction permit was subject to Integrated Processing, it provides for certain changes to then be made in the CAAPP permit to the requirements for the BOFs as needed to accommodate the use of both this new baghouse control system and the existing electrostatic precipitator (ESP) system for control of emissions. However, US Steel has not initiated a revision to the CAAPP permit to incorporate changes as authorized by Permit 11050006 by submitting an application for an administrative amendment of the CAAPP permit.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent the administrative amendment of the CAAPP permit as authorized by Construction Permit 11050006, as the 2022 application requests Integrated Processing, the application requests that revision of Permit 95010001 authorize changes to the current CAAPP permit. As such, the application effectively requests that separate from the revisions that are specifically requested by the application, the Illinois EPA reissue a CAAPP permit that, as related to the BOFs, contains provisions that are no longer accurate. For example, the description of the BOFs in CAAPP Conditions 7.5.1 and 7.5.2 does not indicate the use of the baghouse control system on the BOFs; only the ESP system is addressed. In addition, CAAPP Condition 7.5.5-1 does not address the corrective action procedures for baghouses required by 40 CFR 63.7800(b)(4). The addition of the baghouse system would be appropriately addressed in the CAAPP permit by the earlier amendment authorized by Construction Permit 11050006. As such, it would be contrary to the CAAPP to authorize further revisions to the CAAPP permit by means of Integrated Processing, as is requested by the 2022 application, without first making the revisions to the CAAPP permit authorized by Permit 11050006. Otherwise, the amendment of the CAAPP permit authorized by means of the revision of Permit 95010001 would be deficient. For the BOFs, as such a CAAPP permit, would not address certain applicable requirements, the

permit would not contain provisions to assure compliance with all applicable requirements. It would also continue to include requirements that, as addressed by Permit 11050006, would have become obsolete with the addition of the baghouse control system.

Discussion

The 2022 application does not identify the version of the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, Permit 96030056, that would be eligible for administrative amendment pursuant to the Integrated Processing of the revisions to Permit 95010001 that are requested. This is relevant because the Illinois EPA has already issued a construction permit with Integrated Processing, i.e., Construction Permit 11050006, issued April 1, 2013. This permit addresses the addition of a baghouse system to improve control of particulate emissions of the basic oxygen furnaces from charging and tapping of the furnaces. With the addition of this new system, the furnaces have three points of emissions, i.e., the new baghouse, the historic ESP, and the roof monitor on the furnace shop.[62] Certain work practices that were required by Permit 95010001 for control of particulate emissions of the furnaces with only an ESP system conflicted with the use of the baghouse system or would no longer be appropriate when emissions were also controlled with the new system. To address the fact that these work practices were also present in the CAAPP permit for the facility, Construction Permit 11050006 was subject to Integrated Processing and allowed certain changes to be made to the CAAPP permit by administrative amendment.[63] This was intended to enable use of the new baghouse system for improved control of particulate emissions in compliance with the CAAPP permit without the need for a subsequent permit proceeding to modify the CAAPP permit. However, US Steel has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006.[64]

Section 39.5(13)(a) of the Illinois Environmental Protection Act provides that "The Agency shall take final action **on a request** for an administrative permit amendment within 60 days after **the**

[62] The new baghouse system required a construction permit because this system would affect the requirements that then existed for control of particulate emissions of the basic oxygen furnaces, including their emissions of lead. For purposes of NSR, the construction permit was issued based on the new baghouse system being a project that would reduce the emissions of particulate and lead from these furnaces rather than increase these emissions. The permit was also based on this new system not increasing the emissions of other pollutants from these furnaces. As such, the construction permit for the new baghouse system, Permit 11050006, did not set limits for emissions from the baghouse system. This permit also did not lower the existing limits for the emissions of the basic oxygen furnaces.

[63] To address the changes to the CAAPP permit that would be needed for use of the new baghouse system, Permit 11050006 provides for replacement of Section 7.5 of the CAAPP permit, which addresses the basic oxygen furnace shop, including the basic oxygen furnaces, in its entirety. The new version of Section 7.5 addresses the basic oxygen furnace shop with the new baghouse system. Given the extent of the changes to Section 7.5 that were needed to accommodate addition of a baghouse to the particulate control system for the basic oxygen furnaces, this approach was taken to Permit 11050006 to provide accuracy, clarity and simplicity in the revisions to the CAAPP permit that were being authorized.

[64] The 2022 application does address the addition of the baghouse control system for the basic oxygen furnaces as related to the emission of the furnaces. US Steel does not propose separate limits set for the individual emission points for these furnaces. Instead, the application requests that the revised permit set overall limits for the emissions from the control systems of the basic oxygen furnaces.

receipt of the request." (Emphasis added.) Accordingly, in the absence of a formal request from US Steel to the Illinois EPA to initiate the administrative amendment of the CAAPP permit contemplated by Permit 11050006, the 2022 application can only request Integrated Processing to allow administrative amendments of the current CAAPP permit, as has actually been physically issued by the Illinois EPA.[65, 66]

[65] The timing of the physical issuance of a revised CAAPP permit by the Illinois EPA is critical as a procedural matter because it starts the period within which the Permittee may appeal such action to the Pollution Control Board. Moreover, in PCB 2013-62, US Steel has already appealed certain elements of the changes to the CAAPP permit that are addressed by the administrative amendment to the CAAPP permit authorized pursuant to Permit 11050006.

Given this appeal, the Illinois EPA would not "reinstate" those provisions when issuing the amended CAAPP permit. Instead, it is expected that the amended CAAPP permit would contain notes that explain that the appealed provisions continue to be present in the that existing CAAPP permit as they were appealed. Nevertheless, it is possible that US Steel would appeal those notes in the amended permit as they would acknowledge the continued existence of the appealed provisions.

[66] Concerns are posed by certain conditions in existing Construction Permit 11050006 and the related amendments to CAAPP Permit 96030056 that it authorizes. The 2022 application is not accompanied by a request for changes to Permit 11050006 or a proposal for how to address these concerns so that they would not be perpetuated in the amended CAAPP permit. One concern is that the deadlines in Permit 11050006 for performing emission testing on the new baghouse and completing certain other actions were based on the basic oxygen furnaces being in routine use once the construction of the new baghouse system was completed. The permit did not contemplate the over two yearlong interruption in production that began in December 2015. US Steel undertook this interruption in production in response to the poor markets for domestic steel at that time. As such, although failures to meet certain deadlines in Permit 11050006 likely were reasonable, it is not clear that they would be excused as being due to *force majeur* (i.e., event(s) that could not reasonably be anticipated or controlled by the source).

The other concern with existing Construction Permit 11050006 and the related amendments to CAAPP Permit 96030056 is that they overlook the role of the existing ESP control system in controlling particulate emissions from charging and tapping of the basic oxygen furnaces. Instead, Permit 11050006 incorrectly indicates that the new baghouse system will control emissions from charging and tapping of the furnaces and the existing ESP system will control emissions from the refining process. In fact, the new baghouse system was constructed to improve control of emissions from charging and tapping, with capture hoods to collect particulate emissions that are not captured by the hoods that serve the ESP system. This is perhaps most clearly shown in the 2010 Memorandum of Understanding between US Steel and the Illinois EPA (MOU) as this MOU addresses improvement in the control of emissions from charging of the furnaces. Section 4(d) of the MOU acknowledges the presence of the existing control for charging with the ESP. It also indicates that control of emissions from charging could be improved by ducting either some or all of these emissions to a new baghouse system. In any case, the errors in the description of the new baghouse system for the basic oxygen furnaces in Permit 11050006 should also be corrected so that erroneous information is not perpetuated in the amendments to the CAAPP permit.

15. THE 2022 APPLICATION WOULD NOT CLARIFY THE RELATIONSHIP BETWEEN FUGITIVE DUST CONTROL MEASURES REQUIRED BY PERMIT 95010001 AND MEASURES REQUIRED BY 35 IAC PART 212 SUBPART K

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* As related to practices to reduce emissions of fugitive dust from roadways, parking areas and open areas at the Granite City Works and certain public roadways near this facility, the 2022 application does not propose revisions to clarify the interplay between the associated recordkeeping and reporting that are required by Permit 95010001 and the associated recordkeeping and reporting that are required by Board rules. In this regard, except for Condition 25, Permit 95010001 does not address the Board's rules for control of emissions of fugitive dust. (Condition 25 addresses 35 IAC 212.316(e)(1), which limits the opacity of emissions from roadways and parking areas at the facility to no more than 5 percent, average of four vehicle passes, 3 opacity readings for each pass.) While the CAAPP permit for the facility addresses requirements in Board rules for control of fugitive dust, it is unclear whether the requirements for recordkeeping and reporting in 35 IAC 212.316(g) are applicable for the public roadways for which specific measures to reduce emissions of fugitive dust are required by Permit 95010001. This is because Condition 7.13.9(a) in Part 7.0 of the CAAPP permit, which contains "Unit Specific Conditions for Specific Emission Units," provides that the requirements of 35 IAC 212.316(g) apply for "… any fugitive particulate matter emission unit subject to 35 IAC 212.316," without further elaboration on whether public roads are subject to 35 IAC 212.316. However, Condition 5.3.2(c)(ii) in Part 5.0 of the CAAPP permit, which contains "Overall Source Conditions," explicitly applies the requirements for Fugitive Particulate Matter Operating Programs, 35 IAC 212.309, 212.310 and 212.312, to the public roadways for which measures to reduce emissions of fugitive dust are required. Accordingly, for the subject public roadways, the CAAPP permit indirectly indicates that the requirements of 35 IAC 212.316(g) also apply.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent clarifying information as described above, the 2022 application does not include the necessary information to allow a revision to Permit 95010001 to be proposed, much less issued, for the Project with Integrated Processing, as is also requested by the application. This is because the amendment of the CAAPP permit that would be authorized by means of the requested revision of Permit 95010001 would be deficient. For roadways, parking areas and other open areas, such an amended CAAPP permit, would not clearly delineate the standards for opacity of emissions pursuant to Board rules that apply to the different

categories of emission units (e.g., 5 percent for roadways and parking areas at the facility, 10 percent for storage piles, and 20 percent for the on-site landfill). In addition, if provisions of 35 IAC 212.316 should not be applied to public roadways, as they are not part of the Granite City Works, such an amended CAAPP permit would improperly perpetuate errors in the current CAAPP permit regarding applicability of Board rules.

Discussion

For roadways, parking areas, and open access areas, Conditions 23, 24, 26, 27, 28, 29 and 30 of Permit 95010001 require implementation of control measures for emissions of fugitive dust. The 2022 application does not make clear the relationship between these requirements established by permit and state regulatory requirements for fugitive emissions in 35 IAC Part 212 Subpart K.[67] In particular, Condition 29 requires daily recordkeeping for the implementation of required measures for on-site dust control. However, it does not address the relationship between these permit-mandated records and the recordkeeping required by 35 IAC 212.316(g)(2).[68] At the same time, Permit 95010001 does address one requirement of 35 IAC Part 212 Subpart K as Condition 25 restates the requirement of 35 IAC 212.316(e)(1), which provides that the opacity of fugitive particulate matter emissions from any roadway or parking area at the Granite City Works shall not exceed 5 percent.[69] That Permit 95010001 does not currently deal with

[67] Incidentally, the CAAPP permit for the Granite City Works appears to erroneously apply the requirements of 35 IAC Part 212 Subpart K, to the requirements for off-site dust control in Permit 95010001. These regulatory requirements, including that subject sources must be operated under the provisions of an operating program designed to significantly reduce fugitive particulate matter emissions, are applicable to US Steel for sources of fugitive dust at the Granite City Works. However, 35 IAC 212.302 appears to provide that the various emission standards and control requirements in 35 IAC Part 212 Subpart K, other than the general standard for the opacity of fugitive emissions in 35 IAC 212.301, apply for emission units for fugitive dust at certain types of facilities, including manufacturing facilities. Accordingly, these regulatory requirements would not apply to off-site roadways and the compliance procedures for the control measures for off-site roadways should instead be established by permit.

[68] For example, for roadways and parking areas at a steel mill in Granite City (i.e., the Granite City Works), 35 IAC 212.316(g)(2) requires the owner or operator to keep the following detailed records related to the application of control measures for these units:

> 35 IAC 212.316(g)(2) …
>
> D) For each application of water or chemical solution to roadways by truck: the name and location of the roadway controlled, application rate of each truck, frequency of each application, width of each application, identification of each truck used, total quantity of water or chemical used for each application and, for each application of chemical solution, the concentration and identity of the chemical;
> E) For application of physical or chemical control agents: the name of the agent, application rate and frequency, and total quantity of agent, and, if diluted, percent of concentration, used each day;
> F) A log recording incidents when control measures were not used and a statement of explanation.

[69] In Condition 31, Permit 95010001 also refers to 35 IAC Part 212 Subpart U, which also addresses fugitive emissions. For certain facilities, including the Granite City Works, it requires that the owner or operator prepare a contingency measure plan for reductions in particulate emissions that could be implemented in the event of an exceedance of the NAAQS for PM10, 24-hour average. Incidentally, Illinois has never needed to implement the contingency plans required by 35 IAC Part 212 Subpart U.

regulatory requirements for fugitive dust is an issue as Integrated Processing of a revision of this permit requires that the compliance procedures in the revised permit be consistent with those required by the CAAPP.

16. THE 2022 APPLICATION DOES NOT ADDRESS CHANGES TO THE CAAPP PERMIT THAT ARE NEEDED DUE TO REVISIONS TO 40 CFR 63 SUBPART FFFFF, AS COULD BE EXPEDITED BY INTEGRATED PROCESSING OF PERMIT 95010001

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a) .

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not address or identify changes to Permit 95010001 and, by means of Integrated Processing of the revision to Permit 95010001, the changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are appropriate as a result of certain revisions of the Iron and Steel NESHAP, 40 CFR 63 Subpart FFFFF. Those revisions, which took effect in January 2022, provide that the emission standards in 40 CFR 63 Subpart FFFFF apply at all times. The prior exemptions from these standards for a subject unit during periods of startup, shutdown and malfunction no longer apply. The provisions of 40 CFR 63 Subpart FFFFF are relevant to Permit 95010001 as it directly or indirectly relies on these rules for the compliance procedures that accompany the permit limitations for the particulate emissions of the NESHAP-subject units, as needed to make those limitations enforceable as a practical matter. For the BOFs, Permit 95010001 directly relies on 40 CFR 63 Subpart FFFFF as Condition 9 refers to applicable provisions of 40 CFR 63 Subpart FFFFF for the work practices, opacity limits, operational limits, emission testing, operational monitoring, recordkeeping and reporting that are required. For the blast furnace casthouse and units other than the BOFs that are subject to 40 CFR 63 Subpart FFFFF, the applicable compliance provisions of this NESHAP are currently indirectly relied upon as those requirements are addressed in the CAAPP permit for the facility,. (For the BOFs, the CAAPP permit also addresses the applicable compliance procedures of 40 CFR 63 Subpart FFFFF.)

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent explicit recognition in the 2022 application of the recent revisions to 40 CFR 63 Subpart FFFFF, the version of Permit 96030056 that would be authorized by means of the Integrated Processing of revised Permit 95010001 could continue to reflect the historic version of 40 CFR 63 Subpart FFFFFF, prior to the revisions related to startup, shutdown and malfunction. For example, the current CAAPP permit addresses provisions of 40 CFR 63 Subpart FFFFF that required startup, shutdown and malfunction plans that were removed in the revision of these rules. (Refer to CAAPP Condition 7.4.5-2(a) for the “affected blast furnaces and casthouses [sic]” and CAAPP Condition 7.5.5-2(a) “for BOF [sic].”) This would be an impediment to Integrated Processing of a revision to Permit 95010001 if the revised permit would not provide for compliance requirements that are substantially equivalent to those

required by the CAAPP. It would clearly be contrary to the compliance requirements of the CAAPP if for the casthouse and the BOFs, the amended CAAPP permit that would be authorized be issued by means of Integrated Processing would still include provisions of the historic version of 40 CFR 63 Subpart FFFFF that have ceased to apply.

Discussion

The 2022 application does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020. (85 Federal Register, pages 42,074 – 42,130, July 13, 2020). Among other revisions to 40 CFR 63 Subpart FFFFF, USEPA acted to remove exemptions from the emission and opacity limits in this NESHAP for periods of startup, shutdown and malfunction (SSM). Accordingly, effective January 12, 2022, the emission and opacity limits of this NESHAP became applicable at all times. The requirements of this NESHAP that formerly dealt with SSM ceased to be applicable. Notably, subject sources would no longer be required to keep startup, shutdown and malfunction plans detailing the procedures for operating and maintaining subject emission unit(s) during periods of SSM, as had been required by 40 CFR 63 Subpart FFFFF as it had applied 40 CFR 63.6(e)(3) in the general provisions of the NESHAP regulations to subject sources,

These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the 2022 application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the basic oxygen furnaces and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate. This reliance occurs as the emission limits that are set or would be set by a revised permit would be restated in the CAAPP permit for the Granite City Works, Permit 96030056. The provision currently in CAAPP Permit 96030056 that reflect the exceptions to the requirements of 40 CFR 63 Subpart FFFFF for SSM create a break or interruption in this reliance on the NESHAP for purposes of enforceability of permit limits for emissions, even if the actual nature and effect of this break or interruption is uncertain. Any concern over such interruptions would be eliminated if the former provisions of the NESHAP regulations, which USEPA acted to strike in July 2020, were also no longer present in the CAAPP permit.[70]

[70] From a legal and practical perspective, the continued presence of the former provisions of 40 CFR 63 Subpart FFFFF in the CAAPP permit would be problematic. Would US Steel have to maintain startup, shutdown and malfunction plans as related to particulate emissions of NESHAP-subject units relative to permit limits for particulate emissions? Would the continued presence of these provisions in the CAAPP permit throw Integrated Processing of Permit 95010001 into question as the compliance procedures that would accompany the limits for particulate emissions in revised Permit 95010001 would not be consistent with the procedures required by the CAAPP? Would US Steel and the Illinois EPA have to delineate and then implement a secondary version of the compliance procedures that would deal with emissions of particulate from NESHAP-subject units during SSM events?

17. THE 2022 APPLICATION DOES NOT ADDRESS CHANGES TO THE CAAPP PERMIT THAT HAVE RESULTED FROM SHUTDOWN OF EMISSION UNITS, AS IS RELEVANT FOR THE REQUESTED INTEGRATED PROCESSING OF THE REVISION TO PERMIT 95010001

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency: T*he 2022 application does not identify or address changes to the CAAPP permit for the facility, Permit 96030056, that result from the permanent shutdown of certain emission units at the facility. US Steel has also not taken other action to initiate issuance of a revision of Permit 96030056 that would remove provisions for emission units that are now permanently shutdown. In this regard, for example, Permit 96030056 currently includes provisions addressing the two by-product recovery coke oven batteries at the facility that were permanently shut down in 2015.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information in the 2022 application or other appropriate action by US Steel, as addressed above, the application does not include the necessary information to enable a revision to Permit 95010001 to be issued with Integrated Processing. This is because the application would not show that such a revision to Permit 95010001 would meet the criteria for Integrated Processing, as is specifically requested by the application. That is, the 2022 application would not show that the revisions to Permit 95010001 would provide for procedural and compliance requirements in Permit 96030056 that are substantially equivalent to those provided for by the CAAPP. The application would not support subsequent amendment of Permit 96030056 by means of Integrated Processing that would remove provisions for units that are now shutdown. Instead, absent an appropriate request, the application, would only support issuance of an amended CAPPP permit that would include the current provision for units that are now shut down. In this regard, the Integrated Processing of a construction permit only allows for subsequent amendments to a CAAPP permit as provided for by the construction permit. The Illinois EPA is not given independent authority to revise a CAAPP permit to remove provisions for units that are now shut down but are not otherwise the subject of the construction permit application.

Discussion

The 2022 application does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emission units, as generally addressed by Condition 9.11 of the CAAPP permit.

> Condition 9.11 Permanent Shutdown
> This permit only covers emission units and control equipment while physically present at the indicated source location(s). Unless this permit specifically provides for equipment relocation, this permit is void for the operation or activity of any item of equipment on the date it is removed from the permitted location(s) or permanently shutdown. …

While the 2022 application acknowledges that the by-product coke ovens at the Granite City Works have been shut down, this application does not separately address the consequences for the current CAAPP permit. The shutdown of these batteries was accompanied by the shutdown of coal and coke handling operations, the coke by-products plant, the handling of coke by-products, and possibly certain wastewater treatment processes.[71, 72] In addition, although not shut down, Boilers 11 and 12, Ladle Dryer/Preheaters and Slab Reheat Furnaces are no longer able to use COG as fuel since COG is no longer produced at the facility. As such, provisions in the CAAPP permit that identify or address the use of COG in these units are no longer necessary.[73] It would be improper for the revised version of the CAAPP permit authorized by means of the Integrated Processing of a revision to Permit 95010001 to still physically include provisions that should no longer be present in the revised CAAPP permit given the permanent shutdown of the emission units that were subject to those provisions.[74] The responsibility to identify provisions in

---

[71] The elimination of COG also affected the applicability of emission standards to certain units. For example, 35 IAC 212.458(b)(23) is no longer applicable, to ladle dryers/preheaters, contrary to what is stated in Condition 7.5.3-1 of the CAAPP permit.

[72] US Steel's current application for renewal of CAAPP Permit 96030056, which was received by the Illinois EPA on December 3, 2013, also does not address shut down of the by-product coke oven batteries and other related operations at the facility. This application only acknowledges that changes to the CAAPP permit will be needed in the future to address the addition of the baghouse to the particulate control system for the basic oxygen furnaces when construction of the baghouse is complete.

> The existing equipment descriptions for the individual processes at GCW (Granite City Works) in the CAAPP permit sections 7.1 to 7.4 and 7.6 to 7.13 are generally accurate. However, the Basic Oxygen Furnace process described in the CAAPP permit condition 7.5 will eventually need to be updated with the new secondary baghouse added as part of the Emission Reduction Project (Construction Permit No. 11050006) once construction is complete.
>
> Application for Renewal of CAAPP Permit 95030056, Section 2.2.2, "Process Changes."

[73] Irrespective of whether certain provisions in the CAAPP permit related to use of COG are still necessary, Condition 5.6 of the CAAPP permit limits the SO_2 emissions of these units from use of COG. (This condition restates limits from Federally Enforceable State Operating Permit 94120017, originally issued December 12, 1994.) The absence of COG does not act to excuse US Steel from required recordkeeping and periodic reporting for emissions of SO_2 and PM_{10} from these units from use of COG (CAAPP permit, Conditions 5.9(e) and 5.10.3). It also does not excuse US Steel from required operational monitoring for the use and sulfur content of COG (CAAPP permit, Conditions 5.6(a) and 7.3.9(f)). In this regard, the emission units addressed by CAAPP Condition 5.6, which are addressed by these requirements for operational monitoring, recordkeeping and reporting, have not been shut down.

[74] A fundamental requirement of the CAAPP is that applications for CAAPP permits must be truthful, accurate and complete. In this regard, Section 39.5(5)(e) of the Environmental Protection Act provides that "Each submitted CAAPP application shall be certified for truth, accuracy, and completeness by a

the CAAPP permit that should not be carried forward initially falls on US Steel as it is the CAAPP Permittee for the Granite City Works.[75] Moreover, as the 2022 application requests Integrated Processing of the requested revisions to Permit 95010001, the subsequent revisions to the CAAPP permit that would be authorized by the revisions to Permit 95010001 must fulfill the requirement that a CAAPP permit issued for a source accurately identify or address the emission units that constitute the source is being permitted.

responsible official in accordance with applicable regulations." Section 10(a)(i) of the Act provides that one of the standards of issuance for a CAAPP permit by the Illinois EPA is that "… the applicant has submitted a complete and certified application for a permit, permit modification, or permit renewal consistent with subsection 5 and 14 of this Section [Section 39.5 of the Act], as applicable, and applicable regulations." The requirement for an application to be truthful, accurate and complete is applicable to US Steel's current request for revisions to Permit 95010001 as it includes a request for Administrative Amendment to the CAAPP permit for the Granite City Works by means of Integrated Processing under the CAAPP. The scope of this requirement's applicability is not limited to only certain types of CAAPP applications, such as applications for initial CAAPP permits or renewals of CAAPP permits.

[75] As US Steel is the Permittee for a CAAPP source, it must periodically report compliance or noncompliance with each of the requirements set forth in the CAAPP permit. If US Steel believes that it is "in compliance" with regard to certain requirements in the CAAPP permit because those requirements have been affected by Condition 9.11 of the CAAPP Permit, it is appropriate for US Steel to request appropriate changes to the CAAPP permit by means of an appropriate application for amendment or modification of the CAAPP permit. This is especially true as certain requirements in the CAAPP permit that relate to use of COG apply to emission units that have not been shut down.

18. THE EVALUATION OF BEST AVAILABLE CONTROL TECHNOLOGY (BACT) IN THE 2022 APPLICATION FOR CARBON MONOXIDE (CO) IS NOT SUFFICIENT AND DOES NOT ADEQUATELY SUPPORT US STEEL'S PROPOSAL FOR BACT

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were ranted as requested:* Sections 9(a), 9(b)(2), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*, 201.152***, 201.160(a), 204.280, 204.330, 204.810, 204.820 and 204.1100(c).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* For the blast furnace casthouse, for which BACT for CO must now be set as it has been realized that the casthouse emits CO, the BACT demonstration in the 2022 application does not show that options for BACT for CO other than add-on control devices were considered. For the blast furnace stoves, for which BACT for CO must now be reevaluated as increases in permitted emissions are requested, the application is not accompanied by diagrams and cost data supporting the claim that it is not feasible to conduct emission testing by USEPA reference methods for the CO emissions of the stoves. This information is necessary for the stoves if BACT for CO is to not be set as a numerical standard. (The 2022 application requests that the revised permit recognize CO emissions from the casthouse of about 300 tons/year, of which about 100 tons/year would be the increase from the Production Increase Project; the requested increase in permitted CO emissions from burning blast furnace gas (BFG) in the blast furnace stoves is almost 10,000 tons/year, with an overall increase, also considering the BFG flares and boilers, of more than 20,000 tons/year.) For both the casthouse and the blast furnace stoves, the BACT demonstrations in the application do not include descriptions or documentation for the investigations that were conducted into available options for control of CO.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as addressed above, the BACT demonstrations in the 2022 application for CO are not complete. They do not show that BACT would be utilized for CO with changes in permitted CO emissions of the Project as requested by the application. As such, they cannot be relied upon to conclude that BACT is utilized for CO for the casthouse and blast furnace stoves, much less, for the Illinois EPA to set appropriate requirements as BACT for CO in a revision to Permit 95010001.

Discussion

The evaluation of Best Available Control Technology (BACT) for CO in Section 8 of the 2022 application lacks necessary information to support US Steel's proposal for BACT for CO for the emissions units for which this must be determined or redetermined under the PSD program as a consequence of the requested revisions to Permit 95010001. The evaluation addresses BACT for

CO for the casthouse for which BACT must now be determined as it is now recognized that the casthouse emits CO. It also addresses BACT for CO for the blast furnace stoves as the 2022 application requests that the revision of Permit 95010001 allow for more emissions of CO from these units.

The Scope of the Evaluation

As explained in the 2022 application, consistent with the definition of BACT in Section 169(3) of the Clean Air Act (42 US Code Section 7479(3) and as confirmed by USEPA guidance, a determination of BACT must consider options to control or reduce emissions of an emission unit besides add-on control devices.

> In the BACT analyses herein, the term "available" is used, consistent with U.S. EPA guidance to refer to any control strategy that is potentially applicable to the source type in question (i.e., a technology or control option that has a practical potential for application to the source category in general). These may include fuel cleaning, inherently lower polluting processes, and end of pipe control devices. All identified control strategies that are not inconsistent with the fundamental purpose and basic design of the proposed [sic] facility are listed in this step.
>
> 2022 application, Section 8.2.1.4, "Available Control Options," p. 8-4.

For the casthouse, when identifying control options, the BACT evaluation only identifies end-of-pipe or "add-on control" control options. The evaluation does not identify other process-related control options such as work practices (2022 application, Section 8.2.3.3). In contrast, for the blast furnace stoves, the evaluation identifies both add-on control options and a process-related control option. i.e., "Work Practice Standards, including good combustion practices" (2022 application, Section 8.2.2.3). The evaluation does not explain why process-related control options are not available for the casthouse.[76]

Support Provided for the Scope of the BACT Evaluation

[76] Incidentally, with regard to the blast furnace stoves, the evaluation does not explain why "good combustion practices" are considered to be a type of work practice standard rather than a separate control option. In Section 8.2.2.6 "Step 5 - Establish CO BACT," the evaluation proposes operational monitoring for temperature and oxygen levels to confirm operation of the stoves for efficient combustion of fuel, thereby maintaining CO emissions within the level that is achievable given the nature of the physical and operational design of the stoves. The evaluation also separately proposes the less prescriptive practices that are more often considered to constitute good combustion practices. For example, Section 8.2.2.6 also proposes to, "Conduct annual adjustment and tune-up to include, **at a minimum**, inspecting, adjusting, cleaning, or replacing instrumentation and operational control system components and inspecting the air-to-fuel ratio control system and adjusting as **appropriate** for **proper** operation." [Emphasis added.]
Moreover, this statement of what would constitute "good combustion practices" for the stoves would be problematic as it would not be enforceable given the various qualifications, as highlighted, on the actions that are required actions to be taken.

For both the casthouse and the blast furnace stoves, the BACT evaluation in the 2022 application is not accompanied by supporting documentation for the investigation that was conducted into available control options. Instead, the evaluation simply states that a review of available control options was conducted. For example, for the casthouse, the evaluation states:

> Based on a review for BACT determinations in U.S. EPA's RBLC (RACT/BACT/LAER Clearinghouse) database and other literature, the control options that are potentially available to control CO emissions from the blast furnace casthouse are:
>
> - Capture system and thermal incineration and
> - Capture system and catalytic incineration.
>
> 2022 application, Section 8.2.3.3, p. 8-8.

When a BACT evaluation is submitted, it may be appropriate or necessary[77] for the application to also include documentary support for the review of available control options that was conducted. In this regard, BACT evaluations commonly include copies of information from the RBLC that is potentially relevant to the determination of BACT that must be made. Further explanation is also provided if some of that information is not considered applicable to the units that are the subject of the BACT determination. Likewise, as there is relevant information in the literature, especially as it is addresses available control options for the subject pollutant, copies of that information should be included in a BACT evaluation. This information enables the Illinois EPA, the USEPA and interested parties to confirm that the review of available control options for a BACT evaluation was thorough and can be relied upon to have reasonably identified potentially available control options for BACT.

Support Provided for Work Practices As BACT for the Blast Furnace Stoves

For the blast furnace stoves, the BACT evaluation for CO in the 2022 application proposes that BACT reflect certain good combustion practices for CO, rather than numerical emission standards. [78] However, the 2022 Application is not accompanied by supporting documentation to

[77] For the 2022 application, this information is considered necessary. BACT determinations for the CO emissions of casthouses for blast furnaces and blast furnace stoves are uncommon. The Illinois EPA does not have the ability based simply on its own experience and knowledge to confirm that the potential control options for CO BACT were reasonably identified in the BACT evaluations in the application.
[78] The definition of BACT at 35 IAC 204.280 provides that:

> If the Agency [Illinois EPA] determines that technological or economic limitations on the application of measurement methodology to a particular emission units would make the imposition of an emission standard infeasible, a design, equipment, work practice, operational standard or combination thereof, may be prescribed instead to satisfy the requirement for the application of BACT. Such standard shall, to the degree possible, set further the emission reduction achievable by implementation of such design, equipment, work practice or operation, and shall provide for compliance by means that achieve equivalent results.

support the claim that it is infeasible to measure their CO emissions so that BACT should not be set as a numerical emission standard.[79]

Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. For example, the application does not include diagrams for the existing ductwork of the stoves to address whether the configuration of this ductwork would accommodate installation of test ports at a location that would satisfy USEPA Reference Method 1. The application also does not show how the refractory lining on the stacks or their age, approximately one hundred years old, would present significant technical challenges and costs so that the installation of test ports at a suitable location should be considered infeasible. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

[79] With respect to BACT for the blast furnace stoves, the 2022 application indicates:

> USS Granite City is proposing work practice requirements rather than numeric limits as BACT. Numeric emission limitations are not proposed because direct measurement of emissions --*i.e.*, use of U.S. EPA reference test methods—is not feasible for any of the fuel emissions units subject to the BACT requirements for CO emissions. In particular, for the stack serving the blast furnace A stoves, there is no sampling port,[45] and for the stack serving the blast furnace B stoves there is no sampling port satisfying the location requirement in U.S. EPA Reference Method 1.[46] Each stack is refractory lined and is believed to be approximately one hundred years old.
> For the reasons presented above, numeric CO emission standards are not feasible for the blast furnace stoves.
>
> Footnote 45. For the one-time exhaust gas sampling event discussed in footnote 19 of this permit application, USS Granite City inserted a sampling probe into the stack through a pipe used to inject steam into the stack.
>
> Footnote 46. Appendix A-1 to 40 CFR part 60.
>
> 2022 application, Section 8.2.2.6 “Step 5 – Establish CO BACT,” p. 8-7.

19. THE APPLICATION DOES NOT ADDRESS BACT FOR SULFUR DIOXIDE (SO_2) AND CO FROM USE OF COKE OVEN GAS (COG) IN THE BLAST FURNACE STOVES

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*, 201.152***, 201.160(a), 204.280, 204.330, 204.810 and 204.1100(c).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include demonstrations of BACT for sulfur dioxide (SO_2) and CO from the burning of coke oven gas (COG) in Project-affected fuel burning units.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not allow a revision to Permit 95010001 to be issued for the Production Increase Project (Project)that considers baseline emissions from burning COG. This is because the application does not provide the demonstrations of BACT that is required as the Project is a major modification for SO_2 and CO under PSD. In this regard, unlike the initial permitting of the Project, the 2022 application now quantifies emissions of particulate, NOx and VOM from burning COG and these emissions are included in revised determinations of baseline emissions. (In 1996, the Project was permitted as a major modification for SO_2 and CO but did not quantitatively address emissions from burning COG.) If emissions from burning of COG are to be relied upon for the issuance of a revised permit, the 2022 application must also address the BACT requirements of PSD for the SO_2 and CO emissions from use of COG, as would have been applicable in 1996, when the Project commenced. The fact that the by-product recovery coke batteries at the Granite City Works were shutdown in 2015 and COG is no longer available at the facility, does not alter the applicable requirements under PSD that must be satisfied. PSD would be violated if a revised permit were issued for the Project based on revised NSR applicability analyses that considered use of COG, as contained in the 2022 application, absent demonstrations that the Project utilized BACT for emissions of SO_2 and CO from use of COG.

Discussion

The 2022 application does not demonstrate that Best Available Control Technology (BACT) was utilized as an aspect of the Project for the SO_2 and CO emissions of the blast furnace stoves, as required under the PSD program (e.g., 35 IAC 204.1100(c)). In this regard, unlike the original application, the 2022 application addresses emissions from use of coke oven gas (COG) as fuel in certain Project-affected units. (Refer to the revised netting analyses for the Project for particulate, NOx and VOM and in the 2022 application.) As the 2022 application now addresses emissions of certain pollutants from burning of COG in fuel-burning units, including the blast

furnace stoves, this application must also address the related consequence for emissions of SO_2 and CO under the PSD program from burning COG in the stoves. SO_2 and CO are pollutants for which the Project is a major modification subject to PSD. However, the 2022 application does not address BACT for SO_2 and CO as applied to use of COG in the stoves. As such, the 2022 application does not demonstrate that prior to February 2015, when the by-product recovery coke oven batteries at the Granite City Works were shut down and COG ceased to be available, BACT was being utilized for the SO_2 and CO emissions from use of COG in the stoves.

With respect to CO, it is relevant that the BACT demonstration in the 2022 application focuses on CO emissions from burning of fuels other than COG. For fuel burning units, the 2022 application states that “CO emissions of these units result primarily from incomplete combustion during the firing of BFG and natural gas.” This ignores the historic contribution of COG to the CO emissions of the stoves prior to February 2015. The 2022 application also does not state that, as of February 2015, it was no longer necessary to address CO emissions from use of COG because COG was no longer produced and available for use.

20. AS RELATED TO SO_2 EMISSIONS FROM USE OF BFG, THE 2022 APPLICATION IS INCONSISTENT WITH A PENDING 2008 APPLICATION

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9(b)(2), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* As related to emissions of sulfur dioxide (SO_2) from burning blast furnace gas (BFG), the 2022 application is inconsistent with and conflicts with an earlier application for revisions to Permit 95010001 that was received on February 8, 2008 (the "2008 application"). For the emissions of SO_2 from burning of BFG, the 2008 application requests increases in the emissions that are allowed by Permit 95010001. The 2022 application does not request such increases and does not request any changes to Permit 95010001 related to SO_2 emissions. The 2022 application does not even address the 2008 application to explain why the revisions to Permit 95010001 requested by the 2008 application are no longer needed. US Steel has also not taken other actions that would act to resolve the conflict between the 2022 application, which is being addressed in this proceeding, and the earlier 2008 application, which is still pending. For example, US Steel has not requested withdrawal of the 2008 application. In this regard, it is noteworthy that the approach taken in the 2022 application to SO_2 emissions from burning BFG is different from the approach that is taken for NOx, VOM and particulate. For example, for the BOFs for NOx and VOM, the 2022 application requests revisions to Permit 95010001 to increase permitted emissions so as to facilitate future compliance.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* The conflict between the 2008 application and the 2022 application is an impediment to revision of Permit 95010001 as requested by the 2022 application. Absent resolution of this conflict, either by appropriate information or request in the 2022 application or by other appropriate action by US Steel, the 2022 application should not be considered to show compliance with the SO_2 emission limits for burning BFG that are currently in Permit 95010001. As such, the 2022 application does not meet the standards for issuance of a construction permit.

Discussion

In 2008, US Steel applied for revisions to Permit 95010001 to increase permit limits for the sulfur content of BFG and the SO_2 emissions resulting from the use of BFG. That application (the 2008 application) was received on February 4, 2008. The 2022 application is inconsistent with and conflicts with the 2008 application. As such, these applications, as they currently exist, cannot be processed by the Illinois EPA absent appropriate action by US Steel on one or both of these applications, e.g., changes to the 2022 application so that it requests the same revisions to SO_2 emission limits for use of BFG as the 2008 application. In this regard, the 2022 application "… does not request any changes to the emission limits for SO_2 and lead emissions established in the Construction Permit 95010001." (2022 application, p. 2-2.) The 2008 application does request changes to the provisions of the permit for SO_2., as it is an "Application to modify to correct the emission factors used to develop the original application and permit in light of newly identified information on emissions and emission factors." (October 2008 application, p. 1-1.)

In particular, in the 2008 application:

> …US Steel seeks to revise the Production Increase Permit (95010001) to account for US Steel's revised method for calculating the SO_2 emissions from BFG combustion. This will increase the total allowable SO_2 emissions on an annual basis from combustion of BFG in the Production Increase Permit.
>
> 2008 application, pp. 2-2 and 2-3

The 2008 application specifically requests that the SO_2 emission factor limit for BFG be increased from 6.65 to 16.00 pounds/million cubic feet of gas burned. With the revised emission factor, the permitted SO_2 emissions from use of the 185,030 million cubic feet of BFG per year, as allowed by the permit, would increase from 615.22 to 1480.24 tons/year. However, the 2022 application provides that the limits for SO_2 for use of BFG should be unchanged. As such, the 2022 application indicates that for use of BFG the requested revised permit should continue to limit SO_2 emission to 6.65 pounds/million cubic feet burned and 615.22 tons/year.

Moreover, the existence of the 2008 application suggests that the revisions to SO_2 emission limits that it requested were needed at the time of that application. The 2022 application does not show that this was not the case, as it does not address historic SO_2 emissions from use of BFG to show that an SO_2 emission factor of 6.65 pounds/million cubic feet was appropriate when Permit 95010001 was originally issued in 1996 and that annual SO_2 emissions have never exceeded 615.22 tons/year.

21. AS RELATED TO EMISSION LIMITS FOR SO_2, LEAD AND CO, THE 2022 APPLICATION IS INCONSISTENT WITH PENDING BOARD APPEALS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* For various processes, the 2022 application does not request or propose appropriate changes to the current emission factor limits in Permit 95010001 for SO_2, lead and CO to resolve pending permit appeals (PCB 2013-52 and PCB 2013-62). For these pollutants, Permit 95010001 sets emission factor limits for the blast furnace casthouse and the slag pits for SO_2; for the BOFs for lead and CO; and for desulfurization and reladling for lead. Alternatively, the 2022 application does not indicate that the inclusion of the current emission factor limits in a revised permit is not expected to result in another appeal as these limits are now considered acceptable. For the BOFs for CO, the application also does not indicate that the current emission factor limit, which applies only to the stack emissions from the electrostatic precipitator (ESP), would still be considered acceptable if applied to stack emissions. That is, the current limit would still be acceptable if it applied in aggregate to the CO emissions from the stack of the ESP and the stack of the baghouse, which was subsequently installed to improve control of the particulate emissions of the BOFs (Construction Permit 11050006). This change would be appropriate as particulate emissions of the BOFs are now addressed by two control systems. (Besides particulate, these systems capture emissions of CO and other pollutants from the BOFs but only act to reduce particulate and lead emissions.)

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include information necessary for the Illinois EPA to include conditions in a revised permit to prevent noncompliance with certain current emission factor limits that apply to the subject processes. As the subject limits, as they are or, in the case of PCB 2013-62, would be present in the CAAPP permit, are currently the subject of appeals, it is reasonable for these limitations for the review of the application to be based on compliance not being achieved. Moreover, absent information as described above, the 2022 application does not show that, as the subject limits are appealed and could be stayed in any revised CAAPP permit, these limits should be considered to still meet the substantive requirements of the CAAPP. Finally, it is noteworthy that for the subject processes for the various emission factor limits for PM, PM-10, NOx and VOM, the application does request revisions to the emission factor limits. For those requested revisions, the 2022 application, page 2-3, explains that "USS Granite City anticipates that these revisions will

enable settlement of the permit appeals currently before the Board because they involve provisions of the permit addressing emission factors."

Discussion

As already mentioned, the 2022 application does not request any changes to the emissions limits for SO_2 and lead currently set by Permit 95010001. The application states, "This permit application also does not request any changes to the SO_2 and lead emission limits in Construction Permit No. 950100001, so SO_2 and lead emissions will not be discussed further." [2022 application, Section 2.2, "General Description of Requested Permit Revisions." p. 2-2.] [80, 81, 82] For CO, the 2022 application does request that the revised permit address emissions of CO from

[80] In Section 3 of the application, in which support for elimination of emission factor limits and use of group limits is generally provided, the application only addresses limits for particulate, NOx and VOM. For example, the application states that,

> The approach proposed by USS Granite City with respect to the PM, PM_{10}, NOx and VOM emissions caps to be used in any revised Construction Permit No. 95010001, including the proposed revisions to certain emission limitations, compliance demonstration requirements, and other permit conditions as discussed in detail in Sections 5 through 7 of the permit application ["Proposed Changes to Permit Terms for PM and PM_{10} Emissions Increases Analyses," "Proposed Changes to Permit Terms for NOx Emission Increases Analysis, and "Proposed Changes to Permit Terms for VOM Emission Increases Analyses," respectively] is consistent with policy and precedent and will improve the enforceability of the PTE limitations in Construction Permit No, 95010001. In particular, USS Granite City emphasizes that removal of certain conditions and provisions addressing emissions individual emission units or emission points, including both limits on annual emissions and provisions emission addressing emissions factors will not result in impairment of the enforceability of the PTE limitations.
>
> 2022 application, Section 3, "Discussion of Permit Conditions Used to Restrict PTE [Potential to Emit]," 3-3.]

[81] For process operations, Permit 95010001 currently limits SO_2 emissions from the casthouse and slag pits associated with the blast furnaces in pounds per ton of iron produced and tons per year. For the casthouse, the SO_2 emissions of the main baghouse for the casthouse, the baghouse for the iron spouts at the casthouse, and the uncaptured emissions from the casthouse are limited, respectively, to 0.2006, 0.0073, and 0.0104 pounds per ton of iron produced. The SO_2 emissions of the slag pits are limited to 0.0100 pounds per ton of iron produced. (Permit 95010001, Condition 5 and Table 1.)

Although the emission factor limits for the SO_2 emissions of the casthouse are not identified as Best Available Control Technology (BACT) by Permit 95010001, these limits are considered to be the determination of BACT for SO_2 and should have been identified as such in this permit. BACT is required for the casthouse for SO_2 because the Project was a major modification for SO_2 under the PSD program, as is stated in this permit. Accordingly, as Project included physical changes to the blast furnaces to increase their production capability, BACT is required for the SO_2 emissions of the casthouse.

[82] For operations in the basic oxygen furnace shop, Permit 95010001 currently limits lead emissions in pounds per hour and tons per year. For the basic oxygen furnaces, the lead emissions from the ESP stack and roof monitor are limited to 0.01934 and 0.0129 pounds per hour, respectively. The lead emissions from desulfurization and hot metal transfer are limited to 0.0133 pounds per hour. (Permit 95010001, Condition 18 and Table 2.) The permit does not address the lead emissions of the basic oxygen furnaces that are now captured and controlled by the new baghouse system nor does the 2022 application request any revisions to the permit to address the lead emissions of these furnaces that now occur from the stack of the baghouse.

the casthouse and raise the limits for CO emissions of Project-affected fuel burning units.[83] However, the application does not request revisions to the emission limits currently in Permit 95010001 for the CO emissions of the basic oxygen furnaces, i.e., the limits in pounds per ton of steel produced and in tons per year for the CO emissions of these furnaces through the ESP stack.[84,] As such, the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62, as it does not propose revisions to current permit limits for emissions of SO_2, CO and lead. As previously discussed, in these appeals, US Steel challenged all emission factor limits set by Permit 95010001 for individual process operations. US Steel has not amended these appeals so that they only address emission factor limits for PM, PM_{10}, NOx and VOM and no longer address the emission factor limits that are set for SO_2, CO and lead. In addition, in the 2022 application, US Steel does not explain why the emission factor limits in Permit 95010001 for SO_2, CO and lead that were appealed are no longer considered to be objectionable. That is, US Steel would not again challenge those limits as it has already done in PCB 0013-53 and PCB 0013-62 if a revision to Permit 95010001 were issued that continued to include the current emission factor limits.[85]

With regard to the CO emissions of the basic oxygen furnaces, the 2022 application also does not request revisions to Permit 95010001 as the current permit only addresses CO emissions from the "BOF ESP Stack." The application does not request that these limits be revised so that they address all stack emissions of the basic oxygen furnaces, e.g., CO emissions from both the stack of the new baghouse system and the stack of the ESP system. Moreover, as the 2022 application does not propose such revisions to the current limits for CO emissions of these furnaces, the application effectively requests a relaxation of the current limits. This is because the revised permit would not address the CO emissions of these furnaces that now occur through the baghouse stack. That is, the limits in the revised permit would not account for any CO emissions that are no longer being captured with the ESP system and are instead now being emitted from the baghouse system.[86]

---

[83] In the original application for Permit 95010001, the casthouse was not identified as a source of CO and information for CO emissions was not provided. The application also requests certain updates to the limits for CO emissions from use of blast furnace gas and natural gas in Project-affected fuel burning units to reflect new information for the CO emissions from burning these fuels.

[84] Permit 95010001 currently limits CO emissions of the basic oxygen furnaces through the ESP stack to 8.993 pounds per ton of liquid steel produced and 16,097.47 tons/year. (Permit 95010001, Condition 18, Table 2, Section 1, BOF ESP Stack.) The permit does not address CO emissions that are now captured by the new baghouse system and emitted from its stack or any uncaptured CO emissions, which occur through the roof monitor.

[85] If the subject emission factor limits were included in a revised permit, the Illinois EPA could explain that, if these limits in the revised permit were stayed pursuant to an appeal to the Pollution Control Board, the limits would continue to be enforceable pursuant to Permit 95010001 as issued before the revision of the permit and any appeal of the revised permit to the Board.

[86] The 2022 application also does not request revisions to Permit 95010001 to address uncaptured CO emissions of the basic oxygen furnaces or otherwise address the uncaptured CO emissions of these furnaces. This is not consistent with the approach taken for the casthouse on the blast furnaces. For the casthouse, the application requests that the revised permit limit the overall emissions of CO from the stacks on the control systems serving the casthouse. The application also includes information for the overall CO emissions of the casthouse, including other captured emissions and uncaptured emissions.

22. THE 2022 APPLICATION DOES NOT INCLUDE A SIGNED CERTIFICATION FOR THE ACCURACY AND COMPLETENESS OF THE APPLICATION

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 39(a)* and 39.5(5)(e).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 270.401(f).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include a certification for the truth, accuracy and completeness of the application, as submitted on October 7, 2022. The certification in the 2022 application is a photocopy of an earlier certification dated February 25, 2020, that accompanied a prior application received on March 2, 2020, several years earlier. That certification cannot serve as the required certification. Also note that the 2022 application replaced the prior 2020 application. The transmittal letter accompanying the 2022 application states that, "Due to the nature of revisions throughout this application, the Illinois EPA should refer to this application for permit processing."

   With respect to the "certification" provided in US Steel's Comments responding to the Initial Draft Denial Letter, this was not sufficient to correct this omission. First, this certification, which is dated September 8, 2023, was an attachment to those comments and was not submitted as a supplement to the 2022 application. Second, the certification is not accompanied by an errata or other material correcting erroneous information in the application as either identified by the Illinois EPA in the Initial Draft Denial or identified by US Steel when developing its response to the Initial Draft Denial. Thus, even if the certification had been submitted as a supplement to the 2022 application, its truthfulness and validity would be questionable. The fact that the 2022 application was not certified puts the entire application under a cloud. In other words, as a matter of rule, absent an appropriate certification the Application is deficient. The Application cannot be considered creditable and should not be relied upon for making revisions to Permit 95010001.

As discussed in Section 8.2.3.7 of this permit application [BACT Evaluation for Blast Furnace Casthouse], USS Granite City is proposing a CO BACT emission limit of 70 lb/hr based on total emissions of these two baghouses [main casthouse baghouse and iron spout baghouse], assuming 95% capture efficiency for the capture system associated with the cast baghouse, as discussed in Section 5.2.3 of this permit application {A&B Blast Furnace Casthouse Roof Monitor Emissions PM_{10} Revised], the fugitive CO emissions from the casthouse roof monitor are 3.1 lb/hr. Total CO emissions from the casthouse roof monitor, including both baghouse and fugitive emissions are 73.1 lb/hr and 320 tons per year ("TPY").

2022 application, Section 4.4, "Updated CO Emissions Information for Blast Furnace Casthouse."

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* The 2022 application does not include the certification required by the Act, the Illinois EPA's regulations, and the Board's regulations.

Discussion

The 2022 application does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022. This is required by 35 IAC 270.401(f) and Section 39.5(5)(e) of the Act. This is because the Application requests Integrated Processing for the revisions to Permit 95010001 that are being sought. In place of this certification, the 2022 application includes a photocopy of an earlier certification, dated February 25, 2020, which was submitted with a prior application (2022 application, "Appendix A – Application Forms (Copies of Previously Submitted Versions)"). However, the 2022 application is a revision of the earlier application and US Steel intends the 2022 application to replace the earlier application submitted in March 2020 in its entirety (2022 application, Cover Letter). Accordingly, the 2022 application must include a new certification for its truth, accuracy and completeness.

Appendix A: Listing of Sections of the Illinois Environmental Protection Act (Act) That Are Cited for the Different Denial Points Detailed in Attachment 1 As Sections of the Act Which May Be Violated If a Revised Permit Were To Be Granted As Requested by the 2022 Application

Note: The text of the Act (415 ILCS 5) is available on a website for Illinois Compiled Statutes maintained by the Illinois General Assembly: https://www.ilga.gov/legislation/ilcs/ilcs3.asp?ActID=1585&ChapterID=36

Section 9(a): General prohibition against air pollution as it provides that no person shall "Cause or threaten to allow the discharge or emission of any contaminant into the environment in any State … so as to violate regulations or standards adopted by the Board (Pollution Control Board) under this Act." For various denial points in the Denial Letter, this general provision of the Act is cited as a provision of the Act that may be violated if a revised construction permit were issued as requested in the 2022 application as such permit would threaten to allow violations of Board regulations.

Section 9(b)(2): Prohibition against violating conditions imposed by air pollution control permits. The introductory language of Section 9 and Subsections 9(b) and 9(b)(1) of the Act provide that, "No person shall … Construct, install and equipment, facility … of any type designated by the Board … without a permit granted by the Agency unless otherwise exempt by this Act or Board regulations…." For persons with permits, the prohibition against violating permit conditions is in Subsection 9(b)(2), serving to provide that no such person shall operate any equipment or facility, "In violation of any conditions imposed by such permit."

Section 9.1(d): Prohibition against violations of certain sections of the federal Clean Air Act, including Section 165 (Prevention of Significant Deterioration (PSD)) and Section 173 (Permit Requirements for Nonattainment New Source Review Programs).

Section 39(a)*: Standard under the Act for issuance of permits. The designation "Section 39(a)*" or "39(a)*" is used to refer to the second clause of the first sentence in Section 39(a) of the Act. This clause provides that "…it shall be the duty of the Agency to issue a permit upon proof by that the applicant that the facility, equipment, vehicle vessel, or aircraft will not cause a violation of this Act or regulations thereunder." In the Denial Letter, this provision of the Act is routinely cited as a provision that may be violated because the 2022 application does not include proof that the Act or air pollution control regulations would not be violated if a revised permit were issued as requested by the application.

Section 39(a)**: Permit procedures under the Act. The designation "Section 39(a)**" or "39(a)**" is used to refer to the fifth sentence of Section 39(a) of the Act as it addresses imposition of conditions on permits. In particular, this sentence provides that in granting permits, "In granting permits, the Agency

may impose such other conditions as may be necessary to accomplish the purposes of this Act, and as are not inconsistent with the regulations promulgated by the Board hereunder." (As addressed below, this Section of the Act also provides that the Illinois EPA may impose reasonable conditions in a permit related to an applicant's compliance history as necessary to correct, detect or prevent noncompliance.) For various points in the Denial Letter, this provision of the Act is cited as one that may be violated because the 2022 application does not include information that may be needed for the Illinois EPA to impose necessary permit conditions in a permit that would be revised as requested by the application.

Section 39(a)***: Permit procedures under the Act. The designation "Section 39(a)***" or "39(a)***" is used to refer to the fourth sentence of Section 39(a) of the Act as it provides, "In granting permits, the Agency may impose reasonable conditions in a permit specifically related to an applicant's past compliance history with this Act as necessary to correct, detect or prevent noncompliance." (As discussed above, the Act also provides that permits may include conditions as may be necessary to accomplish the purposes of the Act and as are not inconsistent with Board regulations.) For certain points in the Denial Letter, this provision of the Act is cited as one that may be violated because the 2022 application does not include information that may be needed for the Illinois EPA to impose conditions to enable or facilitate future compliance.

Section 39.5(5)(e): A paragraph in Subsection 39.5(5) of the Act, "Applications and Completeness," in Section 39.5 of the Act, "Clean Air Act Permit Program." This provision requires that "Each submitted CAAPP application shall be certified for truth, accuracy and completeness by a responsible official in accordance with applicable regulations [i.e., 35 IAC 270.102 and the definition of "responsible official at Subsection 39.5(1) of the Act]. This provision is applicable for the review of the 2022 application as US Steel requests in this application that the processing of the revised permit that is requested be subject to Integrated Processing. As a consequence, the procedural and substantive requirements of Section 39.5 of the Act apply to the 2022 application pursuant to Section 39.5(13)(c)(v) of the Act, which provides the authorization for Integrated Processing of a construction permit.

Section 39.5(5)(i): A paragraph in Subsection 39.5(5) of the Act, "Applications and Completeness," in Section 39.5 of the Act. As already explained, the procedural and substantive requirements of the CAAPP are applicable to the Illinois EPA's review of the 2022 application as US Steel has requested that this application and any resulting revised permit prepared pursuant to this application be subject to Integrated Processing. The first sentence in this provision requires that:

> Any applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in a CAAPP application shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information to the Agency."

For several denial points, Subsection 39.5(5)(i) of the Act is identified as a provision of the Act that might be violated if a revised permit were issued as requested by the 2022 application because it does not include "relevant information" necessary for the evaluation of the application. That is, as

related to the particular applicable requirements, the application lacks information addressing the requirements, the information in the application addressing the requirement is insufficient, or the information in the application supports a finding that the requested revisions might not comply with the requirements. Note that as Subsection 39.5(5)(i) of the Act would not be satisfied by an application, a CAAPP permit cannot be issued pursuant to such application. This is because Subsection 39.5(10)(a)(iv), one of the standards for issuance of a CAAPP permit, would also not be satisfied.

Section 39.5(7)(a): A paragraph in Subsection 39.5(7) of the Act, "Permit Content," in Section 39.5 of the Act. This paragraph requires that "All CAAPP [Clean Air Act Permit Program] permits shall contain limitations and conditions and other enforceable terms and conditions, including but not limited to operational requirements, and schedules for achieving compliance at the earliest reasonable date, which are or will be required to accomplish the purposes and provisions of this Act and to assure compliance with all applicable requirements [emphasis added]." For various points in the denial letter, this provision is cited as a provision of the Act that may be violated because the 2022 application does not include information that may be needed for the Illinois EPA to impose necessary permit conditions in a revised version of Permit 95010001 that would be revised as requested by the application. This provision is relevant to the Illinois EPA's review of the 2022 application as US Steel has requested that the application and any resulting permit be subject to Integrated Processing. As provided by Sections 39.5(13)(a) and (a)(iv), as listed below, this makes the application subject to substantive requirements of the CAAPP. It is also noteworthy that, absent Integrated Processing, any revised construction permit that is issued pursuant to the 2022 application would not resolve US Steel's pending appeal of the current CAAPP permit for the Granite City Works (PCB 2013-53) or the related appeal of Construction Permit 11050006 (PCB 2013-62). Resolution of these appeals would require a separate CAAPP permit application and a permit proceeding to revise the CAAPP permit. Moreover, the revised CAAPP permit that would result from the CAAPP proceeding would not necessarily reflect the terms and conditions established in the earlier revision of Permit 95010001. As such, resolution of these appeals could require two more permit proceedings, i.e., a proceeding to modify the CAAPP permit and another proceeding for revisions to Permit 95010001 to address issues identified during the modification of the CAAPP permit.)

Section 39.5(10)(a)(iv): A paragraph in Subsection 39.5(1) of the Act. As Subsection 39.5(5)(i) of the Act would be violated if a revised permit were issued as requested, the 2022 application also would not satisfy Subsection 39.5(10)(a)(iv) of the Act, one of the standards for issuance of a permit under the CAAPP. This is because this application would not include all "relevant information." Subsections 39.5(10)(a) and (a)(iv) of the Act provide that:

> The Agency shall issue a CAAPP permit, permit modification, or permit renewal if all of the following conditions are met:
>
> …

(iv) The Agency has received a complete application and if necessary, has requested and received additional information from the application consistent with Subsection 5 of this Section and applicable regulations.

Section 39.5(13)(c)(v): Paragraphs (a) and (c)(v) in Subsection 39.5(13) of the Act, "Administrative Permit Amendments," in Section 39.5 of the Act. The designation "Section 39.5(13)(c)(v)" or "39.5(c)(v)" are used to refer to these paragraphs. These paragraphs contain the authorization for the Integrated Processing of a construction permit so as to allow the related revisions to the CAAPP permit to be made by administrative amendment, thereby avoiding the need for a subsequent modification of the CAAPP permit by either a minor or significant modification, as appropriate. These paragraphs of Subsection 39.5(10)(c) of the Act provide:

c. For purposes of this Section [Section 39.5 of the Act] the term "administrative amendment " shall be defined as a permit revision that can accomplish one or more of the changes described below:

…

v. Incorporates into the CAAPP permit the requirements from preconstruction review permits under a USEPA-approved program [i.e., Illinois construction permit program for sources of emissions and air pollution control equipment], provided the program meets procedural and compliance requirements substantially equivalent to those contained in this Section [emphasis added].

For various denial points in the denial letter, these paragraphs are cited as provisions of the Act that may be violated because the 2022 application is not sufficient for the Illinois EPA to impose necessary permit conditions in a new version of Permit 95010001 that would be revised as requested by the 2022 application. That is, this application does not include information that is necessary to enable such a revised permit to meet the compliance requirements, i.e., the substantive requirements, that must be satisfied by a CAAPP permit. For example, for certain emissions units, the Application requests that Permit 95010001 be revised to prescribe the actual emission factors that are to be used to determine compliance with limitations on annual emissions set by this permit. However, the application does not provide the supporting information that USEPA has found necessary for a permitting authority, e.g., the Illinois EPA, to set "prescribed emission factors" when issuing a Title V Permit. Similarly, the 2022 application requests certain revisions to the organization and terminology in Permit 95010001 for consistency with the CAAPP permit. However, the application does not request all such revisions that may be appropriate to reasonably achieve consistency in the organization and terminology of these permits.

Appendix B: Listing of Provisions in Subtitle B of Title 35 of the Illinois Administrative Code (IAC) That Are Cited for the Different Denial Points Detailed in Attachment 1 As Provisions Which May Be Violated If a Revised Permit Were To Be Granted As Requested by the 2022 Application

Note: The text of Illinois' regulations for control of air pollution (Illinois Administrative Code (IAC), Title 5, Subtitle B: Air Pollution, are available on a website maintained by the Board: https://pcb.illinois.gov/SLR/IPCBandIEPAEnvironmentalRegulationsTitle35

35 IAC Part 201, Permits and General Provisions

35 IAC 201.152*, Contents of Application for Construction Permit
This rule requires that applications for construction permits include certain data and information. The designation "201.152*" is used to refer to this rule as it requires this data and information to include "information concerning processes to which the emission unit or air pollution control equipment is related.

35 IAC 201.152**, Contents of Application for Construction Permit
This rule requires that applications for construction permits include certain data and information. The designation "201.152**" is used to refer to this rule as it requires this data and information to include "the quantities and types of raw materials to be used in the emission source or air pollution control equipment."

35 IAC 201.152***, Contents of Application for Construction Permit
This rule requires that applications for construction permit include certain data and information. The designation "201.152**" is used to refer to this rule as it requires this data and information include "… the nature, specific points of emissions and quantities of uncontrolled and controlled air contaminant emissions at the source that includes the emission unit or air pollution control equipment …."

~~35 IAC 201.159, Signatures~~
~~This rule requires applications for air pollution control permit submitted to the Illinois EPA to be signed. It provides that, "All applications and supplements thereto shall be signed by the owner and operator of the source, or their authorized agent, and shall be accompanied by evidence of authority to sign the application."~~

35 IAC 201.160(a)(1), Standards for Issuance
In 35 IAC 201.160(a) and (a)(1), the Pollution Control Board (Board) restates the standard of issuance in Section 39(a) of the Act for the Illinois EPA to issue a permit as applied specifically to air pollution control construction permits. This rule provides:

a) No construction permit shall be granted unless the applicant submits proof to the Agency that:

1) The emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or of this Chapter [Title 35, Subtitle B, Chapter I)];

35 IAC Part 203, Major Stationary Sources Construction and Modification

(35 IAC Part 203 is potentially of concern for the Production Increase Project for emissions of NOx, VOM and particulate. This is because, in 1996, when Permit 95010001 was initially issued for this project, the Granite City Works was in areas that were designated nonattainment for the National Ambient Air Quality Stands (NAAQS) for ozone (emissions of NOx and VOM) and particulate matter (emissions of $PM_{2.5}$). The Granite City Works is still in an area that is designated nonattainment for ozone.)

35 IAC 203.123, Federally Enforceable (Definition)
This definition provides that "Federally Enforceable" means enforceable by the United States Environmental Protection Agency [USEPA].” This definition is cited as a basis for certain denial points as the 2022 application requests revisions to Permit 95010001 to set limitations that would take the place of limitations currently in Permit 95010001. However, the application does not include information showing that these proposed limitations should be considered enforceable as a practical matter.

35 IAC 203.128, Potential to Emit (Definition)
This definition of “potential to emit” is cited as a basis for denial points as related to the role of permit limitations, as distinguished from the physical and operational design of a stationary source, in restricting the potential emissions of emission units. 35 IAC 203.128, along with 35 IAC 203.123, are cited as a basis for denial as the 2022 application does not show that certain emission limitations that are proposed, which would replace emission limitations currently in Permit 95010001, should be considered enforceable as a practical matter. In this regard, the second sentence of this definition of “potential to emit” provides that:

Any physical or operational limitation on the capacity of the source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design only if the limitation or the effect it would have on emissions is federally enforceable [emphasis added].

35 IAC 203.201, Prohibition
This provision requires an entity that would undertake a project that is "major" for a pollutant in an area that is designated a nonattainment area for the pollutant to comply with the substantive requirements of 35 IAC Part 203 for that pollutant. The various substantive requirements are then addressed later in Subpart C of 35 IAC Part 203. In this regard, the first two sentences of 35 IAC 203.201 provide:

> In any nonattainment area, no person shall cause or allow the construction of a new major stationary source or major modification that is major for the pollutant for which the area is designated a nonattainment area, except as in compliance with this Part [Part 203]for that pollutant. In areas designated nonattainment for ozone, this prohibition shall apply to new major stationary sources or major modifications of sources that emit volatile organic materials or nitrogen oxides.

As the revised NSR applicability analysis for NOx in the 2022 application does not show that the Production Increase Project would not have been a major modification for NOx with the increases in permitted NOx emissions that are being requested, 35 IAC 203.201 is cited as a basis for denial of this application. This is because the application also does not show that the substantive requirements of 35 IAC Part 203 would be fulfilled as the Project is now a major modification. For example, the 2022 application does not address the requirement in 35 IA3.302 that, as related to the role of emissions of NOx on air quality for ozone, an entity undertaking a major project for NOx in an ozone nonattainment area must provide emission offsets for NOx to compensate for the effect of the project's NOx emissions on ozone air quality.

35 IAC 203.203(b), Construction Permit Requirements and Application
For major projects that would be subject to 35 IAC Part 203, this rule sets forth the information that a permit application must contain. This rule provides that:

> Applications for construction permits required under this Section shall contain sufficient information to demonstrate compliance with 35 Ill. Adm. Code 201 [Permits and General Provisions] and the requirements of this Part [Part 203] including, but not limited to, Subpart C [Requirements for Major Stationary Sources in Nonattainment Areas, including the requirements for the Lowest Achievable Emission Rate (LAER) and the requirement to provide emission offsets].

35 IAC 203.208*, Net Emissions Determination – The Increase in Emissions from a Project
Among other aspects of "netting," this rule sets forth how the increases in emissions from a project should be addressed if a source elects to rely on netting with contemporaneous emissions decreases to show that a project would not be a major modification under 35 IAC Part 203. The first paragraph of this rule, referred to as "35 IAC 203 208*" is cited as a basis for denial of the 2022 application as the revised NSR applicability analysis for NOx in the application, which should address NOx emissions of the Production Increase Project, with the increases in permitted NO_X emissions that are now being requested. For certain units, this analysis does not show that the increases in NOx emissions from the Project have been properly addressed. For a project, itself, this rule provides that the increase in actual emissions due to the project should be addressed. However, since the amount of this increase should be determined during permitting,

i.e., before the project is implemented and the modified units begin normal operation with the project, 35 IAC 203.104(c) further provides that the Illinois EPA shall presume that the potential emissions of units with the project are equivalent to their actual emissions for purposes of permitting. (The circumstances are similar for permitting for a project that was improperly constructed without first obtaining a construction permit. This is because such source cannot rely on permit limitations in lieu of potential emissions absent enforceable limitations.) In particular, the first sentence in 35 IAC 203.208 provides:

> A net emissions increase is the amount by which the sum of any increase in actual emissions from a particular physical change or change in method of operation at a source [emphasis added], and any other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable, exceeds zero.

35 IAC 203.208**, Net Emissions Determination - The Contemporaneous Time Period and Creditability of Emission Decreases

As discussed above, 35 IAC 203.208 lays out the requirement for a NSR Applicability Analysis if a source elects to rely on netting to show that a project would not be a major modification under 35 IAC Part 203. 35 IAC 203.208(a) and (c)(1), referred to as 35 IAC 203.208**, are also cited as a basis for denial of the 2022 application. This is because the revised NSR applicability analysis for NOx in the application, which addresses NOx emissions with the increases in permitted emissions that are being requested for certain units, would improperly rely on certain decreases in NOx emissions that are neither contemporaneous nor creditable. This is contrary to 35 203.208(a) and (c), which do not allow credit in the revised NSR applicability analysis for NOx based on decreases in emissions due to the shutdown of Boilers 1 through 10 and, due to the shutdown of the two by-product recovery coke oven batteries at the Granite City Works, coke oven gas (COG) no longer being available for use in Project-affected fuel burning units.as a fuel. These actions and the accompanying emission decreases occurred after the implementation of the Production Increase Project and were not contemplated by Permit 95010001. In particular, the introductory paragraph in 35 IAC 203.208 and paragraphs 35 IAC 203.208(a) and (c)(1) provide:

> A net emissions increase is the amount by which the sum of any increase in actual emissions from a particular physical change or change in method of operation at a source, and any other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable, exceeds zero. The following steps determine whether the increase or decrease in emissions is available.
>
> a) Except for … [alternative provisions for projects in in serious and severe ozone nonattainment areas], an increase or decrease in actual emissions is contemporaneous only if it occurs between the date that an increase from a particular change occurs and the date five years before a timely and complete application is submitted for the particular change. …
>
> …

c) A decrease in actual emissions is creditable to the extent that:

1) It is federally enforceable at and after the time that actual construction on the particular change begins;

35 IAC 203.301, Lowest Achievable Emission Rate
For a project that is a major modification subject to 35 IAC Part 203, 35 IAC 203.301 sets forth the requirements for a permit application related to Lowest Achievable Emission Rate (LAER) for the emissions units for which LAER is required. 35 IAC 203.301(c) sets forth the requirement that LAER be demonstrated for such emission units. (Ongoing operation of LAER-subject units to comply with LAER is required by 35 IAC 203.601 once a permit is issued setting forth what LAER is for those units.) For the emission units and pollutant(s) for which LAER is required, 35 IAC 203.301(d) explicitly requires that the application include a detailed showing that the emission limitations proposed for the LAER-subject units would constitutes LAER. In this regard, these rules provide that:

c) Except as provided in subsection (e) or (f) below [Alternative provisions for projects ozone nonattainment areas that are classified as serious or severe nonattainment] the owner or operator of a major modification shall demonstrate that the control equipment and process measures applied to the major modification will produce LAER. This requirement applies to each emissions unit at which a net increase in emissions of the pollutant has occurred or would occur as a result of a physical change or change in the method of operation.

d) The owner or operator shall provide a detailed showing that the proposed emission limitations constitute LAER. Such demonstration shall include:

1) A description of the manner in which the proposed emission limitation was selected, including a detailed listing of information resources,

2) Alternative emission limitations, and

3) Such other reasonable information as the Agency may request as necessary to determine whether the proposed emission limitation is LAER.

35 IAC 203.302(a), Maintenance of Further Reasonable Progress and Emission Offsets
For a major project that is subject to 35 IAC Part 203 for a pollutant, this rule sets forth the basic requirement that project be accompanied by emission offsets. Emission offsets are enforceable reductions in the emissions of the subject pollutant, usually by existing source(s) other than the source at which the project would take place, that affect the quality of the ambient air that the emissions of the subject pollutant from the project would affect. The role of the offsets is to counterbalance the effect of the emissions of the subject pollutant from the project on ambient air quality that exceeds the applicable National Ambient Air Quality Standard. In this regard, 35 IAC 203.302(a) provides that:

a) The owner or operator of a new major source or major modification shall provide emission offsets equal to or greater than the allowable emissions from the source or the

net increase in emissions from the modification sufficient to allow the Agency to determine that the source or modification will not interfere with reasonable further progress as set forth in Section 173 of the Clean Air Act (42 U.S.C. 7401 et seq.).

35 IAC Part 204, Prevention of Significant Deterioration

(35 IAC Part 204 is of concern or potential concern for the Production Increase Project for emissions of NOx, SO_2, CO and lead. This is because, when Permit 95010001 was initially issued, the Granite City Works was in various areas that were designated attainment or unclassified, rather than nonattainment, for the NAAQS for CO, SO_2 and lead. It was also in an area designated as attainment or unclassified for the NAAQS for nitrogen dioxide (NO_2). The areas in which the Granite City Works is located are still designated attainment or unclassified for these pollutants. (After the NAAQS for lead was revised in 2008, an area that includes the Granite City Works was then designated nonattainment for lead in 2010. This area was later redesignated to attainment for lead in 2018.)

35 IAC 204.280, Best Available Control Technology (BACT) (Definition)
This definition reflects USEPA's guidance at 40 CFR 51.166(b)(12) for the meaning of this term. It is noteworthy that this definition provides that BACT is to reflect the maximum degree of reduction of emissions for the unit(s) and pollutant(s) for which it is required as determined to be achievable ".. through production processes or available methods, systems and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of such pollutant." As such, in addition to the use of add-on air pollution control equipment, both a BACT demonstration and a BACT determination must consider approaches to reducing emissions other than tradition air pollution control equipment. In addition, this definition provides that while it is preferred that BACT be codified in a permit as an emission limitation or a limitation for visible emissions, "If the Agency determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible, a design, equipment, work practice, operational standard, or combination thereof, may be prescribed instead to satisfy the requirement for the application of BACT."

35 IAC 204.330, Complete (Definition)
For an application for a permit for a major project subject to PSD [Prevention of Significant Deterioration], this definition provides that, "'complete' means, that the application contains all of the information necessary for processing the application."

35 IAC 204.400, Federally Enforceable (Definition)
This definition of "federally enforceable" in 35 IAC Part 204 is similar to the definition at 35 IAC 203.123. This definition also expressly identifies certain limitations that are, by definition, considered enforceable by USEPA (e.g., "…requirements within the SIP, any permit requirements established under 40 CFR 52.21… or this Part [Part 204} or under regulations approved under 40 CFR 51 Subpart I …, including operating permits issued under a USEPA-approved program that is incorporated into the SIP and expressly requires adherence to any permit issued under such

program"). However, it does not provide that limitations in a construction permit are still federally enforceable even if they are not enforceable as a practical matter.

35 IAC 204.550*, Net Emissions Increase (Definition) – The Increase in Emissions from a Project
This provision, which is similar to at 35 IAC 203.208, "Net Emissions Determination," sets forth how the increases in emissions from a project should be addressed if a source elects to rely on netting to show that a project would not be a major modification under 35 IAC Part 204. 35 IAC 204.550(a)(1), referred to as 35 IAC 204.550*, is cited as a basis for denial of the 2022 application as the revised NSR applicability analysis for NOx in the application, which addresses NOx emissions with the increases in permitted emissions that are now being requested for certain units, does not show that certain increases in emissions from the project have been properly addressed. For a project itself, this rule, which did not become effective until October 12, 2021 (86 Federal Register 50459), provides that the increase in actual emissions due to the project should be addressed. However, the application does not address post-project actual emissions. As such, 35 IAC 204.600(a)(4) provides that the potential emissions of units with the project are to be used as their actual emissions for purposes of evaluating applicability of PSD. In 1996, when the Production Increase Project was initially permitted, the requirements for Net Emission Determinations and Net Emission Increase, under the NaNSR and PSD programs respectively, were essentially identical.

35 IAC 204.550**, Net Emissions Increase (Definition) - The Contemporaneous Time Period and Creditability of Emission Decreases
As discussed above, 35 IAC 204.550 lays out the requirement for a NSR Applicability Analysis if a source elects to rely on netting to show that a project would not be a major modification under 35 IAC Part 204. 35 IAC 204.550(b)(2)) and (e)(2), referred to as 35 IAC 203.208**, are also cited as a basis for denial of the 2022 application. This is because the revised NSR applicability analysis for NOx in the application, which addresses NOx emissions with the increases in permitted emissions that are being requested for certain units, would improperly rely on certain decreases in NOx emissions that are neither contemporaneous nor creditable. This is contrary to 35 204.208(b)(2)) and (c)(2), which do not allow credit in the revised NSR applicability analysis for NOx based on decreases in emissions due to the shutdown of Boilers 1 through 10 and the elimination of coke oven gas (COG) with the shutdown of the by-product recovery coke oven batteries at the facility. These actions and the resulting emission decreases occurred after the implementation of the Production Increase Project and were not contemplated by Permit 95010001. In particular, the introductory paragraph in 35 IAC 204.550(b) and (b)(2) and 35 IAC 204.550(e) and (e)(2) provide:

> b) An increase or decrease in actual emissions is contemporaneous with the increase from the particular change only if it occurs between:
>
> …
>
> 2) The date that the increase from the particular change occurs.
>
> e) A decrease in actual emissions is creditable only to the extent that:
>
> …

2) It is enforceable as a practical matter at and after the time that actual construction on the particular change begins;

35 IAC 204.560, Potential to Emit (Definition)
This definition of "potential to emit" is cited as a basis for denial points as related to the role of permit limitations, as distinguished from the physical and operational design of a stationary source, in restricting the potential emissions of emission units. 35 IAC 204.560, along with 35 IAC 204.400, are cited as a basis for denial as the 2022 application does not show that certain emission limitations that are proposed, which would replace emission limitations currently in Permit 95010001, should be considered enforceable as a practical matter. In this regard, this definition of "potential to emit" provides that:

> "Potential to emit" means the maximum capacity of a stationary source to emit a pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is federally enforceable or legally and practicably enforceable (emphasis added) by a state or local air pollution control agency. Secondary emissions do not count in determining the potential to emit of a stationary source.

35 IAC 204.810(a)(3), Source Information
This rule, with the introductory language in 35 IAC 204.810 and 204.810(a), addresses the information that an applicant must include in a permit application if a determination of BACT is required for the requested permit to be issued. In this regard, they provide that:

> The owner or operator of a proposed major stationary source or major modification shall submit all information necessary to perform any analysis or make any determination required under this Part.
>
> a) With respect to a source or modification to which Sections 204.1100, 204.1110, 204.1130, and 204.1140 apply, such information shall include:
>
> …
>
> 3) A detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that BACT, as applicable, would be applied.

35 IAC 204.820, Source Obligation
Any owner or operator who constructs or operates a source or modification not in accordance with the application submitted under this Part or with the terms of any approval to construct (emphasis added), or any owner or operator of a source or modification subject to this Part [35 IAC Part 204] who begins actual construction after September 4, 2020 without applying for and receiving approval under this Part, shall be subject to appropriate enforcement action.

35 IAC 204.1100(c), Control Technology Review
This rule sets forth the BACT requirement for a project that is a major project for pollutant(s) for purposes of Part 204. It provides that:

> A major modification shall apply BACT for each regulated NSR pollutant for which it would result in a significant net emissions increase at the source. This requirement applies to each proposed emissions unit at which a net emissions increase in the pollutant would occur as a result of a physical change or change in the method of operation in the unit.

35 IAC 204.1110, Source Impact Analysis
This rule requires that the applicant for a permit for a project that is a major project for pollutant(s) for purposes of Part 204 demonstrate that the project would not cause or contribute to violation(s) of the relevant National Ambient Air Quality Standard (NAAQS). In this regard, this rule provides that:

> The owner or operator of the proposed source or modification shall demonstrate that allowable emission increases from the proposed source or modification, in conjunction with all other applicable emissions increases [emphasis added] or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of:
>
> a) Any NAAQS in any air quality control region; …

35 IAC 204.1130, Air Quality Analysis
This rule requires that an applicant for a permit for a project that is a major project for pollutant(s) for purposes of Part 204 address the ambient air quality in the area that the project would affect for those pollutant(s). In this regard, 35 IAC 204.1130(a)(1) addresses a "Preapplication Analysis," requiring that:

> 1) Any application for a permit under this Part [35 IAC Part 204] shall contain an analysis of ambient air quality in the area that the major stationary source or major modification would affect for each of the following pollutants:
>
> A) For the source, each pollutant that it would have the potential to emit in a significant amount;
>
> B) For the modification, each pollutant for which it would result in a significant net emissions increase.
>
> …
>
> 3) With respect to any such pollutant for which such a NAAQS does exist, the analysis shall contain continuous air quality monitoring data gathered for purposes of determining whether emissions of that pollutant would cause or contribute to a violation of the standard or any maximum allowable increase.
>
> 4) In general, the continuous air quality monitoring data that is required shall have been gathered over a period of at least one year and shall represent at least the year preceding receipt of the application. However, if the Agency determines that a

> complete and adequate analysis can be accomplished with monitoring data gathered over a period shorter than one year (but not less than four months), the data that is required shall have been gathered over at least that shorter period.
>
> …
>
> 35 IAC Part 270 Clean Air Act Permit Program Procedures

35 IAC 270.401(f), General Application Information (Certification)
This rule expands upon the certification that Clean Air Act Permit Program (CAAPP) applications must contain pursuant to Subsection 39.5(5)(f) of the Act, requiring that such certifications by a responsible official for the source must be based upon information and belief after reasonable inquiry. It provides that:

> A CAAPP application shall contain a certification by a responsible official that, based on information and belief formed by the responsible official after reasonable inquiry, the statements and information in the application are true, accurate, and complete. This certification shall be dated and signed by the responsible official.

ILLINOIS ENVIRONMENTAL PROTECTION AGENCY
1021 NORTH GRAND AVENUE EAST, P.O. BOX 19276, SPRINGFIELD, ILLINOIS 62794-9276 • (217) 782-3397

Notification of Denial Of Application

May 8, 2024

Re: United States Steel Corporation – Granite City Works:
Denial of an Application for Revisions to a Construction Permit/PSD Approval for a Production Increase Project at its Granite City Mill[1]

Source Identification No.: 119813AAI
Permit No. 95010001, initially issued January 26, 2006
Application for Revision: Initially received March 2, 2020, revised application received October 7, 2022

On May 8, 2024, the Illinois Environmental Protection Agency (Illinois EPA) denied the above-reference application for revisions to Permit 95010001, a construction permit that was initially issued in 1996 for a "Production Increase Project" at the Granite City Works.

Thank you for participating in the comment period on the proposed denial of this application. The Illinois EPA has prepared a Responsiveness Summary addressing comments submitted during the public period. The letter denying this application and the Responsiveness Summary are available by the following means:

1. On the Illinois EPA's website:

   https://epa.illinois.gov/public-notices/boa-notices/archive.html

2. For viewing at the following repository:

   Illinois EPA
   1021 N. Grand Ave., East
   Springfield, Illinois 62794
   (217)782-7027

[1] In the application, United States Steel also asks that the requested revisions of Permit 95010001 be processed by the Illinois EPA with "Integrated Processing," as is allowed by Section 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act.

3. By contacting the Illinois EPA by either phone or email to obtain copies of documents free of charge:

Sarah.Brubaker@illinois.gov

Members of the public and entities that participated in the public comment process on either draft of the denial of this application, and that are either aggrieved or have an interest that is (or may be) adversely affected by this denial, may petition the Illinois Pollution Control Board (Board) to review the denial of the Application. (See, Section 40.3(a)(2) of the Illinois Environmental Protection Act (415 ILCS 5/40.3(a)(2)). The denial of this application, as discussed above, is allowed under Illinois rules for Prevention of Significant Deterioration (PSD) as the Illinois EPA has denied an application for revisions to a PSD approval.

The procedures governing appeals are contained in Section 40.3 of the Act, "Review process for PSD permits," and in the Illinois Administrative Code (IAC), i.e., 35 IAC Part 101 "General Rules," and 35 IAC Part 105 Subpart F, "PSD Permit Appeals." Unless the Board, the hearing officer, the Clerk, or the Board's procedural rules provide otherwise, all documents must be filed electronically through Clerk's Office On-Line (COOL). See, 35 IAC 101.302. If allowed by the Board, the hearing officer, the Clerk, or the Board's procedural rules to file an appeal by US mail, it should be sent in a timely manner to:

Pollution Control Board, Attention: Clerk
100 West Randolph Street
James R. Thompson Center, Suite 11-500
Chicago, Illinois 60601-3218

If you have any question about the denial of his application, please contact Sarah Brubaker, (217)786-0790.

Sincerely,

Brad Frost
Manager, Office of Community Relations
Illinois EPA

Responsiveness Summary for Comments on the Proposed Denial of an Application* from United States Steel Corporation – Granite City Works for Revisions to a Construction Permit/PSD Approval Issued for a Production Increase Project at its Iron and Steel Mill in Granite City

Source Identification No.: 119813AAI
Permit No. 95010001, initially issued January 25, 1996
Application for Revision: Initially received March 2, 2020
Revised application received October 7, 2022

* In this permit application, US Steel asks that the requested revisions of Permit 95010001 be processed by the Illinois EPA with "Integrated Processing," as is allowed by Section 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act (Act). Integrated Processing of the revised permit would allow changes to the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, as would be set forth in the revised permit, to subsequently be made by means of an Administrative Amendment of the CAAPP permit. Integrated Processing would require that the revision of the permit provide for compliance requirements that are substantially equivalent to those that are required in CAAPP permits. The processing of the permit must also be subject to procedural requirements that are substantially equivalent to those that apply for issuance of CAAPP permits, including an opportunity for USEPA to review and comment upon a proposed version of the revised permit following completion of a public comment period on the draft of the revised permit.

Table of Contents

1. Decision

On May 8, 2024, the Illinois Environmental Protection Agency (Illinois EPA) denied an application submitted by US Steel for revisions to Permit 95010001, a construction permit that was initially issued in 1996 for a “Production Increase Project” at the Granite City Works.

2. Background

United States Steel - Granite City Works (US Steel) applied to the Illinois EPA for revisions to an air pollution control construction permit (Permit 95010001) for a project at its Granite City Works, the iron and steel mill in Granite City. This project (the “Production Increase Project” or “Project”) involved increases in the permitted production of iron and steel by this facility. As this facility is a source of emissions, Permit 95010001 provided approval for the Project under both Illinois’ construction permit programs for sources of emissions and the Prevention of Significant Deterioration (PSD) program under the federal Clean Air Act. This permit was originally issued in January 1996 to National Steel Corporation (National Steel), the former owner of the facility. This permit was transferred to US Steel after it became the owner of the facility. This proposed denial involves US Steel’s application submittal of October 7, 2022 (the “Application”), which submittal revised or replaced an earlier submittal from 2020. As the Illinois EPA has denied the Application, Permit 95010001 should be expected to continue in effect as it now exists until and unless action is taken to revise this permit based on a subsequent application submitted by US Steel.

A key reason that revisions to Permit 95010001 are needed is that emission testing conducted in 2014 on the two basic oxygen furnaces (BOFs), in which steel is produced, showed their emissions of nitrogen oxides (NOx), as well as their emissions of volatile organic material (VOM), are higher than is allowed by this permit. This is because, in 1996, the initial application for Permit 95010001 understated the NOx and VOM emissions of the BOFs and the emission limits in Permit 95010001 were based on information in the original application. US Steel has worked to prepare an application for revisions to Permit 95010001 that would allow more emissions of NOx and VOM from the BOFs.

The Application also addresses other issues that are now posed by how the Project was initially permitted and subsequent changes that have occurred at the facility. Notably, the emissions of carbon monoxide (CO) of certain units have also been found to be higher than stated in

the initial application. A baghouse control system has been installed for the BOFs to improve control of particulate emissions from charging and tapping of these furnaces. The byproduct coke oven batteries formerly at the facility were shut down in 2015. The requested revisions do not include increases in the permitted production of iron and steel by the facility as allowed by this permit as initially issued in 1996.

The Illinois EPA made a preliminary determination that the Application, as revised by US Steel and submitted to the Illinois EPA in 2022 should be denied. For some of the requested revisions to Permit 95010001, the Application should be denied because it does not show that the revisions would comply with the relevant regulatory requirements and USEPA policy that apply for the revisions to Permit 95010001 that are requested. For other requested revisions, the Application does not include the information needed to support those revisions or enable those revisions to be made. In addition, the application should be denied because it would not allow for processing of a revised permit with Integrated Processing, as has been requested.

More information about the Granite City Works and the Application is available in either of the project summaries that the Illinois EPA prepared to accompany the public comment periods on the Illinois EPA's preliminary determination that the Application should be denied. These project summaries describe the basis of the Illinois EPA's planned action on the application. They include information about the Granite City Works and the ambient air quality in the area in which it is located. They also include information about the Project and the New Source Review (NSR) rules that applied to the Project as initially addressed by Construction Permit 95010001, including the PSD rules, which were applied to the Project as it is a major PSD modification for emissions of sulfur dioxide (SO_2) and CO. The improvement to the particulate matter emission control system for the BOFs, which was first addressed in 2011 by Construction Permit 11050006, is also discussed in the project summaries. Finally, the project summaries also provide an overview of the principal reasons the Illinois EPA was proposing to deny the Application.

3. Comment Period

As already explained, upon review of the Application, as US Steel supplemented or replaced its permit application for revisions to Permit 95010001 in October 2022, the Illinois EPA made a preliminary determination that the Application did not meet the standard for

issuance of a revised version of Construction Permit 95010001 as requested by the Application. The Illinois EPA then prepared a draft of its planned action to deny the Application so that the public, as well as US Steel and the USEPA, could review and comment upon it.

Due to the nature of the requested revisions to Permit 95010001, as this permit also provides the PSD approval for the Project, the Illinois EPA held a public comment period on its preliminary determination that the Application should be denied. As the preliminary determination was that the application should be denied, a draft for the denial letter was prepared setting forth and explaining the reasons why, as a preliminary matter, the Illinois EPA had determined that the Application should be denied. The actual public comment period then enabled the public, as well as US Steel and the USEPA, to consider and comment on both the planned denial of the Application and the draft of the planned letter by which the Application would be denied.

In fact, the Illinois EPA held two public comment periods on the planned denial of the application. The first comment period began with the publication of a notice on the Illinois EPA’s Public Notice webpage on July 21, 2023. This comment period ended on September 11, 2023. It addressed an “initial” draft denial letter. The second comment period began on December 8, 2023, and ended on January 8, 2024. It addressed a revised draft denial letter. The second public comment period was held in response to a comment that was received on the initial draft denial letter. The revised draft denial letter more clearly sets forth the sections of the Illinois Environmental Protection Act (Act), the provision(s) of the Illinois’ regulations (Title 35 Subtitle B: Air Pollution of the Illinois Administrative Code), and the reasons that would be the basis for the Illinois EPA’s proposed denial of the Application.

4. For Additional Information and Copies Of Documents

Questions about the public comment period and the Illinois EPA’s decision to deny the Application should be directed to:

Sarah Brubaker, Community Relations Coordinator
Illinois Environmental Protection Agency
Office of Community Relations
1021 North Grand Avenue, East
P.O. Box 19276
Springfield, Illinois 62794-9506

217-786-0790 Desk line
866-273-5488 TDD

sarah.brubaker@illinois.gov

The letter denying the Application, this Responsiveness Summary and the documents prepared for the public comment periods are available at the Illinois EPA's internet site at https://epa.illinois.gov/public-notices/boa-notices/archive.html. Copies of these documents may also be obtained by contacting the Illinois EPA at the telephone numbers listed above.

5. Appeal Provisions

Members of the public and entities that participated in the public comment process on either draft of the denial of the Application, and who are either aggrieved or have an interest that is (or may be) adversely affected by the denial of the Application, may petition the Illinois Pollution Control Board (Board) to review the denial of the Application. (See, Section 40.3(a)(2) of the Act (415 ILCS 5/40.3(a)(2)).

The procedures governing appeals are contained in Section 40.3 of the Act, "Review process for PSD permits,"[1] and in the Illinois

[1] The Illinois EPA's actions and determinations under Illinois' PSD program are subject to greater deference in an appeal than has traditionally been afforded by the Board in other appeals of permit actions. The relevant language at Section 40.3(a)(2) of the Act was modeled after USEPA's regulations at 40 CFR Part 124, "Procedures for Decision Making." The language provides that an appeal of the Illinois EPA's action must show why its reasoning as to any issue raised was "clearly erroneous" or, alternatively, must show why some discretionary or policy decision made by the Illinois EPA warrants review by the Board. In 35 IAC 105.614 of its rules, the Board provides that decisions on PSD permit applications are to be upheld by the Board "if the technical decisions contained in the permit reflect considered

Administrative Code (IAC), i.e., 35 IAC Part 101 “General Rules,” and 35 IAC Part 105 Subpart F, “PSD Permit Appeals.” Unless the Board, the hearing officer, the Clerk, or the Board’s procedural rules provide otherwise, all documents must be filed electronically through Clerk’s Office On-Line (COOL). See, 35 IAC 101.302. If allowed by the Board, the hearing officer, the Clerk, or the Board’s procedural rules to file an appeal by US mail, it should be sent in a timely manner to:

Pollution Control Board, Attn: Clerk
100 West Randolph Street
James R. Thompson Center, Suite 11-500
Chicago, Illinois 60601-3218

judgment by the Agency.” Additional discussion of the relevant standard of review was set forth in the Board’s *First Notice Opinion and Order, In the Matter of Proposed New Part 204, et. al.*, R19-1, March 5, 2020, pp. 63 through 65.

6. Comments from the Public (Parties Other Than US Steel), with Responses by the Illinois EPA

C1. In their comments, the American Bottoms Conservancy (ABC), the Piasa Palisades Group of the Illinois Chapter of the Sierra Club, and the Metro East Green Alliance express support for the proposed denial of the Application, for the reasons set forth in the draft denial letter.

The Illinois EPA appreciates these expressions of support for the denial of this Application.

C2. In its comments, ABC explains that it objects to the use of "group limits"[2] in any future air pollution control permit that would be issued for the Granite City Works. In this regard, in its 2022 Application, US Steel requested that Permit 95010001 be revised to replace certain emission limits for individual emission units or emission points with "group limits," i.e., permit limits set for the emissions of a group of emission units.
The comment disputes the appropriateness of the three permits cited in the Application as support for the use of group limits. It observes that these permits, which were issued for sources and projects in other jurisdictions, present circumstances that are or were different than those of the Granite City Works. For example, the permit for *Shell Offshore* addressed emissions from seasonal activities for oil exploration conducted with the Kulluk, a drill rig on a towed barge, in the Arctic Ocean north of Alaska.[3] As the circumstances of these sources and projects differ in key respects from those of the Granite City Works, those permits should not be looked at as precedents for the use of group limits in the permitting of the Granite City Works.

---

[2] As used for this matter, "group limits" refer to limits for the emissions of groups of related but different emission units, rather than to individual emission units or emission points or to similar units (e.g., a pair of basic oxygen furnaces (BOFs) that operate in parallel and share emission control systems). For example, the Application requests that Permit 95010001 be revised to limit the overall emissions of a group of units that includes the casthouse for the two blast furnaces and other ancillary units involved in production of iron. The permit currently sets separate limits for the emissions of the casthouse, the emissions from charging the blast furnaces, and the emissions from activities at the slag pits.

[3] As observed in this comment, the Kulluk is no longer in use. In fact, it was damaged as a consequence of a storm and subsequently scrapped.

The Illinois EPA appreciates the concern expressed in this comment. As set forth in the denial letter, one of the reasons that the Illinois EPA denied the Application is that US Steel proposed the replacement of limits for emissions of particulate matter (PM), particulate matter$_{10}$ (PM_{10}), nitrogen oxides (NOx) and volatile organic material (VOM) from the blast furnace casthouse and from the basic oxygen furnaces (BOFs) with limits that would apply to the combined emissions of these units and the associated iron or steel making operations. For example, for the BOF shop, the Application requests that Permit 95010001 be revised to set limits for the combined emissions of these pollutants from these furnaces and other operations in the BOF shop involved in making steel, i.e., the desulfurization and reladling of iron, slag skimming, and ladle metallurgy operations. The Application does not show that it is appropriate for the casthouse and the BOFs, as they are principal emissions at the facility, to simply replace the current permit limits for their emissions with group limits.

C3. In its comments, ABC explains that it "… continues to maintain that US Steel should [be] using continuous monitoring to ensure compliance with emission limits."

The Illinois EPA appreciates the spirit of this general comment. However, it is not appropriate for the Illinois EPA to substantively respond to this comment because the Illinois EPA has denied the Application. The means by which US Steel must verify compliance with permit limitations for emissions would be appropriate for consideration in the future if a new or revised permit is proposed for the facility that would set permit limitations for emissions. At that time, the appropriateness of continuous emissions or operational monitoring, or alternatively, for units and operations that do not have stacks, prescribed emission factors could be assessed for specific emission units and operations relative to the limits for emissions of different pollutants that are intended for such units and operations.

C4. A meeting for the community is requested to better understand the reasons for the proposed denial of the Application.

It was not appropriate for the Illinois EPA to participate in a meeting for the purpose identified in this comment. The reasons for the proposed denial of the Application were detailed in the initial draft denial letter prepared by the Illinois EPA and made available for public review and comment. The draft denial letter was accompanied by a project summary providing relevant background

information for this proposed action and generally discussed the reasons why the preliminary determination of the Illinois EPA was that the Application should be denied. Moreover, these commenters also expressed support for the denial of this Application. Given these circumstances, it would not be proper for the Illinois EPA to expend resources in a general meeting as requested by this comment.[4]

C5. A meeting for the community is requested to better understand the public health impacts increased emissions would have created. A meeting would be an opportunity for the Illinois EPA to educate the community on why the denial of this Application is in the best interests of human health.

It was not appropriate for the Illinois EPA to participate in a meeting for the purposes described forth in this comment. As detailed in the draft denial letters, the Illinois EPA proposed that the Application be denied because it does not show that the requested revision to Permit 95010001 would comply with the requirements of applicable regulations and policy. Notably, the Application does not show that the requested increase in permitted NOx emissions of the BOFs would not result in the Production Increase Project (the "Project") becoming a major modification for purposes of the Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NaNSR) programs, rather than a modification that was not major, as the Project was originally permitted. The Application did not address the applicable substantive requirements of PSD and NaNSR for a project that would be a major modification for NOx.[5]

---

[4] It should also be noted that the Illinois EPA has provided further explanation of the reasons for denial of the Application in the Revised Draft Denial Letter that was prepared and made available for review and comment by the public. As US Steel has submitted comments opposing the proposed denial of the Application, this responsive summary also provides further explanation of the reasons why the Application should be denied as this document provides responses to US Steel's comments.

[5] In addition, the Application was denied because it does not support or adequately support representations or requests made in the Application. Notably, the Application does not support the claim that process measures had been considered as a control alternative for Best Available Control Technology (BACT) for the carbon monoxide (CO) emissions of the blast furnace casthouse and blast furnaces stoves, for which the Application requests increases in permitted emissions. The Application also does not provide support for the emission factors and emissions determination methodology for certain emission units and emission points for which the Application requests that the Illinois EPA now prescribe the use of such factors or method in the revised permit. The

The Application was not denied because of possible health impacts from increases in the permitted emissions of the Granite City Works. In this regard, the Application did not directly address the impacts on human health of the requested revisions to certain emission limits in Permit 95010001 nor was this necessary under the applicable laws, rules or policy governing the requested revisions of Permit 95010001.[6] Rather, US Steel was required in the Application to explain why the requested revisions to the permit should be considered to maintain or enable compliance with applicable substantive and procedural requirements governing emissions of the Granite City Works. For reasons as now set forth in the denial letter, the Illinois EPA has found that US Steel did not make the necessary showings in the Application. Impacts on public health, if any, from the requested increases in the permitted emissions of certain units at the facility were not one of the reasons for denial of the Application.

C6. A meeting of the Illinois EPA with community residents, labor groups and individuals, like us, fighting for a cleaner, safer, more sustainable world is requested to begin a serious discussion about transition to “green steel,” i.e., steel that is produced without the utilization of fossil fuels.

It would not be appropriate for the Illinois EPA to participate in a meeting as requested or discussed by this comment. The Application requests revisions to an air pollution control construction permit that was originally issued in 1996 for increases in the production of iron and steel by the Granite City Works. As such, the laws, rules and policy that apply to the processing of the Application are those for permitting of sources

---

Application was also denied because it does not request revisions and was not accompanied by other actions to facilitate consistency between the revisions to Permit 95010001 that were requested, the Clean Air Act Permit Program (CAAPP) permit for the operation of the Granite City Works, and the emission units and activities at the Granite City Works as are now actually present. Finally, the Application did not adequately address or resolve permit appeals pending before the Pollution Control Board that involve certain provisions currently in Permit 96030056, the CAAPP permit for the Granite City Works.

[6] This is consistent with a fundamental principle in regulation of emissions. That is, sources should control or reduce their emissions of air contaminants as it is practical and reasonable to do so. It is not appropriate for a source to simply be held to levels of emissions that are accompanied by concentrations of contaminants in the atmosphere that can be accommodated without any environmental impacts that would be considered excessive compared to the National Ambient Air Quality Standards (NAAQS) or established values for the concentrations of contaminants in the air. It is desirable for the ambient air to be as clean as is reasonably practical.

of emissions. When taking action on the Application, these laws, rules and policies did not provide for the broader consideration of the matters for which this comment requests that the Illinois EPA meet with the public and other parties.

Notwithstanding this request for a meeting, the Illinois EPA generally supports the development and transition to steel manufacturing processes that have lower impacts on the environment, including, both directly and indirectly, lower emissions of greenhouse gases. It is also desirable that the disruptions from this transition happen in a way that reduces impacts on local communities and on society generally.[7]

[7] It should also be noted the production of recycled steel from scrap in electric arc furnaces does not yet eliminate the demand for iron produced from ore, as is made in blast furnaces. This is because "new iron" may be needed to maintain levels of undesirable, tramp elements, such as copper and tin, in the steel produced by electric arc furnaces within acceptable levels.

7. Comments from United States Steel - Granite City Works (US Steel) with Responses by the Illinois EPA

Explanatory Preface by the Illinois EPA

Organization

US Steel's comments are generally addressed in the order in which US Steel made them. Major headings are generally identified with Roman numerals as used by US Steel (e.g., I, II, …). As US Steel further subdivided its comments, those headings are generally identified by letters, as used by US Steel (e.g., A, B,…). As US Steel's comments appeared to address specific denial points, the Illinois EPA has added an identification of the relevant denial point(s) to the headings provided by US Steel.

US Steel did not provide headings or numeric designations for its initial comments or preamble, which were presented in a series of paragraphs, each with comment(s). Accordingly, these comments have been identified under the heading of "Preamble." An attempt was not made to provide references to the specific denial points, if any, that might be relevant for these comments.

Certain refinements have been to the organization of US Steel's comments to improve clarity of both the comments and the Illinois EPA's response. As the Illinois EPA concluded that comments should be further separated or subdivided for clarity and ease of response, each such "sub-comment" is further identified using conventional numbers (i.e., 1, 2, …) or, as US Steel subdivided its comments and the Illinois EPA further subdivided them, with the letter assigned by US Steel and a conventional number (e.g., A1, A2, …). For these comments that have been subdivided of further subdivided by the Illinois EPA, the headings for the comments were added by the Illinois EPA. Similarly, for the preamble, the comments have also been subdivided (i.e., P1, P2, …), with headings added by the Illinois EPA.

US Steel's Comments

The substance of the comments submitted by US Steel is reflected in this Responsiveness Summary. The Illinois EPA has taken great care to assure that the issues, facts, observations and other matters raised or addressed by US Steel in its comments are accurately conveyed in this document. In this regard, this document reflects each substantive comment made by US Steel. In addition, the Illinois EPA has not combined, consolidated or paraphrased US Steel's comments as is both permissible and acceptable when a responsiveness summary is prepared. However, the wording of US Steel's comments in this document is not necessarily that of the comments as provided by US Steel. As is

appropriate in a responsiveness summary prepared by the Illinois EPA following a public comment period for a planned action on a permit application, in this document, US Steel's comments have been reworded for purposes of consistency, accuracy and simplification.[8] This was done to facilitate understanding of the comments and the responses provided by the Illinois EPA.

General Responses by the Illinois EPA

US Steel's comments repeat, in some cases almost verbatim, certain arguments or statements in multiple comments, these arguments or statements. These statement or arguments may be addressed collectively by the Illinois EPA, with a general response. For example, US Steel's comments claim several times that certain emission factors that are at issue in the denial of the Application have been both accepted and prescribed by Illinois EPA for a period of nearly thirty years for all purposes pertaining to the permitting of the Production Increase Project. Each time this claim is made in US Steel's comments, the Illinois EPA has not fully responded to this claim, which the Illinois EPA considers irrelevant and , perhaps inaccurate. Instead, in Section 8A and Section 8B of this Responsiveness Summary, after the responses to the non-repetitive comments here in Section 7 of this document, the Illinois EPA provides common, "general responses" to also address these statements and arguments.

US Steel's Comments with Responses by the Illinois EPA

P. PRELIMINARY COMMENTS

P1. Request That the Illinois EPA Reconsider its Preliminary Decision and Work with US Steel

United States Steel - Granite City Works (US Steel) requests that the Illinois EPA reconsider its preliminary decision and work with US Steel on resolving any outstanding issues.

Now that the Application has been denied, the Illinois EPA would be pleased to work with US Steel on the issues identified in the Denial

[8] For example, the Production Increase Project, which is the subject of Permit 95010001, is simply referred to as the "Project." The permit application or submittal that US Steel made in October 2020 is simply referred to as the "Application."

Letter, as those issues are amenable to resolution by means of permitting. In this regard, it was important that the deficiencies in the permit application received by the Illinois EPA on October 7, 2022 (the "Application") and the issues that would need to be addressed in a new or revised application for revision to Permit 95010001 to be formally set forth in a denial of the Application.

P2. Request That the Illinois EPA Meet with US Steel In the Interest of Reaching Resolution on Many of the Issues Raised by the Draft Denial

US Steel also requests to meet with Illinois EPA in the interest of reaching resolution considering many of the reasons that Illinois EPA raises in its proposed denial were not known to US Steel until it received the draft denial letter (or very shortly beforehand) notwithstanding the parties met several times to discuss the permit application submitted in 2020. The Illinois EPA did not notify US Steel of any deficiency in the Application or information submitted in such Application pursuant to 35 Illinois Administrative Code (IAC) 201.158 or 204.1300 or Subsection 39.5(5) of the Act. Many of the issues, as explained in US Steel's comments, could have been efficiently resolved if the Illinois EPA raised them during the years while the permit application was pending as is customary.

The fact that US Steel was not informed of certain deficiencies in the Application prior to the release of the Initial Draft Denial Letter is not a valid reason for the Illinois EPA to not have proceeded with denial of the Application.[9] The Illinois EPA is not required to notify an applicant for a state construction permit, including a PSD approval, of deficiencies in a permit application before denying an application. Moreover, the inability or failure of US Steel to foresee certain deficiencies with the Application, as claimed in certain comments, is certainly not an appropriate basis for the Illinois EPA to not have proceeded with denial of the Application.[10]

---

[9] It is noteworthy that US Steel was informed by telephone in December 2022 that a revised permit could not be issued based on the Application. This was because the Application did not show or prove that the Project would not become a major modification for NOx with the requested revision to Permit 95010001 to increase the Permitted NOx emissions of the Basic Oxygen Furnaces (BOFs).* This is the overarching deficiency in the Application.

*** Molten iron from the blast furnaces at the facility, along with scrap metal, are processed in the BOFs to make steel.**

[10] It is also noteworthy that the Application requests substantive revisions to Permit 95010001 as this permit provides the PSD approval for the Project and also requests Integrated Processing of this revised permit. Accordingly, issuance of a revision to Permit 95010001 that is effective is

P3. The Application Requests Revisions of an Issued Permit, Not a New Permit

The Application is for a revision to an issued PSD permit, which was originally issued to National Steel Corporation (National Steel) in 1996 for a Production Increase Project (the "Project") at the Granite City Works. The Application is not a request for a new major modification. Therefore, the scope of the review is more limited and the permitting process is substantially different than when compared to the permitting process for a new major modification.

This comment does nothing to suggest that the Application should not be denied. This comment also downplays the revisions to Permit 95010001 that are entailed by the revisions of Permit 95010001 that are or should be requested by the Application, understating the complexity of a permit proceeding that would revise Permit 95010001. Most significantly, the Illinois EPA's review of the Application has concluded that the revised netting analysis for emissions of nitrogen oxides (NOx) in the Application does not show the Project should not have been originally permitted by National Steel Corporation (National Steel) in 1996 as a major modification for NOx for purposes of New Source Review (NSR). In this regard, the Application does not show that permitting of a "new major modification" is not needed for NOx under both the NSR programs for Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NaNSR). Given the other issues that are now posed for the Project, revision of Permit 95010001 is more complex than if the Project had been properly permitted initially or corrections had been pursued shortly after Permit 95010001 was initially issued.[11]

---

not possible simply by resolution of issues with the Illinois EPA, absent opportunity for USEPA and other interested parties to provide their input. Moreover, as other parties will have an opportunity to provide their input on any revisions to Permit 95010001, the denial of the Application was an appropriate action to inform these other parties of the limited progress that had been made through the informal discussions between US Steel and the Illinois EPA about revisions to Permit 95010001.

[11] There are other reasons why the revisions to Permit 95010001 that are encompassed by the revisions of Permit 95010001 that are or should be requested by the Application would be more complex that an application for a proposed new source or modification. For example, US Steel also seeks revisions to Permit 95010001 to increase permitted emissions of carbon monoxide (CO), which are also greater than initially represented by National Steel. The Granite City Works, i.e., the facility, is now subject to the Clean Air Act Permit Program (CAAPP). The CAAPP permit issued for the facility, Permit 96030056, included

P4. Revised Draft Denial Letter Does More Than Clarify the Initial Draft Denial Letter

The Illinois EPA does more than "clarify" its previous notice of intent to deny the application; but instead raises new bases for its objections. Instead of working with US Steel on addressing any concerns, the Illinois EPA appears to be doubling down on its insistence to deny the Application. In response to US Steel initial comments of September 2023, Illinois EPA's bases for intending to deny the Application have changed and have become a moving target. Again, US Steel would prefer to work collaboratively with the Illinois EPA to address its concerns and to issue a revision of Permit 95010001 that complies with statutory and regulatory requirements; rather than searching for hypothetical and potential reasons why a revised permit should not be issued.

This comment is not relevant to the denial of the Application. It is appropriate that in the Revised Draft Denial Letter, the Illinois EPA take notice of US Steel's initial comments of September 2023. Moreover, this comment is disingenuous as the reason that the Illinois EPA prepared a Revised Draft Denial Letter was in response to a comment by US Steel on the Initial Draft Denial Letter. In that comment, US Steel claimed that the Initial Draft Denial Letter was deficient because it did not include certain information as required by Section 39(a) of the Act.[12] To address this comment and assure that the planned denial of the

---

certain "emission factor limits" that have been appealed in PCB 2013-053 to the Illinois Pollution Control Board (Board) by US Steel. One aspect of this appeal is that Permit 96030056 reflects the emission factor limits for process units currently in Permit 95010001. Another construction permit, Permit 11050006, was issued in 2013 for the addition of a filter system or baghouse to improve control of particulate emissions of the BOFs. This permit has also been appealed to the Board (PCB 2013-062) as it restates the emissions factor limits for the BOFs established in Permit 95010001. The Application also requests that the revision of Permit 95010001 be handled with Integrated Processing. While this avoids sequential revisions to permits, first to Permit 95010001 and then to the CAAPP permit, it means that the revisions to Permit 95010001 must also meet substantive and procedural requirements under the CAAPP.

[12] In its comments of September 2023, US Steel indicates that the Initial Denial Letter is deficient as it does not include information as required by Section 39(a) of the Act when a state permit application is denied. This comment, as follows, also provides the relevant text of Section 39(a) of Act:

> **Section 39(a) of the Act further provides:**
>
> > **If the Agency denies any permit under this Section, the Agency shall transmit to the applicant within the time limitations of this Section specific, detailed statements as to the reasons the permit application was denied. Such statements shall include,**

Application would not be found invalid on procedural grounds, the Illinois EPA prepared the Revised Draft Denial Letter, which was then posted on December 8, 2023. This revised draft of the denial letter clearly provides the information that Section 39(a) of the Act specifies be provided when a permit application is denied.[13]

Two appendices were also added in the Revised Draft Denial Letter. These appendices list, respectively, the various provisions of the Act and the Illinois Code that are cited as the underlying bases for the various denial points, with brief descriptions of the provisions. These

---

> **but not be limited to, the following:**
>
> (i) **the Sections of this Act which may be violated if the permit were granted;**
>
> (ii) **the provision of the regulations, promulgated under this Act, which may be violated if the permit were granted;**
>
> (iii) **the specific type of information, if any, which the Agency deems the applicant did not provide the Agency; and**
>
> (iv) **a statement of specific reasons why the Act and the regulations might not be met if the permit were granted.**
>
> **For the various reasons set forth herein [in US Steel's Comments of September 2023], US Steel maintains that the draft permit denial does not satisfy the above requirements. To summarize the matters discussed in this comment: the Illinois EPA has not clearly specified how certain provisions of the Act and regulations might not be met if the permit were granted; for those areas where certain provisions of the Act and regulations are specified, Illinois EPA is incorrect that those provisions would be violated if the permit were granted; and where the Illinois EPA has asserted that information was not provided, US Steel is providing that information here, is directing the Illinois EPA to the information in the application, or describes why such information is not pertinent to the issues at hand. Accordingly, Illinois EPA should not issue the proposed permit denial. …**
>
> **US Steel's Comments of September 2023, p. 2 and 3.**

[13] The Illinois EPA also corrected certain errors in the Initial Draft Denial Letter. In particular, in its comments of September 2023, US Steel observed that while the Initial Draft Denial Letter identified Section 9.1 of the Act as a reason for the proposed denial of the Application, neither the denial letter nor the project summary explained how this provision might be violated by the revisions to Permit 95010001 that were requested by the Application. The Revised Draft Denial Letter identified subsection 9.1(d) of the Act, rather than Section 9.1 of the Act, as a provision of the Act that might be violated by the requested permit. Section 9.1(d) of the Act prohibits violations of the PSD and NaNSR programs, as it prohibits violations of Section 165 and Section 173 of the federal Clean Air Act.

appendices were added to the revised draft so that the Illinois EPA could explain certain relevant aspects of these provisions as they were cited in the Revised Draft Denial Letter without the need to do so for each denial point. In addition, as these appendices would provide basic explanations of the provisions of the Act and the Illinois Code that were identified as the bases for the planned denial, these explanations would potentially facilitate the review of and comments on the Revised Draft Denial Letter by individuals who are unfamiliar with or do not routinely refer to the Act or the Illinois Code.

As preparation of a revised version of the draft denial letter was effectively requested by US Steel in its initial comments, it is to be expected that that the Revised Draft Denial Letter elaborated and expanded upon the deficiencies in the Application. However, with minor exceptions, the text of the Initial Draft Denial Letter was carried over in the Revised Draft Denial Letter in the discussions for the various denial points in this draft letter.[14, 15]

P5. The PSD Program Is Forward Looking

The PSD program is forward looking. However, in its draft denial letter, the Illinois EPA is pursuing a path that would make US Steel retroactively address all potential operating scenarios under the facility's prior ownership and footprint, for which US Steel does not have the requisite information and for which US Steel is not responsible. Such an approach is inconsistent with the Clean Air Act and legal precedent.

---

[14] For example, as clearly stated in the Revised Draft Denial Letter, in this letter, Denial Point 3 is accompanied by a new denial point, Denial Point 3A. Denial Point 3 addresses the fact that the Application does not include a demonstration that the NOx emissions of Project-affected fuel burning units would not exceed the "future amount" indicated in the Application. Denial Point 3A addresses a related deficiency in the Application that was recognized while the Revised Draft Denial Letter was being prepared. This is, for the Project-affected fuel burning units, the Application also does not provide supporting data and calculations for the value for future NOx emissions provided in the Application.

[15] The Illinois EPA disagrees that the issuance of the Revised Draft Denial Letter improperly created a moving target for US Steel, as implied by this comment. The Illinois EPA could counter that US Steel has provided the Illinois EPA with a moving target as it refers to material in its comments that was not included in the Application. However, it is inherent in the draft-comment-response process that new information be introduced into a permit proceeding.

Moreover, permitting, especially for complex situations, like the requested revision of Permit 95010001, is by its nature a moving target. Any revision of Permit 95010001 will not be complete until a public comment period is held on a draft of the revised permit; USEPA has the opportunity to object to the proposed revised permit, as Integrated Processing is requested; and any appeals of the revised permit are concluded such that the permit becomes effective and can be relied upon by US Steel.

As this comment simply expresses US Steel's opinion as to what is provided for by the PSD program, this comment does nothing to show that the Application should not be denied. As explained in response to US Steel's specific comments with regard to applicability of PSD for emissions of NOx, US Steel's reading and approach to the key provision of the PSD program that is relevant to the Application and revision of Permit 95010001 is not correct. This provision, which addresses relaxations of permit limitations established for a source or project (i.e., increases in permitted emissions), as requested by the Application for the Project, requires that the permitting of the source or project in which such limitations were established be revisited. In this regard, the PSD program is not actually forward looking as claimed by this comment.

Moreover, the Application, itself, indicates that US Steel possesses information to retroactively revisit applicability of PSD for the Project, addressing the initial permitting of the Project where the limitations that are now of concern were established. In this regard, the Application requests certain increases in the baseline emissions of NOx, particulate and volatile organic material (VOM) prior to the Project, as well as increases in the NOx and VOM emissions for which other units are permitted with the Project. Finally, the legal precedents that US Steel cites do not address relaxations of established permit limitations. As such, these legal precedents are not relevant for the revisions to Permit 95010001 that are requested by the Application to increase the permitted emissions of certain units.

P6. In the Comments That Follow, US Steel Addresses the Illinois EPA's Stated Reasons for the Proposed Denial of the Application

US Steel addresses Illinois EPA's stated reasons for its proposed denial of the Application. In the subsequent comments, Sections II through XIII, US Steel addresses the denial points detailed in the draft denial letter, Attachment 1.

A response to this comment is not necessary as it is simply intended to be a guide as to what is subsequently provided in US Steel's comments. However, as this comment may be making a distinction between the comments in Section I of US Steel's comments and its subsequent comments, this comment is not supported nor is it necessarily relevant. Many of the comments made in Section I of US Steel's comments touch on or provide introductions to matters that US Steel only fully addresses in subsequent comments.

I. THE REQUESTED PERMIT REVISIONS WOULD NOT VIOLATE PROVISIONS OF THE ILLINOIS ENVIRONMENTAL PROTECTION ACT (ACT) OR THE REGULATIONS OF THE ILLINOIS POLLUTION CONTROL BOARD FOR AIR POLLUTION

A1. As Shown by Subsequent Comments, the Application Demonstrates That the Illinois EPA Should Proceed with Issuance of a Revised Permit

The Illinois EPA proposes to deny the Application, at least in part, because Illinois EPA preliminarily determined that Section 39(a) of the Illinois Environmental Protection Act *(Act) might be violated*. Section 39(a) states that "it shall be the duty of the Agency to issue … a permit upon proof by the applicant that the facility, equipment, vehicle, vessel, or aircraft will not cause a violation of this Act or of regulations hereunder." As set forth further in its comments, US Steel maintains that the Application demonstrates that the facility and equipment at issue in the Application will not cause a violation of the Act or the regulations thereunder. Therefore, it is Illinois EPA's duty, under the statute, to proceed with issuance of a revised permit.

As this general comment simply expresses US Steel's opinion as to what its other substantive comments "demonstrate" or "show," this comment does nothing to show that that the Application should not be denied. As explained by the Illinois EPA in response to US Steel's comments related to specific denial points, those comments did not show that the Application should not be denied. In particular, US Steel's other comments do not show that the Application provides <u>proof</u> that if the Permit 95010001 were revised and issued as requested, the emission units and activities that are affected by the Project and currently addressed by Permit 95010001 would not violate provisions of the Act or the Illinois Code.[16]

A2. US Steel's Subsequent Comments Are Such That the Application Should Not Be Denied

For the various reasons set forth in US Steel's comments, the Illinois EPA is incorrect that any provisions of the Act or the regulations

[16] It is also noteworthy that as Section 39(a) of the Act also addresses the information that the Illinois EPA must provide when it denies an application, the Act does not require a definitive determination that certain provisions of the Act or the Illinois Code are violated or will be violated if the requested permit were issued. In addition to the types of information that the Illinois EPA deems the applicant did not provide, Section 39(a) of the Act requires a denial letter to provide "…the Sections of the Act which <u>may</u> (emphasis added) be violated if the permit were granted," the provisions of the Illinois Code "… which <u>may</u> [emphasis added] be violated …;" and a statement of the specific reasons why the Act and the Illinois Code <u>might</u> [emphasis added] not be met … ."

thereunder for air pollution, i.e., Title 35: Environmental Protection, Subtitle B: Air Pollution, of Illinois Administrative Code (IAC), would be violated if the permit were granted; where the Illinois EPA has asserted that information was not provided to the Illinois EPA in the Application, US Steel is providing that information here, is directing the Illinois EPA to the information in the Application, or describes why such information is not pertinent to the issues at hand. Accordingly, Illinois EPA should not deny the Application.

Again, as this general comment simply expresses US Steel's opinion as to what its other, substantive comments "demonstrate" or "show," this comment does nothing to show that the Application should not be denied. In addition, this comment suggests, presumably related to the Revised Draft Denial Letter, that, "… where the Illinois EPA has asserted information was not provided to the Illinois EPA in the Application, US Steel is providing that information here [in certain of US Steel's comments]," it is not clear that this is sufficient to remedy a deficiency in the Application that would otherwise necessitate its denial. It is certainly appropriate for U.S. Steel's comments to direct the Illinois EPA's attention to the places in the Application where information that the Illinois EPA claims is missing from the Application is believed to be provided in the Application. Likewise, it is appropriate for comments to direct the Illinois EPA's attention to material for which it is entitled to take official notice, such as statutes, rules, USEPA rulemakings, determinations and guidance by USEPA, USEPA publications, and opinions and decisions of courts. However, it is not clear that where a permit application would have otherwise been found to be deficient and denied because certain necessary information was not included in the application, that an applicant can provide such information by providing it within its comment on a draft of a planned denial letter.[17]

A3. As Discussed in US Steel's Comments, Section XIII.A, It Would Be Inappropriate to Deny the Application Based on Certain Requirements of the Act Related to CAAPP Permits

The Illinois EPA proposes to deny the Application, at least in part, because the Illinois EPA has preliminarily determined that subsections 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), 39.5(13)(a), and 39.5(c)(v) of the Act, pertaining to administrative amendment of Clean Air Act Permit Program ("CAAPP") permits, might be violated. Because the listed provisions of the Act relate only to the CAAPP, it would be

[17] **As US Steel suggests that some of its comments provide new information for the Application, it is fortunate that, at most, a handful of US Steel's comments attempt to do this. As a general matter, the denial of the Application does not hinge on these comments.**

inappropriate to deny the application for a revision of the construction permit and PSD approval based on a failure to satisfy these statutory provisions, as further discussed in Section XIII.A of US Steel's comments.

This comment does not show that the Application should not be denied. As explained in response to US Steel's Comment XIII.A, the Application would be denied because the Application would not meet the cited statutory provisions. In this regard, in addition to seeking revisions to Permit 95010001, the Application, itself, also requests that the revisions of Permit 95010001 that are sought be subject to Integrated Processing. This would authorize changes that are made to the provisions of Permit 95010001 to subsequently be made to Permit 96030056, the CAAPP permit for the facility, by Administrative Amendment of Permit 96030056. As a subsequent Administrative Amendment of the CAAPP permit would be authorized by the issuance of revised Permit 95010001, the subsequent amendment of the CAAPP permit would be a ministerial action by the Illinois EPA. Accordingly, the cited provisions of the Act related to CAAPP permitting are appropriately considered relative to the revisions of Permit 95010001 requested by the Application.

A4. The Denial of the Application Because 35 IAC 203.128 and 204.560 Might Be Violated Would BE Improper Because Thes Rules Are Definitions

The Illinois EPA proposes to deny the Application, at least in part, because Illinois EPA has preliminarily determined that 35 IAC 203.128 and 204.560 might be violated. The cited rules are definitions, not affirmative requirements, and cannot be violated.

This comment does not show that the Application should not be denied because these definitions of "potential to emit" are identified as a basis for denial. These definitions, which are in Illinois' NaNSR and PSD rules respectively, can be violated as the Application does not show that the revised limitations that are proposed by the Application would not be sufficient to restrict the emissions to the levels that that the Application proposes as their potential emissions. This is explained in Appendix B of the Revised Draft Denial Letter.[18]

---

[18] For example, as explained in Appendix B of the Revised Draft Denial Letter with respect to 35 IAC 204.560:

> **35 IAC 204.560, Potential to Emit (Definition)**
> **This definition of "potential to emit" is cited as a basis for denial points as related to the role of permit limitations, as distinguished from the physical and operational design of a stationary source, in restricting the potential emissions of emission units. 35 IAC 204.560, along with 35 IAC 204.400, are cited as a basis for denial as the 2022 application does not**

II. THE APPLICATION SATISFIES 35 IAC 201.159

1. The Applications Satisfies the Requirements of 35 IAC 201.159

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the Application "does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022, as required by 35 IAC 201.159. (The Illinois EPA also observes that "… the 2022 application includes a photocopy of an earlier certification, dated February 25, 2020, which was submitted with a prior application.") This assertion is incorrect in several respects. The Illinois EPA misrepresents this rule, which provided as follows. There is no requirement for a certification of truth, accuracy, and completeness.

> All applications and supplements thereto shall be signed by the owner and operator of the source, or their authorized agent, and shall be accompanied by evidence of authority to sign the application.

This comment does not show that the Application should not be denied based on Denial Point 22 as addressed by the Illinois EPA's responses to US Steel's other comments on the denial point. However, in response to this comment, as 35 IAC 201.159 does not specifically require the signatory for an air pollution control permit application to certify to the truth, accuracy and completeness of an application, this rule is not cited in the Denial Letter as a provision of the Illinois Code that is basis for denial of the Application. This rule is also not otherwise discussed in the Denial

---

show that certain emission limitations that are proposed, which would replace emission limitations currently in Permit 95010001, should be considered enforceable as a practical matter. In this regard, this definition of "potential to emit" provides that: "Potential to emit" means the maximum capacity of a stationary source to emit a pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design only if the limitation or the effect it would have on emissions is federally enforceable or legally and practicably enforceable (emphasis added) by a state or local air pollution control agency. Secondary emissions do not count in determining the potential to emit of a stationary source."

Revised Draft Denial Letter. Appendix B, p. Appendix B, Page 8.

Letter. In other words, the Illinois EPA has accepted the signature of Michael Patton, General Manager, Granite City Works, as provided in the cover letter for the Application, dated October 3, 2002, as sufficient to satisfy the requirements of 35 IAC 201.159.[19, 20]

2. The Application Should Be Considered a Continuation of the Permit Application That Was Initially Submitted in March 2020

The Application, which in the Draft Denial Letters, the Illinois EPA refers to as the "2022 application" is actually a construction permit application submitted on March 2, 2020. This permit application includes a completed 199-CAAPP form, with a certification signed and dated February 25, 2020, and a completed 197-FEE form, with a check for the application fee of $23,000 and a certification signed and dated February 25, 2020. A supplement to the permit application was submitted in October 2022. As required by 35 IAC 201.159, the supplement was signed by Michael Patton, the General Manager of the Granite City Works. No application fee was provided, as is appropriate for a supplement to a pending application for a construction permit.

The Application, i.e., the permit application received by the Illinois EPA in October 2022, is not, "…actually a construction permit application submitted on March 2, 2020," as claimed by this comment. It is also not a supplement to this March 2, 2020, permit application as also claimed by this comment. The Application differs significantly from the March 2020 permit application.[21] The Application addresses the

---

[19] As the Application must be denied for reasons other than 35 IAC 201.159, it is not necessary here for the Illinois EPA to discuss the certification or attestation an individual must make pursuant to 35 IAC 201.159 when he or she signs a permit application. The permit application forms that the Illinois EPA has developed for air pollution control construction permit applications, e.g., Form 199-CAAPP, "Construction Permit Application for a Proposed Project at a CAAPP Source," provide for the person who signs a permit application to certify to the truth, accuracy and completeness of the submittal. This must also be accompanied by evidence of the signatory's authority to sign the Application. For example, Form 199-CAAPP provides for submission of such associated evidence as it provides for the signatory for an application to certify that, "I am the responsible official for the source, as defined by Section 39.5(1) of the Environmental Protection Act.")

[20] It should also be noted that 35 IAC 201.159 provides that both applications and supplements thereto shall be signed.

[21] The Application, as submitted in October 2022, is different from the earlier permit application submitted in March 2020 in a number of respects that are more significant than the changes in organization. For example, the Application requests future permitted annual NOx emissions for the BOFs and Project-affected fuel burning units of 400 and 706 tons/year, respectively, compared to the earlier application, which requested future permitted NOx emissions of 304.3 and 632.5 tons/year, respectively.(Compare Table 6-8 of the Application

revisions to Permit 95010001 that are requested by US Steel without the need to refer to the earlier permit application except as one might want to compare the Application with the earlier application. As such, it is appropriate as both an administrative and a technical matter that the Application, i.e., the permit application submitted in October 2022 be considered to have completely replaced the earlier permit application submitted in March 2020.[22]

This approach to the Application is consistent with the position taken by US Steel in the cover letter submitted with the Application, which states:

> **In March of 2020, United States Steel Corporation – Granite City Works ("U. S. Steel") submitted an application to revise Construction Permit No. 95010001. US Steel and the Illinois EPA**

---

to that in Table 8-7 of the earlier application.) For Project-affected fuel burning units, the Application requests future permitted annual CO emissions of 26,659 tons, compared to the earlier application, which requested future permitted emissions of 19,343 tons/year. (Compare the information in Table 4-2 of the Application to that in Table 3-2 of the earlier application.) For the blast furnace casthouse, the Application includes an analysis of Best Available Control Technology (BACT) as must be established in the revision of Permit 95010001 if it is to provide a PSD approval for these emissions. (See the BACT analysis in Section 8.2.3 of the Application, which analysis was not present in Section 4 of the earlier application.) In this regard, the Application requests that the revision of Permit 95010001, which currently does not address the CO emission of the casthouse, provide for annual emissions of 320 tons/year from the casthouse. Unlike the earlier application, for Project-affected fuel burning units, the Application does not request that the revision of Permit 95010001 prescribe the emission factors that are to be used to determine CO emissions from such for which the Application considers that emissions testing is not feasible, such as the Blast Furnace Stoves, Blast Furnace Gas (BFG) Flare 1, and the Ladle Dryer/Preheaters, which are located in the BOF Shop. (Section 3.5.1.2 of earlier application.) The Application also requests changes to the names or identification of certain units and a control device used in Permit 95010001 and certain changes to the organization of Permit 95010001, as is initially discussed in Section 2.2.2 of the Application. The changes in the place in Permit 95010001 where certain units are addressed is requested so that the placement of units in Permit 95010001 is consistent with their placement in the CAAPP permit, Permit 960300056.

[22] Incidentally, it is appropriate for the Application to be considered a continuation of US Steel's effort to formally initiate action by the Illinois EPA to make certain revisions to Permit 95010001. In this regard, as an application fee, as specified by Section 9.12 of the Act accompanies an air pollution control construction permit application, the applicant is not required to again pay the fee for submittal of an application when a revised application is submitted to the Illinois EPA in response to a notification that the earlier application was incomplete. As such, the Illinois EPA is not denying the Application because it was not accompanied by an application fee since that fee was provided with the earlier March 2020 application.

have been in discussions regarding this application. U.S. Steel has updated the permit application to reflect those discussions. Due to the nature of the discussions throughout the application, the Illinois EPA should refer to this application revision for processing.

Letter, dated October 3, 2022, Michael Patton General Manager, Granite City Works, to Bill Marr, Manager, Permit Section, Bureau of Air, Illinois Environmental Protection Agency.

The Illinois EPA's approach to the Application is also consistent with the Application, itself. In the Application, Appendix A, "Application Forms (Copies of Previously Submitted Versions)" provides copies of the two application forms submitted with the 2020 permit application, "Fee Determination for Construction Permit Application," 197-FEE, and "Construction Permit Application for a Proposed Project at a CAAPP Source," Form 199-CAAPP. As such, while not providing a newly signed versions of Form 199-CAAPP, the Application acknowledged that this form needed to be part of the Application, the permit application submitted in October 2022.

3. The Illinois EPA Did Not Request a New Signature or Certification Prior to Posting the Initial Draft Denial Letter

While the Illinois EPA had the Application for months, and virtually met with US Steel to discuss the Application, the Illinois EPA never requested such a new signature or certification.

This observation does not mean that it is not appropriate for the Application to be denied based on the absence of the certification required by Subsection 39.5(5)(e) of the Act as to the accuracy of the Application. Because of the absence of this certification, the Application does not meet the standard for issuance of a permit in Section 39(a) of the Act.[23]

---

[23] That the Application did not include an appropriate signature* or certification was one of the last deficiencies in the Application to be identified. The implications of the form in the Application being a copy of the form from the March 2020 permit application, which was dated February 25, 2020, was not recognized earlier. When it was recognized, the Illinois EPA had already concluded that the Application should be denied based on other deficiencies. The decision was made to address this deficiency with regard to the certification for the Application in the Draft Denial Letter with the other deficiencies in the Application.
*** As explained above in response to another comment, the Illinois EPA has accepted the signature on the cover letter for the Application as satisfying 35 IAC 201.159.**

III. US STEEL PROVIDED A SIGNED CERTIFICATION OF TRUTH, ACCURACY, AND COMPLETENESS FOR THE APPLICATION WITH ITS COMMENTS OF SEPTEMBER 2023 (DENIAL POINT 22)

1. The Absence of a Signed Certification for the Truth, Accuracy and Completeness of the Application Is Not a Valid Basis for Denial

In the draft denial letters, Attachment 1, the Illinois EPA asserts that the Application "does not include a signed certification for the truth, accuracy and completeness of the Application as it was actually submitted in October 2022" and that such a certification is required by Section 39.5(5)(e) of the Act. This is not a valid basis for denial of the Application for the following reasons.

As explained in Comment II above, the Illinois EPA mischaracterizes the Application, as it was submitted in October 2022, as a new or separate permit application. However, it is merely a supplement to the permit application submitted in March 2020. In the transmittal letter for the supplement, and for administrative convenience US Steel suggested that Illinois EPA refer to the supplement rather than to the initial submittal from March 2020. This was because, as requested by the Illinois EPA following review of the March 2020 permit application, the sections of the permit application were reordered.[24] The cited provision of the Act requires that each submitted permit application include a certification, but it does not expressly require a separate certification for each supplement to a permit application.

As already discussed, as a technical matter, the Application replaced the permit application that was submitted by US Steel in March 2020. As this comment only addresses the reorganization of the Application, this comment misrepresents the extent of the changes between the permit application submitted in March 2020 and the Application. With respect to whether a new certification is needed when a pending permit application is replaced by a new application, the Application, itself, indicates that this is necessary. However, the Application provided a certification that was flawed as it had been provided for the earlier submittal and could not have addressed the contents of the Application, which was submitted more than two years later.

[24] For example, the sections summarizing changes to CO emissions and presenting proposed Best Available Control Technology ("BACT") determinations for CO emissions were Sections 3 and 4 of the March 2020 permit application and were Sections 4 and 8 of the application submitted in October 2022. In the two submittals, the relevant sections were appropriately identified in Section 1, "Introduction," and Section 2. "Overview of Requested Permit Revisions." (Footnote 1 of US Steel's Comments of January 2024.)

2. US Steel Has Provided the Required Certification with Its Comments

Nonetheless, without waiving any rights or defenses, with its September 2023 comments, US Steel provided to Illinois EPA a new certification of the truth, accuracy and completeness of the permit application that was submitted in October 2022. Accordingly, even if Illinois EPA's interpretation of Section 39.5(5)(e) of the Act were correct and a separate certification is required for each supplement to a pending permit application, that requirement was satisfied prior to the proposed denial and this claimed deficiency cannot form a valid basis for denial of the Application.[25]

However, the Illinois EPA asserts in the revised Draft Denial Letter that this was not sufficient, baselessly claiming that the certification or Application is somehow fraudulent (Per the Illinois EPA, "[t]hus, even if the certification had been submitted as a supplement to the 2022 application, its truthfulness and validity would be questionable.") The Illinois EPA then asserts that this puts the Application under a cloud. US Steel is unable to respond to these assertions because, frankly, they are absurd and are without merit. US Steel has worked collaboratively with Illinois EPA in responding to inquiries and requests.

This comment does not show that the Application should not be denied for reasons as set forth in Denial Point 22. This comment misrepresents this denial point as it selectively quotes from the Revised Draft Denial Letter and rearranges the order of the provisions that are referred to compared to their order in the Revised Draft Denial Letter. This comment also does not actually address, perhaps wittingly overlooking, the reasons that the Illinois EPA found the certification attached as Exhibit 1 to its comments of September 2023 to still be inadequate to remedy the deficiency in the Application. In this regard, as explained in the Revised Draft Denial Letter, the certification provided with US Steel's Comments of September 2023 is deficient for two reasons, as explained as follows:

> **With respect to the "certification" and "signature" provided in US Steel's Comments [of September 2020] responding to the Initial Draft Denial Letter, this certification was not sufficient to correct these omissions. First, this material, which is dated September 8, 2023, was an attachment to those comments and was not**

[25] Furthermore, this issue could easily have been avoided if Illinois EPA had simply made a request to US Steel to certify the Application, which US Steel has now done.

> **submitted as a supplement to the 2022 application. Second, the certification is not accompanied by an errata or other material correcting erroneous information in the application as either identified by the Illinois EPA in the Initial Draft Denial or identified by US Steel when developing its response to the Initial Draft Denial. Thus, even if the certification had been submitted as a supplement to the 2022 application, its truthfulness and validity would be questionable. The fact that the 2022 application was not certified and signed puts the entire application under a cloud. Revised Draft Denial Letter, Attachment 1, pp. 74 and 75.**

In response to the perhaps obvious question, why was the certification that US Steel submitted as Exhibit 1 of its comments of September 2023 not considered to be a supplement to the Application, this exhibit was provided "… with these comments." (US Steel, Comments of September 2023, p. 9.) This document was not actually submitted as a supplement to the Application.[26] By means of the Revised Draft Denial Letter, the Illinois EPA informed US Steel that Exhibit 1 of the September 2023 comments was not considered to be a supplement to the Application. US Steel did not proceed in light of the relevant discussion in the Revised Draft Denial Letter to actually submit the certification that it provided with its September 2023 comments as a supplement to the Application. Also, important, in US Steel's comments of September 2023, an error in the Application was acknowledged.[27, 28] However, the certification that was provided in the September 2023 comments did not acknowledge this error. Accordingly, the comments, themselves, contradicted the certification in Exhibit 1 as to the truth and accuracy of certain information in the Application was true, correct and current. Again, US Steel did not take advantage of the Revised Draft Denial Letter as it discussed this contradiction. US Steel did not act to actually supplement the Application with a certification that acknowledged errors in the Application related to the NOx emissions of Boilers 11 and 12, which had already been identified and

---

[26] While the Illinois EPA may add material that it prepares, obtains or receives to the administrative record associated with the review of a permit application, the Illinois EPA cannot by its independent actions alter or amend an application as submitted by the applicant.

[27] As related to NOx emissions from use of coke oven gas (COG) in Boilers 11 and 12, US Steel's comments acknowledge an error in the Application, as follows:

> **The emission factor basis listed in Table 6-4 of the permit application is a scrivener's error.**
> **US Steel, Comments of September 2023, p. 28.**

[28] Incidentally, US Steel's Comments of January 2024 acknowledged additional errors in the Application.

acknowledged elsewhere.[29]

Finally, in response to this comment as it expressed concern over the use of the phrase "under a cloud" in the draft denial letters, the meaning or implications that are intended by the Illinois EPA with the use of this phrase are explained in the Denial Letter. In this letter, the sentence in which the phrase "under a cloud" is used are followed by the following, "In other words, as a matter of rule, absent an appropriate certification, the Application is deficient. The Application cannot be considered creditable and should not be relied upon for purposes of making revisions to Permit 95010001."

IV. PURPORTED FAILURE TO BE CONSISTENT WITH PENDING BOARD APPEALS (DENIAL POINT 21)

1. Denial of the Application on This Denial Point Would Be Without Merit

In the draft denial letter, Attachment 1, Illinois EPA asserts that the application must be denied because it does not address all items that are currently under appeal with the Illinois Pollution Control Board (Board). In particular, the Illinois EPA claims, "the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62." Quite strikingly, Illinois EPA cites to no Board order or regulatory or statutory provision to support its assertion. This is for good reason, as there is none. The assertion is without merit. Although it is logical that Illinois EPA might inquire about contested provisions in the appeals before the Board that may appear to be absent in the Application, the absence of such mention is not grounds for denying the Application. While the Illinois EPA has concerns about the Application in the context of the pending permit appeals before the Board, the Illinois EPA cannot claim these concerns as a basis to deny the Application.

This comment does not show that the Application should not be denied based on Denial Point 21. Contrary to what is claimed in this comment, in the Revised Draft Denial Letter, the Illinois EPA did identify the

[29] Alternatively, US Steel did not submit a supplement to the Application to correct the error that had been identified, as is appropriate when an error in a pending permit application is identified. (The error in the Application is improperly characterized as a scrivener's error in US Steel's comments since this error could still be directly corrected by US Steel's own action.) Moreover, as the error in the Application, itself, indicated that NOx emissions of Boilers 11 and 12 had not been correctly calculated, this supplement also would need to include supporting documentation for the corrected emission calculations for these units.

statutory and regulatory provisions that would be the basis of denial of the Application on this denial point. In addition, this comment overlooks and does not respond to statements made in the Revised Draft Denial Letter that provide the reasons and explain why the Application would be denied based on this denial point, which involves emissions limitation for SO_2, lead and CO that are now in Permit 95010001 and are restated in Permit 96030056, the CAAPP permit for the facility. In particular, in this denial point as the reasons why the Application should be denied are specifically addressed, the Illinois EPA explains:

> **As the subject limits [limits for emissions of SO_2, lead and CO], as they are or, in the case of PCB 2013-62, would be present in the CAAPP permit, are currently the subject of appeals, it is reasonable for these limitations for the review of the application to be based on compliance not being achieved. Moreover, absent information as described above [information showing that "these limits are now considered acceptable" by US Steel], the 2022 application does not show that, as the subject limits are appealed and could be stayed in any revised CAAPP permit, these limits should be considered to still meet the substantive requirements of the CAAPP. Finally, it is noteworthy that for the subject processes for the various emission factor limits for PM, PM-10, NOx and VOM, the application does request revisions to the emission factor limits. For those requested revisions, the 2022 application, page 2-3, explains that "USS Granite City anticipates that these revisions will enable settlement of the permit appeals currently before the Board because they involve provisions of the permit addressing emission factors."**
> **Revised Draft Denial Letter, p. 71 and 72.**

As this denial point is further discussed, the Illinois EPA explains:

> **… the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62, as it does not propose revisions to current permit limits for emissions of SO_2, CO and lead. As previously discussed, in these appeals, US Steel challenged all emission factor limits set by Permit 95010001 for individual process operations. US Steel has not amended these appeals so that they only address emission factor limits for PM, PM_{10}, NOx and VOM and no longer address the t [sic] emission factor limits that are set for SO_2, CO and lead. In addition, in the 2022 application, US Steel does not explain why the emission factor limits in Permit 95010001 for SO_2, CO and lead that were appealed are no longer considered to be objectionable. That is, US Steel would not again challenge those limits as it has already done in PCB 0013-53 and PCB 0013-62 if a revision to Permit 95010001 were issued that continued to include the current emission factor**

limits.[Footnote] 84

[Footnote] 84. If the subject emission factor limits were included in a revised permit, the Illinois EPA could explain that, if these limits in the revised permit were stayed pursuant to an appeal to the Pollution Control Board, the limits would continue to be enforceable pursuant to Permit 95010001 as issued before the revision of the permit and any appeal of the revised permit to the Board.

Initial Draft Denial Letter, Attachment 1, p. 47, and Revised Draft Denial Letter, Attachment 1, p. 73.

In summary, the Illinois EPA provided support and explanation in the Draft Denial Letters for denial of the Application based on Denial Point 21. This comment does not even address this information to attempt to show that the Application should not denied based on this denial point.

2. US Steel Did Not Learn of this Concern during Informal Discussions with the Illinois EPA about the March 2020 Permit Application

The permit application submitted in March 2020 was pending for over 2 ½ years before US Steel submitted the Application in October 2022. During this time, the Illinois EPA and US Steel met in person and virtually on several occasions to discuss the PSD permit revisions, yet only in the Initial Draft Denial Letter released in July 2023 did US Steel learn of Illinois EPA's contention that US Steel was obligated to address in its application all items that are currently under appeal with the Board. US Steel's understanding from these discussions was that, with satisfactory issuance of the revised permit, the pending appeals could be dismissed in their entirety.

This observation is immaterial to the denial of the Application based on Denial Point 21.[30] The Illinois EPA is not required to inform or notify an applicant for a state air pollution control permit of deficiencies in its application before taking action to deny the application.

[30] For purposes of the denial of the Application, this deficiency in the Application was one of the last deficiencies that was identified by the Illinois EPA. In the discussions with US Steel about the 2020 application, the concerns addressed by this denial point were likely considered a minor matter that could be readily addressed during the development of a revised version of Permit 95010001 with submittal of an appropriate supplement to the Application by US Steel. However, when the Illinois EPA determined that it needed to begin the process to deny the Application, it was realized that the Application should also be denied as addressed with Denial Point 21.

V. PURPORTED INCONSISTENCY BETWEEN THIS PERMIT APPLICATION AND THE APPLICATION SUBMITTED IN 2008 REQUESTING REVISIONS RELATING TO SO_2 EMISSIONS (DENIAL POINT 20)

1. Information Now Shows That the Sulfur Content of Blast Furnace Gas (BFG) Is Such That Use of BFG Complies with the SO_2 Emissions Limitations Currently in Permit 95010001

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the application must be denied because it, "… is inconsistent with" a separate permit application submitted in 2008. Unfortunately, the Illinois EPA has not acted on the 2008 application and it is still pending. That application was submitted pursuant to a consent decree (Consent Decree, *People of the State of Illinois v. United States Steel Corporation*, Third Judicial Circuit, Madison County, Decree No. 05-CH-750, December 18, 2007). The 2008 application was submitted based on limited information, as was available when it was submitted. Subsequent information indicates that when averaged over a year, the sulfur content of BFG is such that the limit currently in Permit 95010001 for emissions of sulfur dioxide (SO_2) in pounds/million cubic feet (mmcf) of BFG is appropriate.

This comment does not show that the Application should not be denied based on Denial Point 20. The assertion made in this comment for the sulfur content of BFG is not reflected in information provided in the Application.[31] Indeed, neither the Application nor this assertion is accompanied by data for the actual sulfur content of BFG that would confirm that the sulfur content of BFG is such that the SO_2 emissions from burning BFG comply with the existing limitations in Permit 95010001 (6.65 pounds SO_2/mmcf of BFG and 615.22 tons/year, per Condition 22 and

[31] With regard to this topic, the Application explains that it, "…does not request any changes to the emissions limits for SO_2 and lead established in Construction Permit 95010001." (Application, Section 2.2, "General Description of Requested Permit Revisions," p. 2-2.)

Table 4.)[32, 33]

2. The Act and the Illinois Code Do Not Require the Application to Include a Compliance Demonstration for the Current Emission Limitations

In its explanation of how the inconsistency between the application submitted in 2008 and the more recent application is a deficiency, the Illinois EPA claims that the Application "does not meet the standards for issuance of a construction permit" because it does not "show compliance with the SO_2 emission limits for burning BFG that are currently in Permit 95010001." Admittedly, the Application, which does not request any changes to any SO_2 emission limitations in Permit 95010001 does not include demonstration of compliance with these limitations. The Application does not include demonstrations of compliance with any of the dozens of other emission limits that apply to units and operations at the Granite City Works and are unrelated to the application. There is no provision in the Act or the Illinois Code requiring that an application for a construction permit include such compliance demonstrations.

---

[32] As explained in the Draft Denial Letters, data for the sulfur content of the BFG produced by the facility and the annual SO_2 emissions from burning BFG is needed for the period prior to 2007 that led up to the Consent Decree and the 2008 application, as well as for the period from 2008 to the present. This is because the sulfur content of BFG could have been higher so that the 2008 application for revision of Permit 95010001 was appropriate when it was submitted.

> **Moreover, the existence of the 2008 application suggests that the revisions to SO_2 emission limits that it requested were needed at the time of that application. The 2022 application does not show that this was not the case, as it does not address historic sulfur content of BFG to show that an SO_2 emission limitation for BFG of 6.65 pounds/million cubic feet was appropriate when Permit 95010001 was originally issued in 1996 and that annual SO_2 emissions have never exceeded 615.22 tons/year.**
>
> **Denial Letter, Attachment 1, Denial Point 20.**

[33] Incidentally, several things have interfered with work on the 2008 application. These include the amount of effort needed on the initial CAAPP permit for the facility. The first two CAAPP permits issued by the Illinois EPA had to be revised to address deficiencies identified by USEPA in its response to petitions requesting that it object to the permits that had been issued. Then, additional revisions to Permit 95010001 were found to be necessary, as US Steel is now trying to address with the current application. Work on the application for these revisions to this permit was also disrupted by an interruption in production of iron and steel by the facility. This interruption, which began in 2015 and lasted for over two years, meant that it was uncertain that the facility would resume production.

This comment also does not show that the Application should not be denied Based on Denial Point 20. US Steel, itself, has submitted conflicting information in its permit applications. The earlier application indicates that the limits currently in Permit 95010001 understate the SO_2 emissions from burning BFG and needs to be increased. The Application, as it explicitly states that changes to the relevant limits of SO_2 emissions currently in Permit 95010001 are not requested, indicates that revisions to these limits are not needed. In these circumstances, it is appropriate in the context of the Application for US Steel to resolve this conflict.[34] For example, the Application could have shown that the SO_2 emissions from burning BFG do not violate the current limits and the revisions to Permit 95010001 that are requested by the 2008 application are no longer needed. As such a showing has not been made in the Application and US Steel has not resolved this conflict by other means,[35] the Application does not meet the standard for issuance of a permit in Section 39(a) of the Act. That is, the Application does not provide proof that the SO_2 emissions from burning BFG do not violate the applicable limits currently in Permit 95010001. Therefore, the Application must be denied.[36]

3. Prior Discussions with the Illinois EPA

US Steel discussed this topic with the Illinois EPA during informal discussions concerning the application submitted in 2020. The Illinois EPA did not object to this development during those discussions. To now claim that this discrepancy serves as a basis to deny the application is disingenuous. US Steel cannot simply withdraw the 2008 application at this time but would do so following issuance of the requested revised permit and the termination of the Consent Decree. US Steel has indicated it would work with Illinois EPA on that process and remains

[34] As BFG is burned in Project-affected fuel burning units, the emissions of SO_2 from burning or use of BFG are within the scope of the revisions to Permit 95010001 requested by the Application. This is because the Application requests increases in the CO emissions of these fuel burning units from use of BFG.

[35] For example, this inconsistency could have been dealt with through the 2008 application. That application could have been supplemented with relevant data showing that the SO_2 emissions from burning BFG comply with the current limits in Permit 95010001. At most, the only revision to Permit 95010001 that now might be needed would be a clarification that the limit for the rate of SO_2 emissions from use of BFG addresses the annual average rate of emissions or in practice, the measured sulfur content of BFG on an annual average basis. However, this clarification has already been made in the CAAPP permit issued for the facility.

[36] In addition, if the Illinois EPA were to issue a revision to Permit 95010001 without directly addressing SO_2 emissions from burning BFG, the Illinois EPA would potentially be facilitating violation of the current limitations for those emissions. This would be contrary to Subsections 9(b)(2) and 9.1(d) of the Act.

committed to do so.

Informal discussions between an applicant for a construction permit and the Illinois EPA are not relevant to whether an application, as submitted by the applicant, meets the standard for issuance of a permit set by Section 39(a) of the Act. In this case, the Application does not provide proof that the SO_2 emissions from burning BFG do not violate the applicable limits currently in Permit 95010001. Therefore, the Application must be denied.[37, 38]

VI. THE APPLICATION IS SUFFICIENT AS TO THE PSD AIR QUALITY IMPACTS ANALYSIS FOR CARBON MONOXIDE (DENIAL POINTS 5 AND 5A)

1. Introduction

The PSD approval for the Project for carbon monoxide (CO) is provided by Permit 95010001.[39] As explained in the Application, information now

---

[37] US Steel has also not updated the 2008 application to show that that the revision to Permit 95010001 originally requested in that application is no longer needed based on the additional data that is now available for the sulfur content of BFG.

[38] This comment does not accurately describe the informal discussions between US Steel and the Illinois EPA on the revisions to Permit 95010001 that are now being requested by US Steel in the Application. As such, the Illinois EPA would contend that this comment is perhaps disingenuous. In these discussions, US Steel was informed that the existence of the 2008 application was an impediment to action on the requested revisions to Permit 95010001. US Steel was also informed that the Consent Decree would need to be revised to remove the provision that required the submittal of the 2008 application before Permit 95010001 could potentially be revised based on the March 2020 application. US Steel indicated that it was pursuing such action with the Illinois Attorney General's Office. However, the relevant requirement of the Consent Decree is unchanged and the 2008 application is still pending. In the informal discussions with the Illinois EPA, US Steel did not suggest that this matter would be dealt with after Permit 95010001 was revised, as now suggested. US Steel has also not explained how this could properly occur given the respective roles of the Attorney General's Office in any revisions to the Consent Decree and the Illinois EPA in any revisions to Permit 95010001.

[39] The Project was originally permitted as a major modification under the PSD program for emissions of CO and SO_2 because it involved physical and operational changes that would result in significant net increases in emissions of these pollutants. National Steel, then the owner/operator of the Granite City Works, submitted a PSD permit application for this project in 1995. The Illinois EPA granted a PSD approval for the Project in conjunction with issuance of Permit 95010001 on January 25, 1996, presumably determining

suggests that some of the data for CO emissions relied upon when Permit 95010001 was originally issued in 1996 was not representative. During the informal discussions between the Illinois EPA and US Steel, it was recognized that for Permit 95010001 to be revised to reflect appropriate data for CO emissions and allow for more emissions, the application for revisions to Permit 95010001 would need to include a new air quality impact analysis for CO. The Application includes such an analysis.

In the draft denial letter, Attachment 1, the Illinois EPA indicates that one basis for the denial of the application is that the CO air quality impact analysis in the Application, "cannot be relied upon because the inventory for the CO emissions of the source with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered." In particular, the Illinois EPA indicates it has "concern" there may be some CO emissions from the BOF Shop Roof Monitor which are not reflected in the air quality impact analysis. The Illinois EPA also suggests that the analysis should consider the former by-product coke oven batteries, as the Application "does not explain why the air quality analysis does not consider the CO emissions of the former by-product coke oven batteries at the source." In addition, Illinois EPA asserts that the data for ambient background CO concentration used by US Steel, gathered by ambient air quality monitoring conducted by the Illinois EPA during three calendar years, i.e., 2016, 2017, and 2018, is "not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted." None of these concerns detailed by Illinois EPA with respect to the air quality impact analysis in the Application are deficiencies that warrant denial of the Application.

As explained below, in the individual responses to US Steel's comments on the topics that are mentioned in this introductory comment, these comments do not show that the Application should not be denied for the deficiencies in the air quality impact analysis as detailed in Denial Points 5 and 5A.

Moreover, US Steel has not submitted comments related to Denial Point 5 as it addresses uncaptured CO emissions of the blast furnace casthouse, which occur through the roof monitor on the casthouse. In this regard, one of the reasons that the emissions data that was

---

that this application included all necessary information for issuance of such an approval. A key requirement of the PSD permit program, which Illinois EPA determined had been satisfied by National Steel's application, is an air quality impact analysis (40 CFR 52.21(k)). For pollutants like CO, for which the USEPA has adopted National Ambient Air Quality Standards (NAQQS), an applicant for a PSD permit must demonstrate that the project will not cause or contribute to a violation of the applicable NAAQS.

provided by National Steel and used in the original permitting of the Project was "not representative" was that the casthouse was not identified as a source of CO emissions. This omission is addressed by the Application as it provides data for both the captured and uncaptured emissions of the casthouse.[40] However, the uncaptured CO emissions of the casthouse are not addressed by the new air quality impact analysis for CO provided as part of the Application.[41] As such, the Application is clearly deficient. The Application requests revision of Permit 95010001 as it provides approval for the Project under the PSD program to address errors in the original permitting of the project, i.e., the use of data for CO emissions from use of BFG in Project-affected fuel burning units that is now known to understate emissions and the failure to recognize and address the casthouse as it emits CO. However, the Application does not fulfill a key requirement of the PSD program for this requested revision because the new air quality impact analysis in the Application does not address the uncaptured CO emissions of the casthouse that are elsewhere addressed in the Application.

2. Provisions of Statutes or Rules or of Guidance Documents Are Not Identified That Indicate That the Air Quality Impact Analysis Must Provide the Listed Information

The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a request for revision of a PSD approval include any of the listed information, nor does the Illinois EPA point to even an application form or guidance document suggesting that such information be provided. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application pursuant to 35 IAC 201.152, but that was not done here.

In the Revised Draft Denial Letter, the provisions of the Act and the Illinois Code that are the basis of Denial Points 5 and 5A are identified, contrary to what is claimed by this comment. The

---

[40] The Application, Section 4.4, "Updated CO Emissions Information for the Blast Furnace Casthouse," p. 4-4, indicates that revised Permit 95010001 should provide for total annual CO emissions from the casthouse of 320 tons/year, with an allowance for 13.6 tons/year of CO emissions that would occur through the roof monitor. (As discussed in response to other comments, the Application improperly refers to the emissions that occur through roof monitors as fugitive emissions, rather than uncaptured emissions.)

[41] For the casthouse, the new air quality impact analysis for CO in the Application only addresses captured emissions, which occur through the vents of the casthouse baghouse and the iron spout baghouse. The analysis does not address uncaptured emissions, which occur through the roof monitor. (Refer to the Application, Appendix C, "Air Quality Modeling Report," the table entitled "US Steel Granite City Point Source Model Input.")

identified provisions of the Illinois Code include 35 IAC 204.1110 of Illinois' PSD rules, which provides the following.

> **[35 IAC Part 204] Section 204.1110 Source Impact Analysis**
> **The owner or operator of the proposed source or modification shall demonstrate that allowable emission increases from the proposed source or modification, in conjunction with all other [emphasis added] applicable emissions increases or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of:**
>
> **a) Any NAAQS in any air quality control region; or**
>
> **b) Any applicable maximum allowable increase as set forth in Section 204.900 and/or Section 204.1200, as applicable, over the baseline concentration in any area.**

It is well established that an air quality impact analysis required under the PSD program must be based on accurate information for the emissions of relevant units for their emissions of the pollutant whose impacts are being analyzed. In the absence of such information, an air quality impact analysis cannot be relied upon as having made the showing with respect to impacts on air quality that is required to be made under the PSD program for issuance of a new PSD approval or for issuance of a revised PSD approval where the revisions would potentially increase the air quality impacts of a source or project. The Application, itself, discusses USEPA guidance relative to the information for background air quality used in a PSD air quality analysis.[42]

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a

---

[42] The Modeling Report in the Application explain that:

> **The USEPA Monitoring Guidelines [Footnote] [6], other USEPA interpretative guidance, and USEPA administrative decisions clarify that representative, existing air quality monitoring data may be used to fulfill the PSD pre-construction monitoring requirements and establish background concentration needed for assessing NAAQS compliance, in lieu of monitoring data. USEPA's Monitoring Guidelines suggest specific criteria to determine representativeness of off-site data: *quality of data, currentness of the data, and monitor location*.**
>
> **[Footnote] [6] References: … 6. Ambient Monitoring Guidelines for Prevention of Significant Deterioration, EPA-450/4-87-007, USEPA, May 1987.**
>
> **Application, Appendix C, "Air Quality Modeling Report," Section 4.4, "Monitored Background Data."**

provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. The application must include information that is sufficient to provide proof that the facility or equipment that is the subject of the application will not violate applicable provisions of the Act and the Illinois Code. The Illinois EPA's ability to request additional information to remedy deficiencies in permit applications is not provided by 35 IAC 201.152. In the event of deficiencies in a permit application, including deficiencies in the air quality impact analysis for a new or revised PSD approval, the Illinois EPA is not required to request that the applicant submit a corrected air quality impact analysis, before proceeding to deny the application because the analysis is deficient.

3. The Original Permitting for the Project Did Not Address CO Emissions of the BOFs That Occur Through the Roof Monitor on the BOF Shop

As related to the possibility of CO emissions from the BOF Shop Roof Monitor, the Illinois EPA's prior determination for the original issuance of Permit 95010001 was that the Project would not cause or contribute to a violation of the NAAQS for CO was based on there not being CO emissions from this point.

This observation made in this comment is irrelevant as related to the adequacy air quality analysis for CO provided in the application. In the Illinois EPA's review of the new air quality impact for CO, which is necessarily part of the Application, the Illinois EPA is not required to and should not perpetuate what are now recognized as mistakes in the earlier air quality impact analysis for the Project submitted by National Steel.[43] In addition, as the Application requests revisions to the PSD approval for the Project to increase permitted CO emissions of Project-affected fuel burning units, the Application differs from National Steel's application. This analysis in the Application now also addresses the CO emissions of the blast furnace casthouse, which were not even recognized in 1996. Likewise, the

---

[43] For example, refer to the following statement by the Board in Chemrex, Incorporated v. Illinois Environmental Protection Agency, PCB 92-123, Order and Opinion, February 4, 1993, which, as a matter of principle, confirms that in its review of a new application, the Illinois EPA is not constrained to the decision that was made for an earlier application.

> **…the Board believes that the Agency is entitled to change its position, rather than maintain consistency with an incorrect eligibility determination, in light of the fact that there is no statutory provision, regulation or case law that addresses the issue at hand.**
>
> **PCB 92-123, Opinion and Order, February 4, 1993, p. 7.**

analysis must also address all CO emissions of the BOFs, including uncaptured emissions that occur through the roof monitor on the BOF Shop. As explained in General Response 1, Section 8A of this Responsiveness Summary, the Application may not simply rely on past actions or decisions by the Illinois EPA as proof that the revisions to Permit 95010001 that are requested would not violate relevant provisions of the Act and the Illinois Code.

4. The Scope of the Analysis Is Constrained by the Changes to Existing Terms in Permit 95010001 Requested by the Application

The Application does not request any changes to existing terms of Permit 95010001 relative to the CO emissions of the BOF Shop Roof Monitor.

This fact is immaterial under the PSD program. The scope of the air quality impact analysis that is necessary to support certain requested revisions of Permit 95010001 extends beyond the units for which increases in permitted CO emissions are requested. The "preliminary" air quality analysis for the Project (also referred to as the "Step 1" analysis), with the revisions to specific limits that are being requested, shows that the Project, by itself, would have CO air quality impacts on an 8-hour average that are "significant" under the PSD program. (Refer to the Application, Appendix C, "Air Quality Modeling Report," Section 6.1, "Significant Impact Analysis Results," Appendix C, p. 6-1 of the report.)[44] As such, a full air quality analysis (also referred to as a "Step 2" analysis) is required by the PSD program to support the requested increases in permitted CO emissions. In this analysis, the impact of a project on ambient air quality must be determined considering the emissions of 1) The project, itself;[45] 2) Other units at the facility; 3) Units at other facilities in the area around the facility at which the project would occur; and 4) Background ambient air quality as determined by ambient monitoring at a location that is representative of the location of the facility.[46]

---

[44] The applicable significant impact level under the PSD program for CO on an 8-hour average is 500 microgram/meter^3 (0.5 milligrams/meter^3). The role of significant impact levels is to determine whether a full air quality impact analysis must be performed under the PSD program. They are not indicative of an ambient concentration that should be of concern for its impacts on human health or the environment. For example, the NAAQS for CO on an 8-hour average (10,000 micrograms or 10 milligrams/meter^3) is 20 times more than the significant impact level.

[45] It is perhaps noteworthy that the new air quality impact analysis in the Application did address CO emissions from Ladle Dryer/Preheaters, which are located in the BOF Shop. The emissions of these units are from burning fuel and are released directly into the BOF Shop. It is conservatively assumed that all of their emissions are discharged to the ambient air through the roof monitor of the BOF Shop.

[46] The air quality impact analysis in the Application follows this hierarchical approach to air quality impact analyses. A full analysis is only provided for

5. The CO Emissions of the BOFs That Occur Through the Roof Monitor of the BOF Shop

The Illinois EPA has neither requested that the air quality impacts analysis for CO in the Application address CO emissions of the BOFs that occur through the BOF Shop Roof Monitor, nor has the Illinois EPA provided a quantitative estimate of those emissions. Accordingly, US Steel had no reasonable basis to know that the Illinois EPA had reconsidered its prior determination relating to emissions from the BOF Shop Roof Monitor. It was therefore reasonable for US Steel to conclude that its air quality impacts analysis, with revisions to the CO emission rates only for those emission points where the parties agreed that National Steel's modeled rates should be corrected, was sufficient for the purpose of requesting revisions to the permitted CO emissions from certain Project-affected fuel burning units.

This comment does not show that the Application should not be denied. As explained above, it is not necessary for the Illinois EPA to explain to an applicant for a PSD permit, including an applicant for a revised PSD permit, how to perform a PSD air quality analysis to show that a source or project would not cause or contribute to violations of the applicable NAAQS for a criteria pollutant for which the new or revised PSD approval is needed. There is an extensive body of USEPA guidance addressing how air quality impact analyses are to be conducted under the PSD program.

In addition, the Illinois EPA did, in fact, provide a quantitative estimate in the Draft Denial Letters for the CO emissions that occur through the Roof Monitor on the BOF Shop since estimates for these emissions can be readily made from information for the captured emissions of the BOFs, which occur through the stacks of the particulate control devices.[47] A permit applicant's expectations for the action that the Illinois EPA will take on a construction permit application are not relevant relative to whether the Illinois EPA determines that the application did not meet the statutory criterion

---

CO impacts on an 8-hour average. A full analysis is not provided for impacts on a 1-hour average, for which the Step 1 analysis shows impacts would not be significant.

[47] In Footnote 26 of the Revised Draft Denial Letter, the Illinois EPA provided an estimate, 16.1 tons/year, for the CO emissions of the BOFs that occur through the Roof Monitor of the BOF Shop. This estimate is based on the assumption that the capture efficiency achieved by the ESP system for the particulate emissions of the BOFs from refining is 99.9 percent. Using this value for the capture of CO emissions, the CO emissions of the BOFs through the Roof Monitor would be about 0.1 percent of the 16,097 tons/year of the captured CO emissions for which the BOFs are permitted. (16,097 ÷ {99.9 ÷ 100.0} x {100.0 -99.9} ÷ 100.0 = 16.11, ~ 16.1.)

for issuance of the requested permit and whether the application must be denied. Finally, contrary to what is represented in this comment, there was not agreement during the informal discussions between the Illinois EPA and US Steel on the revisions for Permit 95010001 as to the specific revisions to the CO emission data for the units at the Granite City Works that would be appropriate for the new air quality impact analysis for CO.[48] Moreover, even if the Illinois EPA had informally agreed that the CO emission data for other units need not be updated, this would not excuse deficiencies in the air quality impact analysis in the Application as this analysis cannot be relied upon to make the necessary showing required by the PSD program.

6. Emissions of the Former By-Product Recovery Coke Oven Batteries Need Not Be Addressed Because They Are Now Shut Down

As Denial Point 5 addresses the historic CO emissions of the former by-product coke recovery oven batteries, which are now shutdown, the Application does not request revisions to Permit 950100001 that would provide PSD approval or other authorization for the CO emissions of these batteries. There is no basis for considering emissions under a counterfactual scenario in evaluating whether the changes to Permit 95010001 that are requested will cause or contribute to a violation of any NAAQS. This is one of several instances where Illinois EPA appears to be asserting that the Application is deficient because it does not address facts and circumstances that may have existed for some period since 1996 but are no longer present.[49]

This comment is not responsive to Denial Point 5 as it addresses the fact that the CO emissions of the former by-product recovery coke oven batteries are not addressed by the new air quality impact analysis for CO in the Application. As already explained, this denial point involves the

---

[48] As the application for revisions to Permit 95010001 would involve corrections to the data for the CO emissions of the Project, for purposes of the new air quality impact analysis for CO, it is improbable that the Illinois EPA ever agreed that only corrections to certain emission data needed to be made. In this regard, it is also perhaps relevant that US Steel did make other "updates" to the CO emission data used in the new air quality analysis. In particular, the new analysis addresses the CO emissions of the new cogeneration boiler constructed by US Steel and units at the new heat recovery coke production facility constructed by SunCoke.

[49] To the extent that the Illinois EPA is making such claims, they are without merit, as the requested approval is forward-looking, *i.e.*, is based on the applicable regulations and other circumstances as they exist or will exist at the time of permit issuance. 42 U.S.C. 7410(j). *See, e.g., United States v. EME Homer City Generation, L.P.*, 727 F.3d 274 (3rd Circuit, 2013) (Footnote 4 of US Steel's Comments of January 2024.)

adequacy of the new air quality impact analysis that is part of the Application as the Application requests revisions to Permit 95010001 that would revise the PSD approval for certain units relative to the amounts of CO emissions that are permitted. In particular, as a Step 2 or full air quality impact analysis is necessary under PSD for CO on an 8-hour average, the scope of this analysis is not limited to Project-affected CO emitting units, much less to only Project-affected units for which increases in permitted CO emissions are being requested.

The fact that the by-product recovery coke oven batteries are now shutdown, by itself, is also not a sufficient reason to omit the emissions of units at these batteries from the new air quality impact analysis for CO. These batteries were in operation for almost 20 years following the original issuance of Permit 95010001 in 1996. The Application requests revision of the original PSD approval for the Project to correct errors in the CO emission data that was relied upon for the original permitting of the Project. It would not be unreasonable for the new air quality impact analysis for the Project with certain increases in the CO emissions for which the Project is permitted to address air quality impacts of the Project with the emissions of the former coke oven batteries. Neither the Application nor this comment explain why this would not be reasonable. Indeed, if the Application involved a Project that was not already a PSD major modification for CO, the new air quality impact analysis to support the requested changes to Permit 9501001 would be required to address the CO emissions of the by-product coke oven batteries even though these batteries are now shutdown.[50]

---

[50] If the Project were not already permitted as a PSD major modification for CO, the increase in the permitted CO emissions of the Project requested by the Application would explicitly be subject to certain provisions of the NSR rules addressing relaxations of established permit limitations, i.e., 40 CFR 52.21(r)(4), 35 IAC 204.850 or 35 IAC 203(b).* Under the PSD program, the new air quality impact analysis for CO in the Application would have to address the emissions associated with units, like the former by-product recovery coke oven batteries, that are now shut down. This is because the substantive requirements of PSD must be addressed as if construction on the Project had not yet commenced, i.e., as circumstances were in 1996 before the coke oven batteries were shut down.

By way of explanation, these rules address permitting when a source proposes "relaxation(s)" of established permit limitations that restrict emissions of a source or project so that it is not major for purposes of NSR and the source or project would become major with the requested increase in permitted emissions. These rules address situations like those presented with the Application where the requested relaxations or increases in permitted emissions would not be the result of a further physical change or subsequent change in the method of operation of the source or project. In such situations, the substantive requirements of NSR should not be addressed as they are routinely addressed, considering the circumstances at the time of the application and the associated

Finally, as related to whether this denial point would be improper as the review of the Application should be "forward-looking" rather than address a "counterfactual scenario," with a citation to a court decision in a PSD enforcement action, this comment overlooks the fact that the Application requests revisions to Permit 95010001, the construction permit/PSD approval issued for the Project. Then, as related to emissions of CO and NOx, the Application requests revisions to Permit 95010001, and indirectly, by means of Integrated Processing, to Permit 96030056, the CAAPP permit for the facility, to increase emission limitations for CO and NOx in Permit 95010001 that US Steel has violated or potentially violated

---

contemporaneous time period. Rather, in such situations, the substantive requirements of NSR must be considered in light of the circumstances that were present at the time that the permit was issued that established the limitations that made the source or modification non-major and that would now be relaxed such that the source or modification would become major. In other words, the substantive requirements of NSR must be addressed as if construction had not yet commenced on the source or project.

This would not be required if a revision to established permit limitation(s) would be due to a further physical change or a subsequent change in the method of operation of the source or modification. In that situation, the change would appropriately be addressed for purposes of NSR separately from the prior permitting of the source or project. The change would be addressed as a new project for purposes of NSR, rather than as a revision to a permitted project. In other words, routine NSR permitting would apply for the permit application for such a change.

*** For example, Illinois' PSD rules, 35 IAC 204.850, Relaxation of a Source-Specific Limitation, provide as follows:**

> **At such time as a particular source or modification becomes a major stationary source or major modification solely by virtue of a relaxation in any enforceable limitation, established after August 7, 1980, on the capacity of the source or modification otherwise to emit a pollutant, such as a restriction on hours of operation, then the requirements of Sections 204.810, 204.820, 204.830, 204.840, 204.850, 204.1100, 204.1110 {Source Impact Analysis], 204.1120, 204.1130, 204.1140, 204.1200, and 204.1400 shall apply to the source or modification as though construction had not yet commenced on the source or modification.**

and may violate in the future.[51, 52] This is not the situation that is presented by an after-the-fact enforcement action against a source for the failure to obtain a PSD permit, as is addressed in the cited court decision.[53]

---

[51] The CO emissions of Project-affected fuel burning units from use of BFG are currently limited to 13.7 lbs/million cubic feet (mmcf) of BFG* and 1,267.46 tons/year (Permit 95010001, Condition 22 and Table 4). These limits are restated in the CAAPP permit (Permit 96030056, Condition 5.6.2((a)(iii)(B)(2)). These limits are in effect as they were not appealed by US Steel in PCB 2013-053, and, as such, were not stayed by the Board.

The Application indicates that for the revision to Permit 95010001, the maximum overall CO emissions from use of BFG in these fuel burning units should be 26,226 tons/year. This reflects CO emissions of 321.83 lbs/mmcf and 11,064 tons/year from blast furnace stoves; 32.12 lbs/mmcf and 1,228 tons/year from Boilers 11 and 12; and 697.6 lbs/mmcf and 13,934 tons/year from the BFG flare. (Application, p.4-4, Table 4-2 "Updated CO Emissions from Burning Gaseous Fuels.") (This table is not accompanied by calculations in Appendix B of the Application.) The Application explains that, "These requested changes are not based on any post-1996 Project changes but are based on updated information regarding CO emissions." (Application, Section 4, "Changes to Provisions for CO emissions.") The Application does not request that revised Permit 95010001 set an overall limit for the annual CO emissions from burning BFG. It also does not request that the revised permit prescribe the emissions factor(s) that are to be used to determine CO emissions of units for which emission testing is not feasible.

*** When Permit 95010001 was revised in 2012, the revised permit erroneously indicated that the limit for the rate of CO emissions from these fuel burning units was in lbs/ton. In this note, this limit is correctly expressed in terms of lbs/mmcf, consistent with the terms of this limit in Permit 95010001 as issued in 1996.**

[52] The NOx emissions of the BOF ESP Stack are currently limited to 0.0389 lbs/ton [of steel produced] and 69.63 tons/year (Permit 95010001, Condition 18 and Table 2). The Application requests that revised Permit 95010001 limit the overall captured NOx emissions of the BOF Shop to 400 tons/year. (Application, p. 6-10, Section 6.5.2, "Basic Oxygen Furnace Shop Operations," in Section 6.5, "Requested Changes to Permit Terms Relating to NOx Emissions.") The Application does not address the uncaptured emissions of the BOFs, which occur through the roof monitor on the BOF Shop.

For the Blast Furnace Casthouse, a much smaller increase in the NOx emissions is requested. The Application requests that revised Permit 95010001 limit the overall NOx emissions of the casthouse, including both captured and uncaptured emissions to 24.0 tons/year. (Application, p. 6-9, Section 6.5.1.1, "Proposed NOx Emissions Limitations for Blast Furnace Operations," in Section 6.5, "Requested Changes to Permit Terms Relating to NOx Emissions.")

[53] Interestingly, with respect to the requested changes to Permit 95010001 for the CO emissions of Project-affected fuel burning units, the earlier application, which was submitted in March 2020, requested that revised Permit 95010001 limit the overall CO emissions of these units to 19,343 tons/year (rather than 26,226 tons/year), with this limit addressing emissions from both use of BFG and natural gas. That application also requested that the revised

7. Adequacy of Data for Background CO Air Quality (Denial Point 5A)

As related to the use of 2016-2018 background CO concentration data, this data was the most current quality-assured data available at the time of US Steel's application submittal of March 2020. Use of these data was approved by Illinois EPA following its review of US Steel's dispersion modeling protocol in February 2020. US Steel agrees that the 2016-2018 background CO concentration data is less current now than they were at the time of permit application submittal. "Currentness" of air quality data is one aspect of the permit application review process that is ensured by compliance with the procedural requirements relating to timely processing of permit applications.[54]

This comment does not show that the Application should not be denied for reasons as set forth in Denial Point 5A. As explained in the revised Draft Denial Letter, there are two issues with the value for background air quality used in the air quality impact analysis in the Application. The first is that the value selected for background air quality does not represent air quality in the period prior to 1996 when Permit 95010001 was originally issued. This is the same issue as is posed by the omission of the CO emissions of the former coke oven batteries from the analysis, as discussed above. If US Steel can satisfactorily resolve this issue, the second issue is that the value for background is no longer necessarily representative of current air quality. Five years have passed since the period from which the value for background used in the Application was obtained. The Application

---

permit prescribe the emission factors that are to be used for certain units when determining ongoing compliance with the annual emission limit. For the BFG Flare, the proposed factor was 350 lbs/mmcf, which is significantly lower than the factor used in the Application when updating CO emissions. For the Blast Furnace Stoves, the proposed factor, 322 lbs/mmcf, was essentially the same as the factor used in the Application. For use of natural gas in units other than Boilers 11 and 12, the proposed factor was 84 lbs/mmcf. Only the CO emission of the boilers were proposed to be determined using emission factors from periodic testing. The factor that was proposed for use of natural gas in units other than the boilers, 84 lbs/mmcf, is the same factor used in Table 4-2 of the Application when updating CO emissions of fuel burning units from use of natural gas. (In this regard, it is assumed that CO emissions from all use of natural gas by such units is addressed in Table 4-2 although this table only indicates that emissions from use of natural gas by boilers and the ladle dryer/preheaters are addressed.)

[54] See, Section 165(a) of the federal Clean Air Act (requiring final action on any [completed] PSD permit application not later than one year after filing {of such completed application]). Also see, 35 IAC 201.158 (providing that a state air pollution control permit application shall be deemed to have been filed 30 days after submittal if Illinois EPA has not notified the applicant that it is incomplete) (Adapted from Footnote 5 of US Steel's Comments of January 2024.)

does not explain why this value for background should still be considered representative. In this regard, while monitoring for CO at the station in East St. Louis ceased in early-2019,[55] a value for background could be obtained from another monitoring station in the St. Louis area. The Application does not explain why use of a value for background that is no longer current should still be accepted as being representative for the air quality impact analysis in the Application compared to a current value for background that is available from another monitoring station.[56]

Lastly, final action on the Application was not required by October 2023 pursuant to the provision of the Clean Air Act cited by this comment. This deadline applies to the processing of a complete PSD application. It provides that a complete PSD application shall be granted or denied within one year from the date of filing of the complete application. The Application is not complete because it has substantive deficiencies, as have been detailed in the Draft Denial Letters, of which only one relates to the value for background used in the air quality impact analysis. Moreover, even if the Application were considered to now be complete, the failure of the Illinois EPA to meet the one year deadline for final action on an application for a PSD permit would not preclude denial of the Application as deficiencies are or would be identified were such that the requested PSD approval could not be issued.[57]

---

[55] Ambient monitoring is still conducted at the Illinois EPA's monitoring station in East St. Louis for SO_2, nitrogen dioxide (NO_2), ozone, and particulate matter$_{2.5}$ ($PM_{2.5}$).

[56] With regard to the selection of the monitoring station used to obtain the value for background air quality, the Application states the following:

> **There are many existing ambient CO monitors within 100 miles in [sic] the facility (Figure). Existing monitoring data have been evaluated in relation to the criteria provided in USEPA's Ambient Monitoring Guidelines as being representative of the US Steel site.**
>
> **[Figure 4 is entitled "Ambient Air Quality Monitors in the Vicinity of the US Steel Facility. This figure is a downloaded image of a satellite map whose function is to show the location of ambient monitoring stations, as obtained from an interactive map on a USEPA website. https://epa.gov/outdoor-air-quality-data/ineteractive-map-air-quality-monitors.]**
>
> **Application, Appendix C, Air Quality Monitoring Report, Section 4.4. "Monitored Background Data," p. 4-5 of the report.**

However, the Application does not include documentation for the evaluation of the stations at which ambient monitoring for CO was conducted by US Steel or its consultant.

[57] Whether the Application is considered to be "complete" under 35 IAC 201.158, as also cited by this comment, is not relevant to the denial of the

Finally, the fact that prior to March 2020, the Illinois EPA informally provided preliminary approval for the background air quality data used in the air quality impact analysis for CO in the 2020 application does not show that the Application should not be denied for reasons associated with the continued use of such data from that time period in the Application, as discussed in Denial Point 5A in the Revised Draft Denial Letter.[58] The Application was submitted in October 2022, more than two years after the 2020 application.

VII. THE PERMIT APPLICATION IS SUFFICIENT AS TO BEST AVAILABLE CONTROL TECHNOLOGY (BACT) FOR CARBON MONOXIDE (DENIAL POINT 18 (CO) AND DENIAL POINT 19 (SO_2 and CO)

Application. This rule addresses whether a state air pollution control permit application is considered complete as an administrative or initial matter. In general, if the Illinois EPA finds an application for a state air pollution control permit is not complete within 30 days of the date it is received, the Illinois EPA may take action on the application by means of a notice of incompleteness. In this notice, the Illinois EPA need only identify the deficiencies that it finds with the application, i.e., the information or showings that are missing from the application. As a matter of practice, after 30 days, the Illinois EPA also routinely requests information that is missing from the application by means of a request for additional information. Assuming the applicant supplements or revises the application to rectify deficiencies, the Illinois EPA must issue a permit if the application then meets the standard for issuance of a permit. Otherwise, if the deficiencies in the application are not rectified or the standard for issuance of a permit is not met, the application must be denied, as provided for by Section 39(a) of the Act. An application may also be directly denied by the Illinois EPA if it does not meet the standard for issuance of a permit irrespective of whether the application is considered complete pursuant to 35 IAC 201.158 or the denial could have been preceded by a request for additional information.

[58] It is noted that for background air quality for CO, 8-hour average, the air quality impact analysis in the Application uses a higher value, 1,646 micrograms/m^3, than used in the analysis in the 2020 application, 1,349 micrograms/m^3. The value for background used in the Application is a "maximum" concentration, 8-hour average, measured at the monitoring station in East St. Louis. The value used in the 2020 application was the "highest-second-highest" concentration measured in any year in the three years of ambient monitoring at this station that were used to obtain a background concentration. This value is consistent with the terms of the NAAQS for CO as they set numerical values for the concentration of CO in the ambient air that should not be exceeded more than once per year. The analysis in the Application does not explain why it uses a maximum value for background air quality rather a highest- second-highest concentration, as was done in the 2020 analysis.

A. **Introduction (Denial Point 18)**

The pertinent provision of the PSD rules governing the required contents of a PSD application relative to the establishment of Best Available Control Technology (BACT) provide that a PSD application must include:

> A detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that best available control technology would be applied.
> 40 CFR 52.21(n)(1)(iii) (See also 35 IAC 204.810(a)(3)).

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the application "lacks necessary information" for it to make BACT determinations for CO for the casthouse and the blast furnace stoves. It is undisputed that the Application includes estimates of the CO emissions from the casthouse and the blast furnace stoves. The Application also includes as a detailed description of the systems of continuous emission reduction that US Steel plans to use to control these emissions.

This comment does not show that the Application should not be denied for reasons as detailed in Denial Point 18. In this regard, the Application would not be denied because it does not include the specific information required by the PSD rules addressed in this comment, i.e., "a detailed description as to what system of continuous emission reduction is planned for the source or modification" and "emission estimates." The Application would be denied because it does not show that BACT would be utilized or applied for CO for emissions units as required by the PSD rules. In other words, the Application does not include "any other information necessary to determine that best available control technology would be applied," as is also explicitly required by the PSD rules.[59]

Moreover, with regard to BACT for the casthouse, the Application does

---

[59] It is also noteworthy that the introductory paragraph of 35 IAC 204.810 imposes a broad requirement on the information that an applicant for a PSD permit must submit in its application, as follows:

> **The owner or operator of a proposed major stationary source or major modification shall submit <u>all</u> [emphasis added] information necessary to perform any analysis or make any determination required under this Part [35 IAC Part 204].**

not actually identify the system of continuous emissions reduction (i.e., BACT Technology) used for CO emissions of the casthouse, much less provide a description of such system. Rather, for the casthouse, in Section 8.2.3, "BACT Evaluation for Blast Furnace Casthouse," the Application addresses add-on combustion control systems. (Add-on combustion control systems, commonly known as afterburners reduce the concentration of a combustible pollutant, like CO, in an exhaust stream by subjecting the stream to the temperature at which the pollutant combusts). The Application shows that these systems, even if feasible, would have cost impacts that should be considered excessive and should not be required to be utilized for BACT. This provides certain information that is relevant for the determination of BACT for the casthouse, as it eliminates certain emission control options for consideration as BACT. However, it does not address what system of emission reduction would be utilized for CO to meet BACT instead of add-on control systems.

With regard to BACT for the blast furnace stoves, the Application does identify the system of continuous emissions reduction or technology used for CO emissions, i.e., certain work practices related to good fuel combustion by the stoves that act to lower CO emissions. However, the BACT analysis in the Application does not provide other information necessary to determine that best available control technology BACT would be applied. In particular, the Application, again, does not include information necessary to conclude that BACT need not be set as numerical emission limitation(s).[60] The Application does describe certain aspects of the blast furnace stoves, e.g., their age and height, that might affect whether it would be reasonable to set BACT for the stoves as numerical standards, such that emissions testing would be needed to confirm compliance. However, the Application does not describe the technological challenges and the costs that the identified aspects of the stoves would present for emissions testing, such that BACT need not be set as numerical emission standard(s).

B. CO Emissions from Blast Furnace Casthouse (Denial Point 18)

B1. It Is Unclear Why the BACT Analysis in the Application is Deficient Because It Does Not Include Information of Process-Related Control Options As BACT for CO Emissions of the Casthouse

---

[60] In the PSD rules, the definition of BACT provides that:

> **…If the Administrator determines that technological or economic limitations on the application of measurement methodology to a particular emissions units would make the imposition of an emissions standard infeasible, a design, equipment, work practice, operational standard, or combination thereof may be prescribed instead to satisfy the requirement for application of best available control technology. …**
> **40 CFR 52.21(b)(12) and 35 IAC 204.280.**

For the blast furnace casthouse, as discussed in Section 8.2.3 of the Application, the only control options identified for potential consideration in a BACT determination are add-on air pollution control equipment options, specifically, installation and use of a capture system and some type of afterburner. The Illinois EPA asserts that this part of the application is deficient because it provides neither an explanation of "why process-related control options are not available" nor, with respect to the literature search conducted by US Steel that did not identify any process-related control options for CO emissions from casthouses, "documentary support for the review of available control options that was conducted." It is unclear to US Steel how it would be helpful to Illinois EPA's BACT determination to have copies of reports that contain no pertinent information, and it is even more unclear how US Steel might be expected to know, without receiving from Illinois EPA a request for specific additional information, which reports containing no pertinent information would be most valuable for this purpose.

This comment also does not show that the Application should not be denied based on Denial Point 18. This comment overlooks the interplay between the definition of BACT, the determination of BACT required by the PSD rules as BACT-subject units would be addressed by a PSD approval, and the standard for issuance of state air pollution control permits in Section 39(a) of the Act. As acknowledged in the Application, p. 8-4, Section 8.2.1.4, "Available Control Options," the definition of BACT provides that BACT can involve process-related control measures, as well as end-of-pipe, add-on emission control systems. The Application claims, based on a review that was conducted, that the only control options that are potentially available as BACT for CO emissions are add-on control systems.[61] As such, the Application effectively also makes another, related claim, based on the review that was conducted. This is that other than add-on afterburner

---

[61] In the Application, in Step 1 of the Top-Down BACT Analysis for the casthouse, in which available control options (i.e., air pollution control technologies and techniques with a potential practical application to CO emissions of the casthouse), are to be identified, the Application explains:

> **Based on a review of BACT determinations in U.S. EPA's RBLC [RACT/BACT/LAER Clearinghouse] database and other literature, the control options that are potentially available to control CO emissions from the blast furnace casthouse are:**
>
> - **Capture system and thermal incineration and**
> - **Capture system and catalytic incineration**
>
> **Application, Section 8.2.3.3, "Step 1 – Identify Available CO Control Options," in Section 8.2.3, "BACT Evaluation for Blast Furnace Casthouse," in Section 8, "Best Available Control Technology for CO," p. 8-8.**

systems, there are no other available BACT options for control or reduction of the CO emissions of the casthouse, such as work practices or operational requirements. It is because of this that the Application must provide documentation for the review that was conducted for available control options. As the Application relies on this review to summarily dismiss all possible control options from the BACT analysis other than afterburner systems, it is necessary for this review be documented in the Application. In the absence of such documentation, the Application does not show that control options other than add-on afterburners are not available for the casthouse. In addition, the Illinois EPA and other interested parties cannot independently examine the Application and to even consider whether the review that was conducted was adequate to be considered proof that BACT is or would be used for the CO emissions of the casthouse.

Moreover, the conclusion reached by the Application based on the review that was claimed to be conducted is inherently deficient. If a review of the literature indicates or, by omission, suggests that add-on control technology is not used for control of CO emissions of casthouses, which is likely the case, the issue for the revision to Permit 95010001, is what work practices or other "non-add-on" methods of continuous emission reduction should be imposed as BACT by Revised Permit 95010001. The Application does not address this issue.[62] As the Application suggests that there are not any such methods of continuous emission reduction, the Application inherently acknowledges that it does not propose BACT for CO for the casthouse.

B2. The Illinois EPA Is Familiar with the Chemical Reactions in Blast Furnaces That Yield CO As a By-Product

As to this purported deficiency in the Application related to the casthouse, the Illinois EPA is familiar with the chemical reaction that is intentionally forced to occur in the casthouse as an inherent part of the ironmaking process.[63] Having not received from Illinois EPA

---

[62] **It would be surprising if US Steel were not able to directly address this issue. Personnel involved with the operation of the casthouse at the facility and at other US Steel facilities that have or had blast furnaces, likely have the knowledge and experience of the practices that reduce the carryover of CO with the metal and slag that are tapped from a blast furnace.**

[63] See, *e.g.*, "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (February 4, 2013) p. 4, ("The charge materials (iron ore, coke, limestone and other flux material) are fed into the furnace at the top through a double-bell lock system. Heated air is blown into the furnace through nozzles or tuyeres near the bottom of the furnaces. In the furnaces, the coke undergoes partial combustion to carbon monoxide providing the heat to melt the charge as well as reducing the iron ore to elemental iron.") (Footnote 7 of US Steel's Comments of January 2024.)

a request for specific additional information, US Steel had no way to know that it was necessary to explain in the Application that the partial combustion of coke inevitably yields CO as a reaction product.

This comment does not show that, as related to the casthouse, the Application should not be denied based on Denial Point 18. The issue for this denial point is again the information provided in the Application and what the Application shows or proves. Even if the claim made in this comment as to the knowledge of the Illinois EPA concerning the reason that casthouse emits CO were actually correct, it would be immaterial to the denial of the Application.[64]

Moreover, this comment actually discusses the formation of CO in the blast furnaces, not the CO emissions of the casthouse.[65] Indeed, the information in this comment concerning the CO emissions of the casthouse is inconsistent with information in the Application. For the casthouse, the Application indicates that, "These [CO] emissions are a consequence of the relatively small amount of BFG that leaves the furnaces with the molten metal and slag during the tapping process." (Application, p. 4. Section 4.1.1, "Blast Furnace Casthouse," in Section 4-1, "Process Background and Project.") Accordingly, assuming that the Application accurately describes why the casthouse emits CO, it was appropriate in the BACT analysis for the casthouse in the Application to discuss the systems of continuous emission reduction (i.e., work practices or operational requirements) that are currently used and could potentially be used to reduce the amount of CO in the iron and slag tapped from the blast furnaces. These measures could involve both the operation of the furnaces and the tapping process, itself, as they act or could act to reduce the CO emissions of the casthouse.

B3. Applicable Rules Do Not Require BACT for the Casthouse for CO

---

[64] It is also not reasonable to assume that the occurrence and cause of the CO emissions of blast furnace casthouses is understood by the Illinois EPA. If the presence of these emissions had been recognized by the Illinois EPA in 1996, it might have been raised by the Illinois EPA during the initial permitting of the Project since National Steel's permit application did not address these emissions.

[65] Information is readily available explaining how the production of iron by a blast furnace generates CO. This CO, as well as carbon dioxide and other gases generated by the chemical reactions in the furnace, are collected at the top of the furnace. The collected gas is scrubbed to remove entrained dust. The resulting low-heat content, by-product gas stream is then used as fuel in various units at the facility that are designed and equipped to burn it, notably in the blast furnace stoves.

For the CO emissions of the casthouse, US Steel is currently not subject to any emission limitations and it has not requested any revisions to Permit 95010001 to establish such limitations. US Steel is also not subject to any work practice requirements for the casthouse related to CO emissions, since the work practices required by 40 CFR Part 63 Subpart FFFFF involve measures to control particulate emissions. US Steel did not include any information pertaining to BACT for CO emissions from the casthouse in the application submitted in March 2020. At the request of Illinois EPA, although under no obligation to do so,[66] US Steel voluntarily provided a BACT analysis for the casthouse in the Application. Illinois EPA's proposed denial of the Application will simply ensure the status quo is maintained, i.e., that US Steel is not subject to any limitations on CO emissions from the casthouse.

This comment does not show that the Application should not be denied because of a deficiency in the BACT analysis for the casthouse, as addressed in Denial Point 18. It is first noted that, contrary to what is claimed in this comment, the Application does request a revision to Permit 95010001 to establish BACT for CO for the casthouse. The Application proposes a BACT limit for the captured CO emissions of the casthouse of 70 pounds/hour.[67] This comment is also misleading as it suggests that US Steel simply included a BACT analysis for the casthouse in the Application because the Illinois EPA requested such an analysis. The revision to Permit 95010001, as would be initiated by US Steel's application, provides US Steel, as well as the Illinois EPA,

---

[66] *See, e.g., U.S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677 (N.D. Ill. 2011)(holding that source owner's obligations with respect to BACT are limited to those imposed in a PSD permit). (Footnote 8 of US Steel's Comments of January 2024.)

[67] In the Application, the BACT analysis for the casthouse concludes as follows:

> USS Granite City proposes a CO emission limit of 70 lb/hr, combined for the casthouse baghouse and iron spot baghouse, as BACT for the blast furnace casthouse. This proposed limit is as stringent as any identified limit for a blast furnace casthouse at any similar facility. [Footnote] 48.
>
> {Footnote] 48 The only CO emission limit identified for a blast furnace casthouse is a limit of 56.25 lb/hr for the casthouse baghouse stack at the Dearborn (MI) Works, currently owned and operated by Cleveland Cliffs. This casthouse has a permitted iron production rate of 8,000 tons per calendar day. See https://www.michigan.gov/egle/-/media/Project/Websites/egle/Documents/Permits/AQD/PTI/applications-of-interest/PTI-182-05C-Severstal-Conditions-2014-05-12.pdf (last accessed Sept. 23, 2022).
>
> Application, p. 8-10, Section 8.2.3.7, "Step 5 - Establish CO BACT, in Section 8.2.3, "BACT Evaluation for Blast Furnace Casthouse."

with the opportunity to resolve and put to rest through permitting an error in the original PSD approval for the Project as it overlooked the casthouse as a source of CO emissions.[68] This "clean up" would occur in conjunction with a revision to the PSD approval that is already sought by the Application and is necessary because Permit 95010001 currently limits the CO emissions of the blast furnace stoves to much less than US Steel now believes is representative or correct, i.e., CO emissions of only 1,267.46 tons/year, rather than 11,064 tons/year as now requested for the stoves by the Application. For the Illinois EPA to also revise the PSD approval provided by Permit 95010001 to allow for CO emissions from the casthouse, necessarily requires that the relevant substantive requirements of the PSD rules be fulfilled.

The CO emissions of the casthouse must be addressed by the new air quality impacts analysis for CO in any case as this analysis is a necessary prerequisite to increasing the permitted CO emissions of the blast furnaces stoves. Accordingly, for the casthouse, itself, the substantive requirement of the PSD program that is of specific concern is the BACT requirement. The Application includes a BACT analysis for the CO emissions of the casthouse. Unfortunately, this BACT analysis is deficient as it overlooks the need to also directly consider implementation of measures to control or reduce CO emissions other than add-on afterburner technology. This was likely inadvertent since good combustion practices, an emission control technique other than add-on control technology, are proposed as BACT for the stoves. Nevertheless, the fact that the BACT analysis for the casthouse in the Application does not address use of control measures for the casthouse other than add-on control systems means that the Application does not show that BACT is or will be used on the casthouse for CO. For the Illinois EPA to knowingly overlook this fact would be improper. Absent a full BACT analysis, one cannot know whether BACT for the casthouse for CO would simply formally recognize the measures that have been and are currently used or whether BACT would act to lower the CO emissions of the casthouse as BACT would entail use of additional practices to reduce CO

---

[68] It is also noteworthy that the court decision cited by this comment does not address the circumstance that are now presented with the PSD approval provided by Permit 95010001. That decision involved an after-the-fact enforcement action where the owner of a source did not obtain the PSD approvals that were alleged to be needed for certain major modifications. However, National Steel did obtain a PSD approval for the Project. US Steel is now responsible for the Project and is operating pursuant to the PSD approval originally issued to National Steel. US Steel, not National Steel, has requested revisions to the PSD approval for the Project as it addresses the CO emissions of the blast furnace stoves, as well as other revisions to Permit 95010001. As National Steel's original application and the original permitting of the Project were in error, as they failed to address the CO emissions of the casthouse, the only way to now address this error through permitting is with issuance of a revised PSD approval that also addresses the CO emissions of the casthouse.

emissions.

C. C. CO Emissions from Blast Furnace Stoves (Denial Point 18)

C1. The Determination of BACT for the Stoves Proposed by the Application Is Consistent with PSD Rule Requirements

In the original application for Permit 95010001, National Steel made the following proposal:

> BACT literature indicates that blast furnace stoves at steel mills are not using add-on control equipment for CO emission control. CO emissions can be adequately controlled by the use of good combustion practices. Therefore, the BACT recommendation for control of CO emissions from the blast furnace stoves is the maintenance of present good combustion practices.
>
> National Steel, Original Application, Supplement October 30, 1995, pp. 4-10 and 4-11, Section 4.3.4.1, "BACT - Blast Furnace Stoves," in Section 4.3.4, "Selected BACT – CO," in Section 4.0, "Best Available Control Technology Review.".

This comment does not show that the Application should not be denied because of Denial Point 19. If revised Permit 95010001, as it provides PSD approval for the Project for CO, is to be revised to increase the permitted CO emissions of the blast furnaces stoves as requested by the Application, a new determination of BACT is required under the PSD rules. The BACT determination for the CO emissions of the stoves that is reflected in Permit 95010001 was made decades ago when Permit 95010001 was originally issued, As discussed in General Response 1, Section 8A of this Responsiveness Summary, the discussion of BACT in National Steel's application, which was the foundation for the original issuance of Permit 95010001, does not constrain the BACT determination that is now required for the stoves for CO. Moreover, this new determination of BACT is not a trivial matter as the Application requests a substantial increase in the CO emissions for which the stoves are permitted, i.e., CO emissions of 11,064 tons/year rather than emissions 1,267.46 tons/year. As the BACT analysis in the Application does not show that BACT would be used for the stoves, it is appropriate for the Application to be denied.

C2. The Determination of BACT for the Stoves Proposed by the Application Is Consistent with PSD Rule Requirements

As discussed in Section 8.2.1.1 of the Application, the proposed BACT determination for the stoves is consistent with the PSD rules. For the BACT requirement, the PSD rules expressly provides for a PSD permit to prescribe work practices to satisfy the BACT requirement where the

permitting authority, “determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible.” 40 CFR 52.21(b)(12) and 35 IAC 204.280.

In the Application In the discussion of Step 5 of the proposed BACT analysis for CO for stoves, the Application states as follows in Section 8.2.2.6:

> USS Granite City is proposing work practice requirements rather than numeric limits as BACT. Numeric emission limitations are not proposed because direct measurement of emissions, i*.e.*, use of a USEPA reference test method, is not feasible for any of the fuel emissions units subject to the BACT requirements for CO emissions. In particular, for the stack serving the blast furnace A stoves, there is no sampling port,[Footnote]45 and for the stack serving the blast furnace B stoves there is no sampling port satisfying the location requirement in U.S. EPA Reference Method 1. [Footnote] 46 Each stack is refractory lined and is believed to be approximately one hundred years old.
>
> For the reasons presented above, numeric CO emission standards are not feasible for the blast furnace stoves.
>
> Footnote 45. For the one-time exhaust gas sampling event discussed in footnote 19 of this permit application, USS Granite City inserted a sampling probe into the stack through a pipe used to inject steam into the stack.
>
> Footnote 46. Appendix A-1 to 40 CFR part 60.

The BACT analysis in the Application is deficient relative to relevant requirements of the PSD program because it does not show that, “technological or economic limitations on the application of measurement technology to a particular emissions unit would make the imposition of an emission standard infeasible, ….” This showing is required by 40 CFR 52.21(b)(12) or 35 IAC 204.280, the definitions of BACT in the PSD rules. While the Application describes certain aspects of the stacks for the stoves, the Application does not show that emissions testing should be considered infeasible due to technological or economic limitations associated with the stacks for the stoves. The Application does not explain why the facts that the stacks for the stoves are not currently fitted with test ports, are refractory lined, and are approximately 100 years old create technological limitations such that installation of test ports that would meet USEPA Reference Method 1 should be considered infeasible. The Application also does not include estimates for the costs that would be entailed in installation

of such ports to explicitly show why emission testing should be considered infeasible because of the economic impacts that would be imposed if emission testing were required as BACT for the stoves was set as emission standard(s). As such, the Application does not show that the proposed use of good combustion practices as BACT should be accepted in lieu of numerical emission standard(s).

C3. The Application Does Not Identify Statutory or Regulatory Provisions That Require the Application to Include the Indicated Information

In the draft denial letter, Attachment 1, the Illinois EPA makes the following assertion:

> Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. For example, the application does not include diagrams for the existing ductwork of the stoves to address whether the configuration of this ductwork would accommodate installation of test ports at a location that would satisfy USEPA Reference Method 1. The application also does not show how the refractory lining on the stacks or their age, approximately one hundred years old, would present significant technical challenges and costs so that the installation of test ports at a suitable location should be considered infeasible. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

With respect to both Illinois EPA's general suggestion that "further support" is needed and its list of specific examples, Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a PSD permit application include any particular supporting information, nor does the Illinois EPA point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. Of course, Illinois EPA retains authority pursuant to 35 IAC 201.152 to request additional documentation in conjunction with a construction permit application, but that was not done here.

Contrary to what is suggested in this comment, the statutory and regulatory basis for this deficiency in the Application are provided

in the Revised Draft Denial Letter. The regulatory provisions include the definition of "Best Available Control Technology (BACT)," 35 IAC 204.280; the definition of "complete," 35 IAC 204.330; the information that an applicant for a PSD approval must submit, 35 IAC 204.810; and the BACT requirement for a major modification, 35 IAC 204.1100(c).

In addition, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. The Illinois EPA's ability to request additional information to remedy deficiencies that are identified in permit applications is not provided by 35 IAC 201.152. The Illinois EPA may directly proceed with denial of an air pollution control permit application without requesting that the applicant supplement or revise the submitted application.

C4. When the Illinois EPA Issued the CAAPP Permit In 2013, It Determined That Work Practices Suffice AS BACT for the Blast Furnace Stoves

In 2013, when issuing Permit 96030056, the CAAPP permit for the facility, the Illinois EPA again determined that work practices suffice for the blast furnaces stoves for purposes of demonstrating compliance with the applicable requirements of Permit 95010001.[69]

The observation made by this comment is not correct and does not contribute anything to a discussion of the BACT analysis in the Application for the CO emissions of the stoves. The Illinois EPA did not reexamine the established determination of BACT for the stoves for CO when it issued Permit 96030056 in 2013, as suggested by this comment. Indeed, when issuing a CAAPP permit, the Illinois EPA's authority does not extend to formally reviewing and potentially revising BACT determinations made in PSD approval(s) for units and activities at a source. The Illinois EPA's authority with respect to such determinations, as it also is for the applicable emission

[69] *See,* CAAPP Permit 96030056, Conditions 7.4.12(a) and (b). Condition 7.4.12(a) explains that for blast furnace processes, compliance with applicable standards of Condition 7.4.3 is addressed by, "the work practices, testing, monitoring, recordkeeping, and reporting requirements" in Section 7.4 of this permit. Conditions 7.4.12(b) explains that compliance with the production/emission limits of Condition 7.4.6 and 5.6.2 is addressed by, "the work practices, testing, monitoring, recordkeeping, and reporting requirements in Sections 7.4 and 5 of this permit." Note that Permit 96030056 does not include any testing, monitoring, recordkeeping, or reporting requirements specific to the blast furnace stoves. (Adapted from Footnote 11 of US Steel's Comments of January 2014.)

standards of relevant rules, is restricted to imposing associated compliance procedures (in the terminology of the CAAPP, periodic monitoring) if the existing BACT determination or emission standard does not adequately address how compliance is to be assured with such determination or standard on an ongoing basis. The CAAPP program does not contemplate substantive changes to established BACT requirements being made during the issuance of CAAPP permits since such changes are appropriately made by issuance of a new or revised PSD permit.

Moreover, this comment implies that Permit 96030056 requires use of good combustion practices as BACT for the stoves. Then, presumably because use of such practices is inherent in the day-to-day operation of the stoves, the Illinois EPA did not deem it worthwhile or necessary in 2013 in Permit 96030056 to impose any associated compliance procedures related to the use of good combustion practices for the stoves, i.e., requirements for operational monitoring and/or recordkeeping to verify implementation of good combustion practices. Accordingly, this comment argues that Denial Point 18, as it involves the absence of certain information from the Application related to BACT for the stoves, is unwarranted. However, this argument is not relevant because the increase in permitted CO emissions requested by the Application necessitates making a new BACT analysis and, potentially, a new determination of BACT in revised Permit 95010001. In this regard, the Application requests an almost nine-fold increase in the CO emissions of the stoves, with an overall increase in the CO emissions for which the Project is permitted. This argument is also not valid because Permit 96030056 does not require use of good combustion practices as BACT to reduce or control for CO emissions.[70] This is as should be expected since Permit 95010001, itself, does not require use of good combustion practices as BACT for the stoves. There is nothing with regard good combustion practices for the stoves that had to be restated in Permit 96030056. Thus, it is not surprising that Permit 96030056 does not include compliance procedures related to use of good combustion practices for the stoves since Permit 95010001 does not actually require use of such practices. Further inferences should not be drawn from the fact that Permit 96030056 does not include compliance procedures for the use of good combustion practices.[71]

---

[70] If anything, the BACT determination for the stoves for CO made in Permit 95010001 are the emission factor limits set by this permit, i.e., CO emissions of 40.0 lbs/mmcf for natural gas, 13.7 lbs/mmcf for BFG and 5.0 lbs/1,000 gallons for fuel oil (Permit 95010001, Condition 22 and Table 4). These limits are repeated in Permit 96030056 (CAAPP Condition 5.6.2(a)(iii)(B).) Unlike Permit 95010001, Permit 96030056 provides for emission testing to confirm compliance with these limits (Condition 5.7). Recordkeeping is also required to verify compliance with these limits (Condition 5.9.1(c) and (d)).

[71] In the original application for Permit 95010001, National Steel addresses use of good combustion practices for the blast furnace stoves, explaining, "Good combustion practice is the inherently lowest emitting method of

C5. The Application Provides All Required Information

The documentation provided in the Application regarding infeasibility of emissions testing is more extensive than the documentation provided in the original permit application submitted by National Steel and accepted by Illinois EPA when originally issuing Permit 95010001. The Application includes all information required by the applicable permitting rules and the PSD rules relating to BACT for CO emissions from the stoves.

Whether the Application has "more information" than National Steel provided in its application about the infeasibility of emissions testing for the blast furnace stoves is immaterial as to whether the Application is deficient.[72] The Application does not include information showing that emissions testing is infeasible for the stoves. Therefore, it is appropriate for the Application to be denied.

D. Emissions Associated with Combustion of Coke Oven Gas (COG) (Denial Point 19)

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the Application is deficient because it "does not demonstrate that prior to February 2015, when the by-product recovery coke oven batteries at the Granite City Works were shut down and COG [coke oven

---

controlling CO emissions from combustion sources." (National Steel, Original Application, Supplement October 30, 1995, p. 4-6, Section 4.3.3.1, "Blast Furnace Stoves," in Section 4.3.1, "Inherently Lower-Emitting Processes/Practices," in Section 4.0, "Best Available Control Technology Review.")

However, the use of such practices as BACT for the stoves for CO was not explicitly required by Permit 95010001 as issued. Condition 41(b) of Permit 95010001 acknowledged that PSD was applicable to the Project for SO_2 and CO. However, this condition simply concludes by stating that, "The Agency has determined that these additional requirements [including BACT for affected SO_2 and CO emissions units] have been met." The Illinois EPA's project summary for the public comment period that was held before the initial issuance of Permit 95010001 addressed the BACT requirement of the PSD rules in a single sentence, explaining, "GCD (Granite City Division of National Steel] has shown that the work practices used for SO_2 and CO constitute BACT as used by other steel mills for these pollutants. (Illinois EPA, November 1995, "Project Summary for Proposed Issuance of a Construction Permit for Granite City Division of National Steel Corporation," p. 6.)

[72] The Illinois EPA agrees that the Application is better than the application submitted by National Steel. The Application recognizes that if BACT for an emission unit is not to be set as a numerical emission standard, it must be determined that emissions testing is infeasible for that unit. However, the Application is identical to National Steel's application as it does not make this showing.

gas] ceased to be available, BACT was being utilized for the SO_2 and CO emissions from use of COG in the stoves." US Steel acknowledges that the BACT determination made by Illinois EPA in 1996, based on relying on the application submitted by National Steel, may have been deficient in this regard. Nonetheless, based on a pertinent court decision, Illinois EPA's assertion that any such historical deficiency is relevant to the Application is entirely without merit.[73]

This comment does not show that the Application should not be denied based on Denial Point 19. This comment does not respond to the issues that are raised by this denial point. The situation that was addressed by the court decision cited by this comment did not involve the situation presented by the Application. The cited court decision involved an after-the-fact enforcement action against a source for the failure to obtain a PSD permit. Accordingly, this comment does not show that the Application should not be denied based on Denial Point 19.

By way of further explanation, the Application must address BACT for the blast furnaces stoves for emissions of SO_2 and CO because of the Application, itself, and how it proposes to address emissions of the blast furnace stoves. The Application proposes revisions to the baseline emissions of the Project to reflect what US Steel now considers should have been the baseline emissions for the original permitting of the Project. In particular, updates to the emissions of the blast furnace stoves for particulate, NOx and VOM are proposed to address the emissions of the stoves during the baseline period from use of COG. However, emissions from use of COG were not considered during the original permitting of the Project. That the Application now proposes that emissions from use of COG be addressed for the requested revisions of Permit 95010001 is the reason why the Application must now also address BACT for the stoves for the SO_2 and CO emissions from use of COG, as well as BACT for the CO emissions from use of BFG and natural gas.[74] In this regard, Denial Point 19 in the Revised Draft Denial Letter explains as follows:[75]

---

[73] *See*, e.g., U.S. v Midwest Generation LLC. 781 Fed. Supp. 2d 677 (N.D. Ill. 2011) (holding that a source owner' obligation with respect to BACT are limited to those imposed in a PSD permit.) (Footnote 13 of US Steel's Comments of January 2024.)

[74] As addressed in Denial Point 18, the BACT analysis in the Application for CO emissions from use of BFG and natural gas is also deficient.

[75] As specifically related to BACT for CO from use of COG in the Blast Furnace Stoves, Denial Point 19 in the Draft Revised Denial Letter also explains:

> **With respect to CO, it is relevant that the BACT demonstration in the 2022 application [Application] focuses on CO emissions from burning of fuels other than COG. For fuel burning units, the 2022 application states that "CO emissions of these units result primarily from incomplete combustion during the firing of BFG and natural gas." This ignores the historic**

> **… unlike the initial permitting of the Project, the 2022 application [Application] now quantifies emissions of particulate, NOx and VOM from burning COG and these emissions are included in revised determinations of baseline emissions. (In 1996, the Project was permitted as a major modification for SO_2 and CO but did not quantitatively address emissions from burning COG.) If emissions from burning of COG are to be relied upon for the issuance of a revised permit, the 2022 application must also address the BACT requirements of PSD for the SO_2 and CO emissions from use of COG, as would have been applicable in 1996, when the Project commenced. The fact that the by-product recovery coke batteries at the Granite City Works were shutdown in 2015 and COG is no longer available at the facility, does not alter the applicable requirements under PSD that must be satisfied. PSD would be violated if a revised permit were issued for the Project based on revised NSR applicability analyses that considered use of COG, as contained in the 2022 application, absent demonstrations that the Project utilized BACT for emissions of SO_2 and CO from use of COG.**
>
> **Revised Draft Denial Letter, Attachment 1, p. 67.**

The Application would not be denied based on Denial Point 19 to simply require US Steel to propose corrections to Permit 95010001 to address a potential error in the original permitting of the Project. That is, Permit 95010001 did not provide for BACT for SO_2 and CO emissions from use of COG even though the permit approved a PSD major modification for these pollutants. Instead, given that the usage of COG and associated emissions were not expected to increase with the Project, the emissions from use of COG in Project-affected fuel burning units were not quantitatively addressed by Permit 95010001.[76] However, the PSD rules

---

> **contribution of COG to the CO emissions of the stoves prior to February 2015. The 2022 application also does not state that, as of February 2015, it was no longer necessary to address CO emissions from use of COG because COG was no longer produced and available for use.**
>
> **Revised Draft Denial Letter, Attachment 1, p. 68.**

[76] That the original permitting of the Project did not quantitatively address emissions from use of COG is apparent from National Steel's application and Permit 95010001. For example, in National Steel's application, as the summaries of the netting analysis for different pollutant, Tables 3-1 through 3-6 of the January 1, 1996, supplement to the application,* address emissions of Project-affected fuel burning units, including the blast furnace stoves, only emissions from use of BFG, natural gas and fuel oil are addressed but not emissions from use of COG. Consistent with National Steel's application, Permit 95010001, Condition 22 and Table 4, only set limits for the usages of BFG, natural gas

indicate that determinations of BACT are to be made for all emissions of the relevant pollutant(s) from the subject emissions units, not simply for certain emissions of the relevant pollutant from such units.[77, 78]

---

and fuel oil and associated emissions from use of these fuels, but not for the usage of COG and its associated emissions.

*** Copies of these tables are included in the Application in Appendix B, "Emission Calculations."**

[77] When addressing the applicability of BACT to a major modification for a pollutant, for the units for which BACT is required, the PSD rules require a determination of BACT for all emissions of the pollutant from such units, not just some of the emissions from such units, e.g., only the SO_2 emissions from burning BFG but not the SO_2 emissions from burning COG.

> **A major modification shall apply best available control technology for each pollutant subject to regulation under the [Clean Air} Act for which it would result in a significant net emissions increase at the source. This requirement applies to each proposed emissions unit [emphasis added] at which a net emissions increase in the pollutant would occur as a result of a physical change or change in the method of operation of the unit [emphasis added].**
>
> **40 CFR 52.21(j)(3) and 35 IAC 201.1100(c),**

[78] It is interesting that in a later comment, US Steel Comment appears to take a position that is at odds with the position taken in these comments responding to Draft Denial Point 19. In the later comment, US Steel attempts to show that the revised NSR applicability analysis in the Application for the Project for NOx is appropriate and meets applicable requirements of the NSR rules. Among other things, this comment argues that it is appropriate to update the baseline emissions of Project-affected fuel burning units to now also account for emissions from use of COG in these units. (In this Responsiveness Summary, this particular comment is identified as Comment VIII.D(1).) This comment argues that it is appropriate for all NOx emissions of the subject units to be addressed, now including NOx emissions from use of COG. This is because applicable NSR rules require all emissions of the subject units of the pollutant for which the applicability of NSR is being considered to be addressed, as explained by the comment as follows.*

> **… the major modification applicability test requires a comparison of the pre-project actual emissions of the emissions units or group of units; the post-project actual emissions (or potential to emit) of that emission unit or group of units; the applicable definition of actual emissions does not provide for a calculation that considers only some portions of the units' emissions.**
>
> **US Steel, Comments of January 2024, Comment VIII.D, p. 13.**

However, in response to Denial Point 19, this comment appears to argue that the PSD rules allow a BACT determination for a pollutant for a BACT-subject unit to be made for only some of the unit's emissions of that pollutant.

VIII. PSD AND NANSR APPLICABILITY WITH RESPECT TO NOx EMISSIONS (DENIAL POINT 1)

A. The Denial of the Application Would Be Improper As the Denial Would Be Based on Previously Authorized Emissions and Emissions Increases

A1. The Illinois EPA Appears to Take into Account and Improperly Consider Emissions and Emissions Increases That Were Authorized by Illinois EPA at the Time Permit 95010001 Was Initially Issued to National Steel

The draft denial letter, Attachment 1, Paragraph 1, suggests that the Application is deficient because it does not include or otherwise address the substantive requirements of the PSD and NaNSR programs with respect to NOx emissions. However, in its evaluation of whether the Project is or would become a major modification, Illinois EPA appears to take into account and improperly consider emissions and emissions increases that were authorized by Illinois EPA at the time Permit 95010001 was issued to National Steel but will not occur in the future. In this regard, Permit 95010001, as issued to National Steel on January 25, 1996, provided for a net increase in annual NOx emissions from the Project of 38.3 tons per year. A revised version of Permit 95010001 issued to National Steel on January 25, 1999, which addressed

***Incidentally, as explained in response to the later comment, the argument or claim that is made is not relevant to the reasons that the revised NSR applicability analysis in the Application has been determined to be deficient, such that the Application must be denied. As related to applicability of NSR, one reason that the revised NSR applicability is deficient is that the baseline emissions of NOx have been updated to include NOx emissions of Project-affected fuel burning units from use of COG. However, a similar update was not made for the NOx emissions of these units with greater production of iron and steel as provided for by Permit 95010001 following the Project. If revised NSR applicability analysis for NOx emissions is to be updated in the Application so that it addressed emissions of the Project-affected fuel burning units from use of COG, both the original, "pre-project," baseline NOx emissions and the original NOx emissions of these units with the Project must be updated.**

an increase in permitted usage of natural gas in certain Project-affected fuel burning units, provided for an additional net NOx emissions increase of 31.8 tons/year (31.8 tons/year and 38.3 tons/year yields a combined increase of 70.1 tons/year). As such, the net NOx emissions increase from the Project authorized by the Illinois EPA prior to US Steel's ownership of the Granite City Works in 2003, when National Steel owned and operated the Granite City Works, is greater than the net change in NOx emissions shown in the Application with the revisions to Permit 95010001 that are now requested by US Steel, i.e., a net decrease of 237.3 tons/year.[79]

This comment does not identify a flaw in the Illinois EPA's review of the revised NSR applicability analysis for NOx in the Application, which addresses the increases requested by the Application in the permitted NOx emissions of certain units that are part of the Project.[80] As such, this comment does not show that increases in NOx emissions that are requested would not result in the Project becoming a major NSR modification for NOx. First, the comment does not even explain how the Illinois EPA has improperly considered emissions and increases in NOx emissions that had previously been permitted, as is claimed in this comment, when finding that the Application was deficient because it did not address the substantive requirements of NSR for the Project, as stated in the denial letters. The comment also does not explain why and

---

[79] In this comment, information about the two versions of Permit 95010001 and the Application was presented in a table. In this Responsiveness Summary, relevant information is presented in a narrative. This is because the presentation of information in the table was misleading. For example, the table did not explain that Permit 95010001 was revised in 1999 to address a further change at the Granite City Works. The table also provided a value for the net increase in NOx emissions for this second permit that was the sum of the net increase indicated in Permit 95010001, as original issued for the Project, and the additional net increase in emissions with the further change to the facility. In the table, the Application, is identified as a "permit" that is "pending," rather than the Application, as submitted by US Steel for further revisions to Permit 95010001.The value that is provided for the net increase in NOx emissions for the Application is not clearly identified as the value proposed in the Application, which is based on the revised PSD applicability analysis for the Project in the Application, For the two permits that are addressed, the values for the net increase in NOx emissions either came from or were derived from information in the permits issued by the Illinois EPA.

[80] In the Application, Appendix B, Emission Calculations, this revised applicability analysis is entitled "USS Granite City – 1996 Production Increase Project: Revised NOx PSD [emphasis added] Net Emissions Increase Analysis." In this Responsiveness Summary, this revised analysis is referred to as an NSR applicability analysis, This is because US Steel must address the implications of the increases in emissions of NOx requested by the Application for both PSD and NaNSR.

how such emissions and emission increases should have been handled.

Second, as the Application requests increases in the permitted annual NOx emissions of certain units affected by the Project, i.e., the blast furnace casthouse (casthouse) and the BOFs,[81] it is appropriate for the updated NSR applicability analysis for the Project for NOx to reevaluate applicability of NSR to the Project for NOx. The fact that the Project was previously permitted for net increases in NOx emissions that did not trigger NSR is immaterial since the Application requests corrections to the prior permitting of the Project. In other words, the fact that the original NSR applicability analysis for the Project for NOx was flawed, is indicated by the request in the Application for increases in permitted NOX emissions of certain units affected by the Project. Accordingly, the net increases in NOx emissions of the Project indicated in the Permit 95010001, as originally issued, and in the subsequent revisions to Permit 95010001 should no longer be considered reliable as the NSR applicability analysis that they relied upon is flawed. This is directly contrary to what is suggested by this comment. In addition, as the Application involves changes to the NSR applicability analysis for the Project for NOx, it is appropriate for the Illinois EPA to review this analysis in its entirety and not simply with regard to the NOx emissions of the casthouse and the BOFs.[82]

---

[81] The bulk of the requested increase in NOx emissions involves the BOFs. Permit 95010001 currently limits the annual NOx emissions of these units to 69.63 tons/year. The Application, Table 6-7, "NOx emission Caps," and Appendix B, Emissions Calculations, "USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis," requests that Permit 95010001 be revised to increase the permitted NOx emissions of the BOFs to 400.0 tons/year. The Application also proposes corrections to the baseline, "pre-project" NOx emissions of the BOFs with use of an emission factor of 0.1475 pounds/ton of steel, rather than 0.0389 pounds/ton of steel (Application, Table 6-5, "Pre-Project Actual NOx Emissions and Proposed Changes to Pre-Project NOx Emission Factors for Affected Emissions Units"). The resulting corrected NOx baseline for the BOFs is 179.8 tons/year. The difference between this revised baseline emissions and the revised permitted NOx emissions requested for the BOFs is a net increase of 220.2 tons/year (400 – 179.8 = 220.2).

The NOx emissions of the blast furnaces are much less than those of the BOFs. The proposed correction for the baseline emissions of the blast furnaces would lower their baseline from 15.6 to 4.6 tons/year. The Application requests that the revised permit provide for future NOx emissions of 24.0 tons/year from the blast furnaces, for a net increase of 19.4 tons/year (24.0 – 4.6 = 19.4). (As Permit 95010001 currently limits NOx emissions of the blast furnaces to 22.79 tons/year, the emissions limitation in the permit would actually only change by 1.21 tons/year.)

[82] Separate from the approach to NSR applicability taken by US Steel in this revised analysis for NOx, as is addressed in this series of responses, the Illinois EPA's review of the revised analysis has also identified various

Third, this comment does not clearly explain how the net change in NOx emissions of the Project for purposes of NSR would now be lower than originally permitted. In other words, even though the Application requests that Permit 95010001 be revised to increase the permitted NOx emissions of the casthouse and the BOFs by more than 200 tons, how could that revised permit for the Project be based upon a net decrease in NOx emissions of 237.3 tons/year instead of a net increase in emissions that is substantially greater than 38.1 tons/year. In fact, this comment hints at the answer to this question as it claims that the "Illinois EPA appears to take into account and improperly consider emissions and emissions increases that were authorized by Illinois EPA at the time Permit 95010001 was issued to National Steel but will not occur in the future [emphasis added]." As such, this comment acknowledges that the revised NSR applicability analysis for NOx in the Application addresses current circumstances, nominally starting in 2022 when the Application was submitted, and not circumstances as should have been addressed when Permit 95010001 was originally issued.[83]

This approach to the correction of construction permits for projects that were originally considered non-major projects and not subjected to substantive requirements of NSR is contrary to the NSR rules and long-standing practice. As such, in the revised NSR applicability analysis in the Application, US Steel appears to improperly take into account and consider decreases in NOx emissions that were not made enforceable by Permit 95010001 and, and in fact, did not occur until long after the Project was completed. In other words, the revised NSR applicability analysis for NOx in the Application would rely on "post-project" decreases in NOx emissions that were not part of the original Project.

---

issues with the quantification of NOx emissions for these analyses, as were addressed in the draft denial letters. (For example, see Denial Points 2 and 3A.) As such, in these responses related to the general approach taken in the revised NSR applicability analysis, the value for the net change in NOx emissions from the Application is used for ease of explanation. It does not indicate acceptance of this value by the Illinois EPA given the separate issues with regard to accuracy and appropriateness of the quantification of the Project's NOx emissions in the Application, as were also addressed by the draft denial letters.

[83] The claim that the NOx emissions that are of concern for applicability of NSR "have been authorized" is also problematic as the revised NSR applicability analysis for NOx in the Application addresses emissions from use of coke oven gas (COG) in Project-affected fuel burning units. However, neither National Steel in the original application for the Project nor the Illinois EPA when it originally issued Permit 95010001 for the Project quantitatively addressed emissions from burning COG. As such, it is not clear that the Illinois EPA authorized such NOx emissions in the manner now claimed by this comment.

As such, the revised NSR applicability analysis for NOx in the Application does not address whether NSR should have been applicable for NOx in 1996 if the original permit application had correctly quantified the NOx emissions of the casthouse and the BOFs with the Project. The fact that with certain post-project emission decreases in NOx emissions that have occurred at the Granite City Works, the overall NOx emissions of the Project-affected units may currently be and in the future will continue to be less than the overall NOx emissions that could have originally been allowed by Permit 95010001 is not material to determining whether the requested increases in the NOx emissions of certain units, as requested by the Application, would result in applicability of NSR to the Project for NOx.

In this regard, US Steel's Comments of January 2024 do not include Footnote 13 of its Comments of September 2023. This footnote discussed the "post-project" decreases in NOx emissions that the Illinois EPA found the Application would improperly rely upon for purposes of revised NSR applicability analysis for NOx. This footnote refers to various statements in the Initial Draft Denial Letter describing the developments at the Granite City Works that led to these emission decreases, i.e., the shutdown of ten older boilers and the shutdown of the byproduct recovery coke batteries, which eliminated use of coke oven gas (COG) as a fuel.[84]

---

[84] In US Steel's Comments of September 2023, the reference to Footnote 13 is located after the following sentence, "However, in its evaluation of whether the Production Increase Project is or would become a major modification, Illinois EPA appears to take into account emissions and emissions increases that were authorized by Illinois EPA at the time Permit No. 95010001 was issued to National Steel.[Footnote] 13]" This sentence was clearly erroneous as it stated that the Illinois EPA was taking into account certain emission increases whereas in this denial point the Illinois EPA disputes US Steel's proposed reliance on certain, post-project emission decreases. The entirety of this footnote is provided below.

> **[Footnote] 13 See, *e.g.,* [Draft Denial Letter,] Attachment 1 at p. 4, suggesting that the updated applicability analysis should include "'future' NOx emissions" from Boilers 1 through 10 based on the configuration of those boilers as they existed at the time the Production Increase Project was implemented by National Steel and at the time US Steel purchased the assets in 2003, notwithstanding the fact that those boilers are prohibited from operating currently and in the future; Attachment 1 at p. 4, suggesting that the updated applicability analysis should include greater NOx emission rates from Boilers 11 and 12 based on the configuration of those boilers as they existed at the time the Production Increase Project was implemented by National Steel and at the time US Steel**

It is also noted that separate from Denial Point 1, in Denial Point 3, the Illinois EPA also determined that the requested revised permit should be denied for reasons associated with the new value for the NOx emissions of Project-affected fuel burning units used in this analysis. In Denial Point 3, the Illinois EPA explains that the requested revised permit must be denied because the Application does not show that this new value for the NOx emissions of these units fully accounts for the emissions of these units with the Project. For example, it is observed that the "…the 2022 application does not show that 706 tons/year represents the post-project NOx emissions as could have been addressed when Permit 95010001 was originally issued if emissions from burning of COG [coke oven gas] in these units when operating at levels of iron and steel production that were permitted had been considered," (Revised Draft Denial Letter, Attachment 1, p. 11).[85] Failure to show compliance with the substantive requirements of NSR was not identified as a reason for denial in Denial Point 3. This is different from Denial Point 1 where the issuance of the requested revised permit was denied because the Application did not show compliance with the substantive requirements of NSR for a major project for NOx because the revised NSR applicability analysis for NOx inappropriately relies on certain decreases in emissions.

One final observation, the second version of Permit 95010001 cited in this comment, which is not actually addressed in the Application, was

---

purchased the assets in 2003, notwithstanding the fact that the Boilers are prohibited from operating at those emission rates currently and in the future; Attachment 1 at p. 4, suggesting that the updated applicability analysis should include greater NOx emission rates from Boilers 11 and 12 and from the blast furnace stoves based on the use of coke oven gas as fuel in those units at the time the Production Increase Project was implemented by National Steel and at the time US Steel purchased the assets in 2003, notwithstanding the fact that coke oven gas is not an available fuel at the facility currently or in the future.

[85] Denial Point 3 has similarities to Denial Point 1 from a mathematical perspective, as should be expected. If a value for a parameter is too small because it reflects certain downward adjustments, the value of the parameter also can be described as not being large enough because it does not reflect certain upward adjustments.

an operating permit, not a construction permit.[86, 87] Moreover, as stated in this Operating Permit 95010001, dated January 5, 1999, this permit was revised to "incorporate" or address increases in emissions of NOx and other pollutants authorized by Construction Permit 98110039, date issued December 9, 1998. The subject of that permit was a "Natural Gas Usage Increase," not a "Production Increase," i.e., not the Production Increases Project. Consistent with the application for that permit, Permit 98110039 only provides for increases in permitted emissions of Boilers 1 through 12 and of ladle dryer preheaters with the increase in the permitted usage of natural gas by these units. The natural gas usage of the blast furnace stoves was not addressed.[88]

A2. In the Draft Denial Letter, the Illinois EPA's Avoids the Language of the "Source Obligation Provisions" of the NSR Rules

---

[86] In Appendix D, "Copies of Construction Permits," the Application includes copies of two versions of Permit 95010001. The first is the current version of this permit, dated May 30, 2012, which was revised pursuant to an application from US Steel and issued to U.S. Steel, Granite City. The second version of Permit 95010001 is the original permit for the Project issued to National Steel, dated January 25, 1996.

[87] Prior to the establishment of the Clean Air Act Permit Program (CAAPP), i.e., Illinois' program for operating permits for sources of emissions under Title V of the federal Clean Air Act, sources could obtain separate operating operations for the various emission units at a facility. Construction permits, which were issued for the construction or modification of emission units, were then routinely converted into operating permits that provided for the ongoing operation of the subject new or modified units. This was done using the identical permit number, with the operating permit being titled as such rather than as a construction permit and the introductory language in the permit authorizing the operation of the subject units rather than their construction or modification. This practice was discontinued with the adoption of the CAAPP, since Title V of the Clean Air Act provides that the emissions units at a facility that are owned or operated by a single entity must be addressed by a single facility-wide operating permit issued to that entity.

[88] As indicated in Table I of Permit 98110038, the increase in NOx emissions of the units addressed by this permit (31.83 tons/year), which would accompany the increase in permitted usage of natural gas by these units was determined as the difference between the calculated baseline emissions of these units of 174.11 tons/year (average of annual NOx emissions of 1996 and 1997, reflecting annual average natural gas usage of 1,131 million cubic feet/year) and the new permitted NOx emissions for these units of 205.94 tons/year (NOx emissions calculated based on the new permitted usage of up to 1,347 million cubic feet/year of natural gas).

When summarizing its review of the revised NOx net emissions increase ("netting") analyses in the Application, the Illinois EPA conspicuously avoids using the language of the "source obligation provisions," which are controlling, as specifically discussed in later comments.

The Illinois EPA's responses to US Steel's comments concerning the "so-called" source obligation provisions of the NSR rules[89] will follow those comments by US Steel, also being later in this Responsiveness Summary. By way of a brief preview in response to this specific comment, the subject provisions do not directly address or govern the applicability provisions of the NSR rules, which set out how one determines whether projects are or are not major projects for purposes of NSR. As such, the Illinois EPA did not refer to the so-called source obligation provisions in the Draft Denial Letters since the issue for the increases in NOx emissions requested by the Application is whether they result in the applicability of NSR for NOx as the Project would now become a major modification for purposes of NSR. The so-called source obligation provisions prescribe how the substantive requirements of NSR, e.g., Best Available Control Technology (BACT) under PSD or Lowest Achievable Emission Rate (LAER) under NaNSR, are to be determined for the relevant units affected by certain projects, i.e., projects which become a major new source or a major modification as a consequence of the relaxation of enforceable limitations, once it has been determined that such projects would become major projects for purposes of NSR.

A3. The Draft Denial Letter Appears to Improperly Suggest That a Final Adjudication Has Been Made That the Project Was Originally a Major NSR Modification for NOx

In the Draft Denial Letters, Attachment 1, Footnote 3, the Illinois EPA appears to suggest it has already been determined the Project as authorized prior to US

---

[89] The provisions of the NSR rules that these comments refer to as the "source obligations provisions" are characterized by the Illinois EPA as being "so-called" provisions. In this regard, US Steel uses the term "source obligation provisions" to refer to certain provisions of the NSR rules that refer to or address relaxations of source-specific limitations, i.e., 40 CFR 52.21(r)(4), 35 IAC 203.201 and 35 IAC 204.850. However, these provisions are not actually entitled "source obligation." In Illinois' NSR rules, the relevant provisions, 35 IAC 203.201 and 35 IAC 204.850, are actually entitled "Relaxation of a Source-Specific Limitation." In the federal PSD rules, 40 CFR 52.21(r)(4) is one of several provisions under the general heading of "Source obligation." Moreover, in Illinois' PSD rules, 35 IAC 204.820, the provision that is actually entitled "Source Obligation" does not address the relaxation of limitations. Rather, it deals with the obligation of sources to construct and

Steel's ownership of the Granite City Works was a major modification. In this footnote the Illinois EPA asserts that an analysis of alternatives would have been required as part of National Steel's original application for the Project "… if it had been recognized in 1996 that the Project was a major modification for NOx"). US Steel is unaware of any such final determination or adjudication.[90]

operate in compliance with the terms of their PSD permits. (The federal PSD rules include a similar requirement at 40 CFR 52.21(r)(1).)

In Section 2.2.4 of the Application (Application p. 2-4) , the introductory discussion of the provisions of the NSR rules addressing relaxation of established permit limitations, the relevant rules are specifically cited. The discussion also explains that updated net increases calculations are included in the Application, including calculations for baseline emissions now address emissions from burning coke oven gas (COG) in Project-affected fuel burning units. However, the discussion does not describe approach that is taken to updating the emissions with the Project.

[90] This comment is Footnote 14 of US Steel's Comments of January 2024.

In this footnote, the Illinois EPA was not suggesting that a final determination or adjudication has been made that the Project was or is major for NOx. As is apparent from the Draft Denial Letters, the Illinois EPA has determined that the revised permit requested by the Application should be denied because, among other things, the Application does not provide proof that the Project would not be a major modification for NOx with the requested increases in NOx emissions and does not provide proof of compliance with the substantive requirements of NSR for NOx. In this regard, it is possible that in a new application, US Steel could show that the Project would not become a major modification for NOx, show that the substantive requirements of NSR for a major modification for NOx have been met, or otherwise show that the requirements for issuance of a revision to Permit 95010001 have been met.

In addition, as related to the substantive requirements of NSR for a major new source or major modification, this footnote called attention to the fact that in the recitation of the substantive requirements of NSR in the body of the Draft Denial Letter, the Illinois EPA omitted one such requirement, i.e., the requirement of NaNSR for an Analysis of Alternatives. As explained by the Illinois EPA in the final sentence of the cited footnote, which was not included in the comment, "It is beyond the scope of the revisions of Permit 95010001 that are now requested to address the fact that such an analysis was not originally part of the construction permit application for the Project." This acknowledges the difference in this substantive requirement of NaNSR from other substantive requirements of NSR that can potentially be addressed retroactively with permitting. For example, for BACT or LAER, the Illinois EPA can conceivably issue a permit that simply codifies these requirements for control of emissions so that they are enforceable on an ongoing basis if it is also found that emissions of a project were actually controlled as required by NSR.

A4. The Denial of the Application Would Appear to Be Improper As It Would Shift a burden that is not US Steel's to US Steel

The Draft Denial Letter states that, "The 2022 Application requests that the Permit be permitted for additional NOx emissions but does not show that the Project would still not be a major modification for NOx if the permit were revised as requested." {Denial Letter, Attachment 1, p.3.)[91] With this statement, the Illinois EPA would appear to be

[91] **In US Steel's Comments of January 2024, this statement is characterized without explanation as being ambiguous. The Illinois EPA disagrees with this**

characterization as the cited statement is factual in nature. It explains that while the Application requests Permit 95010001 be revised to increase the permitted NOx emissions of certain units, the Application does not show that the Project would still be non-a major modification for NOx if the Project were permitted with increased emissions as requested. Moreover, this comment does not actually dispute this statement. Instead, the comment appears to argue that US Steel should not be considered responsible for the Project being a major modification for NOx because applicability of NSR for the Project for NOx should now be determined considering post-project decreases in emissions, as was done in the Application. In addition, the comment likely argues that US Steel should not be subject to the substantive requirements of NSR for NOx even if the Project would become major for NOx because Permit 95010001 was originally issued to National Steel based on an application that it submitted.

In its Comments of September 2023, US Steel did discuss why it considered this statement to be ambiguous, as provided below.

> **Illinois EPA's assertions regarding applicability of the substantive requirements of the PSD and NNSR [NaNSR] programs with respect to NOx emissions are ambiguous: US Steel cannot determine from the draft denial letter and associated documents whether Illinois EPA is claiming that the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel prior to US Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs or, instead, if Illinois EPA is claiming that the measures required by Permit 95010001 as issued to National Steel were sufficient to ensure the Production Increase Project would not be a major modification and that the Project would become a major modification solely by virtue of the relaxations requested by US Steel. For purposes of these comments, US Steel has assumed Illinois EPA's claims fall into the latter category, *i.e.,* that the Production Increase Project would become a major modification for NOx solely by virtue of the requested relaxations.**
>
> **US Steel's Comments of September 2023, p. 11.**

In response to that comment, the statement in the Initial Draft Denial Letter of concern to US Steel addresses the Application submitted by US Steel. The Illinois EPA is not editorializing on the circumstances of National Steel relative to the Project. The Illinois EPA also did not claim, as is suggested by US Steel, that the Project would become a major modification for NOx simply because US Steel has requested relaxations of certain limitations for NOx emissions in Permit 95010001. Rather, the Project would become a major modification because NOx emissions of certain units are more than the emissions that are currently allowed under Permit 95010001 and US Steel has not shown that the Project would not become a major modification for NOx with the increases in emissions that are requested by the Application. In other words, major NSR is threatened or triggered for NOx because it has been found that the rates of actual NOx emissions of certain Project-affected emission units are greater than the permitted rates in Permit 95010001. To address this, US Steel has submitted an Application that, among other things, requests

improperly shifting a burden that is not US Steel's to US Steel. US Steel has demonstrated in the Application that the Project would not become a major modification solely by virtue of the relaxations and other revisions requested by US Steel. This is the only demonstration required of US Steel as it relates to applicability of the PSD and NaNSR programs with respect to NOX emissions. In the Denial Letter, Attachment 1. p.11, the Illinois EPA complains that the Application "does not show that the actual NOX emissions of the subject units [Project-affected fuel burning units] in the period from 1996 to the present have not exceeded 706 tons/year," which is the emission limit now proposed for these units by US Steel. However, US Steel has no obligation under the rules to make such a showing.

This comment does not show that the Application should not be denied based on Denial Point 1. In this regard, this comment does not show how, in this denial point, the Illinois EPA would be "…improperly shifting a burden that is not US Steel's to US Steel." US Steel is now the owner and operator of the Granite City Works.[92] US Steel has submitted the Application that requests increases in the permitted NOx emissions of the casthouse and the BOFs. It is these increases in emissions, particularly the requested increase in the permitted NOx emissions of the BOF of more than 200 ton/year that would result in the Project becoming a major modification for NOx for purposes of PSD and NaNSR. In the Application, US Steel provides a revised NSR Applicability Analysis for NOx (Application, Appendix B – Emission Calculations, "Revised NOx PSD Net Emissions Increase Analysis"). This analysis was presumably submitted in an attempt to show that the Project would not become an NSR major modification with the requested increases in NO_X emissions of these units.[93] This applicability analysis must be consistent with the provisions of the NSR rules governing such analyses, e.g., Section 203.208, "Net Emission Determination" in 35 IAC Part 204, Illinois's rules for NaNSR. This would not be the case if the revised analysis for the Project does not address the NOx emissions of

revisions to Permit 95010001 to increase the amounts of NOx certain units are permitted to emit.

[92] Even if, for purposes of discussion, one posits that US Steel was not responsible for the operation and emissions of the Project during the period before it took over the operation of the Granite City Works from National Steel, US Steel became responsible for this facility beginning in 2003 when it acquired this facility.

[93] The are number of deficiencies in this analysis, as addressed in the denial letter and in this Responsiveness Summary as it is responds to US Steel's other comments. As such, this analysis cannot be relied upon to show the Project would not become a major modification for NOx with the requested increases in NOx emissions of the casthouse and the BOFs.

the Project in the period following the initial issuance of Permit 95010001.[94]

As to the claim in this comment that the Project would not become a major modification solely by virtue of the relaxations of current limitations, i.e., increases in the permitted NOx emissions of the casthouse and the BOFs as are being requested, neither this comment nor the Application show how that these increases in the permitted emissions of these units should be considered anything other than correction of the original limitations that were set for these units in Permit 96010001 in 1996. In particular, neither this comment nor the Application suggest that the increases in the NOx emissions of these units are the result of physical changes or changes in the method of operation of these units that are unrelated to and occurred subsequent to the Project.[95]

A5. The Illinois EPA's Claims Regarding Us Steel's Obligations with Respect to NSR for NOx Are Improper As They Are Contrary to Law

Illinois EPA's claims regarding US Steel's obligations with respect to PSD and NaNSR with respect to NOx emissions are improper as they are contrary to applicable law. The claim that Illinois EPA makes here, that the permit for the Project must obligate US Steel to comply with the substantive requirements of these major NSR programs because of emissions increases that may have occurred many years ago, prior to US Steel's ownership, is the same as certain claims previously made by the State of Illinois, the United States of America (the U.S. Attorney General on behalf of the Illinois EPA), and various plaintiff intervenors against Midwest Generation and others. These claims were rejected by both the U.S. District Court for the Northern District of Illinois and the U.S. Court of Appeals for the 7th Circuit. For example, refer to this U.S. District Court's 2011 decision (*U.S. v. Midwest Generation, LLC*, 781 Fed. Supp. 2d 677 (N.D. Ill. 2011) that

---

[94] It is noteworthy that the revised NSR applicability analysis in the Application reflects proposed updates or corrections to the "pre-1996," baseline NOx emissions that were relied upon for the initial permitting of the Project for the casthouse, the BOFs and other Project-affected fuel burning units. However, this revised analysis does not propose comparable corrections to address the NOx emissions with the Project, which would address emissions in the period between 1996 and 2015, when the by-product recover coke oven batteries at the facility were shut down.

[95] The Application does not include an analysis showing that the increase or net increases in NOx emissions from any such subsequent project would not itself be a major modification for NOx purposes of PSD or NaNSR.

held that, where a facility should have been subjected to Best Available Control Technology (BACT) and other substantive requirements of the major NSR permitting programs due to modifications implemented by a prior owner, Section 9.1(d) of the Act does not obligate a subsequent owner to come into compliance with those requirements. (Footnote 15 of US Steel's Comments of January 2024.) In recent years, the Illinois EPA has repeatedly issued construction permits involving the units at the power stations that were the subject of these decisions. For example, refer to Construction Permit 15030051, initially issued October 16, 2015, and subsequently revised on July 15, 2016, May 9, 2017, and July 9, 2020. This permit addresses the construction of a natural gas conversion project for the three coal-fired generating units at Midwest Generation' Joliet Generating Station. This permit did not impose BACT or other major NSR obligations on the generating units. (This permit also provided for operation of the converted generating units until their operation was addressed by a CAAPP permit.) (Footnote 16 of US Steel's Comments of January 2024.)

This comment does not explain why the decisions of the federal courts in the cited cases that dismissed certain claims are relevant to the denial of the Application. It also does not explain why Construction Permit 15030051, which was issued to Midwest Generation, is relevant to the review of the Application. With respect to the subject court decisions, which were not addressed in the Application, the comment does not explain the significance of these decisions for the Illinois EPA's review of the Application. In particular, since US Steel provided a revised NSR applicability analysis for NOx in the Application trying to show the Project would not become a major modification for NOx with the requested increases in the permitted emissions of certain units, it is not clear why the cited decisions are even relevant to the denial of the requested revised permit. Moreover, the circumstances that are being addressed by the Application are clearly not the same as those addressed by the subject decisions. The cited decisions involve a lawsuit in which the plaintiffs sought to apply and address the substantive requirements of the PSD program for major modifications for which a source had not obtained PSD permits.[96] As related to emissions

[96] The lawsuit initially involved six coal-fired generating stations at which the former owner and operator, Com Ed, undertook modifications to the generating units but did not obtain construction permits prior to those modifications, as should have happened under the PSD program. (One of these stations was shut down while the lawsuit was pending and three more are now shutdown.)

of NOx and NSR, the Application entails a request by US Steel to revise a construction permit, Permit 95010001, to increase the permitted NOx emissions of certain units. As such, the relevant issue before the Illinois EPA for the review of the Application was whether the increased NOx emissions, as would be addressed by the requested revisions to Permit 95010001, would, for NOx, result in a major NSR modification.[97]

After the modifications to the six generating stations were completed, the stations were then sold to Edison Mission Energy (EME). EME is the parent company of Midwest Generation, which is the entity that operated these stations at the time of the lawsuit. Neither EME nor Midwest Generation applied for revisions to construction permits for Com Ed's past modifications to the generating units nor were there any such PSD permits for which revisions could have been requested. With regard to PSD, the plaintiffs claimed that Midwest Generation violated relevant provisions of the Clean Air Act and that the continued operation of subject generating units constituted continuing violations of the Clean Air Act. To address these violations, the plaintiffs sought equitable civil penalties and equitable relief (i.e., the use of BACT on the generating units). The claims related to PSD for the past modifications were dismissed under the federal statute of limitations because the various modifications occurred more than five years before the initial lawsuit was filed. (It does not appear that applicability of NaNSR was raised in these cases.) In these cases, it was found that, at the time the lawsuit began, there were not violations because the Clean Air Act only explicitly requires that a source obtain a PSD permit for the construction of a major new source or a major modification, not for the subsequent operation of the source or modification. The Clean Air Act does not provide for subsequent enforcement for the absence of a PSD permit if the statute of limitations has run.

[97] The nature of the cited decisions is also different from the nature of this Application. With respect to NSR, this lawsuit primarily involved compliance under the Clean Air Act and other federal laws. Compliance with Illinois law, i.e., Section 9.1(d) of the Act, was a secondary matter. This was explained by the U.S. District Court for the Northern District, which stated as follows:

> **By specifically quoting a portion of section 9.1(d) in their Amended Complaint, Plaintiffs do not present any cause of action that was not presented in their original compliant; nor do they allege any new facts to support a violation of Illinois law. Plaintiffs simply raise a new question for statutory interpretation. The opportunity for such arguments has lapsed.**
>
> **…**
>
> **Plaintiff's new interpretation is inconsistent with, and contrary to, the Court's prior ruling that Midwest Generation does not commit a PSD violation by operating a source that previously constructed without a construction permit. Thus, even if their argument had not been waived, Plaintiffs have failed to state a claim for any direct violation of Section 9.1(d) that is sufficient to survive Midwest and EME's motion to dismiss under this theory. United States v. Midwest Generation LLC, 781 F. Supp. 2nd 677, p. 683-684.**

This comment also does not explain why the issuance of Construction Permit 15030051 by the Illinois EPA supports issuance of the revision to Permit 95010001 as requested by the Application. Again, the circumstances of this permit are not the same as those addressed by the cited lawsuits or Permit 95010001. For the natural gas conversion project addressed by Permit 15030051, Midwest Generation submitted an application and obtained a construction permit before undertaking this project. For various pollutants,[98] the application included NSR applicability analyses comparing the baseline actual emissions of the generating units at the Joliet Station and the total future permitted emissions of the station, i.e., the emissions of the existing generating units after conversion to natural gas and the emissions of certain new, auxiliary units that would be installed to facilitate operation on natural gas. These analyses conformed with the applicable requirements of the NSR rules. The analysis for NOx showed that this project would not result in a significant increase in emissions and, indeed, would result in a net emission decrease of over 2000 tons/year (Permit 1503031, date issued July 9, 2020, Attachment 1.) The subsequent revisions of this permit did not provide for increases in permitted emissions of the subject units. They involved other aspects of the permit, i.e., exceedances of the applicable NOx emission standard during startup and malfunction/breakdown and the timing of the testing for CO and VOM emissions required by the permit for Unit 6 (Boiler 5).[99]

---

[98] For volatile organic material (VOM), the application showed that, with the conversion project, the station would continue to be a non-major source under NaNSR.

[99] The July 2016 revision of Permit 15030051 responds to Midwest Generation's request that the permit provide for the possibility that the NOx emissions of the units might violate 0.30 pounds/million Btu, the limit in 35 IAC 217.141(a), during startup and malfunction/breakdown (SMB). Relevant terms of 35 IAC Part 201 Subpart I, Malfunctions, Breakdowns or Startups, were added to the permit, along with related operational requirements and recordkeeping and reporting requirements. (Note that 35 IAC Part 201 Subpart I was repealed effective July 25, 2023.)

The May 2017 version of Permit 15030051 responds to a request that an additional year be provided for testing of Unit 6 for CO and VOM. The additional time was sought because of the low capacity factor at which this unit was being operated, In addition, this emissions testing was required during maximum operation and other representative operating conditions of Unit 6. This necessitated coordinating this testing with the conditions in the Des Plaines River so that the warm cooling water discharged from the station would not result in a violation of the limits for the temperature of river water set by the applicable National Pollutant Discharge Elimination System (NPDES) permits, Permits IL0064254 and IL000002216.

The July 2020 revision of Permit 15030051 responds to a request that testing of Unit 6 for CO and VOM not be required every three years due to the very low

B. Source Obligation

B1. The NSR Rules Provide for After-The-Fact Permitting As Proposed by the Application

As explained in Section 2.2.4 of the Application, the PSD and NaNSR rules provide that after-the-fact PSD and/or NaNSR permitting is required when a project becomes a major modification "solely by virtue of a relaxation in" a synthetic minor limitation. (For PSD, see 40 CFR 52.21(r)(4) and, now, 35 IAC 204.850.[100]) These "source obligation" provisions effectively require updated PSD and NaNSR applicability analyses in situations where the source or applicant proposes to relax a synthetic minor limitation in a permit.

Applicability analyses performed in order to determine whether the source obligation provisions apply in conjunction with a requested relaxation are prospective, not retrospective. All of the facts as they will exist at the time of the requested relaxation are considered in the updated emissions increase calculations; there is

---

capacity factor at which it was now operating. The revised permit only requires such testing for Unit 6 upon specific request of the Illinois EPA.

[100] Under the PSD and NaNSR programs as in effect in 1996, at the time of the Project, where a project involved changes to existing emissions units that are so significant that the emissions unit was deemed not to have begun normal operation, the post-change actual emissions of that unit are assumed equal to its potential to emit. 40 CFR 52.21(b)(21).* The major modification applicability test was therefore based on a comparison of the pre-project actual emissions and the post-project potential to emit of the emissions unit or group of units. 40 CFR 52.21(b)(2)-(3). An emissions unit's potential to emit is its maximum capacity to emit a pollutant under its physical and operational design. 40 CFR 52.21(b)(4). Limitations on the capacity to emit a pollutant are treated as part of the design of an emissions unit or group of units if the limitation or the effect it would have on emissions is legally enforceable and enforceable as a practical matter. Where the potential to emit of a unit or group of units is governed by enforceable limitations rather than by the unrestricted physical capacity of that unit or those units, and where those limitations were necessary to a determination that a project was not a major modification, the term "synthetic minor" is commonly used to describe the project and the associated limitations.

* Except as noted, all citations to the applicable PSD rules in US Steel's comments are to the federal PSD rule as codified and in effect at the time of issuance of Permit 95010001 in 1996; where the corresponding provision of the then-effective NaNSR rule is equivalent, separate citations are not provided. (This explanation for the approach to regulatory citations taken in US Steel's comments is Footnote 17 in US Steel's comments of January 2024.)

no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time. This approach is demonstrated by USEPA's finding with regard to a project by Pfizer Pharmaceuticals Incorporated, LLC (the "Pfizer determination"). In the relevant letter, USEPA expressed acceptance of the proposed relaxation in 2015 of synthetic minor limitations that had been imposed in 1995 in order to establish synthetic minor status for NOx emissions.[101]

This comment does not show that the position taken in this comment, i.e., that revised NSR applicability analyses that are conducted in conjunction with requested increases in permitted NOx emissions of the casthouse and the BOFs, should be prospective rather than retrospective, is appropriate or correct. The comment reflects a faulty understanding of the "so-called" source obligation provisions of the NSR rules, likely based upon a superficial review of these provisions. This comment only provides a single concrete piece of support for the position that it takes, the Pfizer Determination. As will be discussed further below, a review of the Pfizer determination shows that it does not actually support the position taken in this comment. In addition, the fallacious nature of the position taken by this comment is evident when one considers other matters that are instructive for how NSR applicability analyses that are prepared to accompany proposed relaxations of permit limitations should be conducted, as will also be discussed below.

<u>The Approach Put Forth in this Comment for NSR Applicability for Relaxation of Limitations Is Contrary to Established Practice</u>
It is well-established that when revisions are requested to an

[31] *See,* letter from S.C. Riva, USEPA, to R. Frontanes, Pfizer Pharmaceuticals LLC, Sept. 23, 2015 ["Pfizer Determination"]. In the Pfizer determination USEPA conveys its non-applicability determination for proposed relaxation of synthetic minor limitations that had been imposed in 1994 in order to establish synthetic minor status with respect to NOx emissions from a project that involved installation of five diesel generators and two boilers. The synthetic minor limitations imposed in 1994 established the combined potential to emit NOx from the seven new units at 56 tons per year; if the combined potential to emit had been 65 tons per year or more, the project would have been a major modification. USEPA's 2015 applicability determination allowed relaxation of the limitations such that the new potential to emit would be 90 tons per year; the USEPA's source obligation analysis relied on the fact that other facts had changed during the intervening time period and it gave no consideration to the fact that, had the combined potential to emit been 90 tons per year historically, the project would have been a major modification. [Footnote 19 in US Steel's comments of January 2024.]

air pollution control construction permit for a project to correct errors in the previous permitting of the project, as is requested by the Application, one must return to or revisit the previous permitting of the project. If correction of errors in the previous permitting of a project are requested concurrently with a request for permitting of a new project, the correction of past errors and the permitting of the new project must be considered separately. The requests cannot be simply considered together or merged without distinguishing between the two requests because the relevant circumstances underlying the determinations of NSR applicability for the requests are almost certainly not the same. In addition, the regulatory provisions governing the NSR applicability determinations may be different as USEPA revised the applicability provisions of its NSR rules in its 2002 NSR Reform Rulemaking.

<u>The Approach Put Forth in this Comment for NSR Applicability for Relaxation of Limitations Is Not Supported by Applicable Rules</u>
The interpretation of the so-called source obligation provisions in the PSD and NaNSR programs claimed by this comment is not supported by the actual language of the provisions.[102] Indeed, the actual language of these provisions suggest that when an NSR applicability analysis that resulted in a project being permitted as a non-major project must be revisited because increases in the established permit limitations are requested, the new applicability analysis should address circumstances as they should previously have been addressed for purposes of applicability of NSR. That is, a "retrospective approach" is required, not a prospective approach as claimed by this comment. A "retrospective approach" to applicability of NSR is directly suggested by the subject provisions as a superficial reading of these provisions could lead a person to conclude that all aspects of NSR shall be addressed in such a permit proceeding as if construction of the subject source or modification "had not yet been commenced." In other words, applicability of NSR needs to be addressed as it should have originally been addressed, i.e., "as if construction of the source or modification had not yet commenced." As such, the interpretation of the source obligation provisions claimed in this comment cannot simply be accepted on

[102] To address errors in the original permitting of the Project, the Application requests increases in the permitted NOx emissions of certain emission units. These requests seek "relaxation" of the current limits as a relaxation may be defined simply as "a loosening or slackening" or "a reduction in strictness or severity." (*The American Heritage College Dictionary, Third E*dition, 1993).

its face.

Moreover, what is more significant, is that this comment does not show that the revised NSR applicability analyses for the Project in the Application actually conform to the requirements of 35 IAC 204.550(a) and (b) and 35 IAC 203.208(a) and (b). This is because these analyses for the Project for emissions of PM, PM_{10}, NOx and VOM, are "prospective" since they rely on decreases in emissions that are not contemporaneous with the Project, as it was permitted in 1996. Moreover, as the Application requests corrections to Permit 95010001 to address errors in the original permitting of the Project, the revisions to Permit 95010001 are not directly governed by the so-called source obligation provisions of the NSR rules.[103]

With regard to the language of the so-called source obligation provisions, these provisions do not address whether the "new" or updated NSR applicability analysis for a project for which relaxation(s) in limitation(s) are requested should address the circumstances as of the original permitting of the project or, as audaciously claimed by this comment, the circumstances as of the time of this request. This is clear from the language of the rules.[104] This comment also acknowledges, perhaps unintentionally,

---

[103] It is also noteworthy that all the revised "NSR applicability analyses" in the Application are entitled "Revised [Pollutant} PSD Net Emissions Increase Analysis," (Application, Appendix B – Emission Calculations). In particular, there is not a separate revised analysis for NOx addressing the applicability of NaNSR. Likewise, there are not revised analyses for NaNSR for particulate even though in 1996, Granite City was in an area that was nonattainment for PM_{10}. It is assumed that this was inadvertent and US Steel intended to address applicability of PSD and/or NaNSR as appropriate for different pollutants. Thus, the Illinois EPA in its response refer to all revised applicability analyses in the Application as NSR analyses.

In this regard, the mechanics of the applicability provisions of PSD and NaNSR are such that if a project is "PSD major" for a pollutant, it would also be "NaNSR major" for the pollutant if NaNSR was applicable for that pollutant. However, the converse is not true because the applicability provisions of PSD and NaNSR are not identical. In particular, Illinois' NaNSR rules, 35 IAC Part 203, have not been revised to reflect NSR Reform and do not provide for Project Emissions Accounting.

[104] For example, 35 IAC 204.850, the so-called Source Obligation provision in Illinois' PSD rules, which have been SIP-approved by USEPA, provides:

> **At such time that a particular source or modification becomes a major stationary source or major modification by virtue of a relaxation in any enforceable limitation established after August 7, 1980, on the capacity of the source or modification otherwise to**

that a distinction exists between the determination of NSR applicability for a proposed increase in the permitted emissions of a project and the requirements of NSR that are actually addressed in the so-called source obligation provisions.[105]

Once it is recognized that the so-called source obligation provisions do not provide for a different approach for the NSR applicability analyses for certain relaxations of limitations, one realizes that such determinations are subject to the provisions of the NSR rules that generally apply for such determinations. This is evident as the introductory clauses of the so-called applicability provisions provide that "At such time (emphasis added) that a particular (emphasis added) source or modification becomes a major stationary source or major modification." As such, the provisions address how permitting of relaxation(s) of limitation(s) established for a source or project should be addressed when such relaxation(s) are requested. The provisions then go on to indicate those relaxation(s) should be addressed "…as though construction had not yet commenced (emphasis added) on the source or modification." A straightforward reading of this phrase would indicate that the provisions of NSR for a project for which a so-called source obligation provision becomes applicable should address the circumstances of the project as they would have been previously addressed with the relaxation(s) that are now being requested. This reading is buttressed as it is preceded by the phrase, "at such time …." In other words, requirements should not be applied as of the time that that the relaxations are made but as of an earlier time, "… as though construction had not yet commenced on the source of modification." With respect to applicability of NSR for a project, relaxations of emission limitations should not be addressed "prospectively" as broadly claimed by this comment.[106]

> **emit a pollutant, such as a restriction on hours of operation, then the requirements of Sections 204.810, 204.820, 204.830, 204.840, 204,850, 204.1100, 304.1110, 204.1120, 204.1130, 204.1140, 204.1200 and 204.1400 (emphasis added) shall apply to the source or modification as though construction had not yet commenced on the source or modification.**

[105] This is shown as this comment states that "Applicability analyses performed in order to determine whether the source obligation provisions apply (emphasis added) in conjunction with a requested relaxation are prospective, not retrospective."

[106] When examining the language of the source obligation provisions, it is also noteworthy that, when applicable, they actually provide that the

The Approach Put Forth in this Comment for NSR Applicability for Relaxation of Limitations Is Contrary to Sound Public Policy

An approach to relaxation of emission limitations that prohibits unrestricted "backsliding" is generally appropriate as a matter of public policy. It serves to prevent a source from benefiting as it would circumvent NSR solely by virtue of the relaxation of emission limitation(s) that have been established by the permitting authority and accepted by the source for a project so that it would not be a major project. For example, as a project would become a major project as a consequence of the relaxation of limitation(s), consideration should not be given in the determination of Best Available Control Technology (BACT) for the additional cost (economic impact) of retrofitting BACT technology for units given their current configuration. Any such retrofit costs that would now be posed by applicability of NSR due to a relaxation should not be considered as those costs would not have been present if the determination of BACT had originally been made and used for the project.[107]

The approach put forward in this comment to NSR applicability

---

"requirement of NSR" shall apply as though construction had not yet commenced. This comment presumes that the term "requirements of NSR" extends to the applicability provisions of NSR, rather than only encompassing the substantive provisions of NSR for a major project, such as BACT. In this regard, 35 IAC 204.850, makes clear that the requirements that are being addressed for a relaxation of limitations are the substantive provisions of PSD and not the applicability provisions of PSD. This is because it specifically identifies the provisions of 35 IAC Part 204 that would apply as if construction had not yet commenced. (The substantive "permit provisions" of 35 IAC Part 204 listed in 35 IAC 204.850 are: Sections 204.810, Source Information; 204.820, Source Obligation; 204.830, Permit Expiration; 204.840, Effect of Permits; 204.850, Relaxation of a Source-Specific Limitation; 204.1100, Control Technology Review; 204.1110, Source Impact Analysis; 204.1120, Air Quality Models; 204.1130, Air Quality Analysis; 204.1140, Additional Impact Analysis; 204.1200, Additional Requirements for Sources Impacting Federal Class I Areas; and 204.1400, Recordkeeping and Reporting Requirements for Certain Projects at Major Stationary Sources.) As such, the Source Obligation provisions should not be read to contradict the general principle that corrections to permits require that the permitting action in which the error was made be revisited.

[107] Likewise, in the air quality impact analysis for a project pursuant to the PSD rules, the impacts of the entire project with the requested relaxation should be addressed, not just the impacts of the increases in emissions from the relaxations. The impacts of a project for purposes of PSD should not be allowed to be understated simply due to a relaxation of the limitations previously established for the project.

analyses when permitted emissions of a project would increase is absurd. It would potentially allow a source to simply renounce or renege on commitments made in the previous permitting of a source or modification to avoid status as a major project. This is because it would allow the permitted emissions of a project to be increased with relaxation of limitations established for the project relying on emission decreases that were not originally part of a project and are outside of the contemporaneous period for the previous permitting of the project. As such, it would be contrary to the fundamental principle that, as NSR permitting is based on potential emissions, limitations that are established to restrict potential emissions cannot simply be relaxed without undergoing NSR if the relaxation would result in a project that was previously non-major becoming a major project.[108]

<u>The Approach Put Forth in this Comment for NSR Applicability for Relaxations Is Not Supported by Relevant USEPA Determinations</u>

The approach to the so-called source obligation provisions put forth by this comment is not consistent with USEPA's well-established practice in prohibiting circumvention and back-sliding as a result of relaxation of limitations established in permits. This is shown in a USEPA determination addressing back-sliding in the context of a proposed relaxation of limitations established for and accepted by Bombardier Motor Company of America to establish status as a non-major source. (A copy of this determination, "the Bombardier determination," is provided in this Responsiveness Summary as Appendix 1.1.[109]) This determination involved the change in nonattainment designation of an area from severe nonattainment for ozone under the former

---

[108] From this perspective, it should be apparent that USEPA adopted the so-called source obligation provisions in its NSR rules to appropriately address revisions of permits that would relax limitations and increase permitted emissions of projects absent any accompanying physical change or change in the method of operation, i.e., absent a new project. If USEPA had intended that such relaxations be addressed in the manner claimed by this comment, USEPA would not have needed to adopt these provisions.

[109] Copies of the Bombardier Determination, as well as two other USEPA determination referred to by the Illinois EPA in this Responsiveness summary, are included in this as appendices to this Responsiveness Summary. This was done to enable interested parties to readily review these USEPA determinations in their entirety and independently review the representations about these determinations made in US Steel's comments and the Illinois EPA's responses. In this regard, not all of these determinations are currently available on the USEPA's internet compendium of NSR documents, New Source Review Policy and Guidance Document Index.

National Ambient Air Quality Standard (NAAQS) on a 1-hour average (major source threshold of 25 tons of VOM per year) to moderate nonattainment under the NAAQS for ozone on an 8-hour average (major source threshold of 100 tons of VOM per year). USEPA found that the relaxation of the limitations established when the area was severe nonattainment to keep VOM emissions below 25 tons/year would trigger the substantive requirements of NaNSR as if construction of the source had not yet commenced. USEPA referred to the so-called source obligation provisions in the federal guidelines for state PSD programs, 40 CFR 51.165(a)(5)(ii). USEPA found the following:

> **Bombardier's 25 TPY emissions limit was a requirement in a minor NSR permit, and the limit was taken to avoid application of major NNA NSR [NaNSR]. Based on the language in the rule, the revocation of the 1-hour NAAQS should not allow relaxation of the permit limit without triggering major NSR.**
> **Bombardier Determination, Letter from Pamela Blakley, Chief, Air Permits Section, USEPA, Region 5, to Jeffrey Hanson, Permits and Stationary Source Modeling Section, Bureau of Air Management, Wisconsin Department of Natural Resources, September 22, 2005.**

The USEPA's approach to the so-called source obligation provisions is more fully explained in a determination for PSE & G Fossil LLC (the "PSE & G Determination). (A copy of the PSE & G Determination is included as Appendix 1.2 of this Responsiveness Summary.) In this determination, USEPA explains that the proposed relaxation of certain operating and limitations in the existing permits for the subject generating stations would necessitate two separate analyses to determine NSR applicability, i.e., one would be concurrent with the request for relaxation of limitations; the other would address the relaxation as though construction had not yet commenced on the modification.[110] This USEPA determination again shows that

---

[110] **In the PSE & G determination, USEPA explains that:**

> **In order to determine PSD applicability in this case, two specific, separate and independent tests must be performed: (1) the standard PSD applicability test pursuant to 40 CFR § 52.21(a)(2)(ii) to determine whether a significant net emissions increase under a physical change or change in the method of operation would occur; and (2) the 40 CFR 52.21 test which treats a modification "as though construction had not commenced on the source or modification." Each applicability test is to have its own baseline period**

the revised NSR applicability analysis accompanying the relaxation of the NOx emission limitations for certain units requested by the Application must revisit the original permitting of the Project.

The Approach Put Forth in this Comment for NSR Applicability for Relaxations Is Not Supported by the Pfizer Determination

The USEPA's determination for Pfizer Pharmaceutical, as cited by this comment (the "Pfizer Determination," which is included in this Responsiveness Summary as Appendix 1.3), did not involve corrections to permit limitations to address errors in the prior permitting of a project. As such, this determination is not illuminating as to the approach that should be taken for the revised NSR applicability analyses in the Application. It certainly does not support the position put forth in this comment.

Unlike the revisions to Permit 95010001 requested by the Application, the Pfizer Determination did not involve a situation where a non-major project would potentially become a major project due to the requested changes to established permit limitations. Rather, the Pfizer Determination, as specifically described in the determination, involved a potential change or

---

and contemporaneous period that will be different for each test. The general applicability review in accordance with the first citation above would subject a modification to PSD requirements in those cases where a physical change or a change in the method of operation would result in a significant emissions increase of a regulated pollutant.

…

The second test under 40 CFR § 52.21(r)(4) has not been done. While you acknowledge in your December 3rd letter that EPA verbally communicated to your consultant our position that the aforementioned PSD provisions would apply in this case, you have indicated that you disagree with this interpretation. … Regardless, EPA remains of the opinion that the (r)(4) provision applies in this case. This PSD provision does not discuss intent; it simply states that any relaxation of an established limit that would make the project "major" would at that point in time make PSD applicable. That is, the (r)(4) provision must be considered for the life of any project for which enforceable limits were established such that any subsequent request for a relaxation of the aforementioned limitations will necessitate their review within the originally-issued permits.

Letter, February 11, 2009, from Steven Riva, Permitting Section Air Programs Branch, USEPA, Region 2, to William Viola, Director Power Generation PJM, PSE&G Fossil LLC, Re: Request for PSD Applicability Determinations for the Burlington 12 and Kearny 12 Generating Stations.

relaxation in 2015 to an emission limitation for NOx established for a 1994 project in view of subsequent permitted construction projects since 1994 at the facility. The determination does not involve revisions to the established limitation in order to correct error(s) that occurred when that limitation was established. Indeed, nothing in this determination suggests that Pfizer requested that the subject limitation be raised because NOx emissions have been or may be higher than were allowed. USEPA considered whether the requested relaxation of the limitation would involve circumvention of PSD and found that "…Pfizer is not attempting to circumvent PSD applicability …."[111]

The Approach Put Forth in this Comment for NSR Applicability for

---

[111] The Pfizer Determination was made in 2015 for a pharmaceutical manufacturing facility located in Puerto Rico. As described in this determination, the permitting for the 1994 project, for which the relaxation of the emission limitation was requested, took place when the facility was a major source for PSD (potential emissions of both SO_2 and VOM more than 100 tons/year). When the 1994 project was permitted, the overall NOx emissions of the facility were limited to 56 tons/year. This served to restrict the net increase in NOx emissions from the project to 28.88 tons/year. As such, the net increase in NOx emissions from the project was limited to less than 40 tons/year, the NSR significant emission rate for NOx, so the project was not a PSD major modification.

As part of the permit for a subsequent, 2002 construction project, the facility's emissions of all NSR pollutants were each limited to below 100 tons/year so that the facility was no longer an NSR major source. Then, in 2015, in conjunction with another construction project, Pfizer also requested that the 56 tons/year permit limitation for NOx set for the 1994 project be replaced or subsumed by the overall limitation for the NOx emissions of the facility, 90 tons/year. USEPA found that this request was approvable, after specifically observing that Pfizer has stated that it had operated as a minor PSD source since 2002.

> **EPA's review of the information indicates that Pfizer is not attempting to circumvent PSD applicability [emphasis added] by requesting to increase the 1995 PSD non-applicability NOx PTE limit from 56 tons/year to 90 tons/year because the facility or the 1994 [sic] modification does not become a major stationary source or major modification solely by virtue of this NOx emission limit relaxation, In addition, the "synthetic minor" minor status has been maintained by Pfizer since 2002 and will continue to be maintained after the proposed modification, Furthermore, Pfizer is also not requesting any changes to its annual fuel and hours of operation restriction put in place pursuant to the 1995 non-applicability determination.**
>
> **Pfizer Determination, p. 2.**

Relaxation of Limitations Is Contrary to Statements by USEPA

Certain statements made by USEPA in a 1989 rulemaking on NSR are instructive as to the function of the so-called source obligation provisions. In this rulemaking, USEPA directly explains that these provisions require a source or modification that has been permitted as being non-major for NSR but is subsequently determined to be major because it cannot comply with limitations established in the non-major permit issued for the source or modification, must then be subject to major NSR permitting.[112]

---

[112] In its 1989 rulemaking on NSR, the USEPA addresses the so-called source obligation provisions in discussions concerning the "potential to emit" or potential emissions and the enforceability of limitations that restrict potential emissions. In this rulemaking, the USEPA concluded that it was appropriate to require that limitations that restrict the potential to emit be federally enforceable. While USEPA subsequently found that it is also acceptable for such limitations to be legally and practically enforceable by a state or local air pollution agency, this does not affect USEPA's conclusions with regard to enforceability of limitations and the so-called source obligation provisions. The USEPA also acknowledged that the so-called source obligation provisions could result in after-the-fact, retrospective review and NSR permitting for a new source or modification. In this regard, the USEPA made the following observations. While in certain places, these observations refer to "sources," the observations are equally applicable for modifications.

> **These same qualities of a federally enforceable permit make it much easier to determine if, at a later date, whether the terms or intent of the permit have been violated and, if so, what enforcement action is appropriate. There are three options available to EPA [USEPA] for when a federally enforceable State permit has been or will be violated.**
>
> **One option is simply to enforce under section 113 [of the Clean Air Act], the limitations in the permit which enable the source to avoid NSR in the first place, with the result that the source retains its minor status. This is appropriate where, despite the permit violations, it appears that the source intends to adhere to the emissions limitations in the future. However, EPA retains the right to enforce PSD or nonattainment NSR violation as well.**
>
> **The second option is to invoke the "source obligation" regulations, e.g., 40 CFR 52.21(r)(4), and treat the source as major requiring to obtain a PSD or nonattainment major source permit. This course is appropriate where the source, through a change in business plans, or <u>through belated realization that its original plans cannot accommodate the design or operational limitations reflected in its minor source permit</u> [emphasis added], can no longer adhere to the limitations in that permit, and so exceeds them. As discussed in the preamble to the 1980 regulations, this option is also appropriate where the source (after receipt of its minor source permit) notifies the permitting authority in advance of its changed plans or expectations and the need for a future relaxation of the limitations in its current permit, without actually violating those limitations before obtaining a major source permit (see 45 FR 52689). Under either set of**

The Approach Put Forth in this Comment for NSR Applicability for Relaxation of Limitations Is Not Actually Taken in the

---

circumstances, pursuant to the "source obligation" regulation, EPA treats the source "as though construction had not yet commenced" for purposes of PSD or nonattainment permitting purposes (emphasis added).

The EPA believes that the exceedance or relaxation of a minor source permit, and the subsequent obtaining of a major source permit through compliance with the "source obligation" regulation, may not routinely involve penalties or additional sanctions other than those provided in section 113 for any period in which the source actually exceeded the limitations in its minor source permit. The EPA today clarifies, though, that a third general enforcement option is necessary and available under the [Clean Air] Act and EPA's regulations in certain situations.

This third enforcement option is appropriate where EPA determine that a source obtained a permit containing limitations allowing it to escape preconstruction review as a major new source or major modification, not for the purpose of adhering to those limitations for an appreciable period of time in accordance with some legitimate business plan, but primarily with an intent to construct, and possibly begin operation of a major new source or major modification without first obtaining a PSD or nonattainment permit. In such circumstances, EPA enforces the "source obligation" regulations, as in option two above "as though had not yet commence." In keeping with the retrospective orientation of the "source obligation" regulations [emphasis added], however EPA looks to the beginning of actual construction on the new source or modification for additional enforcement action under sections 113 and 167 as well. …

… As a general matter, it is abundantly clear that Congress intended the NSR provisions in Parts C and D [of the Clean Air Act] to require preconstruction review of major new sources and modifications. See, *e.g.*, section 160(5), 165(e)(1) and (2), 110(a)(2)(I), 172(a)(1), 172(b)(6), and 173. The evident air quality planning and technology-forcing purposes of the [Clean Air] Act's NSR provisions make the reasons for Congress' choice of statutory framework equally obvious. It is much easier, both in technical and practical terms, to consider air quality impacts and pollution control requirements of a major new source of air pollution before it has been constructed and begun operation rather than after. Nevertheless, there is a need to accommodate sources which, for legitimate business reasons, have constructed and begun operation as minor sources, but later discover that they now do, or in the future will, emit air pollutants that will require them to be treated as major. In those circumstances, postconstruction review is unavoidable and the "source obligation" regulations in 40 CFR 52.21(r)(4) and elsewhere are designed to fulfill this need.

USEPA, 40 CFR Parts 51 and 52: Requirements for Preparation, Adoption and Submittal of Implementation Plans; Approval and Promulgation of Implementation Plans, Final Rule, June 28, 1989 (54 Federal Register 27274), p.27280.

Application

The approach taken in the revised NSR applicability analyses in the Application is not actually consistent with the approach to the so-called source obligation provisions argued for in this comment. This is because, contrary to what is claimed, the revised NSR applicability analyses in the Application do engage in "…mixing facts from different points in time." The baseline emissions in the revised applicability analyses are revised determinations of baseline emissions as US Steel now believes should have been originally determined for the Project. In this regard, the revised determinations of baseline emissions for certain pollutants reflect revised values for certain emission factors for which the original factors have been found to be erroneous. The revised determinations of baseline emissions also now account for emissions from burning coke oven gas in Project-affected units, which were not addressed originally. As such, in the Application, US Steel has addressed baseline emissions for the Project as if it were 1996 and construction on this Project had not been commenced.[113] However, future emissions with the Project are addressed beginning at a point in time over almost 20 years later, when there have been certain decreases in emissions from various actions.[114]

B2. The Application Shows That the Project Would Not Become a

---

[113] In this regard, if one accepts that the so-called source obligation provisions give guidance on how applicability of NSR should be addressed when revisions to limitations established for a Project are requested, the provisions act to preserve the time period that is to be used for the determination of baseline emissions. A source is not required to make an entirely new determination of baseline emissions that is representative of a time period that is contemporaneous with the request for relaxation(s) in limitation(s). And, indeed, in the Application, US Steel has not provided new determinations of baseline emissions that would be contemporaneous relative to the timing of the Application.

The situation would be different if, rather than requesting relaxation(s) of limitation(s) established for an existing project, a source is requesting a permit for a new project. In this regard, a new proposed project would involve something more than relaxation of the established limits, such as proposed physical changes to emission units that would increase their operational capacity, with accompanied potential increases in emissions. Appropriate determination(s) of baseline emissions would be required for the new project, with such determinations being representative of actual emissions in the time period before the proposed project, as required by the then applicable NSR rules.

[114] Neither this comment or other comments submitted by US Steel address, much less provide support for, the disjointed or asynchronous approach to the revised NSR applicability analyses actually provided in the Application.

Major Modification with the Requested Increases in NOx Emissions

The Revised NOx emissions increase calculations in the Application fully conform to and satisfy the source obligation provisions of the PSD and NaNSR rules. US Steel's prospective calculation of potential NOx emissions from the certain fuel combustion units affected by the Project includes zero emissions from Boilers 1 through 10, which accurately represents the future potential to emit of those boilers because they no longer exist; does not include the greater NOx emission rates of Boilers 11 and 12 prior to the required retrofit of flue gas recirculation in those boilers; and includes zero emissions from combustion of coke oven gas (COG) as fuel, which accurately represents the future emissions of units that previously burned COG because COG is no longer an available fuel at the facility. As discussed further in comments below, if the Illinois EPA were to revise Permit 95010001 with the requested relaxations and other changes to the limitations in the permit currently in effect, the Project will not become a major modification solely due to those relaxations.

In this comment, US Steel confirms that the revised netting analysis in the Application for NOx, PM, PM_{10}, and VOM are not proper because, as they address emissions with the Project, are "prospective" in nature. That is, the calculations in the Application for the net increase in emissions from the Project address the future potential emissions of the Project-affected units but not the potential emissions of the Project with the requested increases in the permitted NOx emissions of certain units. In this regard, as specifically confirmed by this comment, the revised netting analysis would rely on certain decreases in emissions as identified in this comment that were not contemporaneous with the Project and, indeed, did not occur until long after the Project was completed and US Steel took ownership of the Granite City Works. Then, the Illinois EPA's review of relevant data found that, absent these decreases in NOx emissions due to the listed actions, the Project could be a major modification for NOx with the increases in NOx emissions of the BOFs that are requested to correct errors in the original permitting of the Project as are still reflected in the current permit for the Project.[115]

[115] Incidentally, the comment also incorrectly states that for NOx emissions with the Project, the revised NSR applicability analysis "… includes zero

C. NOx Emissions Associated with a Facility Configuration No Longer Authorized or Under a Counterfactual Hypothetical Are Immaterial to the "Source Obligation" Demonstration

Contrary to the plain language of the source obligation provisions, Illinois EPA suggests that the revised NOx netting analysis for NOx provided in the Application is deficient because it reflects the prospective reality for the Project-affected fuel combustion units at the facility, not any counterfactual hypothetical. The Illinois EPA theorizes that "Accordingly, in 1996, the NOx emissions of fuel burning units allowed by Permit 95010001 must necessarily be more than the baseline emissions…" and that, "…the future NOx emissions of the fuel burning units for purposes of any revised netting analysis should be expected to be substantially greater than their baseline emissions." (Denial Letter, Attachment 1, Footnote 11, p. 6)[116] For purposes of the source obligation analysis, this is plainly untrue, as the total baseline NOx emissions of these units are 956 tons per year and the total maximum future emissions are 706 tons per year. The Draft Denial Letter does not identify any provision of the Act or the Illinois Administrative Code requiring an applicant to anticipate, address, or refute the unsupported expectations of the Illinois EPA as part of the construction permit review process.

---

emissions from combustion of coke oven gas [COG] as fuel, which accurately represent the emissions of units that previously burned coke oven gas (emphasis added)." However, Project-affected units that were burning COG, e.g., the blast furnace stoves, were not shutdown when COG ceased to be available. Rather, they continued to operate with their other fuels, e.g., blast furnace gas and natural gas, and continued to emit NOx. In addition, the principal way to make up for the inability to use COG in these units would have been to use natural gas, increasing the usage of natural gas.

[116] See, also, Attachment 1 at pp. 5 and 11, suggesting that the revised NSR applicability analysis for NOx should include "future NOX emissions" greater than zero from Boilers 1 through 10; at p. 5, suggesting that the revised applicability analysis should include greater NOx emission rates from Boilers 11 and 12 based on the configuration of those boilers as they existed at the time the Project was implemented; at p. 5, suggesting that the revised applicability analysis should include greater NOx emission rates from Boilers 11 and 12 and from the blast furnace stoves based on the use of coke oven gas as fuel in those units. Each of these suggestions is demonstrably inconsistent with the current and future operation of the Granite City Works and is not properly considered in the source obligation analysis. (Footnote 20 of US Steel's Comments of January 2024.)

As already explained, the so-called source obligation provisions do not provide what this comment claims with regard to the revised NSR applicability analysis that must accompany US Steel's requests for relaxation of established permit limitations, i.e., that these provisions provide that such analysis must be prospective or forward looking rather revisit the prior NSR applicability analysis that led to the imposition of the limitations for which revisions are requested. US Steel's comments have not identified any language, much less "plain language," in the source obligation provisions that specifies that the NSR applicability analyses accompanying requested relaxations of established limitations are to be prospective in nature in circumstances when the source or modification becomes major solely by virtue of the requested relaxations.[117, 118]

---

[117] As already discussed, the Application does not indicate that the increases in the NOx emissions of the blast furnace casthouse and the BOFs that are requested are due to further physical changes or changes in the method of operation of these units, i.e., modifications as defined by the NSR rules of these units separate from changes that were originally part of the Project. In addition, the revised NSR applicability analysis for NOx in the Application addresses applicability of NSR for the Project, not applicability of NSR for certain subsequent physical changes or changes in the method of operation of these units.

[118] An important aspect of the so-called source obligation provisions, which is not directly confronted in US Steel's comments, is that, as written, these provisions only apply to circumstances in which a source or modification becomes major solely due to the relaxation of limitations that previously served to constrain the source or modification so that it would not be major for purposes of NSR. These provisions arguably do not apply where the emissions of a source or modification would increase due to a "new project," that is, a new physical change or change in the method of operation that qualifies as a modification under the NSR rules. In those circumstances, the applicability of major NSR to the changes to a source is to be addressed as generally provided by the NSR rules. That is, the applicability of NSR is to be determined considering the increases in emissions from the new project and, if proposed by the source, the net increases in emissions for the new project. The contemporaneous period for the permitting of the new project is related to the timing of the new project. If the new project is determined to be a major new source* or a major modification, the substantive requirements of NSR, as applicable, are addressed concurrently with the permitting of the new project. The substantive requirements of NSR are not addressed retroactively, as provided by the source obligation provisions. That is, these requirements are not addressed as if construction had not yet begun on the earlier project for which limitations had been set so that such source or modification would not be major.

The so-called source obligation provisions are applicable only where the relaxation in established emission limitations and the request for increases in permitted emission occur independent of new physical changes or changes in the method of operation, i.e., absent a new or separate project. In such circumstances, there is not a new project that governs the timing of the

The claim that the Illinois EPA has improperly posed "a counterfactual hypothetical" is also clearly erroneous.[119] In this regard, this comment acknowledges that for the ten boilers that were originally part of the Project but are now shutdown, "U.S. Steel's prospective calculation of potential NOx emissions includes zero emissions of Boiler 1 through 10…, does not include the greater NOx emissions of Boilers 11 and 12 prior to the required retrofit of flue gas recirculation in those boilers; and includes zero emissions from combustion of coke oven gas…."[120] As such, the concern expressed in the Draft Denial Letters with

---

contemporaneous period and whether contemporaneous emissions increases and decreases are creditable for the purposes of NSR applicability. The revised analysis of applicability of NSR with the requested relaxation of limitations and increases in emissions is still governed by the contemporaneous period and what would have been creditable for the original project. Then, if the subject project becomes major with the requested relaxations of limitations, the source obligation provisions provide that the substantive requirements of NSR apply as if construction of the original project had not yet commenced. Thus, the source obligation provisions impose appropriate consequences if a source or modification would become a major source or major modification due to the relaxation of enforceable limitations that served to avoid applicability of major NSR. The substantive requirements of NSR must be addressed as if construction had not yet been commenced.

*** Note that the NSR rules provide that for a source that is not a major source, a physical change that would occur at the source that would constitute a major source, by itself, is also considered a major source. (For example, refer to 35 IAC 203.206(c).) The provisions of the NSR rules that set forth what is a major modification are not applicable to a source that is not a major source.**

[119] For this purpose, it is assumed that the term "counterfactual" is used in this comment with its standard meaning to indicate that the Illinois EPA was addressing something that did not happen but could have happened or something contrary to fact. As such, it is unclear what was intended by the use of the term "counterfactual hypothetical," since the term "hypothetical" describes a premise that has not been proven to be true, at least at the time that such premise is being discussed or contemplated.

Then, in light of these meanings for these terms, the comment proceeds to suggest that it is improper for the Illinois EPA in the review of permit applications to consider "counterfactual hypotheticals." However, consideration of "counterfactual hypotheticals" is inherent in the review of permit applications, especially as construction permit applications address proposed emission units and control devices, proposed projects, proposed revisions to issued permits, or proposed increases in permitted emissions. The obligation of sources to address "counterfactual" circumstances or "hypotheticals" is set forth by Section 9 of the Act since, to obtain a permit, an applicant must submit an application that provides proof that applicable statutory and regulatory requirements will not be violated.

[120] Incidentally, the comment also incorrectly states that for the NOx emissions with the Project, the revised NSR applicability analysis "… includes zero emissions from combustion of coke oven gas as fuel, which accurately represent

respect to improper reliance on certain past decreases in NOx emissions does not even involve a counterfactual hypothetical as claimed by this comment.

Finally, the Illinois EPA does not dispute that Boilers 1 through 10 cannot resume operation, Boilers 11 and 12 must comply with 35 IAC 217.164, and the by-product coke oven batteries that have been shutdown cannot be returned to service.[121] However, Permit 95010001 did not require the shutdown of these units and, as such, provided for or authorized their continued operation. The shutdown of Boilers 1 through 10 was required much later, by Permit 06070023, originally issued in January 2008.[122] This permit authorized construction of a new cogeneration boiler at the facility. Condition 2.6(a) of this permit required Boilers 1 through 10 to be permanently shut down following the shakedown of this new boiler. (US Steel now refers to this boiler, which was constructed, as Power Boiler 1.) The installation of flue gas recirculation (FGR) systems on Boilers 11 and 12 was stimulated by the adoption 35 IAC 217.150 and 217.164 in August 2009. Compliance with the new emission standards was required to begin January 1, 2015. Finally, the shutdown of the two byproduct recovery coke oven batteries became enforceable after 2015 because US Steel had not applied for and has not been issued the construction permit that would be needed to rebuild these batteries and return them to service. As such, these actions and associated decreases in NOx emissions were not enforceable in 1996, when Permit 95010001 was originally issued. As such, these emission decreases are not creditable for purposes of emissions netting. This is because the relevant provisions for netting provide that for an emission decrease to be creditable for netting, the decrease must be enforceable at the time construction begins on the project for which

---

the emissions of units that previously burned coke oven gas (emphasis added)." However, Project-affected units that previously burned COG, e.g., the blast furnace stoves, were not shutdown when COG ceased to be available. Rather, they continued to operate with the other fuels, e.g., blast furnace gas and natural gas, and continued to emit NOx.

[121] As related to these coke oven batteries, it would have been better if US Steel had requested that the CAAPP permit for the facility be amended and reissued so as to no longer address these batteries and the associated byproduct recovery plant.

[122] The planned shutdown of Boilers 1 through 10 was acknowledged earlier in a construction permit that addressed certain emission reduction projects at the Granite City Works, Permit 06070022, initially issued in January 2007. Condition 1(c) of that permit indicates that, "This permit also acknowledges the planned permanent shutdown of Boilers 1-10, which would accompany construction of a new cogeneration facility." The applications for Permit 06070022 and Permit 06070023 for the new cogeneration facility were submitted on the same day in July 2006.

the net emissions increase is being evaluated. For example, 35 IAC 204.550(e) and (e)(2) provide that, "A decrease in emissions is only creditable to the extent that: … It is enforceable as a practical matter at and after the time that actual construction on the particular change begins …."

In summary, this comment does nothing to address the fundamental difference in the positions of the Illinois EPA and US Steel with respect to how applicability of NSR for NOx should be addressed for the requested increases in the NOx emissions of the casthouse and BOFs. This comment certainly does not show that denial of the revised permit requested by the Application is inappropriate because there have been decreases in NOx emissions as a result of the shutdown of certain units that have taken place since the initial issuance of Permit 95010001 was National Steel commenced operation under Permit 95010001.

D. Project Emissions Increases and Net Emissions Increases

D1. The Illinois EPA's Review Relies on Calculations for NOx Emissions That Are Inconsistent with Requirements of the NSR Rules

The Illinois EPA's proposed denial of the revised permit requested by the Application is erroneous because, to the extent that Illinois EPA's review of the revised NSR applicability analysis for NOx in the Application relies on separate calculations of increases and decreases based on specific fuels and changes in fuels, the Illinois EPA's calculations are inconsistent with PSD and NaNSR rule requirements. The major modification applicability test requires a comparison of the pre-project actual emissions of the emissions unit or group of units with the post-project actual emissions (or potential to emit) of that emissions unit or group of units.[123] The definitions of net emissions increase do not provide for a calculation that considers only some portions of the units' emissions. For the certain fuel combustion units affected by the Project, the change in actual NOX emissions is properly calculated as the total post-project actual NOX emissions, regardless of the fuel or fuels being burned to generate those emissions, minus the total pre-project actual NOX emissions, regardless of the fuel or fuels that were burned to generate those emissions. This is the basis for the values shown in Table 6-8 of the Application.

[123] By definition, the net emissions increase from a project is the sum of two values: The increase in actual emissions from the project and "Any other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable." 40 CFR 52.21(b)(3)(i).

This comment does not show that the Illinois EPA's review of the revised NSR applicability analysis for NOx in the Application is flawed. Indeed, the comment is ridiculous. The NSR rules specify that applicability of NSR is determined comparing two values for emissions, the baseline emissions or emissions before a project before a project and the emissions with the project [124] However, the NSR rules do not specify that these values for emissions of a project-affected unit or units must be calculated in a particular was as claimed by this comment.[125] Moreover, continuous emission monitoring is not conducted for the various Project-affected fuel burning units for the amount or mass of NOx emitted. Accordingly, it is not possible to directly determine the overall emissions of these units from monitoring data. Most of the Project-affected fuel burning units burn more than one fuel, i.e., blast furnace gas (BFG) and natural gas, and, in some cases, at least in 1996, COG. The different heat content and composition of these fuels mean that their NOx emission rates in pounds/million Btu or pounds/million cubic foot (cf) of fuel burned are not identical. Thus, it is both reasonable and appropriate that the NOx emissions of individual units or groups of similar units be separately determined for each fuel with the overall emissions of each unit or group of similar units calculated as the sum of the contribution of the NOx emissions of each fuel to the overall emissions. Indeed, this is exactly what is done in the Application as it proposes corrections to the pre-project or baseline NOx emissions of Project-affected fuel burning units in Table 6-5 and in Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project; Revised NOx PSD

---

[124] Indeed, the definition for "net emissions increase," which is referred to by this comment, as well as other relevant provisions of the NSR rules addressing the net emissions, i.e., 35 IAC 203,208 and 35 IAC 204.550, do not even address the emissions of individual units or groups of emission units. Instead, they address the emissions of a "source," which, as defined in part by 40 CFR 52.21(b)(5) and (6) and 35 IAC 204.690 and 204.290, is a collection of pollutant emitting activities, i.e., a collection of emission units.

[125] the NSR rules do not specify, for example, for different types of emission units and circumstances when addressing applicability of NSR whether emissions are to be calculated based on emissions factors derived from unit-specific testing, emissions factors derived from representative emission testing of similar units, emission factors published by USEPA, emission factors developed by organization s other than USEPA, emissions factors developed from engineering calculations that account for the reduction in emissions that will be provided by the control measures that will be installed on units, or material balance calculation based on analysis of the pollutant content of the fuel, coatings or other raw materials. The NSR rules also do not specify how emissions are to be calculated for emissions units that have more than one mode of operation or several point of emissions.

Net Emissions Increase Analysis.[126]

D2. The Illinois EPA's Review Improperly Determined That Certain Emission Decreases Are Neither Contemporaneous Nor Creditable

As set forth in the Revised Draft Denial Letter, Attachment 1, Denial Point 1, page 4, the Illinois EPA proposes to deny the revised permit requested by the Application, at least in part, because Illinois EPA preliminarily determined that "additional decreases in NOx emissions that would now be proposed to be relied upon" by US Steel are not contemporaneous and otherwise creditable. These decreases occurred at certain fuel burning units affected by the Project. Emissions changes at these emissions units must be included in the calculation of the emissions increase that will occur as a result of the Project, under the first element in the definitions of the term "net emissions increase."[127] Therefore, it was proper to include the emissions changes involv2ing Project-affected fuel burning units in the updated calculation of the NOx emissions increase from the project, -10.7 tons per year, as shown in Tables 6-8 and 6-9 of the Application. (For convenience, copies of these tables are provided below.)

Table 6-8 of the Application:

NOX Project Emissions Increase Analysis

[126] For Project-affected fuel burning units, the Application uses NOx emission factors, in pounds/million cubic feet (cf) of fuel, of 5.28 for BFG, 306.0 for natural gas,* 80 for COG burned in blast furnace stoves and 404 for COG burned in Boilers 11 and 12. The NOx emissions calculated from burning each fuel in these units are then added together to provide overall values for the pre-project NOx emissions of the Project-affected fuel burning units. (Emissions of NOx from use of natural gas in continuous casting are not addressed.) (Refer to the Application, at p. 6-5, Table 6-5. Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project NOx Emissions Factor for Affected Emissions Units, and at Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project; Revised NOx PSD Net Emissions Increase Analysis.)
*** For natural gas, a single emission factor, 306.0 pounds/million cf, is used for the blast furnace stoves, the boilers, the ladle dryer-preheater, the BFG flares, and, presumably, the continuous casting molds.**

[127] Contrast this with the emissions changes at the blooming mill and galvanizing line shown in Table 6-9. Because those units were not affected by the Project, decreases in emissions at these units are among the contemporaneous changes that are considered under the second element in the definitions of net emissions increases. [Footnote 22 in US Steel's comments of January 2024.]

	NOX Pre-Project Actual Emissions (TPY)	Proposed Revised NOX Emissions Caps (TPY)	NOX Change (TPY)
Blast Furnace Operations	4.6	24.0	19.4
BOF Shop	179.8	400.0	220.2
Continuous Casting Operations	0.0	0.0	0.0
Certain Fuel Burning Units	956.3	706.0	-250.3
Total	1140.7	1130	-10.7

Table 6-9 of the Application:

Updated Net Emissions Increases for NOx for the 1996 Project

		NOx
Start of Contemporaneous Period		Jan 1990
End of Contemporaneous Period		Jan 1996
Project Emissions Increases		239.6
Significant Emission Rates		40
Whether Significant?		Yes
Project Emissions Changes (includes decreases at the fuel combustion units)		-10.7
Contemporaneous Emissions Increases	Date	
Installation of #8 Galvanizing Line	Mar-1996	n/a
Contemporaneous Emissions Decreases		
Blooming Mill Shutdown	Apr-1991	-217.8
Batch Annealing Shutdown	Dec-1991	-8.7
Net Emissions Increase		**-237.3**
Whether Significant?		No

This comment does not show that the Illinois EPA's proposed denial of the revised permit requested by the Application would be erroneous. This comment simply reflects US Steel's position with respect to the revised NSR applicability analysis for NOx with the requested increases in the permitted NOx emissions of certain units. That is, US Steel's position that the revised NSR applicability analysis should be prospective and should not revisit the NSR applicability analysis for the Project that originally led to such limitations being established. This comment cloaks US Steel's position under the guise of a definition of "net emissions increase," summarily claiming that the subsequent, "post-project" decreases in NOx emissions at certain Project-affected fuel burning units should be considered as part of the changes in emissions from the Project, rather than resulting from other "Non-project" actions. The only support provided for this claim is that these emissions decreases occurred at fuel burning emission units that

were Project-affected fuel burning units for the purpose of the original permitting of the Project. This is wholly inadequate to support treating these actions that reduced or eliminated the NOx emissions of the affected fuel-burning units as part of the Project.

It should be apparent by inspection that these actions are not part of the Project. They were not contemplated in 1996 and were not addressed by, much less required by, Permit 95010001 as issued in 1996. (They have never been addressed in Permit 95010001.) The first of these actions, the shutdown of Boilers 1 through 10, occurred more than ten years after operation of the Granite City Works began with the Project. The shutdown of these ten boilers was required by Permit 06070023, the construction permit issued for the construction of the new cogeneration boiler at the Granite City Works. As a general matter, the NSR programs do not require, as implied by this comment, that all projects that occur at an emission unit be aggregated together so as to be treated as a single project for purposes of NSR. The NSR programs also recognize that discrete projects that are separate can occur at unit(s).[128]

This comment also ignores the presence of the word "project" in the provisions of the NSR rules addressing "net emissions increases." The definitions of "project" and USEPA's determinations that involve the meaning of this term clearly indicate that when addressing the increase in emissions from a project for purposes of NSR, "post-project" emission decreases are not part of a project. In this regard, 40 CFR 52.21(b)(52) and 35 IAC 204.590 simply provide that "'Project' means a physical change or the change in method of operation of a source." They do not indicate that all changes at an emission unit constitute a project simply because they occur at the same unit. USEPA's policy on the meaning of the term "project" mainly focuses on whether changes that are treated by the owner or operator of a source as nominally separate projects, and not as a single modification, should appropriately be aggregated and considered a single project for purpose of applicability of NSR. While this is the converse of the issue presented by the Application, USEPA policy on when changes should be aggregated are also instructive as to when changes should not be aggregated. In this regard, USEPA has concluded that changes should be aggregated when they are substantially related, with consideration given to both technical and economic relationships that exist among the

[128] For example, refer to a memorandum concerning interpretations of the *de minimis* provisions of the PSD rules. (Memorandum, from Sheldon Meyers, Director of Office of Air Quality Planning and Standards, USEPA, to David Howekamp, Director, Air Management Division – Region IX, USEPA, Subject: Net Emission Increase Under PSD, undated (circa May 1983).)

various changes. USEPA has also found the timing of separate activities cannot, by itself, be used to determine whether they are substantially related. However, USEPA has also recognized that timing can be a simpler way, at least initially, to assess whether nominally separate changes are substantially related. The USEPA also broadly rejected the argument that as nominally separate changes at a facility all contribute to the basic business purpose and economic vitality of the facility, changes should be aggregated. The USEPA found that this overarching relationship between all projects at a source is not sufficient basis to aggregate projects for purposes of applicability of

NSR.[129, 130]

---

[129] **At this time, USEPA's official policy on "aggregation" for purpose of NSR, as reflected in this response, is its "2009 Aggregation Policy," as published in the Federal Register. (USEPA, 40 CFR Parts 51 and 52: Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NSR): Aggregation and Project Netting, Final Rule (74 Federal Register 2376, January 15, 2009).**

USEPA affirmed the appropriateness of its "2009 Aggregation Policy" in 2018, upon concluding reconsideration of this policy. In its 2018 action, USEPA reinstated the 2009 Aggregation Policy, effective beginning November 15, 2018, lifting the stays on this policy. (USEPA, 40 CFR Parts 51 and 52: Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NNSR): Aggregation; Reconsideration, Final Action (83 Federal Register 57324, November 15, 2018).

The USEPA's 2018 notice for the conclusion of reconsideration of the 2009 Aggregation Policy also provides insight on the meaning of the term "project" for purposes of NSR as it summarizes the 2009 aggregation policy and discusses USEPA's rationale for affirming this policy. As particularly relevant to the review of the Application, in this 2018 notice, USEPA touched on the issue posed by the revised NSR applicability analysis for NOx presented by the Application. USEPA notes that it was mindful that, as well as inappropriately treating changes as separate projects, permit applicants could propose to improperly aggregate separate projects in an attempt to circumvent NSR. Accordingly, USEPA's 2009 Aggregation Policy is appropriately applied to address both aggregation and "disaggregation" for purposes of applicability of both PSD and NaNSR. In this regard, USEPA states the following in its 2018 notice:

> **To date, the EPA's [USEPA's] focus in formulating criteria for project aggregation has been to ensure that NSR is not circumvented through some artificial separation of activities as Step 1 of the NSR applicability analysis [the evaluation of the increase in emissions of the project] where it would be unreasonable for the source to consider them to be separate projects. However, in a March 13, 2018 memorandum[Footnote]8 on the topic of "project emissions accounting," the EPA broached the question of whether it might also somehow be possible for a source to circumvent NSR through some wholly artificial grouping of activities to include decreases in Step 1 of the NSR applicability analysis – i.e., assessing whether a project by itself results in a significant emissions increase before reaching Step 2, where one then determines whether there will be a significant net emissions increase by taking into account all contemporaneous increase and decreases across the source. While we [EPA] have been mindful of this question in deciding to employ the criteria described in this action, we intend to more fully [address] this scenario in the context of a subsequent rulemaking on the topic of project emission accounting.**
>
> **[Footnote] 8. Memorandum from E. Scott Pruitt, Administrator, titled, "Project Emissions Accounting Under the New Sources Review Preconstruction Permitting Program" (March 13, 2018)(hereinafter "Project Emissions Accounting Memorandum").**
>
> **83 Federal Register 57324 (November 15, 2018), p. 57326.**

Applying this guidance, it is readily apparent that the post-project activities and associated decreases in NOx emissions that have occurred at the Project-affected fuel burning units should not be considered part of the Project. These decreases were not the result of actions that were taken at the Granite City Works to achieve the increases in production of iron and steel authorized by Permit 95010001. Rather, these post-project activities involve actions taken by US Steel to benefit from co-generation of steam and electricity, to comply with newly adopted emission standards, and to streamline the facility by shutting down old by-product recovery coke oven batteries. The timing of these post-project decreases is well beyond the presumption adopted by USEPA that projects that are separated by more than three years should not be aggregated, absent rebuttal due to the substantial technical and economic relationships that are present.

Considering all the above, it should be apparent that Tables 6-8 and 6-9 from the Application, for which this comment includes copies, do not reflect an appropriate revised NSR applicability analysis for NOx for the Project. This is because the post-project decreases in NOx emissions, which are at issue, are not explicitly addressed, nor are they addressed elsewhere in the Application. In this regard, Table 6-9 does correctly show that the contemporaneous period for the Project for netting ended in January 1996. However, Table 6-8, which evaluates the increase in NOx emissions from the Project, considers and accounts for

---

[130] In its 2020 rulemaking on the subject of "Project Emissions Accounting," the USEPA also specifically recognized the role of the 2009 Aggregation Policy for applicability of NSR. In this rulemaking, USEPA specifically found that the 2009 Aggregation Policy also provided appropriate guidance for "disaggregation" of projects for purposes of Project Emissions Accounting, as follows. (Note that this rulemaking is not directly applicable to Illinois' NSR rules as only federal NSR rules (i.e., 40 CFR 51.165. 51.166 and 52.21) were revised.)

> **… while not previously contemplated by our [USEPA's] project aggregation policy, the EPA [USEPA] has concluded after review of the comments received in this proposal for action [[Project Emissions Accounting] that the "substantially related test from our 2018 final action on project aggregation interpretation and policy provides the appropriate basis for source to determine the scope of a project in Step 1 of the NSR applicability analysis. We believe that applying the 2018 final action of project aggregation interpretation and policy in this context alleviates concerns about potential NSR circumvention in Step 1 of the NSR modification applicability test.**
>
> **USEPA, 40 CFR Parts 51 and 52: Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NNSR): Project Emissions Accounting, Final Rule (85 Federal Register 74890, November 24, 2020), p. 74900.**

decreases in NOx emissions that are reflected in the "proposed revised NOx emissions caps" now proposed by the Application, 706 tons/year.[131] Thus, Table 6-8 does not actually address the increase in NOx emissions from the Project, i.e., the increase in emissions from the particular physical change or change in the method of operation for which the net increase in emissions to be evaluated.

As a counter to this comment, as it includes copies of two tables from the Application that provide revised NSR applicability analysis for NOx for the Project in the Application, the Illinois EPA has prepared several tables that, building upon the information for emissions provided in US Steel's analysis, depicting how this analysis would appropriately be viewed. The counter analysis, "Attachment A: "The Proper Approach, As Prepared by the Illinois EPA, to the Increase and Net Increase in the NOx Emissions of the Project with the Requested Revisions to Permit 95010001," is in Section 9 of this Responsiveness Summary. Attachment A includes three tables EPA that illustrate how the increase and net increase in NOx emissions from the Project with the requested increases in the NOx emissions of the casthouse and the BOFs would properly be addressed. They highlight the difference in how the Application approaches the revised NSR applicability analysis for NOx for the Project and how applicability of NOx should be addressed purposes of NSR. These tables depict why the Project would become a major NSR modification for NOx with the increases that the Application seeks in the permitted NOx emissions for these units. In this regard, this attachment relies on estimates for the increase in NOx emissions from the Project-affected fuel burning units with the Project that the Application does not address. These estimates for the Project-related emissions increase from these units, which are not addressed by the Application, range from about 160 to 235 tons/year. As such, the net increase in the NOx emissions from the Project almost certainly becomes more than the NSR significant emissions rate for NOx, 40 tons/year, with the requested revisions to Permit 95010001 to increase the permitted NOx emissions of the casthouse and the BOFs by more than 200 tons/year.[132]

---

[131] It should not be overlooked that, as addressed in the Illinois EPA's response to Comment 1, Footnote 4, the Illinois EPA has not accepted the revised values in the Application for the NOx emissions of the Project-affected fuel burning units, e.g., the revised baseline NOx emissions of 956.3. This is because of concerns about the basis of the new calculations for NOx emissions, as are addressed by Denial Points 2 and 3A in the Revised Draft Denial Letter.
[132] This is as should be expected. Permit 95010001 was initially issued based on a 38.1 tons/year net increase in NOx emissions from the Project (Permit 95010001, issued January 25, 1996, Condition 41(a)). The Application requests that Permit 95010001 be revised to increase the permitted NOx emissions of the

D3. Even Omitting the Dispute Decreases in NOx Emissions from the Revised NSR Applicability Analysis for NOx. The Project Would Not Become Major

Even if the contribution of certain Project-affected fuel burning units was properly considered as among the other decreases under the second element of the provisions of NSR dealing with net emissions increases, rather than being considered with the emissions increase from the Project under the first element of these provisions, the contribution of the Project-affected fuel burning units need not be relied upon for the non-applicability determination for NOx in the application. The net NOx emissions increase from the Project as presented in Table 6-9 of the Application is -237.3 tons/year; even if the decrease of 250.3 tons/year as calculated by Illinois EPA is omitted from the analysis, the net emissions increase is 13.1 tons/year (-237.3 + 250.3 = 13.1). This is less than 40 tons/year, the NSR significant emission rate for NOx. significant level, so demonstrates that the Project would not become a major modification solely by virtue of the relaxations requested by US Steel. This alternative approach to the NSR applicability for NOx is presented below in Alternative Tables 6-8 and Alternative Table 6-9.

Alternative Table 6-8. NOx Project Emissions Increase Analysis (TPY)

	NOx Pre-Project Actual Emissions	Proposed Revised NOx Emissions Caps	NOx Change
Blast Furnace Operations	4.6	24.0	19.4
BOF Shop	179.8	400.0	220.2
Continuous Casting Operations	0.0	0.0	0.0
Certain Fuel Burning Units	956.3	706.0	0.0*
Total	1140.7	1130	239.6*

* For the revised NSR applicability analysis for NOx, this Alternative Table 6-8 presents an alternative approach to the evaluation of the increase in NOx emissions from the project by itself. In this alternative approach, a decrease in NOx emissions from the fuel burning units, 250.3 tons/year, is not counted. This is because it is considered to not be a creditable or contemporaneous decrease.

blast furnace casthouse and the BOFs by more than 200 tons/year. The Application does not identify errors in the original permitting of the Project that would lower the Project emissions in an amount that would compensate for this requested increase.

Alternative Table 6-9. Updated Net Emissions Increases for NOx for the 1996 Project (NOx Emissions in tons/year)

Project NOx Emissions Increase		
Project Emissions Change (excludes decrease at the fuel burning units)		239.6*
Significant Emission Rate for NOx		40
Is the Project Emissions Increase Significant?		Yes
Contemporaneous NOx Emissions Increases and Decreases (Contemporaneous time period January 1990 through January 1996)		
Contemporaneous Increases	Date	
None		
Contemporaneous Decreases		
Blooming Mill Shutdown	Apr-1991	-217.8
Batch Annealing Shutdown	Dec-1991	-8.7
Total		-226.5
Net NOx Emissions Increase		
Project Increase		239.6
Contemporaneous Increases and Decreases		-226.5
Net Change		13.1
Is the Net Change Significant?		No

* For the revised NSR applicability analysis for NOx, this Alternative Table 6-9 presents an alternative approach to the evaluation of the net increase in emissions from the project. In this alternative evaluation, the NOx emissions decrease of 250.3 TPY from fuel combustion units is not counted because it is considered not to be creditable or contemporaneous.

The “alternative approach” to the revised NSR applicability analysis for the Project for NOx presented and discussed in this comment does not demonstrate that the Project would not be a major modification for NOx with the requested increases in the permitted NOx emissions of the casthouse and the BOFs. This comment does nothing to advance US Steel’s position with respect to how applicability of NSR for the Project for NOx should be addressed for the requested increases in the NOx emissions of the casthouse and the BOFs. Rather, this comment again simply reflects US Steel’s position that, when evaluating the change in emissions of the Project with the requested revisions to Permit 95010001 to increase the permitted NOx emissions of the casthouse and BOFs, the revised NSR applicability analysis should be prospective, addressing the future emissions of the Project after considering certain decreases in NOx emissions that have occurred since 1996 and the present.

In effect, contrary to relevant provisions of the NSR programs, this comment again claims that the revised NSR applicability analysis for the Project should overlook the fact that the Project was originally permitted for a substantial increase in the NOx emissions of Project-affected fuel burning units.[133, 134] While in Alternative Table 6-8, the increase in the NOx emissions from these fuel burning units is zero (rather being a decrease as in Table 6-8 in the Application), this assumption is still not proper. In the alternative analysis, this flawed assumption again acts to free up or "repossess" the original contemporaneous and creditable emission decrease that were relied upon to keep the Project from being a major modification for NOx. These decreases are then being relied upon a second time to compensate for the requested increases in the permitted NOx emissions of the casthouse and BOFs. As such, the flaw in this alternative NSR applicability analysis is similar to the flaw in the analysis in the Application.

In addition, as has previously been explained, contrary to what is suggested in this comment, the Illinois EPA has not established a specific value that is appropriate for the "corrected" net increase in NOx emissions of the Project, i.e., the net increase in NOx emissions of the Project also now addressing the increases in the permitted NOx emissions of the casthouse and the BOFs that are requested by the Application.[135] The Illinois EPA has determined that this increase is such that the Project should be expected to become a major modification for NOx with the requested increase in permitted emissions. As discussed elsewhere in this Responsiveness Summary, this is based on estimates for the corrected net increase in NOx emissions of the

---

[133] As already discussed, the netting analysis for NOx in National Steel's application for the Project, for which the Application included a copy, indicates that the Project was originally permitted for an increase in the NOx emissions of Project- affected fuel burning units from use of BFG and natural gas of 168.9 tons/year (488.48 tons/year, project emissions – 329.54 tons/year, baseline) = 168.9 tons/year, increase). (Application, Appendix C – Emission Calculations, Emissions Calculations Included in the 1995 Construction Permit Application, Table 3-2: Granite City Division of National Steel, Netting Analysis Summary – NOx (orig. 1/16/96).)

[134] US Steel has not shown that advantage was not taken of the permitted increase in the NOx emissions of the Project-affected fuel burning units provided for by Permit 95010001, as originally issued in 1996. The earliest that the actual NOx emissions of these units began to be enforceably lowered was in 2009 or 2010 in conjunction with the completion of construction and startup of the new cogeneration boiler.

[135] It should also be noted that the 250.3 tons/year decrease in NOx emissions that this comment indicates was "as calculated by the Illinois EPA" was actually provided by US Steel. (See the value for the NOx Change for Certain Fuel Burning Units in Table 6-8 of the Application.)

Project made by the Illinois EPA based on information in the Application. The lowest estimate for the corrected increase in the NOx emissions of the Project is more than 100 ton/years. Accordingly, in Alternative Table 6-8 the "NOx Change" for "Certain Fuel Burning Units" should be at least 100 tons/year, not zero tons/year. The corrected total increase for the Project then becomes at least 339.6 tons/year {19.4 (Casthouse) + 220.2 (BOF Shop) + >100 (Certain Fuel Burning Units) > 339.6). In Alternative Table 6-9, the corrected net increase in the NOx emissions of the Project becomes more than 113.1 tons/year, rather than 13.1 tons/year. {>339.6 (project increase) – 226.5 (contemporaneous and creditable decreases) > 113.1.) Thus, the Project would be a major modification for NOx with the requested revisions to Permit 95010001. The Application does not otherwise provide proof that if the corrected net increase in NOx emissions of the Project were properly evaluated in accordance with provisions of the NSR programs, the Project would not be a major modification for NOx.

In summary, the alternative revised NSR applicability analysis for the Project presented in this comment only shows a decrease in NOx emissions from the Project because this analysis relies upon post-project actions that have reduced the NOx emissions of the Project-affected fuel burning units.[136] In a proper revised NSR applicability analysis, which conforms to the relevant requirements of the NSR programs, the increase in NOx emissions from the Project-affected fuel burning units would be a positive amount, rather than being zero or negative. The increase in NOx emission from the Project would also be larger by that amount. As already discussed, the amount of this increase would almost certainly be large enough that the Project becomes a major modification for NOx given the increases in the

[136] In the alternative revised NSR applicability analysis presented in this comment, the assumption is that the NOx emissions of the Project-affected fuel burning units are now "unchanged." That is the magnitude of the "post-project" decreases that reduced their NOx emissions is such that their NOx emissions are now no more than their baseline NOx emissions (zero increase). Based on lowest estimate for the increase in the NOx emissions of these units with the Project made by the Illinois EPA, this is equivalent to the NOx emissions of these units now having been reduced by at least 100 tons/year compared to the NOx emission that were originally allowed by Permit 95010001.

The revised NSR applicability analysis in the Application indicates that the magnitude of the NOx emissions of the Project-affected fuel burning has actually been much greater, such that their NOx emissions are now at least 350 tons/year lower than their baseline emissions. Based on lowest estimate for the increase in the NOx emissions of these units with the Project made by the Illinois EPA, this is equivalent to the NOx emissions of these units now having been reduced by at least 350.3 tons/year (250.3 + 100.0 = 350.3) compared to the NOx emission that were originally allowed by Permit 95010001.

permitted NOx emissions of the Casthouse and BOFs that are requested by the Application.

E. Substantive Requirements of the PSD and NaNSR Programs Are Not Applicable with Respect to NOx Emissions

Because the Project would not become a major modification for NOx solely by virtue of the relaxations requested by US Steel, the substantive requirements of the PSD and NaNSR programs, i.e., the requirements of 35 IAC 203.601, 203.602, 204.1100, 204.1110, 204.1120 and 204.1130, are not required elements of the Application and the fact that these requirements are not addressed in the Application is not a valid basis for denial of the revised permit requested by the Application.

This comment does not show that the revision to Permit 95010001 requested by the Application should not be denied. If anything, this comment would present a reason why the requested revised permit should be denied. If one accepts for purposes of discussion that the requested increases in the permitted NOx emissions of the blast furnace casthouse and BOFs would not be solely due to the requested relaxations of the established limitations, as claimed by this comment, the Application does not identify or describe the "other cause(s)," i.e., reason(s) or purpose(s) for the requested revisions to the limitations for the blast furnace cathouse or BOFs established in Permit 95010001 other than correction of errors in the quantification of their emissions during the original permitting of the Project. The Application also does not address applicability of NSR with respect to the other cause(s) or reason(s) for the requested increases in the permitted emissions of these units, with new, "cause-specific" determinations of pre-project baseline emissions reflecting actual emissions prior to the occurrences of these other cause(s) or reason(s). Moreover, as the Application specifically requests increases in the permitted NOx emissions of the blast furnace casthouse and the BOFs of more than 200 tons/year, the Application does not show that these other cause(s) would not, by themselves, constitute a project that is a major NSR modification. Alternatively, if these other cause(s) would constitute a major NSR modification of the blast furnace casthouse and the BOFs, the Application does not address the substantive requirements of NSR as applicable relative to a major project due to those other cause(s) or reason(s). In other words, if one accepts the claim made in this comment, the Application is utterly deficient.

In fact, the Illinois EPA questions the truth of the claim made in this comment. US Steel submitted an Application that requested increases in or relaxations of the limitation established in Permit 95010001 for the

NOx emissions of the blast furnace casthouse and BOFs. If US Steel believed that the requested revisions to the established limitations for the NOx emissions of these units should be attributed to something other than errors in the original quantification of their emissions, it would have prepared the Application accordingly. Alternatively, US Steel would have submitted a separate application for a new construction permit to address that project.

IX. THE APPLICATION INCLUDES ALL REQUIRED INFORMATION PERTAINING TO PRE-PROJECT (BASELINE) AND POST-PROJECT NOx EMISSIONS CALCULATIONS ((DENIAL POINTS 2 AND 3))

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the Application is deficient in that it omits certain information that is purportedly necessary for Illinois EPA to validate the PSD/NaNSR non-applicability determinations. As explained below, these assertions are without merit.

A. Usage of Coke Oven Gas (COG) During the Pre-Project, Baseline Period (Denial Point 2)

In the Draft Denial Letters, Attachment 1, the Illinois EPA correctly observes that the updated calculations of the NOx emissions change from the Project include the difference between the pre-project and post-project actual emissions from certain fuel burning units and that the calculation of pre-project actual NOx emissions rates for some of these units includes consideration of NOx formed from burning of COG, among other fuels.
The Illinois EPA asserts that the pre-project COG usage rates used in calculating these emission contributions “are not accompanied by any documentation or explanation,” suggesting that it is not enough to identify the quantity of COG consumed in each type of affected fuel burning unit. With respect to an “explanation,” this assertion is incorrect. The Application discusses the use of COG as fuel during the pre-project baseline period.[137]

Notably, the documentation provided for COG in the Application is indistinguishable from the documentation provided with respect to other fuels, both in the Application and in the original application submitted by National Steel, which was accepted by Illinois EPA when issuing Permit 95010001 in 1996. In all cases, what was provided was a table of usage values, with no primary source documents such as strip charts, because it is neither required nor customary to provide such

[137] See*, e.g.,* pp. 2-4, 4-2, 5-5, and 11-2 of the Application. Information is also provided in the appendices to the Application.

documents. Of course, pursuant to 35 IAC 201.152, the Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application but that was not done here.[138]

With respect to additional documentation or further explanation, Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any particular documentation or explanation in conjunction with a historical operational rate or emissions rate, nor does it even point to even an application form or guidance document suggesting that such documentation or additional explanation be provided.

As this comment suggests that the requested data has been provided by the information in the Application, this comment does not respond to the deficiency addressed by Denial Point 2. This denial point relates to the absence of "supporting (emphasis added) documentation or explanation for the baseline usage of COG utilized in the revised netting analysis." (Draft Denial Letter, December 2023, p. 8.) This comment does not show that the Application contains such supporting information. While the Application does explain that COG was used as fuel in certain Project-affected fuel burning units during the baseline period, as observed in this comment, this does not constitute support for the specific data in the Application for the baseline usages of COG in these units.

Although, the data for baseline usage of COG provided in the Application may be superficially characterized as indistinguishable from the data provided for usage of other fuels, there is a critical difference from that other data. The data provided for baseline usage of BFG and natural gas reflects data originally provided by National Steel. (Application, Appendix C – Emission Calculations, Emissions Calculations Included in the 1995 Construction Permit Application, Table 3-2: Granite City Division of National Steel, Netting Analysis Summary – NOx (orig. 1/16/96)). However National Steel did not provide data for usage of COG. As such, it is reasonable and appropriate for US Steel to provide supporting information or other explanation for how it obtained or developed the data in the Application for usage of COG.[139]

---

[138] See, *e.g.*, 35 IAC 201.152, which provides that, "The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted."). (Footnote 25 of US Steel's Comments of January 2024.)

[139] **For example, was data for the usage of COG available for the individual Project- affected fuel burning units? If not, how was the data for COG usage of individual units or groups of similar units derived from aggregate data for usage of COG or from data for coke production?**

Absent such information, the Application does not provide proof that the baseline emissions of NOx attributable to use of COG provided in the Application should be considered accurate and should properly be relied upon for the purpose of the requested revisions to Permit 95010001.

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. An application is not shielded from denial because the Illinois EPA did not formally request the applicant to supplement, revise or replace the application to remedy deficiencies in the application. The application must include information that is sufficient to provide proof that the facility or equipment that is the subject of the application will not violate applicable provisions of the Act and the Illinois Code. In this regard, this comment does not even address the provisions of the Act and the Illinois Code that might be violated if a revised permit were issued without information as addressed by this denial point, i.e., Sections 9(a), 9.1(d) and 39(a) of the Act and 35 IAC 201.152 and 201.160, as identified in the Revised Draft Denial Letter. The fact that the second sentence of 35 IAC 201.152[140]

---

[140] It is noted that in this comment, the footnote providing the text of 35 IAC 201.152 only provides the second sentence of this rule. This is the sentence that addresses the procedures that the Illinois EPA may adopt to elaborate upon the required contents of a construction permit application. The first sentence of this rule, which provides certain explicit requirements for the content of applications for air pollution control permits, is provided below.

> **Section 201.152 Contents of Application for Construction Permit**
> **An application for a construction permit shall contain, as a minimum, [emphasis added] the following data and information: The nature of the emission unit and air pollution control equipment, including the expected life and deterioration rate; information concerning processes to which the emission unit or air pollution control equipment is related; the quantities and types of raw materials to be used in the emission source or air pollution control equipment; the nature, specific points of emission and quantities of uncontrolled and controlled air contaminant emissions at the source that includes the emission unit or air pollution control equipment; the type, size, efficiency and specifications (including engineering drawings, plans and specifications certified to by a registered Illinois professional engineer) of the proposed emission unit or air pollution control equipment; maps, statistics and other data reasonably sufficient to describe the location of the emission unit or air pollution control equipment. …**

As the first sentence of 35 IAC 201.152 explicitly requires certain information to be provided in an application, it addresses information describing the subject of an application, e.g., the emission units and air pollution control equipment and their emissions. The specific information that might need to be

acknowledges that the Illinois EPA may adopt procedures further specifying the required contents of applications for air pollution control construction permits does not mean that the Illinois EPA must adopt such procedures.[141]

B. NOx Emission Factor for Use of COG in Boilers 11 and 12 (Denial Point 2)

In the draft denial letters, in Attachment 1, the Illinois EPA correctly observes that Table 6-4 in the Application indicates the emission factor used in calculating the amount of NOx formed from combustion of COG gas in the boilers during the pre-project baseline period is based on emissions testing performed at one of the by-product coke oven batteries.

The "basis for the emission factor" indicated in Table 6-4 of the Application is a "scrivener's error," a minor mistake in the Application. This error was pointed out to US Steel's consultant by Illinois EPA staff by telephone in January 2023. The factor is actually based on emission testing performed at Boiler 12, which is one of the boilers whose NOx emissions are the subject of the calculation. This fact was conveyed to Illinois EPA staff by telephone in January 2023.

As indicated by this comment, there is a material mistake in Table 6-4 of the Application. While US Steel may view it to be minor, so as to be able to be characterized as a "scrivener's error," this does not act to alter the Application. In this regard, the deficiency in the Application addressed by this Denial Point is not that the emission factor used to calculate the NOx emissions from the use of COG by 12 boilers at the facility in 1996 is incorrectly shown as being based on emissions testing on the combustion stack of one of the coke oven batteries. The deficiency is that the calculations for NOx emissions of boilers attributable to use of COG cannot be accepted as accurate and relied upon for issuance of the revision to Permit 95010001 requested by the Application. This is because Table 6-4 indicates that these calculations use an emission factor that was based on testing of the

---

provided in particular permit applications to show compliance with the applicable substantive requirement in the Illinois Code is not addressed. In this regard, this rule recognizes that the information that is specified is only the minimum information that must be contained in an application.

[141] **Even if the Illinois EPA had adopted procedures elaborating on the required contents of applications for air pollution control construction permits, it would be extraordinary for such procedures to address the unique circumstances that are presented with the Project for the use of coke oven gas (COG) at the Granite City Works. The emissions of NOx that are now of concern for use of COG were not addressed in 1996 when Permit 95010001 was initially issued for the Project. The Application now requests that the NSR applicability analysis for the Project for NOx be revised to account for such NOx emissions.**

combustion stack of a by-product coke oven battery. The NOx emissions from the combustion of COG at a by-product coke oven battery for heating of the coke ovens, as is measured at the combustion stack of a by-product coke oven battery, cannot be assumed to be similar to those from burning COG in a boiler. This is discussed in the Draft Denial letter (For example, see Footnotes 14 and 15 of the Revised Draft Denial Letter).

In this regard, the telephone conversations between US Steel's consultant and a staff member at the Illinois EPA reviewing the Application, as described in this comment, did not and could not act to change the Application. Moreover, these conversations did not even result in an informal resolution to the basic issue posed by the calculation in the Application for the NOX emissions of boilers from use of COG. This is that the NOx emissions factor used in these calculations did not appear representative. In particular, as discussed in the Denial Letters, the emissions calculations for the boilers use a NOx emission factor of 404 pounds/million cubic feet of COG; the USEPA's Webfire Database provides a much lower factor, 80 pounds/million cubic feet of COG.[142] Absent the submittal of information to resolve this issue, the Application does not provide proof that the baseline emissions of NOx attributable to use of COG provided in the Application should be considered accurate and, accordingly, can properly be relied upon for the purposes of the requested revision to Permit 95010001.

C. Emission Factor for Use of Natural Gas in Ladle Preheaters (Denial Point 3)

In the Draft Denial Letters, Attachment 1, the Illinois EPA correctly observes that, in the calculations presented in the Application in support of the pre-project actual NOx emissions from certain fuel combustion units affected by the Project, US Steel used a single emission factor for all such units, including ladle preheaters. The Illinois EPA then asserts that the Application "does not show that it is appropriate to utilize this emissions factor for ladle preheaters." Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that an application include any particular documentation or justification for the emission factors used to estimate historical emissions, nor does it point to even an application form or guidance document suggesting that such documentation or justification be

[142] Incidentally, the recollection of the Illinois EPA staff member that participated in these telephone calls is that it was stated that US Steel personnel were looking for a copy of the report for the testing that was believed to be the basis of the NOx emission factor that was used for burning COG in boilers. A copy of that report would be provided to the Illinois EPA when it was located. However, a copy of such a test report was not provided to the Illinois EPA.

provided. Notably, for a period of nearly 30 years, the emission factor at issue has been used consistently for all purposes pertaining to the permitting of the Project and has been accepted by Illinois EPA for that purpose.[143] In light of Illinois EPA's repeated acceptance of and reliance on this emission factor for calculating NOx emissions from burning natural gas in ladle preheaters in numerous permitting actions over a period of nearly 30 years, including several permitting actions occurring prior to US Steel's ownership of the facility, US Steel reasonably concluded that no further justification was needed as part of the permit application submitted in March 2020 and supplemented in October 2022.

A lengthy response to this comment is not needed because this comment, by omission, acknowledges that the Application does not show that the emission factor used for ladle preheaters in the calculations for NOx emissions is appropriate. Instead of attempting to show that this factor accurately represents the NOx emissions of these units, the comment instead explains why it was reasonable for US Steel to assume that the NOx emission factor used for these units would be acceptable. However, absent information in the Application providing proof that the NOx emission factor for the ladle preheaters used in the calculations in the Application should be considered representative, those calculation cannot properly be relied upon for the purposes of the requested revision to Permit 95010001.

By way of some brief observations, it is unquestioned that information provided in permit applications must be accurate.[144] In the Application, US Steel elected to revisit the original NSR applicability analyses for the Project. Therefore, the obligation to use appropriate emission factors in the revised analyses in the Application clearly rests with US Steel. This obligation is not met by reference to prior permitting by National Steel. As further discussed in General Response 1, US Steel also cannot avoid this obligation by simply pointing to historic decisions by the Illinois EPA. When acting upon the Application, the Illinois EPA is not required to perpetuate

---

[143] *See, e.g.,* "Calculation Sheet" prepared by Jim Ross of Illinois EPA, Dec. 5, 1995 (summarizing Illinois EPA's review of the application submitted by National Steel, which was initially filed with the Illinois EPA on Jan. 3, 1995) at p. 12; application supplement submitted by National Steel Jan. 16, 1996, at p. 3-2; Permit 95010001 as issued Jan. 25, 1996, at Table 4; Permit 95010001 as revised Dec. 17, 2012, at Table 4; Construction Permit 95010001 as revised Dec. 17, 2012, at Table 4 (Footnote 26 of US Steel's Comments of January 2024.)

[144] **This comment does not address the provisions of the Act and the Illinois Code that the Revised Draft Denial identifies as potentially being violated if a revised permit were issued without information as addressed by this denial point, i.e., Sections 9(a), 9.1(d) and 39(a) of the Act and 35 IAC 201.152 and 201.160.**

any past mistakes that may have been made. As explained in the Draft Denial Letters, it is questionable that emission factors developed for boilers like those being addressed accurately represent the NOx emissions of ladle preheaters. Ladle preheaters heat the refractory on the interior surface of ladles by direct heat transfer, rather heating water by indirect heat transfer. The rated heat input capacities of individual ladle preheaters are also lower than the rated heat input capacities of the various boilers.

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, The fact that particular emission factors have been accepted or have not been questioned by the Illinois EPA in past permitting actions does not preclude reexamination of those factors by the Illinois EPA as part of proposed revisions to Permit 95010001. In addition, the fact that particular emissions factors may have previously been accepted by the Illinois EPA during permitting does not show that the Illinois EPA has prescribed the use of such factors on an ongoing basis. Nothing in the cited permits identifies the subject emission factors as being prescribed factors, rather than being emission limits.[145] Nothing in the public comment periods associated with the issuance of a few of these permits indicated that such limits were intended to be prescribed emission factors. Moreover, even if this had been the case, this would not serve to preclude reevaluation of those emissions factors as part of the requested revisions to Permit 95010001.

---

[145] As discussed in the Draft Denial Letters, the provisions in Permit 95010001 that are in the form of emission factors (e.g., are in pounds of pollutant emitted per unit of throughput, output or fuel input), are enforceable emission limitations.

By way of further explanation, the emission factor limits currently in Permit 95010001 are addressed in the Draft Denial Letters because the Application requests that this permit be revised to no longer include these limits. Instead, as generally discussed in Footnotes 24 and 31 in the Draft Denial Letters, as necessary to enforceably limit emissions to address nonapplicability of NSR for various pollutants, only the annual emissions of various groups of related Project-affected units would be limited. In the Application, these limitations on annual emissions are referred to as "emission caps." This revision to Permit 95010001 would facilitate resolution of the two appeals of air pollution control permits currently pending with the Illinois Pollution Control Board (PCB 2013-053 and PCB 2013-062).

In addition, for certain Project-affected units, in place of enforceable emission factor limits, the Application requests that the revision to Permit 95010001.prescribe or specify the particular emission factor(s) that US Steel must use on an ongoing basis when showing compliance with the relevant annual emission cap(s). (For example, refer to Comment XII.C and Denial Point 10 as it addresses uncaptured NOx and VOM from the blast furnace cast house, which emissions occur the through the roof monitor on the casthouse.)

D. Emissions from Use of Natural Gas on the Continuous Casting Lines (Denial Point 2)

In the Draft Denial letters, Attachment 1, the Illinois EPA correctly observes that in the calculations in the Application supporting the pre-project actual NOx emissions from units affected by the Project, US Steel indicated there is no NOx formation from the continuous casting operation other than from combustion of natural gas and, because all natural gas consumption in the continuous casting operation is accounted for elsewhere, US Steel did not account for any additional pre-project actual NOx emissions from the continuous casting operation.

Illinois EPA then incorrectly asserts that US Steel's failure to double-count the pre-project actual NOx emissions from the continuous casting operation is "problematic." US Steel's election not to overstate the pre-project actual NOx emissions from emissions units affected by the Project is correct and appropriate, as it best represents the increases in actual emissions with the project, consistent with the requirements of the PSD and NaNSR rules. However, the manner in which the usages of natural gas and associated NOx emissions during the pre-project baseline period was presented in the Application is unclear. This lack of clarity appears to have caused confusion on the part of the Illinois EPA.

The total pre-project baseline actual NOx emissions from natural gas used in certain units affected by the Project is correct. In this regard, this information reflects information provided in Table 3-2 in National Steel's original application. The total natural gas usage by the affected units during the pre-project baseline period is 1,145 million cubic feet (cf) /year, with 57 million cf/year attributable to the continuous casting operations. The total associated NOx emissions attributable to burning natural gas during the baseline period are 175.18 tons/year, including 8.72 tons/year from the continuous casting operations.[146] What was likely confusing is that

[146] The complete information for natural gas usage during the pre-project baseline period, as shown in Table 3-2 of National Steel's application, is provided below. (Table 3-2 in the application supplement submitted by National Steel Jan. 16, 1996, a copy of which is provided in the Application in Appendix B - Emission Calculations.)

Information on Usage of Natural Gas and Associated NOx Emissions, As Extracted from Table 3-2: Granite City Division of National Steel: Netting Analysis Summary – NOx					
Unit(s)/Fuel	NOx Emission Factor (lb/mmcf)	Base Year Usage (mmcf)	Actual Emission (T/Y)	Projected Usage (mmcf)	Projected NOx Emissions (T/Y)

National Steel's projection of the total post-project natural gas usage in the affected units, including the continuous casting operations, was the same as the pre-project amount, both being 1,145 million cf/year. In other words, the Project would not entail an increase in natural gas usage from the baseline level.

When issuing Permit 95010001 in 1996, the Illinois EPA set limitations on total post-project natural gas usage (1,145 million cf/year) and total post-project NOx emissions from burning natural gas (175.19 tons/year). (Permit 95010001, issued January 26, 1996, Condition 21 and Table 4). These limits match the information shown in Table 3-2 of National Steel's application, which did address natural gas usage by the continuous casting operations. In Condition 21 and Table 4 of this permit, the Illinois EPA also listed the fuel burning units to which these limitations applied. Almost certainly inadvertently, the Illinois EPA omitted the continuous casting operations from the listings of units to which these limitations applied. For the Project, it is undisputed that Illinois EPA accepted and relied upon both the baseline information and the projections presented in Table 3-2 of National Steel's application related to usage of natural gas and associated emissions.[147]

In the prior application submitted in March 2020 and in the Application, the total natural gas usage by affected units during the pre-project baseline period is shown as 1,145 million cf/year. However, consistent with the Illinois EPA's error in drafting Permit 95010001, US Steel omitted the continuous casting operations from the list of units burning natural gas and contributing to the total associated NOx emission from burning natural gas with project. Nevertheless, as explained above, the contribution of the continuous casting operations to NOx emissions from natural gas combustion were actually accounted for, both in pre-project baseline emissions and in

Boiler House 1 (Blrs 1-10) – NG	306	361	55.23	included below	
Boiler #11 – NG	306	226	34.58	included below	
Boiler #12 – NG	306	218	33.35	included below	
BOF Preheaters/Dryers – NG	306	283	43.30	included below	
Continuous Caster #1 & #2 – NG	306	57	8.72	included below	
Totals		1,145	175.18*	1,145	175.19*

* These numbers appear as not being the same due to the difference in the rounding of results, with baseline emissions being the sum of separate calculations for emissions and the project emissions being the result of a single calculation for emissions.

[147] The total NOX emissions increase from the Project, prior to contemporaneous emissions decreases, as addressed by Permit 95010001 in 1996, is also the same as shown by National Steel in Table 3-2. i.e., 238.8 tons/year. (Permit 95010001, issued January 26, 1996, Condition 42 and Table 6.)

the post project emissions.

This comment does not actually respond to the relevant deficiency in the Application identified by the Illinois EPA in the Draft Denial Letters. Moreover, it also identifies an error in the Application as the Application perpetuates an error in Permit 95010001 on the units that are identified as being subject to certain limitations set by this permit. That is, the Application continues to omit the continuous casting operations from the limitations set by this permit for the usage of natural gas and associated emissions.

Specifically with regard to Denial Point 2 as it addresses the NOx emissions of the continuous casting, the Illinois EPA did not claim that the Application's "failure to double-count" certain NOx emissions was problematic. Indeed, the Illinois EPA did not express concern about historic double-counting and, as explained by this comment, the original approach to baseline usage of natural gas and baseline NOx emissions were not inflated due to double-counting. Rather, the Denial Letters indicated that the corrections proposed by the Application were problematic for several reasons, as they did not fully address the issues associated with accounting in the Application for the NOx emissions of the continuous casting operations. The first issue is that the Application does not appear to address NOx emissions from the natural gas-fired torches used in the slab cutting and slab ripping processes that take place as part of continuous casting or otherwise show that these processes do not emit NOx. (For example, are there any such emissions? Does Permit 95010001 actually account for such emissions? Should the listing of units whose usage of natural gas is limited be broadly stated so as to simply apply to the "continuous casting operations"?) Second, the Application does not show that the NOx emissions factor used to calculate NOx emissions from burning of natural gas in the continuous casting operations, 306 pounds/million cf, which is proposed to be used for other units burning natural gas is also appropriate for use for the caster molds. Third, the Application does not identify the caster molds as "Project-affected fuel burning units," with the blast furnace stoves, boilers, etc., in the various listings of Project-affected fuel burning units in the Application (e.g., Application, Table 6-5).

E. Post-Project NOx Emissions (Denial Point 3)

In the draft denial letters, Attachment 1, the Illinois EPA asserts that the Application is deficient because it does not include supporting information related to the maximum future NOx emissions of 706 tons per year from the certain fuel burning units affected by the Increase Project, such as "the maximum annual amounts of fuels burned in these units" and "the emission factors used to calculate annual emissions." As discussed in detail in other comments (US Steel Comment

XII.J), US Steel included all of this information in the permit application submitted in March 2020 but omitted it from the Application based on Illinois EPA's informal comments regarding the initial submittal. Notably, the Application does not request a new construction permit; rather, it requests revision of an existing permit, which existing permit has since 1999 limited the NOx emissions from the Project-affected fuel burning units to 706 tons per year. Because the Application requests no change in the maximum NOx emissions from the fuel burning units, US Steel reasonably assumed that no additional information was needed with respect to this calculation.

Of course, in accordance with 35 IAC 201.152, the Illinois EPA retains authority to request additional information in conjunction with a construction permit application, but that was not done here.

This comment does not show that the Application should not be denied. As a preliminary matter, the claim made in this comment is false. The information that is lacking in the Application, which is the reason for this denial point, was not provided in the earlier application received by the Illinois EPA in March 2020. In fact, in that application, the proposed revised NOx emissions cap from "certain fuel burning units" was 632.5 tons/year (March 2020 application, p. 8-7, Table 8-8). As such, that application would not have provided supporting information for a proposed value for post-project NOx emissions of these units of 706 tons/year. The value of 706 tons/year for the proposed revised NOx emissions cap for these units first appeared in the Application, i.e., the current application, as submitted in October 2022. (Application, pp. 6-6 and 6-7, Tables 6-6 and 6-7.) It is perhaps noteworthy that Table 8-8 in the March 2020 application also shows an increase in the NOx emissions of these units with the Project of 137.4 tons/year (the difference between the revised baseline emissions of 495.2 tons/year and proposed revised emission cap of 632.5 tons/year as provided in the application).

More generally, as related to the revised NSR applicability analysis for NOx in the Application, this analysis cannot simply rely on certain elements of a previous analysis without showing that those elements are still correct and appropriate. In the Application, US Steel provides a revised NSR applicability analysis for NOx with the objective of showing the Project would still not be a major modification for NOx for purpose of NSR with the requested increases in the permitted NOx emissions of the blast furnace casthouse and the BOFs. The revised NSR analysis addresses higher NOx emissions from the casthouse and BOFs with the Project. It also accounts for NOx emissions from Project-affected fuel burning units from use of COG, which was not done in previous NSR analyses. The baseline NOx emissions of these fuel burning units in the revised NSR analysis are now higher than in the original NSR analysis. To the extent that there are errors that overstate the

baseline NOx emissions of these units, as would be perpetuated by using a value of 706 tons/year for emissions of the Project, the requested revised permit would potentially allow circumvention of the substantive requirements of NSR for a major modification for +NOx. Finally, as part of the Application, US Steel also requests that the current emission factor limits for Project-affected fuel burning units be eliminated and their NOx emissions be addressed with, at most, annual limitations for their NOx emissions. This is more than enough to support the reopening of the entire revised NSR analysis, with explanation and justification for this analysis by US Steel in the Application and opportunity for scrutiny by the Illinois EPA. In summary, the fact that since 1999, Permit 95010001 has suggested that it allows NOx emissions from the Project-affected fuel burning units of 706 tons/year is not sufficient support to justify use of this value in the revised NSR applicability analysis for NOx.[148] In addition, in light of the above, it is questionable that the Illinois EPA ever suggested in informal discussions on the March 2020 application that support for information in the revised NSR applicability analyses should not be included in the application for revisions to Permit 95010001.

Finally, as already discussed and as addressed in General Response 1, 35 IAC 201.152 does not act to block denial of a permit application if the application does not include information providing proof of compliance with relevant requirements. As this rule provides that the Illinois EPA may adopt procedures elaborating on the required contents of air pollution control permit applications, it does not require that the Illinois EPA adopt such procedures.

---

[148] In fact, for Project-affected fuel burning units, Condition 22 and Table 4 of Operating Permit 95010001, as issued in 1999, specifically limits NOx emissions from use of natural gas to 205.94 tons/year, use of BFG to 488.48 tons/year, and use of fuel oil to 10.04 tons/year. The sum of these individual limits is 704.46 tons/year. (These limits were not altered when Construction Permit 95010001 was revised in December 2012.) The value of 706 tons/year, which is in Table 5 of these permits, is more than the sum of the fuel-specific limitations. As such, it is unclear that Permit 95010001 has in practice ever allowed NOx emissions of 706 tons/year from the Project-affected fuel burning units, even assuming that this overall limit was not intended to also limit NOx emissions from use of COG in these units.* Thus, the Application actually proposes a new value for the overall permitted NOx emissions of the Project-affected fuel burning units with the Project.

*** Table 4 of Permit 95010001 has never included specific limits for the emissions of NOx from burning COG in the affected units. The applications that were the basis of these permits did not quantitatively address those NOx emissions. These NOx emissions were first quantified and explicitly addressed in the revised analysis of NSR applicability for NOx in the Application.**

X. THERE ARE NOT QUANTIFIABLE FUGITIVE EMISSIONS OF NOx OR VOM FROM THE BOFs (DENIAL POINT 4 – NOx and VOM[149])

In the draft denial letter, Attachment 1, the Illinois EPA states that the Application "does not address uncaptured emissions" of NOx and VOM from the BOFs and that the emissions calculations presented in the Application reflect an assumption "that all emissions of these pollutants from the BOFs are now captured" and routed to atmosphere through the electrostatic precipitator or baghouse. Illinois EPA also acknowledges that such uncaptured emissions, if they exist, are not significant and that, if estimated quantities of such uncaptured emissions were added to the calculations supporting the PSD/NaNSR non-applicability demonstrations, would yield smaller (rather than greater) emissions increases.

With one minor exception, Illinois EPA's general statements characterizing the emissions increase calculations presented in the Application, as summarized above, are correct. The minor exception is this: The application does not reflect an assumption that there are zero uncaptured emissions of NOx and VOM from the BOFs but rather reflects the conclusion that, if there are any such uncaptured emissions, those emissions are fugitive emissions[150] and are not quantifiable. Fugitive emissions are counted for purposes of PSD and NaNSR applicability determinations only to the extent that such emissions are quantifiable.[151] The emissions capture systems serving the

---

[149] In this comment, US Steel only responded to Denial Point 4 as it addressed the deficiency in the Application that emissions of NOx and VOM that occurred through the roof monitor on the BOF Shop. It did not respond to the denial point as it also addressed uncaptured emissions of carbon monoxide (CO) through the roof monitor. As such, this comment does not show that the Application should not be denied based on Denial Point 4, as has now occurred, because it did not address uncaptured emissions of CO, which occur through the roof monitor.

In its Comment VI, US Steel does acknowledge the fact that the Application does not address the uncaptured CO emissions of the blast furnace casthouse in the revised CO air quality analysis for the Project provided in the Application. This analysis reflects a greater increase in CO emissions from the Project, as described by the Application, compared to the original quantification of the emissions of the Project by National Steel, which has been found to understate the CO emissions increase from the Project. As explained in its response to US Steel's Comment VI, this comment also does not show that the fact that the Application does not consider uncaptured CO emissions in the revised CO air quality analysis in the Application is not a reason why the Application should not be denied.

[150] Fugitive emissions are "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." 40 CFR 52.21(b)(20). (Footnote 33 in US Steel's Comments of January 2024.)

[151] See, *e.g.*, 40 CFR 52.21(i)(4)(vii)(exempting a project from PSD permitting requirements if it would be major "only if fugitive emissions, to the extent

BOFs satisfy the stringent requirements of 40 CFR Part 63 Subpart FFFFF, which reflects USEPA's determination of the maximum degree of reduction in emissions that is achievable for existing BOFs. (Section 112(d)(2) of the federal Clean Act (42 U.S.C. 7412(d)(2)).) These capture systems reflect the state of the art and that, to the extent there are any uncaptured emissions of NOX or VOM, those emissions could not reasonably be captured or controlled and thus are fugitive emissions.

Although Illinois EPA presents speculation regarding possible fugitive emissions of NOX and VOM from the BOFs, that speculation is not a sufficient basis to determine that such emissions exist and are quantifiable. Neither US Steel nor Illinois EPA has not identified any evidence of such quantifiable emissions in the literature or in the permitting records of other iron and steel mills.
The fact that there are fugitive particulate emissions from the BOFs is not indicative of the formation of NOX or VOM emissions. The capture system for the baghouse for the BOFs is a large ventilation system that generally evacuates the space around the BOF vessels during charging, refining, and tapping. The primary mechanism for formation of particulate during charging and tapping is the oxidation of molten metal. This formation mechanism cannot be expected to result in the formation of NOx or VOM.

This comment does not show that there is not a deficiency in the Application as addressed by this denial point, much less meaningfully challenge this denial point. Rather, this comment reflects a misapplication of the term "fugitive emissions," as defined in the NSR rules. The deficiency in the Application addressed in this denial point involves "uncaptured emissions" from the BOF, not fugitive emissions. Even if the capture systems serving the control systems of the BOFs are state-of-the art, this is irrelevant.[152] USEPA's commentary in

---

quantifiable, are considered" and it would occur at a source that is not in a listed source category); *see, also,* 45 FR 52676 at 52692 (Aug. 7, 1980)(USEPA explains that it is declining to extend the exemption at § 52.21(i)(4)(vii) to the listed source categories, such as iron and steel mills, but stated, "EPA emphasizes, however, that fugitive emissions from a source in one of the listed categories will only be included in threshold calculations 'to the extent quantifiable'"). (Footnote 33 in US Steels Comments of January 2024.)

[152] Whether the capture systems in the add-on particulate control systems serving the BOFs are state-of-the-art is also arguable. A determination by USEPA as to what is appropriate for capture of emissions as a matter of rule in the context of a NESHAP rulemaking should not be assumed to be transferable to determinations for what should be considered reasonable for the possibility of enclosure and capture of emissions for purposes of the NSR definition of fugitive emissions. In addition, if the BOF shop at the Granite City Works were new for purposes of the NESHAP, 40 CFR 63.7790(a) would set a more stringent limit for the opacity of emissions from the roof monitor, i.e., 10 percent

rulemakings concerning fugitive emissions, as cited in this comment, is not applicable. Rather the NOx and VOM emissions addressed in this denial point are governed by the fundamental principle that air pollution control permit applications must accurately and reasonably reflect or address the emissions of the units for which a permit is requested.

By way of explanation, the terms "uncaptured emissions" and "fugitive emissions" are not synonymous. Uncaptured emissions are the emissions of unit(s), which although served by control system(s), do not pass through those system(s). In other words, uncaptured emissions are the emissions that go directly to the atmosphere bypassing the control system(s). Uncaptured emissions, as is the case for uncaptured emissions of the BOFs, are not necessarily fugitive emissions. Uncaptured emissions may still enter the atmosphere through a stack, vent or other functionally equivalent opening, as occur for the BOFs as their uncaptured emissions enter the atmosphere through the roof monitor on the building housing the BOF shop. In this regard, this comment does not explain why the NOx and VOM emissions that are addressed by this denial point should be considered fugitive emissions even though they enter the atmosphere through a roof monitor. Accordingly, as this comment is based on the NOx and VOM emissions at issue being "fugitive emissions" rather than "uncaptured emissions," the comment is not responsive to this denial point.

The claim that this denial point is insufficient because the Illinois EPA does not show that there are "fugitive emissions" is baseless. First, US Steel must address uncaptured emissions of the BOFs in its permit application as revisions to Permit 95010001 are requested to increase the permitted emissions of the BOFs such the Project would become a major modification for NOx for both PSD and NaNSR. Under the NSR programs, as the Granite City Works are an iron and steel mill, USEPA has explained that US Steel would, at most, only be excused from addressing fugitive emissions in threshold calculations for NSR applicability to the extent that those emissions are not quantifiable. However, US Steel has not made a showing that the emissions of NOx and VOM through the roof monitor serving the BOFs are not quantifiable. Estimates for the amounts of these emissions can be made from: 1) the results of testing of the captured emissions of NOx and VOM, which occur through the stacks of the electrostatic precipitator (ESP) and baghouse that control particulate emissions of the BOFs, and 2) engineering design and calculations for the capture efficiency achieved by these control systems for the emissions of the BOFs. This is what

---

opacity on a 3-minute average, except for one period during each steel production cycle with opacity greater than 10 percent but less than 20 percent. As this BOF shop is considered an existing shop, the NESHAP limits the opacity from its roof monitor to only 20 percent opacity on a 3-minute average.

was done for the uncaptured particulate emissions of the BOFs, which also are not directly measured.

This claim is also flawed because it downplays the fact that the existence of uncaptured emissions of NOx and VOM from the BOFs was overlooked during the original permitting of the Project.[153] The representation in this comment about the origins of the NOx and VOM emissions specifically addresses the primary mechanism for formation of particulate during charging and tapping of BOFs, then claiming, without any support, that this mechanism cannot be expected to result in the formation of NOx and VOM. This does not address mechanisms that might directly result in the formation of NOx and VOM during charging and tapping of the BOFs. For example, during charging are NOx and VOM formed by the oxidation of nonmetallic material present in the scrap metal, such as paint or plastic? Since the BOF shop is equipped with a roof monitor and is not a closed building, to what extent do uncaptured emissions of NOx and VOM from the BOFs consist of a portion of the NOx and VOM formed in the BOFs vessels during refining that simply eludes capture by both the ESP and baghouse control systems? Even if a search of the literature or permitting records for other steel mills indicates that uncaptured emissions of NOx and VOM have not been previously addressed, this does not show that such emissions do not exist. The traditional focus for control of emissions of BOFs has been on their particulate emissions, which are amenable to add-on control.

Finally, this claim is flawed because it does not consider the empirical evidence indicating the existence of uncaptured emission of NOx and VOM from the BOFs, as discussed in Denial Point 4 in the Draft Denial Letters. The emission testing conducted for the new baghouse control system for the BOFs measured emissions of NOx and VOM in the

---

[153] As cited in Denial Point 4, with respect to the NOx emissions of the BOFs, the Application explains the following. (A similar statement is made for VOM emissions.) The Application does not go on to address whether the Application fully addresses the uncaptured emissions of NOx and VOM of the BOFs that were overlooked in 1996.

> **At the time of the 1999 Application, the BOF Shop did not include a baghouse to capture secondary emissions. Secondary emissions were released to the atmosphere through the BOF Shop roof monitor. No information was available at that time about the NOx emissions from the BOF Shop roof monitor. Since then, the BOF Shop includes a capture system for secondary emissions that are routed to a baghouse. NOx emission testing for the BOF Shop baghouse, completed in 2019-2020 timeframe, shows an average NOx rate of 0.0075 lb/ton for the BOF Shop Baghouse stack, USS Granite City added the BOF Shop secondary NOx emission baseline based on the result of the stack test for the BOF Shop Baghouse stack.**
>
> **Application, p. 6-4, Section 6.2.6 "BOF Baghouse – Secondary Emissions (New)".**

exhaust from the baghouse. As this baghouse system was installed to enhance control of particulate emissions from charging and tapping of the BOFs, a portion of these measured NOx and VOM emissions should be attributed to the improvement to the capture of emissions from charging and tapping of the BOFs provided by this new system. However, with respect to emissions of particulate, the Application does not suggest that 100 percent capture of the particulate emissions of the BOFs is now achieved, instead still accounting for the presence of uncaptured particulate emissions through the roof monitor on the BOF shop. This indicates that there are also still uncaptured emissions of NOx and VOM from the BOFs even with the improvement in capture of emissions provided by the new baghouse system.

XI. THE APPLICATION INCLUDES ALL REQUIRED INFORMATION PERTAINING TO PRE- PROJECT (BASELINE) PARTICULATE MATTER EMISSIONS CALCULATIONS (DENIAL POINT 11 – DEFICIENCY WITH REGARD TO BASELINE EMISSIONS)

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the Application is deficient for the following reason:

> With regard to baseline particulate emissions, the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not provide needed supporting information for the "corrected" determinations of baseline particulate emissions of these operations as it is not accompanied by detailed calculations for the emissions from handling each material.

The assertion regarding a deficiency in the application is, without merit. The Application includes all information required by the applicable permitting rules. The Illinois EPA's characterization of these pre-project (baseline) emission rates as "corrected" is erroneous. These are the values presented in the original permit application submitted by National Steel and accepted by Illinois EPA when issuing Permit 95010001 in 1996.[154] US Steel made no change to these values and is not in possession of information that would allow such change. In light of Illinois EPA's acceptance of and reliance on these values during that prior permitting action, which preceded US Steel's ownership of the facility, US Steel reasonably concluded that

[154] The Application indicates that this information is provided in Table F-3 of National Steel's application, "Granite City Division of National Steel: Base Case PM10 Emissions and Contemporaneous Emissions Reductions – Material Handling Table." A copy of Table F-3 is included in the Application in Appendix B, "Emissions Calculations."

no further justification was needed as part of the present permit application.

The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any particular supporting information, nor does the Illinois EPA point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application pursuant to 35 IAC 201.152, but that was not done here.

This comment does not show that there is not a deficiency in the Application and the Application should not be denied. As explained in this denial point, the deficiency in the Application is that the summary information for PM10 emissions in National Steel's Table F-3 is not sufficient. This table only provides information for emissions on an annual basis. It does not include calculations and background information for how annual emissions from handling the various material were determined, including the specific emission units that were addressed. Table F-3 also only provides information for the PM_{10} emissions of these operations, not the PM emissions. However, in the Application, like current Permit 95010001, baseline PM emissions are unrealistically assumed to be no more than the PM_{10} emissions. As such, it is reasonable for concerns to exist about the nature of and the accuracy of the information for baseline particulate emissions from handling of coke, pellets, and limestone, as represented in the Application in Table 5-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM Emissions Factors for Affected Units" and Table 5-6, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM_{10} Emissions Factors for Affected Units,", as they rely on Table F-3 from National Steel's application.[155] The presence of errors in this

[155] It is also noteworthy that Permit 95010001, Table 5, "Limits on Emissions from Major Processes Activities," indicates that the PM and PM_{10} emissions of the subject material handling operations should both be no more than 2.0 tons/year. In fact, the Application requests that revised Permit 95010001 provide for more than 2.0 tons/year of PM and PM_{10} emissions from the subject operations. This is an aspect of revised NSR applicability analyses for the Project for PM and PM_{10}, as summarized in the tables in Appendix B of the Application, "USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis," and "USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis." As the Application requests a revision to a provision in Permit 95010001 that currently addresses the emissions of the subject operations, it is essential that the Application include supporting information for the baseline emissions of the subject operations as now being represented in the Application.

information would have become apparent and likely avoided if US Steel had provided detailed calculations in the Application for the baseline emissions of these operations.[156] In summary, this comment did not show that the Application should not be denied based on Denial Point 11 as it addresses a deficiency in the Application with regard to the information that is provided for the baseline emissions of these material handling operations.

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. The application must include information that is sufficient to provide proof that the facility or equipment that is the subject of the application will not violate applicable provisions of the Act and the Illinois Code. The Illinois EPA is also not required to request information from a permit applicant to address deficiencies in the submitted application before proceeding to deny the application.

XII. THE APPLICATION INCLUDES ALL REQUIRED INFORMATION RELATING TO POST- PROJECT ACTUAL EMISSIONS OF PM, PM_{10}, NOX, AND VOM AND TO ENFORCEABLE LIMITATIONS ON POTENTIAL EMISSIONS OF THESE POLLUTANTS (VARIOUS DENIAL POINTS)

A. It Is Feasible to Establish Enforceable Emission Caps for Groups of Emissions Units and Emission Points as Proposed in the Application (Denial Point 6)

As correctly observed by the Illinois EPA in the draft denial letter, Attachment 1, the Application proposes that PM, PM_{10}, NOx and VOM emissions be subject to annual emission caps covering groups of related emissions units and emission points. For the blast furnace operations and the BOF shop, the proposed groupings include the principal emission points and lesser emission units. For example, for particulate, the grouping would include the casthouse (the main baghouse, the iron spout baghouse and the roof monitor), and charging of the blast furnace and the slag pits. The Application also acknowledges that these emission caps must be made enforceable as a

[156] The issue addressed by Denial Point 11 relative to baseline emissions was raised in the informal discussions between US Steel and the Illinois EPA on the March 2020 application. US Steel acknowledged that the baseline emissions of the subject operations should be greater. US Steel prepared its own calculations of emissions for these operations, which among other things, showed that their PM emissions were more than the PM_{10} emissions.

practical matter as they would serve as synthetic minor limitations (See discussion of synthetic minor limitations in US Steel's Comments, Section VIII.B.)
In the Draft Denial Letter, the 1Illinois EPA explains that there may be alternative groupings of emissions units and emission points that could be addressed by enforceable emission caps or other limitations:

> … It would be reasonable and appropriate for both the annual emissions of the casthouse and the annual emissions of the two basic oxygen furnaces to be directly limited separately from the emissions of any other units. …
>
> Revised Denial Letter, Attachment 1, p. 28
>
> …
>
> … Alternatively, limits specifically for the emissions of the casthouse for the blast furnaces and the basic oxygen furnaces, i.e., the principal units at the facility for iron and steel production, could be accompanied by group limits for the overall emissions of these principal units and the other, "non-principal" units in these areas of the facility. For example, limits could be set for both emissions of the casthouse and for the emissions of the casthouse, charging of the blast furnaces, and the slag pits. …
>
> Revised Denial Letter, Attachment 1, p. 29, Footnote 33.

US Steel generally agrees that there are potentially suitable groupings other than those proposed in the Application and that the approach suggested by Illinois EPA is likely permissible under the applicable permitting rules. However. it is unclear whether Illinois EPA's discussion of other potentially suitable groupings of other emissions units and emission points is intended to explain Illinois EPA's proposed denial of the Application. Notably, Illinois EPA has not claimed that the groupings and approaches proposed by Illinois EPA would result in limitations that are not enforceable as a practical matter or that are otherwise impermissible under the applicable rules. If Illinois EPA's discussion of other potentially suitable groupings of other emissions units and emission points is intended to provide a reason for denial of the Application, this is not a valid basis for such denial. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. A permit applicant has no obligation to reflect in the application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

As related to groupings of units addressed by emission caps, the denial of the Application is based on the Illinois EPA's determination that

the group limits proposed in the Application are not acceptable as they would eliminate limitations that actually apply only to the blast furnace casthouse and the BOFs. As this comment explains, "It is the responsibility of the Illinois EPA to draft permits with conditions it judges to be suitable and appropriate." In the Illinois EPA's judgment, the groupings of units that the Application proposes for the emission limitations that would be established in the requested revised permit are not appropriate.[157]

This constitutes a valid reason for the Illinois the EPA to deny the Application. As an initial matter, it would be irresponsible for the Illinois EPA to have omitted this point from the Denial Letter. US Steel should not become aware of this issue only when it is provided with a working draft of a revised permit, after it has remedied the deficiencies in the Application that are identified in the Denial Letter.[158] Then, it is inherent in this denial point that the Application is deficient as related to the groupings of units that it proposes. In this regard, this comment overlooks US Steel's role in providing support in the Application for the groupings of units that are proposed. Such support is essential because the Application requests that Permit 95010001 be revised to set limitations that apply to groups of units. This is a fundamental change to the emissions limitation set in Permit 95010001, which for decades since it was issued in 1996, have limited the emissions of individual units, and, for the casthouse and BOFs separately addressed the emissions of these units from different

---

[157] The Illinois EPA's discussion In the Draft Denial Letters of alternative, potentially acceptable groupings of emission units, other than the grouping proposed in the Application, was not provided to explain the reason for the proposed denial of the Application. Rather, it was provided to convey the Illinois EPA's willingness, at least on a preliminary basis, to pursue group limits as the Illinois EPA had found that the use of group limits to limit potential emissions did not appear to be precluded by applicable rules and USEPA policy. This discussion also served to alert US Steel, USEPA and other interested parties to this fact.

[158] During informal discussions before the Application was submitted, the Illinois EPA's probable position on the grouping of units for the revised limitations planned to be proposed by the Application was conveyed to US Steel.* The Illinois EPA also explained that it was willing to consider "nested" group limits, i.e., limitations for the casthouse and the BOFs by themselves and limitations that applied to each these units and, respectively, the associated iron or steel making operations. However, the Application did not address nested limits, either by altering its proposal for the group limits for the casthouse and the BOFs or, alternatively, providing further support for grouping of limits that was proposed.

*** In light of these discussions, inclusion of Denial Point 6 in the Denial Letter is also reasonable as it officially informs US Steel of the Illinois EPA's position on the groupings of units for the revised limitations proposed in the Application.**

emission points.[159] Indeed, in the Application, US Steel does address why it believes that the proposed groupings of units should be considered acceptable. However, in this comment, US Steel does not more fully explain why the groupings of units that are proposed in the Application should be considered permissible or appropriate notwithstanding the position taken by the Illinois EPA in Denial Point 6 in the Draft Denial Letters. In particular, this comment does not attempt to refute the Illinois EPA's finding, as provided in Denial Point 6 of the Draft Denial Letters, that the three permit actions cited as precedents for group limits as proposed in the Application do not address the circumstances that exist for the Granite City Works and the Project.[160] As such, they do not support establishment of group limits, as proposed by the Application, that would eliminate individual emission limitations for the blast furnace cast house and the BOFs.

B. Particulate Emissions Associated with a Facility Configuration No Longer Authorized Are Immaterial to the "Source Obligation" Demonstration (Denial Point 11 – Deficiency in Information Provided for Emissions from Handling of Coke, Iron Pellets and Limestone with the Project)

In the draft denial letter, Attachment 1, with regard to the particulate emissions from handling of coke, iron pellets and limestone with the Project (post-project emissions), the Illinois EPA correctly observes that the Application does not include supporting information for the emissions from the handling of coal and coke at the by-product coke oven batteries that were permanently shut down in

---

[159] For the casthouse and the BOFs, the Application also proposes that limitations in Permit 95010001 for the emissions from individual emission points, rather than for the total emissions of these units, be eliminated. (While not explicitly stated, this would be a result of the proposed emission caps.) The Illinois EPA does not find this to be unacceptable and it is not an element of Denial Point 6. However, it is recognized that the elimination of limitations for the separate emission points from a unit could affect the compliance provisions that are developed for ongoing quantification of the overall emissions of the unit. In particular, to the extent that the provisions for quantification of the uncaptured emissions of a unit would act to understate those emissions, the provisions would act to allow more captured emissions from the unit, which emissions could actually be verified by testing.

*** The treatment of the two BOFs as a single unit for purposes of permitting is appropriate. Both the BOFs share common control systems and the uncaptured emissions of BOFs occur through the same roof monitor.**

[160] In the Application, Section 3, pp. 3-1 thru 3-3. US Steel points to three permit actions that occurred outside of Illinois as support for group limits as proposed by the Application. These permit actions involved a permit issued to Shell Offshore, Inc., by USEPA Region 10; a permit issued to Tucson Electric Power by the Department of Environmental Quality for Pima County, Arizona; and a permit issued to Pencor-Masada Oxynol, LLC, by the New York Department of Environmental Conservation.

2015. As the Illinois EPA asserts that this omission represents a deficiency in the Application because these emissions should be included in the total post-project actual emissions quantity as used in determining whether NSR permitting requirements should apply, this assertion is without merit. Although this information may be relevant to an evaluation of whether the Project as authorized by Illinois EPA and as implemented by National Steel prior to US Steel's ownership was a major modification subject to the substantive requirements of the NSR programs, it is not relevant to the "source obligation" analysis and demonstration that are required here. As discussed in US Steel's Comment VIII.B, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.

This comment does not show that the Application should not be denied for the reason identified in Denial Point 11 as this denial point addresses the absence of supporting information for "Project Emissions."[161] First, this comment only directly addresses whether supporting information is provided in the Application for the particulate emissions from handling of coal and coke. However, this denial point also observed that the Application did not include supporting information for the Project emissions from handling of iron pellets and limestone, as well as from handling of coke.[162] As such, this comment does not show that there is not a deficiency in the Application as it does include supporting information for project emissions of particulate from handling iron pellets and limestone. These emissions clearly have not been eliminated with the shutdown of the two by-product coke oven batteries in 2015 as iron pellets and limestone are raw materials for the blast furnaces. In this light, the Application should have included detailed emissions calculations to delineate which materials (i.e., coke, coal, iron pellets, and/or limestone) were being addressed by the representation made in the Application for the Project emissions from handling of these materials.

With respect to lack of supporting information for Project emissions of particulate from handling of coke, this comment claims that it is appropriate for the Application to not have even addressed these emissions. The comment claims that because the two by-product coke oven batteries at the facility were permanently shut down in 2015, the Project emissions from handling coke do not have to be

[161] US Steel addresses Denial Point 11 as it concerns baseline emissions in Comment XI, as already addressed earlier in this Responsiveness Summary.
[162] Although emissions from handling of coal are mentioned in this comment, this denial point does not actually address emissions from handling coal.

considered when determining post-project emissions.[163] In particular, as previously discussed in US Steel's Comment VIII.B, when reevaluating applicability of NSR when relaxation of permit limitation(s) for a project are requested, the revised NSR applicability analysis does not have to consider what should have been permitted if the emissions of a project had previously been correctly quantified when the subject limitations were established. However, as explained in detail by the Illinois EPA in its response to that comment, in a situation like that of the Project, the emissions of units that have been shutdown subsequent to a project must still be considered when reevaluating applicability of NSR with the relaxation of permit limitations or the increases in permitted emissions that are being sought for the project.[164]

Moreover, the Application does request a relaxation or an increase in the emissions for which the material handling operations for coke, iron pellets and limestone are permitted. As already discussed, the Application indicates that the emissions of PM and PM10 of these operations with the Project should now both be 17.2 tons/year, rather than the maximum emissions of 2 tons/year from these operations, as currently indicated in Permit 95010001, Table 5, Limits of Emissions of Major Processes and Activities. Notwithstanding various general representations made in the Application,[165] the Application does not

---

[163] This claim is actually flawed as it presumes that the shutdown of the by-product coke oven batteries eliminated all handling of coke as addressed by Permit 95010001. However, coke continues to be a raw material for the blast furnaces and continues to be handled at the facility.

[164] Based on the detailed information for the revised PSD net emissions increase analyses for PM and PM_{10} in Appendix B of the Application, US Steel may have actually included emissions from handling coke in the information provided in the Application for the Project emissions of the material handling operations for coke, iron pellets and limestone, contrary to what is claimed by this comment. In these presentations for the net changes in emissions with the revised NSR applicability analyses for the Project, the baseline emissions and the future or project emissions of these material handling operations both for PM and for PM_{10} are the same, all being 17.2 tons/year. The emissions with the Project are not lower than the baseline emissions.

[165] The actual request for this relaxation in Permit 95010001 is generally discussed in the Application, Section 5.3, "Post-Project PM and PM_{10} Emissions Limitations."

> **A comparison of the PM and PM_{10} emissions caps from Table 5 of Construction Permit No. 950100001 and the proposed revisions to these emissions caps is provided in Table 5-8 [PM and PM_{10} Emissions Caps]. USS Granite City is proposing only minor changes to these emissions limitations as part of this permit application. (The changes are primarily attributable to the redistribution of emission caps, including establishment of a separate emissions cap for certain material handling operations [the material handling operations for coke, iron pellets and limestone addressed in this**

explain why this revision to Permit 95010001 is requested. For example, the Application, Table 5-8, "PM and PM_{10} Emissions Caps," when addressing the current "Emissions Caps" from Permit 9505010001, simply indicates that for Material Handling Operations, such emission caps are "n/a" in Permit 95010001. It then indicates that the Proposed Revised Emissions Caps for Material Handling Operations are 30 and 19 tons/year for PM and PM_{10}.[166, 167] Only in the detailed presentations of the

---

response and the material handling operations currently addressed with blast furnace operations, the BOF shop and continuous casting operations.)

The proposed revisions to post-project PM and PM_{10} emissions caps reflect three categories of changes: corrections of certain emission factors used to calculate both pre-project and post-project emissions as shown in Table 5-5 and Table 5-6 herein;[Footnote]28 changes to post-project operating rates as shown in Table 5-7 ["Project Post-Project Operating Rates for PM and PM_{10}, showing an increase in the use of natural gas and the elimination of use of COG and oil]; and changes to emissions unit groups for certain material handling operations as discussed in footnote (a) of both Table 5-5 and Table 5-6 herein…

[Footnote] 28 In the 1995 Application for post-project PM and PM_{10} emissions from the BOF roof monitor, National Steel proposed lower emissions factor reflecting the implementation of measures to improve capture and control efficiency in the BOF. Illinois EPA agreed with this proposal, incorporated lower emissions factors in the 1996 Construction Permit and recognized the PM and PM_{10} emissions reductions in the netting analysis for these pollutants. No changes are proposed by USS Granite City to the post-project PM and PM_{10} emission factors for the BOF Shop roof monitor. [Emphasis added, as this statement is inconsistent with Section 5.5.2.2 of the Application as it requests that the revised Permit 95010001 prescribe use of particulate emission factors for the BOF Shop roof monitor that are lower or more stringent than the current emission limits for those emissions.]

[Footnote of both Tables 5-5 and 5-6} (a) Emission unit grouping have been revised slightly. The identified line items associated with material handling operations were grouped with the blast furnace operation of BOF in Construction Permit No. 95010001. Material handling for coke, [iron] pellets and limestone are now included in project emissions. Baghouse 1 for Material Handling is also now grouped with material handling operations. In addition, the Baghouse 3 for Argon Stirring and Ladle Metallurgy is now grouped with BOF shop operations.

Application, Section 5.3, "Post-Project PM and PM_{10} Emissions Limitations," pp. 5-11 and 5-12.

166 Incidentally, Table 5.8 of the Application erroneously repeats the proposed revised emissions caps for Material Handling Operations, 30 and 19 tons/year for PM and PM_{10}, respectively, as the totals of the revised emission caps that are proposed for all of the various groups of units.

167 As already discussed, project emissions of 17.2 tons/year from these operations are more than the maximum emissions of these operations, 2 tons/year as now indicated in Permit 95010001, Table 5, Limits of Emissions of Major Processes and Activities. The value of 2 tons/year for maximum future PM_{10} emissions of these operations is consistent with information in Table F-3 from

revised net emissions increases analyses in Appendix B of the Application, "USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis," and "USS Granite City – 1996 Production Increase Project: Revised PM_{10} PSD Net Emissions Increase Analysis," is it apparent that relaxations in Permit 95010001 are being requested for the material handling operations for coke, iron pellets and limestone. However, these tables do not explain why these relaxations are being requested or why the specific changes that are requested would be appropriate. They also do not explain why the baseline emissions for these operations for PM and PM_{10} are identical at 17.2 tons/year.[168]

National Steel's original application. Table F-3 indicates that the baseline PM10 emissions of these operations, 17.2 tons/year, would be reduced with the Project by the required control measures to no more than about 2 tons/year (actually 2.26 tons/year), with an increase in PM_{10} emissions with the Project of 0.79 tons/year. As such, the Application requests a relaxation in Permit 95010001 relative to the maximum emissions of these operations as currently indicated in this permit. Accordingly, it was clearly appropriate for the Application to provide supporting information for the representations that it makes with regard to the emissions of these material handling operations with the Project.

[168] The two tables in Appendix B of the Application that set forth US Steel's revised PSD applicability analyses for the Project for PM and PM_{10}, provide the following information for the Material Handling Operations at BF (Blast Furnace) and BOF:

Information Provided for Material Handling at BF and BOF*					
Emissions Point	Pre-Project Annual Throughput and Units	PM/PM_{10} Pre-Project Emission Factor	PM/PM_{10} Baseline Emissions (T/Y)	PM/PM_{10} Future Emissions (T/Y)	Change from 1996 analysis
Material Handling for Coke, Pellets, Limestone	Table F-3 of the 1995 Permit Application	_	17.2/17.2	_	This activity was previously only listed in the contemporaneous changes
Iron Pellet Screen	2,803,242 tons of charge material	0.00375/0.00131 lb/ton charge material	5.3/1.8	_	USS representation of 85% control to crushed stone EF
BOF Hopper Baghouse	2,413,406 tons of steel	0.00032/0.00032 lb/ton steel**	0.4/0.4	_	No change other than regrouping
BOF Bin Floor Baghouse	"	0.0016/0.0016 lb/ton steel**	1.9/1.9	_	"

*** This heading suggests that only emissions from material handling operations for coke, pellets and limestone at the blast furnaces were being addressed.**
**** These emissions factors are identical to the applicable emission factor limits currently set in Table 2 and Table 3 of Permit 95010001.**

C. The Application Includes All Required Information Relating to Quantifying Emissions of NOx and VOM from the Casthouse Roof Monitor (Denial Point 9)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that, among the procedures proposed by US Steel in the Application for demonstration of compliance with the proposed NOx and VOM emission caps, US Steel proposed that emissions of these pollutants from the Blast Furnace Casthouse Roof Monitor be calculated as 5.3 percent of the measured emission rate from the Blast Furnace Casthouse Baghouse. (This value reflects the assumption that the emissions from the baghouse represent 95.0 percent of the total emissions from the casthouse and the uncaptured and unmeasured emissions represent 5.0 percent of the total (0.05 ÷ 0.95 = 0.053.)

The Illinois EPA then asserts that the Application does not demonstrate that the proposed methodology would yield calculated emission factors that are representative of actual emissions from casthouse roof monitor under all conditions. In particular, the proposed methodology might underestimate actual emissions if the capture efficiency is less than the 95 percent assumed in the Application. Finally, the Illinois EPA suggests that prescribing specific emission factors for NOx and VOM in the permit could be more easily shown to be representative than the approach proposed in the Application. As these assertions are intended to support the proposed denial of the Application, they are not a valid basis for denial of the Application. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the Illinois EPA will exercise its judgment regarding these matters.

There is potentially a problem, as discussed in Denial Point 9, that an actual capture efficiency less than 95 percent would not be reflected in the calculation methodology proposed in the Application. However, this problem is only theoretical. This scenario is effectively prohibited, as operation of the blast furnace casthouse capture system is subject to stringent requirements under 40 CFR Part 63 Subpart FFFFF, particularly 40 CFR 63.7790(b). Thus, if it were up to US Steel to decide on an appropriate emission determination methodology for the revised permit, the proposed 5.3 percent ratio

***** The revised PSD analyses in the Application also address the changes in the overall emissions of these material handling operations, indicating an increase of 1.0 ton/year for PM and a decrease of 6.6 tons/year for PM_{10}.**

approach would be used. However, US Steel recognizes that this decision is within the judgment and discretion of Illinois EPA.

As an initial matter, as the comment acknowledges the responsibility of the Illinois EPA to prepare permits that it considers suitable, it is unclear whether a detailed response is even needed to this comment. With respect to the emission determination methodology for NOx and VOM emissions from the casthouse roof monitor proposed by the Application, the Illinois EPA has determined that it cannot prepare a permit that would prescribe use of such methodology because the Application does not show that this would be appropriate. In particular, as discussed in detail in General Response 2, Section 8B of this Responsiveness Summary, when a permit applicant requests an air pollution control construction permit that would prescribe use of an emission factor, including a methodology that would set forth how emission factors would be developed on an ongoing basis, it is incumbent on the applicant in its application to show that the requested emission determination methodology would be appropriate. If an application for an air pollution control construction permit does not make such showing, the application would not meet the standard for issuance of a permit at Section 39(a) of the Act.

That said, the Illinois EPA will provide a brief explanation why, in the absence of any meaningful substantive support in the Application, the Illinois EPA has determined that the proposed emissions determination methodology should not be considered appropriate. This is because it presumes that a positive correlation or relationship will always exist between NOx and VOM emissions measured from the baghouses controlling particulate emissions of the casthouse (i.e., captured emissions) and the NOx and VOM emissions that occur through the roof monitor on the casthouse (uncaptured emissions).[169] As such, the Application does not confront the possibility that the actual rate of NOx or VOM emissions through the

[169] Of particular concern for the proposed emission determination methodology is what would occur when the rate of NOx or VOM measured by testing is lower than the rate measured in the previous test. With the proposed methodology, it would be presumed that if testing shows a lower rate of captured NOx or VOM emissions, the rate of uncaptured emissions is also lower. However, the Application does not show there could be other causes for the lower measured rate of NOx or VOM. For example, lower measured emissions could be due to atypical operating conditions during the casting process in the casthouse. It could also reflect operation of the capture systems for the particulate control devices at minimum operating levels necessary to comply with the opacity standards that apply to the casthouse roof monitor, rather than at normal levels of operation. The Application does not address the possibility that the emission factors for NOx and VOM resulting from the proposed emission determination methodology could be affected or impacted by such phenomena.

casthouse roof monitor is unchanged even though the measured emissions of captured NOx or VOM are lower.[170]

Finally, this comment does not support its claim that an actual capture efficiency for the casthouse that is less than 95 percent is only theoretical because of applicable requirements of 40 CFR 63 Subpart FFFFF, e.g., requirements under 40 CFR 63.7790(f). This rule involves operational requirements for the capture systems on casthouses for compliance with the standard for the opacity of particulate emission from any opening in the casthouse or structure housing the casthouse, e.g., the roof monitor. However, this NESHAP does not directly address the level of capture efficiency that must be achieved for particulate emissions. The Application also does not show that at this facility, a capture efficiency of at least 95 percent must be achieved for particulate emissions of the casthouse to be able to comply with the applicable standard in 40 CFR 63 Subpart FFFFF for the opacity of emissions from the roof monitor.

D. The Application Includes All Required Information Relating to Quantifying Emissions of Particulate from the Blast Furnace Casthouse Roof Monitor (Denial Point 10 – Particulate Emissions from the Casthouse Roof Monitor)

In the draft denial letter, Attachment 1, Illinois EPA correctly observes that, among the things requested by the Application, the Application requested that revised Permit 95010001 prescribe that particulate emissions from the casthouse roof monitor be calculated using emission factors for PM and PM_{10} of 0.030 and 0.0153 lb/ton of iron, respectively.[171] The Illinois EPA then asserts that the Application

---

[170] The Application also does not explain why an emissions determination methodology is proposed to be prescribed for uncaptured emissions of NOx and VOM from the casthouse that relates the emissions factors that are used to calculate these emissions to the measured NOx and VOM emission rates of captured emissions. For particulate emissions, specific emission factors are proposed for uncaptured emissions of the casthouse, which factors would be independent of the rates of captured emissions of particulate measured in periodic emission tests. For uncaptured NOx and VOM emissions of the casthouse, what makes it preferable to prescribe an emission determination methodology whereby the emission factors that must be used to calculate uncaptured emissions of NOx and VOM would change over time as testing is conducted for captured emissions of these pollutants?

[171] These emission factors for emissions through the roof monitor are derived from the factor for uncontrolled or "pre-control" PM emissions, 0.6 lb/ton of iron, in USEPA's *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 4th Ed. (May 1983), Section 7.5, "Iron and Steel Production," Table 7.5-2, "Particulate Emission Factors for Iron and Steel Mills."

is deficient as relating to these factors because the Application "does not include relevant supporting information," "only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency," and therefore does not demonstrate that the proposed emission factors would yield calculated emission rates that are representative of actual emissions from the casthouse roof monitor.

This assertion of a deficiency in the Application is without merit. The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any particular supporting information, nor does the Illinois EPA point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. The Application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the Application regarding the emission factors at issue is more extensive than the documentation provided in the application submitted by National Steel and accepted by Illinois EPA when issuing Permit 95010001 in 1996. Emission factors of 0.031 and 0.155 lb/ton for PM and PM_{10}, respectively, based on the assumption that 95 percent capture efficiency is achieved at the casthouse at this facility, have been consistently used by Illinois EPA in permitting for decades.[172]

By way of some background on this issue, in the application submitted in March 2020, US Steel used PM and PM_{10} emission factors of 0.031 and 0.0155 lb/ton of iron, respectively, which were also proposed to be prescribed. Among Illinois EPA's informal comments regarding that application, the Illinois EPA pointed out that these historically assumed emission factors are slightly higher than the values that would result from correctly deriving the emission factors using an assumptions of 95 percent capture efficiency. It was also explained that the Illinois EPA's records do not appear to contain an explanation for this discrepancy. It was suggested that US Steel use the revised and corrected emission factors, i.e., factors of 0.030 and 0.0.0153 for PM

The factor for PM then assumes 95 percent capture efficiency, *i.e.*, uncaptured emissions are 5 percent of the factor for uncontrolled emissions (0.05 x 0.6 = 0.030). The factor for PM_{10} is based on 51 percent of the PM being PM_{10} (0.51 × 0.030 = 0.0153), based on the particle size distribution in USEPA's *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 5th Ed. (January 1995), Section 7.5, "Iron and Steel Production," Table 7.5-2, "Size Specific Emission Factors." (Adapted from Footnotes 37 and 38 of US Steel's Comments of January 2024.)

[172] See, *e.g.,* Permit 95010001 issued January 25, 1996, and the "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA, February 4, 2013, p. 41. (Footnote 39 of US Steel's Comments of January 2024.)

and PM_{10}, respectively, which it did in the Application submitted in October 2022.

In light of Illinois EPA's repeated acceptance of and reliance on the assumption of 95 percent capture efficiency in numerous permitting actions over many years, including several permitting actions occurring prior to US Steel's ownership of the facility, and in light of the informal suggestion by Illinois EPA to correct the emission factor calculations in the manner described above, US Steel reasonably concluded that no further justification was needed as part of the Application, as submitted in October 2022. Of course, Illinois EPA retains authority pursuant to 35 IAC 201.152 to request additional information in conjunction with a construction permit application, but that was not done.

Alternatively, if the Illinois EPA now believes there is insufficient data to quantify the capture efficiency of the state-of-the-art capture systems at the casthouse at this facility and that the emissions from the casthouse roof monitor, are therefore not quantifiable, then, as these emissions are fugitive emissions under the NSR rules (e.g., 40 CFR 52.21(b)(20)), these emissions should be omitted from the analyses performed to determine whether the source obligation provisions apply in conjunction with the permit revisions requested by US Steel. As already discussed in Comment XI, fugitive emissions are counted for purposes of PSD and NaNSR applicability determinations only to the extent that such emissions are quantifiable.

This comment does not show that the Application should not be denied based on Denial Point 10 as it addresses particulate emissions from the roof monitor on the casthouse. In this regard, the comment ignores the fact that the Application requests that the revision to Permit 95010001 that is sought prescribe the emission factors that US Steel must use for these particulate emissions. As a consequence, the Application must also provide substantive support for the emission factors that are being proposed, as discussed in the "General Response 2, Section 8B of this Responsiveness Summary. The Application did not do this. As discussed in General Response 2, the fact that the Illinois EPA has historically accepted the emission factors that are now proposed for purposes of applicability of NSR is not sufficient to show that it would be appropriate for the requested revision to Permit 95010001 to now prescribe the use of such factors on an ongoing basis. Similarly, US Steel's expectations for the information that needed to be included in the Application are not relevant to the standards for issuance of a construction permit or denial of an application.

In addition, as in the alternative, this comment claims that the uncaptured particulate emissions of the blast furnace casthouse should be treated as "fugitive emissions" for purposes of NSR, such treatment

would be contrary to the definitions of fugitive emissions under the NSR programs. Tapping of the blast furnaces occurs in a structure, the casthouse. The uncaptured emissions that accompany tapping of the furnaces are released to the atmosphere through the roof monitor on the casthouse, an opening that is designed to facilitate venting of hot air and emissions from the casthouse. As such, the uncaptured emissions of the casthouse are emissions that pass through a stack, chimney, vent or other equivalent opening. The fact that these emissions are not captured and directed to the particulate control systems on the casthouse is not relevant to the appropriate treatment of these emissions under the NSR programs.

The claim in the comment that the capture systems on the casthouse are state-of-art is also irrelevant. This is because the issue is whether uncaptured emissions from the casthouse would be appropriately quantified based on the emission factors proposed in the Application. The issue is not whether the level of capture being achieved for the emissions of the casthouse is appropriate.[173]

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. The application must include information that is sufficient to provide proof that the facility or equipment addressed by the application will not violate applicable provisions of the Act and the Illinois Code. The Illinois EPA's ability to request additional information to remedy deficiencies in permit applications is not provided by 35 IAC 201.152. The Illinois EPA may directly proceed with denial of an air pollution control permit application without requesting that the applicant supplement or revise the submitted application.

---

[173] The claim that the capture systems for the emissions of the casthouse are state-of the art is also questionable. Under the Clean Air Act, Maximum Achievable Control Technology (MACT) for a source is not necessarily identical to "state-of-art."* Moreover, even if the NESHAP is considered to require state-of-art technology, the capture systems for the casthouse should at least comply with the opacity limit of the NESHAP for new sources, not the limit for existing sources, i.e., a limit for opacity on a 6-minute average of no more than 15 percent, rather than 20 percent.

*** Under Section 112(d)(3) of the Clean Air Act, for existing sources MACT need only be at least as stringent as the average emission limitation achieved by the best performing 12 percent of the existing sources in a source category or, if emission information is only available for less than 30 sources, at least as stringent as the average emission limitation achieved by the best performing five sources.**

E. The Application Includes All Required Information Relating to Quantifying Particulate Emissions of the Slag Pits (Denial Point 10 – Slag Pits)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that, among other things, the Application requests that the revisions to Permit 95010001 prescribe use of an emission factor of 0.00417 lb/ton of hot metal for the particulate emissions of the Slag Pits. The Illinois EPA then asserts that the Application is deficient as relating to this emission factor because the Application "does not include relevant supporting information" and therefore does not demonstrate that the proposed emission factor would yield calculated emission rates that are representative of actual emissions of the Slag Pits.

This assertion regarding a deficiency in the Application is without merit. The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any particular supporting information, nor does the Illinois EPA point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. The application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the Application regarding the emission factor at issue is more extensive than the documentation provided in the permit application submitted by National Steel in 1995 and accepted by Illinois EPA when issuing Permit 95010001 in 1996. The emission factor of 0.00417 lb/ton for the Slag Pits at the facility has been consistently applied by Illinois EPA for decades. The summary of the derivation of that factor as provided by US Steel in the Application is simply a paraphrasing of Illinois EPA's description.[174]

In light of Illinois EPA's repeated acceptance of and reliance on this emission factor in permitting actions over the years, including several

---

[174] See, *e.g.,* "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (February 4, 2013), p. 42, as it indicated stated the following relative to the PM/PM_{10} emissions of the slag pits:

> Emission Factor: 0.00417 lbs/ton of iron
> Origin of EF: Calculated from EPA Assessment of Atmospheric Emissions from Quenching of Blast Furnace Slag. Also, AP-42, Table 13.2.4-4, Fugitive Uncontrolled emissions. Summation of the following emission factors:
> a. Slag Quenching = 0.0026 lbs/ton iron,
> b. Slag Digging = 0.00157 lbs/ton iron.
> Update Methodology: Refer to Conditions 7.4.9(i). 5.9.6(c) and 5.13 of the permit.

(Footnote 45 of US Steel's Comments of January 2024.)

permitting actions occurring prior to US Steel's ownership of the facility, US Steel reasonably concluded that no further justification was needed as part of the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application pursuant to 35 IAC 201.152, but that was not done here.

This comment does not show that the Application should not be denied based on Denial Point 10 as it addresses particulate emissions from the slag pits. In particular, as discussed in detail in General Response 2, Section 8B of this Responsiveness Summary, when a permit applicant requests an air pollution control construction permit that would prescribe use of certain emission factors, it is incumbent on the applicant in its application to show that the proposed factors would be appropriate. Absent such a showing, the Illinois EPA cannot issue the requested permit as it would not meet the standard for issuance of a permit at Section 39(a) of the Act. As explained in General Response 2, as well as in General Response 1, even if the Illinois EPA had prescribed the use of certain emissions factor(s) in past permitting actions, which it has not done,[175] this would not be sufficient to justify issuance of a revision to Permit 95010001 that would prescribe the continued use of such factors. This comment ignores the all-important fact that US Steel, in its Application, requests that revised Permit 95010001 prescribe the emission factors that US Steel is to use on an ongoing basis to calculate emissions of certain units and emission points for the purpose of determining compliance with limitations on annual emissions. The Illinois EPA does not have the obligation to show that emission factors that a permit applicant, not the Illinois EPA, itself, proposes to be prescribed are appropriate.

In addition, this comment's claim that the Illinois EPA prescribed use of emission factors in 2013 when acting on Permit 96030056, the CAAPP permit for the facility, does not hold up to scrutiny. The Illinois EPA's February 4, 2013, Statement of Basis for the planned revisions to Permit 96030056, as referenced by this comment, does not show that a revision of Permit 96030056 was planned that would prescribe the use of specific emission factors for particulate emissions of the slag pits, much less that the Illinois EPA actually issued a revised permit that

[175] As already discussed, the Illinois EPA considers the provisions in Permit 95010001 that limit emissions of units in pounds/ton produced or handled; pounds/million cubic feet of fuel burned; or pounds/hour, including the limits for the slag pits, to be enforceable limits on the emissions of the subject units. These limits were included in Permit 95010001 in 1996 to enforceably limit the emissions of these units either so that the Project would not be a major modification for a pollutant or, as the Project was a major modification for SO_2 and CO, to enforceably limit emissions of SO_2 and CO to the amounts provided for by means of the PSD approval.

prescribed use of particular emissions factors. The information for the slag pits in the attachment to that Statement of Basis, as referred to by this comment, was provided in this document to inform the USEPA and the public of the emission factors that US Steel was using to determine emissions of Project-affected process emission units at the time this document was prepared.[176]

F. The Application Includes All Required Information Relating to Quantifying Particulate Emissions of the Continuous Casting Operations (Denial Point 8 – Continuous Casting Operations)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that, among the procedures proposed by the Application for the ongoing demonstration of compliance with the proposed emission caps, US Steel proposed that the PM and PM_{10} emissions of the Caster Mold, Slab Cutoff, and Slab Ripping operations be calculated using prescribed emission factors. Illinois EPA then asserts that as related to these emission factors, the Application is deficient because the Application does not include supporting information "sufficient to show that the emission factors that are proposed as prescribed factors are representative."

The assertion of a deficiency in the Application is without merit. The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any particular supporting information, nor does the Illinois EPA point to even an

---

[176] The information in an attachment in the Statement of Basis for the planned revisions of Permit 96030056 referenced in this comment was part of the Illinois EPA's planned response to deficiencies, as identified in USEPA Order,* in the CAAPP permit for the facility that was issued in May 2011. As explained in this statement of basis, in the planned revision to Permit 96030056, the Illinois EPA was not planning to prescribe emission factors for various emission units. Rather the information in the attachment responded to a finding by USEPA in its Order that, "The Illinois EPA shall make available for public comment the emission factors that US Steel initially intends to use to demonstrate compliance with the subject emission limits [emissions limitations for Project-affected process units set by Permit 95010001]." (Statement of Basis, p. 22 of 47.) The cited attachment made the emission factors being used by US Steel directly available for review by the public, as required by the Order. The Illinois EPA also explained, "The revised CAAPP permit that the Illinois EPA now plans to issue would include a listing of the emission factors that US Steel is currently using to determine compliance with the subject limits." (Statement of Basis, p. 22 of 47.)

*** Before the Administrator, United States Environmental Protection Agency, In the Matter of: United States Steel Corporation - Granite City Works, CAAPP Permit No. 96030036 Proposed by the Illinois Environmental Protection Agency. Order Responding to Petitioner's Request That the Administrator Object to the Issuance of State Operating Permit; Order Granting in Part and Denying In Part Petition for Objection to Permit, December 3, 2012.**

application form or guidance document suggesting that such documentation or additional explanation be provided. The Application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the application regarding the emission factors at issue is more extensive than the documentation provided in the application submitted by National Steel in 1995 and accepted by the Illinois EPA when issuing Permit 95010001 in 1996. These PM/PM_{10} emission factors for the continuous casting operation at the facility have been consistently accepted by the Illinois EPA for the purpose of permitting over many years.[177]

In light of Illinois EPA's acceptance of these emission factors in various permitting actions over the years, including permitting actions before US Steel's ownership of the facility, US Steel reasonably concluded that no further justification was needed as part of the Application. Of course, Illinois EPA retains authority pursuant to 35 IAC 201.152 to request additional information in conjunction with a construction permit application, but that was not done here.

This comment does not show that the Application should not be denied based on Denial Point 10 as this denial point addresses particulate emissions from continuous casting. In particular, as discussed in detail in General Response 2, Section 8B of this Responsiveness Summary, when a permit applicant requests an air pollution control construction permit that would prescribe use of certain emission factors, it is incumbent on the applicant in its application to show that the requested factors would be appropriate. If an application does not make such showing, the application would not meet the standard for issuance of a construction permit at Section 39(a) of the Act. In addition, as explained in General Response 2, as well as in General Response 1, even if the Illinois EPA has prescribed the use of certain emissions factors in past permitting actions, which it has not done, this would not be sufficient to justify issuance of a revision to Permit 95010001 that would prescribe the continued use of these factors. Like an earlier comment, this comment again ignores the fact that the Application requests that the revision to Permit 95010001 prescribe the emission factors that US Steel must use on an ongoing

---

[177] See, *e.g.*, "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (February 4, 2013) at p. 47. For example, the following was indicated relative to the PM/PM_{10} emissions of Slab Cutoff:

> Emission Factor: 0.0071 lbs/ton of steel
> Origin of EF: Illinois EPA 1991 EIS PM/PM_{10} Report
> Update Methodology: Refer to Conditions 7.6.9(c). 5.9.6(c) and 5.13 of the permit.

(Footnote 47 of US Steel's Comments of January 2024.)

basis for certain units and emission points when determining compliance with limitations on annual emissions.

Again, the Illinois EPA's February 4, 2013, Statement of Basis for planned revisions to Permit 96030056, as referenced by this comment, does not show that the Illinois EPA was planning to issue a revision of this permit that would prescribe use of specific emission factors for particulate emissions of the continuous casting operations. As already discussed earlier in response to US Steel's Comment XII.E concerning the slag pits, the information for the continuous casting operations in the attachment to this Statement of Basis, as referred to by this comment, was provided to inform the USEPA and the public of the emission factors that US Steel was using to determine emissions of Project-affected process operations at the time that this statement of basis was prepared.

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. The Illinois EPA is also not required to request information from a permit applicant to address deficiencies in the submitted application before proceeding to deny the application.

G. The Application Includes All Required Information Relating to Quantifying Particulate Emissions from the Iron Pellet Screen (Denial Point 10 – Iron Pellet Screen)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that, among the emission factors that the Application proposes be prescribed, for the Iron Pellet Screen, the Application proposes an emission factor for both PM and PM_{10} of 0.00131 lb/ton of material. As explained in the Application, this emission factor is derived from the PM_{10} emission factor published by USEPA for crushed stone screening, 0.0087 lb/ton of material, applying 85 percent control efficiency.[178]

[178] USEPA, *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 5th Ed., Aug. 2004, Section 11.19.2, "Crushed Stone Processing and Pulverized Mineral Processing," Table 11.19.2-2, "Emission Factors for Crushed Stone Processing Operations," updated Aug. 2004. A control efficiency of 85 percent was applied for this operation, [USEPA, *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 4th Ed., Supplement No. 14], May 1983] Section 7.5, "Iron and Steel Production," Table 7.5-2, "Particulate Emission Factors for Iron and Steel Mills." (Footnote 49 in US Steel's Comments of January 2024.)

Illinois EPA then asserts that the Application is deficient as related to its request that the revised permit prescribe the emission factors that are to be used for the iron pellet screen. This is because the Application, "does not include relevant supporting information." In particular, the assumption of 85 percent control efficiency is not supported. The use of an emission factor for PM derived from an emission factor for PM_{10} is also questioned, as USEPA's published factors show that more PM emissions than PM_{10} emissions. Therefore, the Application does not demonstrate that the proposed factor would yield data for emissions that is representative of actual emissions of the Iron Pellet Screen and the Application is deficient. In fact, the proposal of the PM_{10} derived emission factor as the prescribed factor for PM emissions was an error.[179] US Steel's intent was that corresponding PM emission factor of 0.00375 lb/ton of material, as shown in Table 5-5 of the Application, be prescribed.

Nonetheless, the assertion regarding a deficiency in the Application is without merit. The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any proposed emission quantification methods for fugitive emissions, nor does the Illinois EPA point to even an application form or guidance document suggesting that such a proposal be provided. The Application includes all information required by the applicable permitting rules. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate, including recordkeeping requirements and other compliance demonstration methods. The permit applicant has no obligation to reflect in its application a correct guess as to how the Illinois EPA will exercise its judgment regarding these matters.

This comment does not show that the Application should not be denied based on Denial Point 10 as it addresses the emissions of the Iron Pellet Screen. In particular, as discussed in detail in General Response 2, Section 8B of this Responsiveness Summary, when a permit applicant requests an air pollution control construction permit that would prescribe use of certain emission factors, it is incumbent on the applicant in its application to show that the proposed factors would be appropriate. Absent such a showing, the Illinois EPA cannot issue the requested permit as it would not meet the standard for issuance of a permit at Section 39(a) of the Act. Like earlier comments, this comment again ignores the fact that the Application requests that revised Permit 95010001 prescribe the emission factors

[179] While this comment characterizes this error as a scrivener's error, this characterization in not appropriate. When this comment was made, the Application was still pending. US Steel had the ability to unilaterally, without any concurrence by the Illinois EPA, to submit an erratum to correct the Application.

that US Steel must use on an ongoing basis for certain units and emission points when determining compliance with limits on annual emissions.

Moreover, this comment actually provides support for denial of the Application based on Denial Point 10 as it addresses the Iron Pellet Screen. For this unit, the Application simply identifies the proposed prescribed emission factor without providing any further explanation.[180] The comment indicates that the Application was in error as it proposed the same factor be prescribed for both PM and PM_{10}.[181] In addition, the comment also acknowledges that the proposed factor reflects application of a control efficiency of 85 percent to a published USEPA factor. However, the comment does not identify place(s) in the Application where support was provided for use of a particulate control efficiency of 85 percent for this unit. This comment does not even describe the control measures, control practices or considerations that act to lower its rate of emissions from the uncontrolled factor provided by USEPA.[182]

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an

---

[180] With respect to the Iron Pellet Screen, Section 5.5.4.2, "Prescribed Emission Factors for Material Handling," the Application simply states:

> **USS Granite City is proposing the following prescribed emissions factors for emission points for which emission testing is not feasible.**
>
> **a) For Iron Pellet Screen fugitives, use PM/PM_{10} emission factor of 0.00131 lb/ton."**

[181] Upon reflection, the Application is also likely flawed as Section 5.5.4.2 refers to Iron Pellet Screen <u>fugitives</u>, rather than simply to the emissions of this unit. As the proposed factor is identified as addressing the fugitive emissions of this unit, it suggests that this unit has both "uncaptured emissions" and, as emissions are controlled, "captured emissions." The factor that is proposed only addresses the uncaptured emissions. In fact, the characterization of the proposed factor as addressing the fugitives of this unit is likely gratuitous. All emissions of this unit are likely being addressed. Rather than use of an add-on air pollution control device, the control measures or considerations that lower emissions compared to the published factor for uncontrolled emissions are reflected in the proposed factor.

[182] With respect to use of a control efficiency of 85 percent, this comment attempts in a footnote to now provide support for this efficiency. (This footnote appears to refer to information in a May 1983 update to USEPA's *Compilation of Air Pollutant Emission Factors*.) However, in that document, the referenced table, Table 7.5-2, does not address handling or processing of raw materials at an iron and steel mill, much less the reduction in particulate emissions from various control measures.

application for an air pollution control construction permit. The application must include information that is sufficient to provide proof that the facility or equipment that is the subject of the application will not violate applicable provisions of the Act and the Illinois Code.

H. The Application Includes All Required Information Relating to Quantifying Particulate Emissions of the Mag Lime Silo (Denial Point 8 – Mag-Lime Silo)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that the Application proposes a prescribed emission factors for the particulate emissions of the Mag-Lime Silo, i.e., 0.009 lb/hour for both PM and PM_{10}. The Illinois EPA then asserts that the Application is deficient as relating to this factor because the application does not include supporting information demonstrating that the proposed factor is representative of actual emissions from the Mag Lime Silo.

The assertion regarding a deficiency in the Application is without merit. The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a permit application include any proposed compliance demonstration methods, nor does the Illinois EPA point to even an application form or guidance document suggesting that such a proposal be provided. The Application includes all information required by the applicable permitting rules. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate, including recordkeeping requirements and other compliance demonstration methods. A permit applicant has no obligation to reflect in the permit application a correct guess as to how the Illinois EPA will exercise its judgment regarding these matters.

This comment does not show that the Application should not be denied based on Denial Point 8 as it addresses the Mag-Lime Silo. The comment does not show that the Application contains any supporting information for the emission factor that it proposes be prescribed for the Mag-Lime Silo by Revised Permit 95010001. As discussed in detail in General Response 2, Section 8B of this Responsiveness Summary, when a permit applicant requests an air pollution control construction permit that would prescribe use of certain emission factors, it is incumbent on the applicant in its application to show that the proposed factors would be appropriate. If such showing is not made, the application would not meet the standard for issuance of a permit at Section 39(a) of the Act. Like earlier comments, this comment again ignores the fact that the Application requests that revised Permit 95010001 prescribe the emission factors that US Steel must use on an ongoing basis for certain units and emission points to

determine compliance with limits on annual emissions.[183]

Finally, as discussed in General Response 1, Section 8A of this Responsiveness Summary, it is not necessary for there to be a provision of the Act or the Illinois Code, or other guidance that specifies the particular information that must be included in an application for an air pollution control construction permit. The application must include information that is sufficient to provide proof that the facility or equipment that is the subject of the application will not violate applicable provisions of the Act and the Illinois Code.

I. The Application Includes All Required Information Relating to Quantifying Particulate Emissions of from the BOF Shop Roof Monitor (Denial Point 8 – Particulate Emissions from the BOF Shop Roof Monitor)

I1. The Proposed Prescribed Factors Are Lower Than the Factors That Were Used by National Steel in Its Emission Calculations

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that the Application proposes that emissions of PM and PM_{10} from the BOF Shop Roof Monitor be calculated using prescribed emission factors that are lower than the factors used by National Steel in the original application for Permit 95010001.

This comment does not show that the Application should not be denied based on Denial Point 8 as it addresses the particulate emissions of the BOFs from the roof monitor on the BOF shop. In particular, as discussed in detail in General Response 2, Section 8B of this Responsiveness Summary, when a permit applicant requests an air pollution control construction permit that would prescribe use of certain emission factors, it is incumbent on the applicant in its

[183] As US Steel also claimed in this comment that, although it had no obligation to do so, it requested that emissions from the Mag-Lime Silo be subject to limits, this claim is both unsupported and irrelevant. The Mag-Lime Silo is a particulate emission unit, admittedly with very few emissions. It should have been addressed by National Steel in its original Application for the Project.

As US Steel also claims that related to the emissions of the Mag-Lime Silo, the proposed denial of the Application will simply ensure the status quo is maintained, *i.e.,* that US Steel is not subject to any limitations on emissions from this unit, this is both irrelevant and overly simplistic. The particulate emissions of the Mag Lime Silo are trivial due to the filter control that is an inherent aspect of pneumatic loading of this silo. Would this unit appropriately be addressed in the revised permit as an insignificant emission unit? If the particulate emissions of this unit are limited, why should they be limited by an emission cap that applies to this unit along with other more substantial, discrete units that also involve material handling and processing?

application to show that the proposed factors would be appropriate. If the application does not make such showing, application would not meet the standard for issuance of a permit at Section 39(a) of the Act. Like earlier comments, this comment again ignores the fact that the Application requests that revised Permit 95010001 prescribe the emission factors that US Steel must use on an ongoing basis for certain units and emission points when determining compliance with limits on annual emissions.

This comment does not address, much less show that the Application includes substantive information supporting the emission factors that are proposed to be prescribed for the particulate emissions for the BOFs that occur through the roof monitor on the BOF shop.[184] Accordingly, this comment does not show that the Application should not be denied based on Denial Point 8 as particulate emissions of the BOFs from the roof monitor are addressed.[185]

I2. The Application Includes All Required Information Relating to Quantifying Particulate Emissions of the BOF Shop Roof Monitor

The Illinois EPA acknowledges in the Draft Denial Letter, Attachment 1, Footnote 42, that the emission factors proposed by US Steel for BOF emissions through the roof monitor may be representative of the current configuration of the BOF Shop. In Footnote 42, the Illinois EPA further asserts that "particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the BOFs, should be used in the revised netting analyses for PM and PM_{10}." The Illinois EPA goes on to assert that the Application is deficient as related to these factors because "those prescribed factors would not be representative of emissions before the new baghouse system was installed and operation of this system was required."

These assertions are without merit. Although this information may be relevant to an evaluation of whether the Project as authorized by Illinois EPA and as implemented by National Steel prior to US Steel's ownership was a major modification subject to the substantive requirements of the NSR programs, it is not relevant to the "source

[184] Since the emissions factors that the Application proposes be prescribed for particulate emissions of the BOFs from the roof monitor on the BOF shop are not the emission factors used in previous permitting, this comment cannot even point to "earlier reliance" to support the proposed factors.

[185] Incidentally, in US Steel's Comments of September 2023, attention is called to an error in the Draft Denial Letter with respect to the PM and PM_{10} emissions factors that the Application proposes be established as prescribed factors for the BOF Shop Roof Monitor. The factors for PM and PM_{10} are interchanged. US Steel's Comments of January 2024 again call attention to this error. However, based on the original comment pointing out this error, this error was corrected and was not made in the Revised Draft Denial Letter.

obligation" analysis and demonstration that are required here. As already discussed in US Steel's Comment VIII.B, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.

As this comment does not actually address the deficiency in the Application identified in Denial Point 8, or a deficiency identified in another denial point, this comment is not relevant to the proposed denial of the Application. Rather, this comment responds to possible deficiencies in the Application that are of US Steel's own creation and were not identified as a basis for the proposed denial of the Application in the Draft Denial Letters. In this regard, this comment misrepresents Footnote 43 of the Draft Denial Letters as the footnote addresses the emission factors that are proposed for uncaptured particulate emissions of the BOFs (i.e., the particulate emissions that occur through the roof monitor of the BOF shop).[186] In this footnote, the Illinois EPA does not identify deficiencies in the Application but instead provides some clarifying explanation, as is appropriate in a Responsiveness Summary.[187]

---

[186] **In its entirety, Footnote 43 of the Draft Denial Letter reads is as follows:**

> **The emission factors that the 2022 application proposes to be prescribed for particulate emissions from the roof monitor on the basic oxygen furnaces may be appropriate at the present time given the installation of a baghouse control system on these furnaces. Nonetheless, for a revised permit to be issued that prescribes emission factors for emissions from the roof monitor, the application must show that those factors are representative with the emission control measures that are required by the permit. It must also be recognized that those prescribed factors would not be representative of emissions before the new baghouse system was installed and operation of this system was required. As such, particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}.**

[187] **The first sentence in Footnote 43 confirms that the deficiency that is identified in Denial Point 8 with respect to the absence of supporting information for the emission factors that are proposed for uncaptured particulate emissions of the BOFs (i.e., the particulate emissions that occur through the roof monitor of the BOF shop), is not that these factors are lower than the rates of emissions that were previously used. That is, factors that are lower than factors that were previously used may now be appropriate given the addition of the baghouse control system to the BOFs. The deficiency in the Application is that the Application does not provide information showing that the "new factors" that are proposed for uncaptured emissions would be representative considering the control measures that would be required by the permit. The footnote then observes that, as the new emissions factors would address emissions with the new baghouse system, they would not address emissions before this system was installed and began operation. The final**

This comment specifically takes umbrage with the last sentence in this footnote. In this sentence, with respect to the uncaptured particulate emissions of the BOFs (i.e., the emissions that occur through the roof monitor of the BOF shop), the Illinois EPA observes that, "As such, particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}." The position of the Illinois EPA reflected in this sentence is contrary to the position of US Steel, as set forth in Comment XIII.[188] This fact is acknowledged. However, this does not affect the denial of the Application since the Denial Letter does not identify a deficiency in the Application with respect to the particulate emissions data for the BOFs with the Project used in the revised NSR applicability analyses for PM and PM_{10} in the Application.[189]

J. The Application Includes Adequate Explanation of Projected Post-Project Actual Emissions from Fuel Combustion Units (Denial Points 3 and 7))

J1. The Explanation in the Application for Projected Post- Project Actual Emissions from Fuel Combustion Units Is Adequate (Denial Point 3)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that the Application represents the maximum total post-project actual NOx emissions from the Project-affected fuel burning units as 706 tons per year. The Illinois EPA then asserts that the Application is deficient because it "does not explain why actual NOx emissions of the subject units would not exceed this amount going forward if the permit

---

sentence of this footnote observes that it would not be proper to use the new emissions factors in the revised NSR applicability analyses for the Project.

[188] As explained in the Illinois EPA's extensive response to US Steel's Comment VIII, the approach to reevaluation of NSR applicability put forth in Comment VIII, which is referred to by this comment, is not correct. Rather, as revised NSR applicability analyses must be prepared to address errors in the original or prior NSR applicability analyses for a project, those analyses must be revisited.

[189] Incidentally, contrary to what this comment implies, it does not appear that the revised PSD applicability analyses in the Application take into consideration the reduction in particulate emissions that resulted from the addition of a baghouse control system for the BOFs. In this regard, for the BOFs, the revised net emissions increase analyses for the Project for PM and PM_{10} indicate "No change" from the 1996 NSR applicability analyses. (Appendix B of the Application, "USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis," and "USS Granite City – 1996 Production Increase Project: Revised PM_{10} PSD Net Emissions Increase Analysis.")

were revised" as proposed. This assertion is without merit. The explanation is provided in Table 6-7 of the Application, where the proposed revised NOx emissions cap for these units is indicated as 706 ton/year.

This comment does not show that the Application should not be denied. This comment, in condensed form, restates US Steel's Comment IX.E. As explained by the Illinois EPA in response to that comment, the Application did not provide the information identified in this comment in Table 6-7 of the Application. Accordingly, the Application is deficient for the reason detailed in Denial Point 3.

J2. The Application Includes Adequate Explanation of Projected Post-Project Actual NOx Emissions from Fuel Burning Units and Does Not Diminish Illinois EPA's Authority to Impose Enforceable Limits (Denial Point 7)

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that the Application requests elimination of the gaseous fuel usage limits for Project-affected fuel burning units. The Illinois EPA further asserts as follows:

> While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed above, this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the 2022 application does not show that new limits for fuel usage and emissions would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shutdown. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown. (Internal footnote omitted.)

By way of a brief review of US Steel's approach to this issue, the application submitted in March 2020 expressly requested enforceable emission caps for emissions of NOx and other pollutants from the Project-affected fuel burning units and provided emission calculations supporting these proposed caps. Among Illinois EPA's informal comments regarding that application, it was correctly pointed out that enforceable emission caps are superfluous and unnecessary where the

potential emissions of the affected unit or units are less than or equal to the emission caps that would be under consideration. Accordingly, in the Application, US Steel omitted the express request for enforceable emission caps for the Project-affected fuel burning units.

Notwithstanding this history, it remains the responsibility of the Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. If Illinois EPA is not persuaded that the future actual emissions from the Project-affected fuel burning units will be less than or equal to the values represented in the Application in the absence of enforceable limits on fuel usage in or enforceable emission caps for these units, then the Illinois EPA undisputedly has the discretion and authority to impose such limits in the permit. A permit applicant has no obligation to reflect in the permit application a correct guess as to how the Illinois EPA will exercise its judgment regarding these matters. That should be especially true where, as here, the Illinois EPA conveys its preliminary judgment, the applicant revises its permit application to be consistent with that representation, and then the Illinois EPA vacillates.

With regard to Illinois EPA's observation that the revised limitations may need to "address fuel burning units other than the Project-affected units currently addressed by the permit," such as the slab reheat furnaces and the co-generation boiler at the facility, US Steel disagrees that such limits would be appropriate. As these emissions units were not among the units affected by the Project, the emissions from these units are not relevant to the "source obligation" analysis and demonstration that are required here, as already discussed in US Steel's Comment VIII.B.

This comment does not show that the Application should not be denied based on Denial Point 7. As acknowledged by this comment, for Project-affected fuel burning units, the Illinois EPA informally questioned whether emission limitations in Permits 95010001 needed to be perpetuated in the requested revision to Permit 95010001. This is because, with the shutdown of ten boilers, the potential emissions of certain pollutants from these units may now be less than would be allowed based on revised analyses of NSR applicability for the Project.[190] However, the Application does not concretely respond to this issue. Instead, when discussing the requested revision to Permit 95010001 related to emissions of PM, PM_{10}, NOx and VOM, the Application,

[190] As this comment addresses the actual emissions of fuel burning emissions units, e.g., "the future actual emissions from the Project-affected fuel burning units will be less than or equal to the values represented in the Application," this comment is not responsive to Denial Point 7. As discussed, this deficiency involves the potential emissions of these units, not their actual emissions.

p. 2-4, simply states that, "USS Granite City is also requesting revision/elimination of gaseous fuel usage limits for project-affected combustion units." The Application proceeds to explain that the shutdowns of the two by-product coke oven batteries and ten of the twelve boilers at the facility, "… have greatly reduced the emissions from fuel combustion in project-affected emission units and obviate the need to preserve limits to restrict PTE (potential to emit) of the remaining units." However, the Application does not actually explain or show how these actions have obviated the need for the revisions to Permit 95010001 to continue to limit fuel usage and emissions of Project-affected fuel burning units. That is, the Application does not provide information for the potential emissions of relevant pollutants from the Project-affected fuel burning units, i.e., units other than the ten boilers that are now shutdown, with use of only BFG and natural gas, since COG is no longer available. In these circumstances, as the Application requests a particular revision to Permit 95010001 but does not provide support for such revision, it is appropriate that this deficiency in the Application be a reason for denial of the Application.[191]

This comment also does not show that the Application is not deficient as related to the four slab reheat furnaces and co-generation boiler at the facility that are not Project-affected fuel burning units. In this regard, however, the Illinois EPA does not claim in Denial Point 7 that the Application is deficient because the revised NSR applicability analyses for the Project do not address these units. Rather, the observation made in Denial Point 7 is that the Application may be deficient as it does not address the effects of the shutdown of the two by-product coke oven batteries on the operation and emissions of the four reheat furnaces that historically burned both COG and natural gas. Moreover, given the timing of the shutdown of the coke oven batteries and any resulting increase in the usage of natural gas by these reheat furnaces, the increases in emissions from the new co-generation boiler may be contemporaneous relative to any increases in emissions from the reheat furnaces. In summary, the Application does not show that requested revision to Permit 95010001 should not continue to include

---

[191] As this comment broadly claims that it is the Illinois EPA's responsibility to draft a revised permit with conditions that the Illinois EPA judges to be suitable and appropriate, this comment does nothing to refute the proposed denial of the Application, as detailed in Denial Point 7. If anything, it supports this denial as the Application does not include information that would be needed to impose permit conditions in the requested revised permit that, in the judgment of the Illinois EPA, would be suitable and appropriate.

Moreover, if this general pronouncement concerning permit conditions were to actually reflect the authority given to the Illinois EPA to impose conditions on permits, the Illinois EPA would have the authority in the requested revision to Permit 95010001 to impose conditions to carry out the purposes of the Act without regard to information provided by US Steel in the Application.

limitations for fuel burning units at the facility, that now also address emissions of the four reheat furnaces, to ensure that the increased use of natural gas due to the shutdown of the coke oven batteries has not resulted in a major modification for NSR. The Application simply requests an increase in the permitted usage of natural gas and allowable emissions of the Project-affected fuel burning units.[192] As such, given this comment does not address this second aspect of Denial Point 7, this comment also does not show that the Application should not be denied.[193]

---

[192] For example, as related to NOx emissions from use of fuels, the Application explains:

> **The post-project emission caps for the project affected emissions units are developed by USS Granite City using the operating rates shown in Table 6-6. Other than the natural gas usage, which is proposed to increase, and the oil usage, which is proposed to be eliminated, these rates are unchanged from the operating rates in the permit [maximum annual rate or iron production, maximum annual rate of steel production, and maximum annual rate of generation/burning of BFG]. As previously noted in Section 5.3 [Post-Project PM and PM_{10} Emission Limitations], due to the 2015 shutdown of the Coke Plant, this application addresses [an] increase in the natural gas usage for the fuel burning units affected by the project and also addresses elimination of COG at the affected units.**
>
> **Application, Section 6.3, Post-Project NOx Emissions Limitations, p. 6-6,**

[193] In this comment, with respect to the broad claim that a permit applicant need not reflect in its application, "… a correct guess as to how the Illinois EPA will exercise its judgment," a further claim is made, "That this should be especially true where, as here, the Illinois EPA conveys its preliminary judgment, the applicant revises its permit application to be consistent with that representation, and then the Illinois EPA vacillates." It should first be noted that the Illinois EPA did not vacillate. Rather, when informally reviewing the March 2020 application, the Illinois EPA questioned whether, because of the shutdown of ten boilers at the facility, certain limitations for fuel burning units would still be necessary in the requested revision to Permit 95010001. Moreover, even if the Illinois EPA had vacillated, it would not act to shield the Application from denial.

By way of restatement, the deficiency in the Application being addressed here does not involve guesses for how the Illinois EPA will judge the Application. The deficiency involves the absence of relevant information that directly supports a request made by the Application. As US Steel was informed about an issue that is posed by its request for revision of Permit 95010001, US Steel could have substantively addressed this issue in the Application, as submitted in October 2022. In this regard the Application does claim that the elimination of COG and the shutdown of boilers eliminates the need for limits to restrict the potential emissions of the remaining units. However, this claim is not actually accompanied by data for the potential emissions of the "remaining units." This data was needed in the Application so that the validity of the claim and the request, which would possibly simplify one aspect of the revisions to Permit 95010001, could have been reviewed.

XIII. THE APPLICATION INCLUDES ALL INFORMATION NECESSARY FOR INTEGRATED PROCESSING UNDER THE CAAPP OR, IN THE ALTERNATIVE, ANY DEFICIENCIES ARE NOT A BASIS FOR DENYING THE APPLICATION (VARIOUS DENIAL POINTS)

A. Claimed Deficiencies in the Application As Related to Integrated Processing Under the CAAPP Do Not Form a Basis for Denying the Application

As correctly observed by Illinois EPA in the draft denial letter, in the Application, US Steel requests that the revision of Permit 95010001 be subjected to "integrated processing," as provided for by Subsections 39.5(13)(a) and (c)(v)of the Act. This would allow the requirements in the requested revision to Permit 95010001 to be incorporated into the facility's CAAPP permit using the CAAPP's process for administrative amendment.

Numerous deficiencies in the Application detailed in the Draft Denial Letter are claimed to be deficiencies only because of US Steel's request for integrated processing. US Steel does not agree with these deficiencies, as discussed in US Steel's Comments XIII.B through X.III.I, below. In addition, none of these deficiencies form a valid basis for denying the Application. Even if Illinois EPA were correct that these deficiencies would prevent the use of integrated processing, that would only provide a valid basis for denial of the request for integrated processing of the revised permit and associated revisions of the CAAPP permit.

This comment does not show that the Application should not denied because of deficiencies in the Application that are a result of the Application's request that the revision of Permit 95010001 be subject to Integrated Processing.[194] In this regard, Integrated Processing affects the Application. It sets certain criteria for the contents of

---

[194] The authorization for Integrated Processing of a construction permit application and an associated construction permit is provided in Subsections 39.5(13)(c) and (c)(v) of the Act. They provide that:

> **c. For purposes of this Section [Section 39.5 of the Act] the term "administrative permit amendment" shall be defined as a permit revision that can accomplish one or more of the changes described below:**
>
> **…**
>
> **v. Incorporates into the CAAPP permit the requirements from preconstruction review permits [construction permits] authorized under a USEPA-approved program, provided the program meets procedural and compliance requirements of this Section.**

the revised permit that is sought by this Application. It also addresses the procedures by which this revised permit is processed. Both must be substantially equivalent to what would be required if a CAAPP permit were being issued, rather than a revised state construction permit/PSD approval. It is also noteworthy that public notice and opportunity for comment are not required for the administrative amendment of a CAAPP permit.[195] The actual administrative amendment of a CAAPP permit for a CAAPP source by the Illinois EPA once a construction permit that has been subject to Integrated Processing has been issued is a ministerial function. The Illinois EPA does not have the authority to reconsider the revisions to the CAAPP permit that are allowed by such construction permit.

The claim in this comment that the request for Integrated Processing made in the Application could be denied separately from the rest of the Application is unsupported. When reviewing an air pollution control construction permit application, the Act does not give the Illinois EPA the authority to divide an application, issuing a permit for part of an application and denying a permit for the rest. Rather, when taking final action on a construction permit application, Section 39(a) of the Act only provides for the Illinois EPA to either grant a permit or deny the application. For the Application, the Illinois EPA must necessarily consider the request for Integrated Processing as it is an element of the Application. The deficiencies in the Application related to Integrated Processing of the requested revision of Permit 95010001 are not of the type that are amenable to remedy by means of permit conditions.[196]

B. The Application Includes All Necessary Information Relating to General Provisions in the CAAPP Permit Governing Selection of Emission Factors (Denial Letter, Point 13)

In the draft denial letter, Attachment 1, the Illinois EPA correctly

---

[195] For the administrative amendment of a CAAPP permit, the Illinois EPA must only provide a copy of the amended CAAPP permit to USEPA (Subsection 39.5(13)(a) of the Act). A source may implement the changes addressed by its request for an administrative amendment immediately upon submittal of the request (Subsection 39.5(13)(f) of the Act).

[196] The deficiencies in the Application related to Integrated Processing could have been readily disposed of if US Steel simply submitted a modification to the Application removing the request for Integrated Processing. Of course, any revisions to Permit 95010001 issued pursuant to such a modified application would not serve to also provide for changes to Permit 96030056, the CAAPP permit for the facility, as are ultimately desired. Integrated Processing of the Application is of benefit for both US Steel and the Illinois EPA. This is because it would enable the issues that are raised in US Steel's appeal of Permit 96030056, as it includes certain limitations established in Permit 95010001, to be directly addressed and potentially resolved by means of the revisions to Permit 95010001.

observes that Permit 95010001 does not specify how emissions are to be quantified for purposes of demonstrating ongoing compliance with annual emission limits set by this permit and that, in the absence of such provisions, the Illinois EPA imposed monitoring and recordkeeping requirements in the CAAPP permit for the facility sufficient to assure compliance with applicable emission limits as required by Subsection 39.5(7)(p) of the Act.

The Illinois EPA then asserts that the Application does not request revisions to Permit 95010001 "that would enable revisions to the CAAPP permit for the facility, Permit 96030056, to be made by administrative amendment to allow prescribed emission factors to be used to determine ongoing emissions of certain units." However, in the Application, US Steel generally requested that the requested revision to Permit 95010001 be subjected to "integrated processing." This requires the Illinois EPA to process the Application and draft any revised permit using a program that "meets procedural and compliance requirements substantially equivalent to those" imposed in the CAAPP program. Although this request was general, and the Application did not specify with precision the monitoring and recordkeeping requirements to be imposed in the revised construction permit and the amended CAAPP permit, that was appropriate. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the Illinois EPA will exercise its judgment regarding these matters. Inherent in the request for integrated processing is an implied request that Illinois EPA satisfy its mandate to draft a revised permit that includes the minimum elements of a CAAPP permit, including monitoring, reporting, and recordkeeping requirements sufficient to assure ongoing compliance with applicable emission limits and to remove or revise conflicting or redundant permit terms.

This comment appears to be directed at Denial Point 13 in the Draft Denial Letters. However, this comment does not respond to the actual deficiency in the Application identified in Denial Point 13. As such, this comment does not show that this denial point should not be a basis for the denial of the Application. In this regard, this denial point is not concerned with the detailed "compliance provisions" that would be included in any revision to Permit 95010001 to set forth how US Steel is to determine the emissions of various emission units on an ongoing basis to demonstrate continuous compliance with the annual emission limits set by the revised permit and other applicable emission standards. The Illinois EPA recognizes that compliance provisions, e.g., provisions for ongoing operational monitoring, emission testing, recordkeeping, and reporting, are usually developed by the Illinois EPA during the drafting of a construction permit, with consideration given to relevant information provided in a permit application for, e.g., the

operational monitoring and recordkeeping, related to compliance that a source is currently conducting for emission units and control devices.[197] Moreover, as the Application proposes that Permit 95010001 be revised to prescribe the emission factors that are to be used for certain units, the Application does not address the nature of the compliance procedures that are expected to then be required for such units.[198]

The deficiency in the Application addressed by Denial Point 13 relates to a specific provision currently in Permit 96030056, the CAAPP permit for the facility. This provision, CAAPP Condition 5.13, sets forth the approach that must generally be used to determine compliance with emission limits for process units set by Permit 95010001. As explained in Denial Point 13, "The procedures that were established in the current CAAPP permit do not provide for use of established emission factors. Rather, the CAAPP permit generally requires US Steet to use 'appropriate emission factor,' i.e., emission factors that do not understate emissions, with the primary responsibility for the appropriateness of the factors that are used placed on US Steel." Accordingly, as the Application requests that the revision to Permit 95010001 prescribe use of specific emission factors and an emission determination methodology for certain Project-affected process emission units, it is appropriate for US Steel to also propose revisions to Permit 95010001 to facilitate the actual use of such factors and procedures as Permit 96030056 currently does not provide for their use.

Moreover, as noted in this denial point, CAAPP Condition 5.13, is currently the subject of an appeal to the Board, PCB 2013-053. As one objective of US Steel for the revisions of Permit 95010001 requested by the Application is to facilitate the resolution of this appeal, it is certainly appropriate for US Steel in the Application to contemplate and directly address revisions to Permit 95010001 that it considers are

---

[197] The Illinois EPA has the primary role in developing the compliance provisions in Illinois' air pollution control permits. This is because these provisions are largely within the Illinois EPA's area of expertise. When drafting a new, renewed or revised permit, the Illinois EPA also develops the compliance provisions considering the provisions in permits that have been issued for similar or comparable units and control systems. However, such provisions, are ideally developed with timely input and suggestions by the permit applicant based on its review of a working draft of the permit prepared by the Illinois EPA.

[198] For example, for the units for which emissions factors would be prescribed, is it expected that the associated compliance procedures would only entail recordkeeping for monthly and annual emissions? Alternatively, would the associated compliance procedures for such units be expected to also include requirement for operational monitoring and/or recordkeeping to verify that such units are being operated in a manner such that the prescribed emissions continue to be appropriate?

needed to resolve this appeal. It would be unsound for the Illinois EPA to simply proceed with revisions to Permit 95010001 that prescribe use of specific emission factors for certain units and emissions points, as requested by the Application, if the actual implementation of such revisions would not be feasible given what is provided for by CAAPP Condition 5.13. In addition, as related to CAAPP Condition 5.13, the Illinois EPA should not have to make a guess as to the revisions related to this condition that US Steel might find acceptable. US Steel, not the Illinois EPA, has proposed that revised Permit 95010001 prescribe certain emission factors, which is what results in the need for related changes relative to CAAPP Condition 5.13.

Finally, when reviewing the Application, it would be improper for the Illinois EPA to rely on the assertion made in this comment that, because the Application requests the revised permit be subject to Integrated Processing, the Application has by implication requested, "… that the Illinois EPA draft a revised permit that meets the minimum [emphasis added] elements of a CAAPP permit…."[199] At a fundamental level, as is confirmed by this comment, the Application, itself, does not request that the Illinois EPA prepare a revised permit that meets the minimum elements of a CAAPP permit, much less a revised permit that provides for compliance requirements that are substantially equivalent to those that would be provided pursuant to the CAAPP. As such, the Application does not show that the revision of Permit 95010001 requested by the Application would meet the criterion for issuance of a construction permit in Subsection 39(a) of the Act. As a general matter, for a project that has been completed, when an application is submitted for revision(s) to the construction permit for the project, it is essential that the application clearly address the revisions to the permit that are being requested. This is because such an application usually does not reopen the entire permit for review by the Illinois EPA.[200] The implied request for the revisions to Permit

---

[199] For convenience, the entirety of relevant part of this comment is provided below:

> **Inherent in the request for integrated processing is an implied request that Illinois EPA satisfy its mandate to draft a revised permit that includes the minimum elements of a CAAPP permit, including monitoring, reporting, and recordkeeping requirements sufficient to assure ongoing compliance with applicable emission limits and to remove or revise conflicting or redundant permit terms.**

[200] Applications for revisions to a construction permit for a project must be clear and specific as to the revisions to the permit that are being requested. The review by the Illinois EPA of such an application is generally bounded by the revisions that are requested and the consequences or implications of the requested revisions for other provisions in the permit.* The application does not automatically act to reopen the entirety of a project for review by the Illinois EPA as if a new application was being submitted for the project. This

95010001 posited by this comment does not even attempt to identify the implications or consequences of the requested revisions to Permit 95010001 for the provisions currently in the CAAPP permit, Permit 96030056. Finally, the "implied request" that this comment asserts is inherent in the Application is not set forth in sufficient detail to conclude that the request extends to all of the requirements that might be found necessary for the revision to Permit 95010001 to provide for compliance requirements that are substantially equivalent to those that would be required by the CAAPP. Indeed, would the implied request be defective simply because it only extends to "minimum" requirements? This word places a restriction on the requirements that the Application requests be addressed by the revisions of Permit 95010001 that is not present in the CAAPP when it establishes the criteria that a construction permit must satisfy to qualify as having been subject to Integrated Processing.[201, 202]

---

appropriately recognizes and addresses the fact that the applicant for a revised permit already holds a construction permit for the project. Some or many of the provisions in that permit may address units for which construction has been completed that would not be involved in or affected by the requested revisions to the permit.

*** The requested revisions to Permit 95010001 have implications and consequences that extend beyond this permit, itself, to the provisions of the current CAAPP permit. As Integrated Processing is requested for the revised permit, those implications and consequence must be confronted in the Application.**

[201] It also appears that the implied request is defective because, when considered as a whole, it indicates that US Steel has requested that the revisions to Permit 95010001 provide for establishment in Permit 96030056 of appropriate compliance procedures, e.g., provisions for monitoring and recordkeeping. However, for Integrated Processing, the Act requires that a construction permit provide for compliance requirements that are substantially equivalent to those that would be required by the CAAPP. The comment does not use the statutory term. As examples of compliance procedures, the comment only describes activities that might be considered "periodic monitoring" under the CAAPP. The meaning of "compliance requirements" is necessarily broader than "compliance procedures." The CAAPP mandates that CAAPP permits include requirements in addition to compliance procedures or periodic monitoring. For example, CAAPP permits must accurately identify and address the emission units at a facility. CAAPP permits must also accurately identify and address the emission standards that apply to the different units and activities at a facility.

[202] It is also worrisome that the assertion made in this comment is contrary to a statement made in US Steel's Comment XIII.I, as provided below. That comment responds to Denial Point 17, which finds the Application to be deficient because US Steel has not provided information in the Application or in a separate application to amend the CAAPP permit that identifies emission units that are now permanently shut down but are still included in the current CAAPP permit. In particular, the two by-product recovery coke oven batteries at the facility and associated by-product recovery equipment, which ceased operating in 2015, are still identified in Permit 96030056.

C. The Application Includes All Required Information In Conjunction with the Request for Changes to Emission Point Naming (Denial Point 12 – Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy))

In the draft denial letter, Attachment 1, the Illinois EPA correctly observes that the Application asks that the requested revision to Permit 95010001 refer to the unit currently identified as the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" be renamed and identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." The Illinois EPA then asserts that the Application is deficient for the following reasons:

> However, the application does not actually identify the specific units that would be addressed by the proposed new term. In this regard, the application is not accompanied by an itemized list of the equipment and activities that would be covered by this new term or a diagram that identifies this equipment and activities. US Steel's request also does not explain how the requested revision to Permit 95010001 would do what has generally been requested as the proposed new term would refer to a "Material Handling Tripper." As the 2022 application requests changes to terminology in Permit 95010001, the changes should act to better identify the emissions units that would be addressed, improving the specificity and clarity of the revised permit.[Footnotes] 51, 52
>
> [Footnote] 51 For example, the proposed new term would not make clear that the basic oxygen furnace shop actually has two ladle stirring stations and one ladle metallurgy furnace, all served by Baghouse 2.

By this statement, US Steel effectively refuses to provide such information. The Illinois EPA considers such information would be necessary to assure that the amendment of the CAAPP permit that would be authorized by Integrated Processing of the requested revised Permit 95010001 would provide for compliance requirements that are substantially equivalent to those provided for by the CAAPP. In this regard, US Steel's pending application for renewal of the CAAPP permit includes units that are now shut down. Subsection 39.5(5)(i) of the Act requires that when a source becomes aware that it has submitted incorrect information in a CAAPP application, it shall submit correct information to the Illinois EPA.

The Application was submitted for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NaNSR applicability evaluations relating to the Project implemented by National Steel.

US Steel's Comments of January 2024, p. 37, Comment XIII.I

[Footnote] 52 The requested change to the terminology for these emissions unit(s) is also problematic as it would refer to a control device, Baghouse 2, rather than to the equipment or activities that generate emissions. Applied literally, the proposed term would only address captured emissions; it would not address the uncaptured emissions, which elude capture for control by the baghouse.

The deficiency alleged in the subject denial point is without merit. As an initial matter, US Steel has not characterized the listed item as emissions units, regardless of the naming convention. It is an emission point, and that is how US Steel characterized it in the Application. Permit 95010001 limits both its emissions of both PM and PM_{10} to 0.00715 pounds/ton of steel and 12.8 tons/year, which limitations apply solely to the emission point and not separately to “the equipment or activities that generate emissions.” Any uncaptured emissions from that equipment or activities occur through the BOF Shop Roof Monitor. Those emissions are subject to the separate emission limitations for the item referenced as “BOF Roof Monitor.” This is consistent with the approach originally taken in Permit 95010001, in which the limitations for the particulate emission of casthouse and BOFs apply to emission points. For example, for the BOFs, separate limitations are set for the particulate emissions of the “BOF ESP Stack (charge, refine, tap) and the “BOF Roof Monitor.”

A similar change to the item naming was made by Illinois EPA in 2013 when issuing the CAAPP permit, Permit 96030056. In CAAPP Condition 7.5.6(g), the units to which these particulate emission limits, i.e., 0.00715 pounds/ton and 12.8 tons/year, apply are identified as “Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2), rather than “Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy),” as in Permit 95010001. The list of the equipment and activities that would be covered by this proposed new term, *i.e.*, “Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility,” is similar to the list of the equipment and activities that are currently covered by the term “Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)” in Permit 95010001 and by the term “Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)” in Permit 96030056. US Steel reasonably concluded that Illinois EPA would understand this fact because the Application requested and enumerated only discrete changes to Permit 95010001, none of which related to reconfiguring the equipment and activities venting to this emission point.

Notwithstanding the above, it remains the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. The assertion in this denial point that, as the Application requests changes to current terminology in Permit

95010001, "…the changes should act to better identify the emission units that would be addressed, improving the specificity and clarity of the revised permit," is unfounded. If the Illinois EPA wishes to revise the permit to better identify the emissions units that would be addressed by particular emission limitations, Illinois EPA has the authority and discretion to make such revisions.

Finally, the Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that a straightforward request for revision of the name of an emission point be accompanied by a list of the equipment and activities venting to that emission point, nor does the Illinois EPA point to even an application form or guidance document suggesting that such information be provided. A permit applicant has no obligation to reflect in its application a correct guess as to how the Illinois EPA will exercise its judgment regarding these matters. Of course, Illinois EPA retains authority, pursuant to 35 IAC 201.152, to request further information documentation in conjunction with a permit application, but that was not done here.

This comment does not show that the Application should not be denied. The "renaming" of the subject units that is requested by the Application is not trivial. It does not involve a change to reflect the names or designations now used by US Steel for units or equipment.[203] Rather, a revision to Permit 95010001 is requested that would entail a change to the units to which certain emission limitations in this permit currently apply. However, the Application does not address the implications of the requested change as to the units for which these limitations would then apply. An applicant for an air pollution control permit has a general responsibility to submit an application that clearly identifies the emission units and control devices that are the subject of the application and to provide information for their emissions.[204]

---

[203] For example, US Steel has changed the name of the new boiler constructed pursuant to Permit 06070023. In this permit, this boiler is referred to as the "Cogeneration Boiler." In the subsequent CAAPP application for the facility, this boiler is referred to as "Power Boiler 1." The applicability of the emissions limitations established for this boiler by Permit 06070023 is not altered by referring to this boiler as Power Boiler 1 in Permit 96030056, the CAAPP permit for the facility.

[204] US Steel's request for renaming of the subject units is not accompanied by a listing of units or process equipment or a process flow diagram that reasonably provides specific information as to the units or process equipment that are actually the subject of the request. It may be reasonable for an applicant when quantifying emissions to further refine the data that is provided, e.g., the emissions from use of different fuels or the captured emissions from units, which occur from the control device(s), and the uncaptured emissions from units. However, this does not alter the fundamental obligation of a permit

The Illinois EPA cannot issue a revision to Permit 95010001 absent information in the Application for the units served by a particular control device, based merely upon the opinion or belief of the Illinois EPA as to the units at the Granite City Works that such control device serves.

In particular, the change in naming of these units requested by the Application is not a straightforward request. The change would directly alter the applicability of the current emissions limitations. In Permit 95010001, the subject particulate emissions limitations apply to the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy))," (Permit 95010001, Condition 20 and Table 3). **If the identification of the operations to which these limitations apply were changed by renaming as requested, these limitations would apply to a particular baghouse. The limitations would not apply to emission units served by that baghouse and would no longer apply to or address all emissions of the subject units. Moreover, as this comment indicates that uncaptured particulate emissions from these units, which would not be addressed with the requested change to the permit, occur through the BOF shop roof monitor, this comment suggests, if anything, another reason to deny the Application.[205] This is because, for the roof monitor on the BOF shop, the Application only accounts for particulate emissions from the BOFs. The Application does not account for the uncaptured emissions of the subject units, which this comment indicates also occur through the roof monitor.[206]**

As a general matter, this denial point reflects the care that should be exercised when making changes to the naming or identification of the emission units and/or emission points to which the emission limitations set by a permit apply. US Steel, not the Illinois EPA, has proposed the renaming of these units. The request does not involve a simple change

---

applicant to clearly identify the units whose emissions are being addressed in its application.

[205] In fact, the Application does not suggest that these limitations apply to an emission point, rather than to emission units. When requesting that these units be renamed, the Application refers to them as emission units or an "operation," (Application, Section 11.1.2, p. 11-2).

[206] Incidentally, the position taken in this comment with respect to the subject emission units is inconsistent with the position taken in the Application with respect to the casthouse and BOFs. For those units, the Application requests that the revision of Permit 95010001 no longer set separate emission limitations for the various emissions points from the units. The Application requests that revised Permit 9501001 prescribe emission factors for uncaptured emissions that occur through the associated roof monitors. For the units addressed by Denial Point 12, the comment simply claims, without support, that the current emission limitations in Permit 95010001 only address emissions of these units that occur through one emission point, i.e., the captured emissions through the stack of a baghouse.

to reflect the names by which these units are now known. As such, it was incumbent for US Steel to adequately support its request, which it did not do. Accordingly, the Application does not show that the requested revision of Permit 95010001 would comply with applicable requirements if these units were renamed as requested by the Application.

Finally, this comment does not support its other claims that the deficiency in the Application addressed by Denial Point 12 relative to the Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy) is without merit or would be improper. The Illinois EPA prepared the Revised Draft Denial Letter to better identify the provisions of the Act and the Illinois Code that might be violated if a revision to Permit 95010001 were issued as requested by the Application. The comment does not address the provisions that were identified for this denial point to show that they do not provide a valid basis for denial of the Application. As this comment observes that the Illinois EPA could have requested relevant supporting information without denying the Application, this fact does not preclude denial of the Application, as explained in General Response 1. As also addressed in General Response 1, 35 IAC 201.152 addresses certain information that is to be included in a permit application. It does not address all information that must be included in an application if the requested permit is to be issued. 35 IAC 201.152 also does not address the process by which the Illinois EPA may request supplemental information be provided for an application after it has been deemed to be administratively complete. Lastly, as also addressed in General Response 1, the historic naming or designations of emissions units or emission points used by the Illinois EPA in prior permitting is not relevant for whether the requested change should be found acceptable. US Steel's expectations for the Illinois EPA's reaction to this requested change are also not relevant to the merits of this denial point.

D. The Application Includes All Required Information Relating to the Steel Slag Removal Station and the Handling Operation for Raw Materials Used in Ladle Metallurgy (Denial Point 12 – Deslagging Station and Material HS (Handling System))

In the draft denial letter, Attachment 1, the Illinois EPA observes that the Application "does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS. These emissions units are currently addressed in Permit 95010001 with Continuous Casting Operations (Permit 95010001, Condition 20 and Table 3.)" Although US Steel did not request any revisions to Permit 95010001 with respect to these units that it considers to be substantive, the Application did request that the units to which these limitations apply be renamed as "Baghouse 1 for Material Handling." This revision was

suggested for two reasons. First, applying these limitations based on the emission point rather than the emitting activity is more consistent with the naming convention generally used in Permit 95010001, as discussed in US Steel's Comment XIII.C, above. Second, the historical naming of this item is misleading, as this baghouse does not serve to control emissions from any slag removal operation; the steel slag removal station at the facility is not served by any capture system or baghouse.

The requested renaming is consistent with the naming used by Illinois EPA in Permit 96030056, Attachment 3, "Current Emission Factors for Certain Emission Limits," which refers to this item as "Baghouse #1." CAAPP Conditions 7.1.6(b)(i) and 7.6.6(a) in Permit 96030056, respectively, limit emissions of the "Material HS and Deslagging Station" and the "Deslagging Station and associated Material Handling System. (Permit 96030056 addresses these units both in Part 7.1 of the permit as a Material Handling Operation and in Part 7.6 as a Continuous Casting Operation.)[207]

As related to the steel slag removal station (i.e., the activity identified as "deslagging station" in past permitting), The Illinois EPA asserts that the Application is deficient because it "does not explain why steel deslagging should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the BOF shop." US Steel has claimed neither that the steel slag removal station should not appropriately be categorized as slag skimming nor that it should not be addressed with the other slag skimming operations in the BOF shop. US Steel was under no obligation to offer, as part of the Application or otherwise, a justification for a claim that it was not making.

In addition, the Illinois EPA states that the Application "does not request revisions to Permit 95010001 to facilitate amendment of the CAAPP permit to appropriately address the emissions of this deslagging station and the associated material handling system." The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that an application for a construction permit revision, even one for which Integrated Processing is requested, include a request for revisions "to facilitate amendment of the CAAPP permit" for the facility. It is the responsibility of Illinois EPA to draft both a construction permit and a CAAPP permit with conditions it judges to be suitable and appropriate. A permit applicant has no obligation to reflect in an application to correctly guess as to what revisions to one permit would be viewed by the Illinois EPA as facilitating

[207] In CAAPP Condition 7.1.2, "List of Emission Units and Air Pollution Control Equipment," the use of Baghouse #1 is indicated for control of emissions of the LMF Conveyors and Storage Bins.

revisions to another permit.

This comment does not show that the Application should not be denied for reasons as detailed in Denial Point 12 with respect to the "Deslagging Station and Material HS." As an introductory matter, the Application does not actually appear to request that these units be renamed, as claimed in this comment.[208] Then, as the comment claims that the Application requests that these units be renamed "Baghouse 1 for Material Handling," the comment, itself, acknowledges a flaw in this request since the emissions of the Deslagging Stations are not controlled by Baghouse #1 (or any other baghouse).[209] Indeed, if units were to be renamed, as this comment claims is requested by the Application, it appears that the Application requests that revised

---

[208] If, in fact, the Application did request that the Deslagging Station and Material HS, be renamed as is claimed by this comment without any reference to the relevant page(s) in the Application, the Illinois EPA did not find this request. Moreover, the approach taken in the Application for the renaming of the Deslagging Station and Material HS would be distinctly different from the approach taken for the Argon Stirring Station and Material Handling Tripper. For the Argon Stirring Station and Material Handling Tripper, the Application requested renaming of these units in three places in the Application, i.e., Section 5.5.2, "Basic Oxygen Furnace Shop Operations;" in Section 5.5, "Requested Changes to Permit Terms Relating to PM and PM_{10} Emissions;" and in Section 11.1.2, "National Emissions Standards for Hazardous Air Pollutants (NESHAP, 40 CFR Part 61 and 63)" in Section 11, "Regulatory Applicability Review." In Section 11.1.2, the Application explains that, "… for clarity and consistency with these federal rule requirements, USS Granite City requests that that this operation be renamed as the 'Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility' and grouped with the BOF Shop Operations." However, comparable requests are not made in the Application for the Deslagging Station and Material HS.*

*** For the Deslagging Station, there is also a similar issue as to whether this station is subject to requirements of 40 CFR 63 Subpart FFFFF, either as it is a "skimming station" or "ladle metallurgy" as defined by 40 CFR 63.7852. That is, is the deslagging Station either a location in a BOF Shop, prior to casting, where slag is removed from the top of the molten metal or a secondary steelmaking process that is typically performed in a ladle after refining in a BOF to adjust or amend the chemical or mechanical properties of steel. The Application does not include a description or other information for the Deslagging Station showing that it is not an affected unit under 40 CFR 63 Subpart FFFFF, such that revised Permit 95010001 need not address requirements of these rules for this unit. This determination is important. If this unit is subject to these rules, the revision of Permit 95010001 must consider the relevant compliance requirements imposed on this unit by these rules.**

[209] This illustrates the deficiency that can result if emission limitations are set for control devices without appropriately addressing all emissions of the units that are being controlled, as is discussed above in response to US Steel's Comment XIII.C, concerning the Argon Stirring Station and Material Handling Tripper.

Permit 95010001 not even address the existing Deslagging Station and its emissions.[210]

The deficiencies in the Application with respect to the Deslagging Station and Material HS are similar to those for the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)," as discussed above in response to US Steel's Comment XIII.C. However, the deficiencies in the Application related to the Deslagging Station and Material HS are more extensive. The Application requests that revised Permit 95010001 address units engaged in handling of raw materials as a separate category of operations, as was done in the CAAPP permit, Permit 96030056. The shifting of the Argon Stirring Station and Material Handling Tripper from Continuous Casting Operations to BOF Shop Operations would simply entail moving these units from one section of Permit 95010001 to another section.[211] Moving the Material HS that is currently addressed with the Deslagging Station would be more involved.[212]

The overarching deficiency in the Application with respect to the Deslagging Station and Material HS is inconsistency in the treatment of these units and the treatment of the Argon Stirring Station and Material Handling Tripper. For the latter units, the Application requests revisions to Permit 95010001 to address issues posed by the conditions currently in this permit that address these units. Most notably, the Application acknowledges applicability of the requirements of 40 CFR 63 Subpart FFFFF. It requests that these units be addressed in the revised permit as BOF Shop Operations rather than Continuous Casting Operations. However, as revisions to Permit 95010001 are not

---

[210] Neither Section 5.5.2 nor Section 5.5.3 of the Application list the Deslagging Station as a unit that would be addressed by, respectively, either the proposed emissions cap for the "Basic Oxygen Furnace Shop Operations" or the proposed cap for the "Continuous Casting Operations." Prescribed emission factors are also not proposed for the Deslagging Station.

[211] The Argon Stirring Station or Stations at the facility are directly subject to requirements of the NESHAP, 40 CFR 63 Subpart FFFFF as they are BOF Shop Ancillary Operations. As such, compliance with the requirements of 40 CFR 63 Subpart FFFFF is also required for the Material Handling Tripper as its particulate emissions are being controlled by a baghouse, Baghouse #2, that also controls NESHAP-subject units.

[212] Moving the Material HS that is currently combined with the Deslagging Station would be more involved as it would entail allocating the current permitted emissions between these units. The allocation for the Material HS would then be addressed in the new section of Permit 95010001 for units engaged in handling or processing of raw materials. The emissions from the Deslagging Station would either stay with the section for Continuous Casting Operations or be moved to the section for BOF Shop Operations. Finally, since emission testing is not feasible for the Deslagging Station, as it is not served by an add-on control device, it is expected that prescribed emission factors would need to be developed and justified for this unit.

requested for the current conditions in Permit 95010001 for the Deslagging Station and Material HS, the implication is that these conditions do not pose issues. As already discussed, this is not the case. The issues that are posed by the current conditions for the Deslagging Station and Material HS and the resolution of these issues would be more involved than resolution of the issues posed by the conditions for the Argon Stirring Station and Material Handling Tripper.

Finally, this comment does not support its other claims that the deficiency in the Application addressed by Denial Point 12 relative to Deslagging Station and Material HS is without merit or would be improper. The Illinois EPA prepared the Revised Draft Denial Letter to better identify the provisions of the Act and the Illinois Code that might be violated if a revision to Permit 95010001 were issued as requested by the Application. The comment does not directly address the various provisions that were identified for this denial point to show that they do not provide a valid basis for denial of the Application. As this comment specifically claims that denial based on this denial point would be improper because the Illinois EPA has not identified a provision that requires this Application to, "include a request for revisions 'to facilitate amendment of the CAAPP permit' for the facility," it ignores the implications of the Application's request for Integrated Processing for the contents of the Application. The amendment to the Permit 96030056 that would be authorized by revised Permit 95010001 must provide for compliance requirements that are substantially equivalent to those that would be required by the CAAPP. The Application proposes that the Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy), that are BOF Shop Operations be transferred from the provisions of Permit 95010001 for Continuous Casting Operations to the provisions for BOF Shop Operations, so the emission standards that apply to those units would be properly addressed. By this request, US Steel directly poses the related question whether other operations, i.e., Deslagging Station and Material HS, should also be transferred from Continuous Casting Operations to BOF Shop Operations.

E. The Application Includes All Required Information Relating to the Ladle Drying Preheaters (Denial Point 12 – Ladle Drying/Preheating)

In the draft denial letter, Attachment 1, with respect to the Ladle Drying Preheaters, Illinois EPA claims that the Application is deficient because US Steel "does not request any changes to Permit 95010001 to maintain consistency with the approach to these units in the CAAPP permit."

This assertion is without merit. The Illinois EPA does not identify any

provision of the Act or the Illinois Code requiring that any application for a construction permit revision, even one for which Integrated Processing is requested, include a request for revisions "to maintain consistency with the approach to these units in the CAAPP permit" for the facility. It is the responsibility of Illinois EPA to draft both a construction permit and a CAAPP permit with conditions that it judges to be suitable and appropriate. A permit applicant has no obligation to reflect in its permit application a correct guess as to what revisions to one permit would be viewed by the Illinois EPA as maintaining consistency with another permit.

This comment does not show that the Application should not be denied based on Denial Point 12 as it addresses a deficiency in the Application with respect to Ladle Drying/Preheating. This comment ignores the fact that the Application requests a revision to permit 95010001 to increase the emissions of NOx for which the BOFs are permitted.[213] In Section 6.5.2, the Application requests changes under Table 2 of Permit 95010001, proposing new Condition 18(b), which would provide that, "NOx emissions from the BOF ESP and BOF baghouse stacks shall not exceed 400 tons/year on a monthly rolling 12 month-total." However, Section 6.5.2 does not propose any changes to Condition 18 and Table 5 of Permit 95010001 as they currently limit NOx emissions of the BOF Shop to 70 tons/year.[214]

The absence of a request in Section 6.5.2 of the Application that new "Condition 18(b)" be accompanied by removal of the limit of 70 tons/year from Permit 95010001 was almost certainly an oversight. The more serious issue for the Application is that Permit 96030056 currently limits the NOx emissions of the BOF shop to 70 tons/year (CAAPP Condition 7.5.6(b)). Ladle Drying/Preheating, which physically takes place in the BOF Shop, is identified as a Basic Oxygen Process (CAAPP Condition 7.5.2, "List of Emission Units and Pollution Control Equipment"). As such, on its face, Permit 96030056 restricts the combined NOx emissions of Ladle Drying/Preheating and the BOFs, with an overall limit of 70 tons/year.[215] The Application does not propose revisions to relevant conditions in Permit 96030056. In the absence of appropriate changes to those conditions, those conditions would be an

---

[213] Permit 95010001 currently limits annual NOx emissions of the BOFs to 69.63 ton/year (Condition 18, Table 2). The annual NOx emissions of the BOF Shop are limited to 70 tons/year (Condition 18 and Table 5).

[214] It should be noted that the Application has also been denied as related to this proposed limitation for the NOx emissions of the BOFs, 400 tons/year, because the Application does not address uncaptured NOx emissions of the BOFs, only the captured NOx emissions of the BOFs. This is addressed in Denial Point 4, for which US Steel submitted its Comment X, as discussed in this Responsiveness Summary.

[215] Ladle Dryer/Preheaters are also addressed elsewhere in Permit 96030056 with other Project-affected fuel burning units.

impediment to amending Permit 96030056 to reflect the increase in permitted NOx emissions of the BOFs as proposed by the Application.[216] This deficiency would not have been present if the Application had proposed revisions to Permit 95010001 that, by means of Integrated Processing, would have enabled appropriate changes to be made to Permit 96030056 by administrative amendment so that Ladle Drying/Preheating would not be addressed as a Basic Oxygen Process.

Finally, this comment does not support its other claims that the deficiency in the Application addressed by Denial Point 12 relative to Ladle Drying/Preheating are without merit or would be improper. The Illinois EPA prepared the Revised Draft Denial Letter to better identify the provisions of the Act and the Illinois Code that might be violated if a revision to Permit 95010001 were issued as requested by the Application. This comment does not directly address the provisions that were identified for this denial point to show that they do not provide a valid basis for denial of the Application. As this comment specifically claims that denial based on this denial point would be improper because the Illinois EPA has not identified a provision that requires this application to maintain consistency with the approach to the emission units in the CAAPP permit, this claim misconstrues the basis of the denial. The Application has been denied because it does not show that the requested revised permit would meet substantive statutory and regulatory requirements. As related to Ladle Drying/Preheating, the Application does not consider the implications of relevant conditions currently in Permit 96030056 for the requested revised permit. That is, the Application does not show that the revisions to Permit 96030056 for Ladle Dryer/Preheaters that would be authorized by the administrative amendment of revised Permit 95010001, as requested by the Application, would provide for compliance requirements for these units that are substantially equivalent to what would be provided for by the CAAPP. In this regard, the Application requests that the Argon and Material Handling Tripper (Ladle Metallurgy) be moved from the provisions of Permit 95010001 for Continuous Casting Operations to the provisions for BOF Shop Operations, so they would be addressed with other BOF Shop Ancillary Operations. This directly raises the question for the Ladle Drying/Preheating whether it is also properly addressed in the provisions of Permit 96030056 for BOF Shop Operations. Alternatively,

[216] For example, the Application does not propose that revised Permit 95010001 set an overall cap for the NOx emissions of the BOFs and the NOx emissions from Ladle Drying/Preheating. Alternatively, the Application does not propose changes to make clear that Ladle Drying/Preheating should only be addressed as it involves Project-affected fuel burning units and not as a Basic Oxygen Process.

as seems more likely, is Permit 96030056 flawed as it addresses Ladle Drying/Preheating as a BOF Shop Operation?[217]

F. The Application Includes All Required Information Related to Identification of the Version of the CAAPP Permit That Would Be Administratively Amended Pursuant to Integrated Processing of the Requested Revised Permit Application (Denial Point 14)

In the draft denial letter, Attachment 1, the Illinois EPA explains that the Application is deficient because it "does not identify the version of the Clean Air Act Permit Program (CAAPP) permit for the facility, Permit 96030056, that would be eligible for administrative amendment pursuant to the Integrated Processing of the revisions to Permit 95010001 that are requested." Relatedly, Illinois EPA asserts that US Steel "has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006."

These assertions are without merit. US Steel has initiated the process of incorporating the provisions of Construction Permit 11050006 into Permit 96030056, the CAAPP permit for the facility. In November 2013, US Steel applied for renewal of this permit for the facility. In that application, US Steel expressly requested that Illinois EPA incorporate requirements from Permit 11050006 into the CAAPP permit and noted that "the Basic Oxygen Furnace process described in the CAAPP permit Condition 7.5 needs to be updated with the new secondary baghouse added as part of the Emission Reduction Project (Construction Permit 11050006)." (CAAPP Renewal Application, p. 2-1.) Pursuant to Subsection 39.5(5)(f) of the Act, that application was subsequently deemed complete by operation of law.

In addition, the Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that any application for a construction permit revision for which integrated processing is requested to specify the "version" of the CAAPP permit that would be amended. It is solely the responsibility of Illinois EPA to make revisions and amendments to CAAPP permits in conformance with applicable rules and laws.

This comment sidesteps the deficiency that is addressed in Denial Point 14. As such, this comment does not show that it was improper to deny the Application for the reason set forth in this denial point. The deficiency

---

[217] It is noteworthy that, as Denial Point 12 calls attention to certain conditions in the CAAPP permit that address Ladle Drying/Preheating, the concern is not that the Application does not request revisions to Permit 95010001 that would be consistent with the approach to these units taken by the CAAPP permit. Rather, the concern is the converse. The approach to these units taken in the Application should not be the approach taken by the current CAAPP permit. That approach is problematic and would be an impediment to effectuating changes requested to Permit 95010001.

arises because a construction permit that was processed with Integrated Processing, Permit 11050006, has already been issued to US Steel, thereby authorizing certain revisions to Permit 96030056 to be made by administrative amendment. However, US Steel has never submitted an application to the Illinois EPA for the administrative amendment to Permit 96030056 that is authorized by Permit 11050006, leading to the actual issuance of an amended CAAPP permit. Thus, for the purpose of the request in the Application that the revision to Permit 95010001 be subject to Integrated Processing, there are effectively two versions of Permit 96030056. One is Permit 96030056 as currently in effect. The other is an "amended" version of this permit that would take effect if and when US Steel submits its application to the Illinois EPA for administrative amendment of 96030056, as has been provided for by Permit 11050006. This would not be the case if US Steel simply submitted an application for the administrative amendment to Permit 96030056 that is already authorized by Permit 11050006.

Simply as related to the physical drafting of the revisions to Permit 95010001 that are requested, the possibly for there to be two different versions of Permit 96030056 obstructs the preparation of a revised version of Permit 95010001. The revision of Permit 95010001 requested by the Application must be crafted so that the amendments to Permit 96030056 that it authorizes can take place seamlessly. The subsequent amendment of Permit 96030056 would be a ministerial function by the Illinois EPA. The nature and location of the specific changes to Permit 96030056 that are being authorized must all be decided upon and laid out during the preparation and issuance of revised Permit 95010001. To do this, the version of Permit 96030056 that would be revised must be known. If not, the revised version of Permit 95010001 could be prepared relative to one version of Permit 96030056 but the other version of Permit 96030056 would have become effective when the administrative amendment of Permit 96030056 is actually submitted.

The forethought and advance planning that are needed when preparing a revised version of Permit 95010001 are critical for the procedures that are followed for this revised permit. The future changes to the Permit 96030056 that are authorized by means of the revised version of Permit 95010001 must be clearly set forth. This is essential so that the public and USEPA may review and comment on the planned changes, as reflected in draft and proposed versions of the revised permit before a revised version of Permit 95010001 is issued and becomes effective. This is because the public and USEPA will not subsequently have the opportunity to review and comment on the administrative amendment of Permit 96030056 that has been authorized.

As already explained, this comment does not respond to the deficiency detailed in Denial Point 14 to attempt to show that it is without merit. The submittal of an application for renewal of the CAAPP permit,

Permit 96030056, is not the submittal of an application for an administrative amendment of this permit.[218, 219] Moreover, Denial Point 14 does not suggest that the deficiency that it addresses necessitates updates to the pending application for renewal of Permit 96030056.

With respect to the other claims in this comment, they are without merit. Indeed, these claims illustrate how similar claims made elsewhere in US Steel's comments are erroneous or inane. US Steel ignores the fact that the Revised Draft Denial Letter does identify the statutory and regulatory basis for Denial Point 14. Notably, Subsection 39.5(13)(c)(v) of the Act is identified, which provides the requirements that a construction permit must satisfy to qualify as having been subject to Integrated Processing.[220] In this case, to accomplish this, it is essential for US Steel to deal with the administrative amendment to Permit 96030056 that is already authorized

---

[218] The renewal of a CAAPP permit is addressed by Subsections 5, 7, 8, 9 and 10 of Section 39.5 of the Act. Among other things, a draft version of the renewed CAAPP permit must be made available to the public for review and comment, pursuant to Subsection 39.5(8); a proposed version of the renewed permit must then be provided to USEPA for its review and possible objection to the proposed permit, pursuant to Subsection 39.5(9). Administrative amendments are addressed by Subsection 39.5(13) of the Act. The issuance of an administrative amendment by the Illinois EPA is a ministerial function. Opportunity for review and comment by the public and USEPA are not provided for administrative amendments of CAAPP permits.

[219] It is also perhaps noteworthy that, with respect to the BOFs, US Steel's 2013 CAAPP renewal application actually explains that "… the Basic Oxygen Furnace process described in CAAPP permit condition 7.5 will eventually [emphasis added] need to be updated with the new secondary baghouse added as part of the Emissions Reduction Project (Construction Permit No. 11050005) once construction is complete."

In addition, in the renewal application, Appendix F - Proposed Permit Changes, more than 25 discrete changes are requested or proposed to Section 7.5 of the CAAPP permit as part of the renewal of the CAAPP permit. The changes that have already been authorized to be made by means of administrative amendment pursuant to Permit 11050006 are not differentiated from other proposed or requested changes.

[220] As already explained, the Act does not require the Illinois EPA to adopt procedural rules that elaborate on the necessary contents of applications for air pollution control construction permits. It would certainly be unreasonable to adopt such rules for applications that request Integrated Processing since such applications are extraordinarily rare. (This is likely because fulfilling the procedural requirements of the CAAPP acts to significantly delay issuance of a permit compared to when a permit might otherwise be issued.) In fact, the Illinois EPA has issued only one construction permit with Integrated Processing, Permit 11050006, the permit issued to US Steel for which it has not submitted an application for administrative amendment of the CAAPP permit. As such, even if such rules were adopted for applications that requested Integrated Processing, it is ridiculous to expect that they would address the situation that is presented with the Application.

by a construction permit but US Steel has not actually initiated. This is something that is outside the ability of the Illinois EPA to remedy through the conditions of the requested revision to Permit 95010001, much less during a subsequent amendment of the CAAPP Permit pursuant to Permit 11050006, the earlier construction permit.[221] As such, as the Application requests that the revision to Permit 95010001 that is sought also be subject to Integrated Processing, the Illinois EPA's responsibility was to deny the Application, which it has done. The Illinois EPA is not required to notify an applicant for an air pollution control construction permit of deficiencies in its application before denying the application.

Finally, as this comment claims that denial of the Application would be improper on procedural grounds because US Steel was not previously informed of this deficiency, this comment by US Steel in response to the Draft Denial Letters confirms that US Steel was informed in writing of the deficiencies in the Application before the Application was denied. What is noteworthy is that US Steel did not utilize the information in the Draft Denial Letters to attempt to remedy deficiencies presented by the Application that could readily be rectified by US Steel, such as Denial Point 14, as is discussed here.

G. The Application Includes All Required Information Relating to the Relationship Between Fugitive Dust Control Measures Required by Permit 95010001 and Requirements of 35 IAC Part 212 (Denial Point 15)

In the draft denial letter, Attachment 1, the Illinois EPA claims that the permit application is deficient because it "does not make clear the relationship between these requirements established by permit [requirement in Condition 23, 24, 26, 27, 28, 28 and 30 of Permit 95010001, relating to emissions of fugitive dust from roadways, parking areas, and open access areas] and state regulatory requirements for

---

[221] As this comment states that, "It is solely the responsibility of Illinois EPA to make revisions and amendments to CAAPP permit in conformance with applicable laws and rules," this observation is irrelevant in the context of Denial Point 14. The issue in this denial point is that the Application does not show that the Project, with revisions to Permit 95010001 as requested by the Application, would meet the standard for issuance of a permit.

In this regard, as related to the request for Integrated Processing, it is essential that the revision to Permit 96030056 authorized by Permit 11050006 be addressed. Otherwise, the Illinois EPA cannot proceed with a revised version of Permit 95010001 as requested by the Application. Accordingly, the Application must be denied. In the context of this denial point, as well as several other denial points, the relevant observation for the Application about the responsibility of the Illinois EPA should be that it is the responsibility of the Illinois EPA to deny a permit application when the application does not meet the standard for issuance of a permit.

fugitive emissions in 35 IAC Part 212 Subpart K." This assertion is without merit. The Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that any application for a construction permit revision, even one for which Integrated Processing is requested, specify the relationship between existing permit terms and applicable rule requirements. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws.

This comment does not show that the Application should not be denied based on Denial Point 15. This comment downplays the implication of the Application's request for Integrated Processing of the requested revisions to Permit 9501000. This request affects the required contents of the revised permit and, therefore, the required contents of the Application. As already discussed, Subsection 39.5(13)(c)(v) of the Act provides that for a construction permit to qualify for having undergone Integrated Processing, the compliance requirements in the permit must be substantially equivalent to the requirements that would be required by the CAAPP. As related to the provisions of Permit 95010001 that require implementation of control measures for sources of fugitive dust, the Application is deficient as it does not show that these compliance requirements, either in Permit 95010001 or in Permit 6030056, the CAAPP permit for the facility, are substantially equivalent to those that would now apply if Permit 96030056 were being renewed or modified. In this regard, Denial Point 15 identifies several deficiencies in the Application related to the requirements for the control measure for fugitive dust, including the following, This comment does not show that these deficiencies are not present in the Application.

> **The Application does not propose revisions [to Permit 95010001] to clarify the interplay between the associated recordkeeping and reporting that are required by Permit 95010001 and the associated recordkeeping and reporting required by Board rules. In this regard, except for Condition 25 [addresses 35 IAC 216.361(e)(1), which limits opacity for roadways and parking areas at the facility to more than 5 percent], Permit 95010001 does not address the Board's rules for control of fugitive dust.**
>
> **…**
>
> **While the CAAPP permit for the facility addresses requirements in Board rules for control of fugitive dust, it is unclear whether the requirements for recordkeeping and reporting in 35 IAC 212.316(g) are applicable for the public roadways for which specific measures to reduce emissions of fugitive dust are required by Permit 95010001…**
>
> **… the amendments of the CAAPP permit that are authorized by means of the requested revisions of Permit 95010001 would be deficient.**

> **For roadways, parking areas and other open areas, such an amended CAAPP permit would not clearly delineate the standards for opacity of emissions pursuant to Board rules that apply to different categories of emission units (e.g., 5 percent for roadways and parking areas at the facility, 10 percent for storage piles, and 20 percent for the on-site landfill). In addition, if provisions of 35 IAC 212.316 should not be applied to public roadways, as they are not part of the Granite City Works, such an amended CAAPP would improperly perpetuate errors in the current CAAPP permit regarding applicability of Board rules.**
>
> **Revised Draft Denial Letter, Attachment 1, pp. 55 and 56.**

In addition, this comment does not support its claims that the deficiency in the Application addressed by Denial Point 15 is without merit. The Illinois EPA prepared the Revised Draft Denial Letter to better identify the provisions of the Act and the Illinois Code that might be violated if revisions to Permit 95010001 were simply made as requested by the Application. This comment does not address those provisions to show that they do not provide a valid basis to deny the Application. As the comment specifically claims that Denial Point 15 would be improper because the Illinois EPA has not identified a provision of the Act or the Illinois Code that requires an application for a construction to specify the relationship between existing permit terms and applicable requirements in rules, this claim misrepresents the basis of the denial. As related to requirements for control of fugitive dust, the Application would be denied because the Application does not show the content of the requested revision of Permit 95010001 would meet the statutory requirements for this revised permit to qualify for having been subject to Integrated Processing.[222] This comment also does not refute the inadequacies in the compliance requirements related to control measures in the current permits for sources of emissions of fugitive dust, as also addressed in this denial point.

---

[222] In the Application, US Steel could have proposed specific compliance requirements related to control measures for fugitive dust that it considered would be substantially equivalent to the requirements that would be provided for by the CAAPP, subject to review of the proposal by the Illinois EPA. Alternatively, the Application could have acknowledged that Permit 95010001, as well as Permit 96030056, currently do not contain compliance requirement that fulfill this criterion, identifying areas in which these permits are inadequate. This could be accompanied by a request that the revisions of Permit 95010001 prepared by the Illinois EPA pursuant to the Application include compliance requirements for the control measures for fugitive dust that are intended to be substantially equivalent to the requirements that should now be required under the CAAPP.

H. The Application Includes All Required Information Relating to Applicable Provisions of 40 CFR Part 63 Subpart FFFFF (Denial Point 16)

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the Application is deficient because it "does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020." In Denial Point 16 in the Draft Denial Letter, the Illinois EPA observes that:

> These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the 2022 application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the basic oxygen furnaces and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate.

US Steel generally agrees with Illinois EPA's regarding the relevance of the requirements of the NESHAP. However, the current requirements of the NESHAP, as adopted by USEPA, are legally enforceable. The work practice, monitoring, testing, and recordkeeping requirements of 40 CFR 63 Subpart FFFFF provide a sound technical basis for demonstrating compliance with limits for particulate emission. This is the case regardless of whether the Illinois EPA would reopen Permit 96030056, the CAAPP permit for the facility, to assure compliance with 40 CFR 63 Subpart FFFFF, as reopening of a CAAPP permit is provided for by Subsection 39.5(15)(a)(iv) of the Act.

However, the assertion regarding a deficiency in the Application is without merit because the Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, to include suggested bases upon which Illinois EPA might reopen the facility's CAAPP permit. It is solely the responsibility of Illinois EPA to reopen a CAAPP permit when the Illinois EPA determines that the permit must be revised or revoked to assure compliance with all applicable requirements.

Contrary to the claims made in this comment, the deficiency in the Application addressed in Denial Point 16 is an appropriate basis for the Application to be denied. In particular, for this denial point,

the Revised Draft Denial Letter summarizes the deficiency in the Application. It also provides the reason why this deficiency results in the legal standard for issuance of a permit not being met for the revision to Permit 95010001 that is requested by the Application.

> **The 2022 application [Application] does not address or identify changes to Permit 95010001 and by means of Integrated Processing of the revision to Permit 950100001, the changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are appropriate as a result of certain revisions of the Iron and Steel NESHAP, 40 CFR 63 Subpart FFFFF. …**
>
> **Absent explicit recognition in the 2022 application of the recent revisions to 40 CFR 63 Subpart FFFFF, the version of Permit 96030056 that would be authorized by means of Integrated Processing of revised Permit 95010001 could continue to reflect the historic version of 40 CFR 63 Subpart FFFFF, prior to the revisions related to startup, shutdown and malfunction….**
>
> **It would clearly be contrary to the compliance requirements of the CAAPP if for the casthouse and the BOFs, the amended CAAPP permit that would be authorized [to] be issued by means of Integrated Processing would still include provisions of the historic version of 40 CFR 63 Subpart FFFFF that have ceased to apply.**
>
> **Revised Draft Denial Letter, Attachment 1, pp. 58 and 59.**

As the comment observes that the Illinois EPA may undertake the reopening of a CAAPP permit if it determines that a CAAPP permit must be revised to assure compliance with applicable requirements (e.g., limitations established in construction permits and applicable requirements of 40 CFR 63 Subpart FFFFF), this observation is not relevant. Denial Point 16 concerns a deficiency in the Application, not Permit 96030056. While this deficiency results because certain provisions in Permit 96030056 do not reflect revisions to 40 CFR 63 Subpart FFFFF made by USEPA,[223] this is not the actual reason for denial of the Application. Rather, the Application is being denied because it does not show that the Project-affected emissions units that are subject to 40 CFR 63 Subpart FFFFF would be required to comply with the current requirements of these rules, rather than with

---

[223] As discussed in the Draft Denials, due to USEPA's revision of 40 CFR 63 Subpart FFFFF, certain provisions in Permit 96030056 are now not correct. In particular, in July 2020, USEPA revised 40 CFR 63 Subpart FFFFF to remove the exemption from applicable standards during periods of startup, shutdown and malfunction (SSM). The conditions in the Permit 96030056 addressing 40 CFR 63 Subpart FFFFF are now flawed as they continue to provide that the applicable standards do not apply during SSM. Instead, other, alternative work practice requirements apply for SSM.

the provisions of Permit 95030056 as it indicates these rules provide exemptions from certain standards during periods of startup, shutdown and malfunction. The Application also does not request revisions to Permit 95010001 or alternatively, by means of Integrated Processing, administrative amendments to Permit 96030056 that would explicitly provide that Project-affected units that are subject to 40 CFR 63 Subpart FFFFF must comply with the current requirements of these rules.[224] In the absence of such information in or request by the Application, the Application would not show that the requested revisions to Permit 95010001 would provide for compliance with 40 CFR 63 Subpart FFFFF. Indeed, the Application does not even address USEPA's revision to 40 CFR 63 Subpart FFFFF related to periods of startup, shutdown and malfunction.[225] In summary, this comment does not confront, much less refute, Denial Point 16.

This comment also does not support its claim that denial of the Application based on Denial Point 16 would be improper because the Illinois EPA did not identify the provisions of the Act or the Illinois Code that would require that the Application suggest reason(s) why the

---

[224] Since the applicable requirements of 40 CFR 63 Subpart FFFFF must be addressed in detail in the CAAPP permit for the facility, it would seem preferable that the Application set forth these requirements in the CAAPP permit by means of or reliance upon Integrated Processing of the revision to Permit 95010001. Otherwise, if the detailed requirements of 40 CFR 63 Subpart FFFFF are set forth in Permit 95010001, these requirements would have to again be set forth in the CAAPP permit.

[225] For what is referred to by Permit 95010001 as the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)," the Application specifically addresses applicability of 40 CFR 63 Subpart FFFF as follows:

> **… for clarity and consistency with these federal rule provisions [provisions of 40 CFR 63 Subpart FFFFF], USS Granite City request that this operation … be grouped with BOF Shop Operations.**
>
> **Application, Section 11.1.2, "National Emission Standards for Hazardous Air Pollutants (NESHAP), 40 CFR Parts 61 and 63," p. 11-2.**

This is noteworthy because it means that the Application requests changes to Permit 95010001 that involve 40 CFR 63 Subpart FFFFF. However, the Application does not set forth the specific requirements of 40 CFR 63 Subpart FFFFF that apply to the units for which applicability of these rules are addressed. Instead, the Application presumably relies on the provisions of Permit 96030056 that set forth the requirements of these rules for a "ladle metallurgy operation." For example, CAAPP Condition 7.5.3(e)(iii) sets forth the standard of 40 CFR 63.7790(a) for the PM emissions from a control device applied to such an operation. The Application does not acknowledge that USEPA has revised 40 CFR Subpart FFFFF so that it no longer provides an exception to certain requirements for SSM, contrary to what is currently indicated in Permit 96030056.

CAAPP permit for the facility should be reopened. As explained above, the absence of such information from the Application is not the deficiency in the Application identified in this denial point.[226] The Illinois EPA prepared the Revised Draft Denial Letter to better identify the provisions of the Act and the Illinois Code that might be violated if a revision to Permit 95010001 were issued as requested by the Application. This comment does not address the provisions that were identified for this denial point show that they are not a valid basis for denial of the Application.[227]

I. The Application Includes All Required Information Relating to Equipment that is Listed in the CAAPP Permit and Has Been Permanently Shut Down (Denial Point 17)

In the draft denial letter, Attachment 1, the Illinois EPA asserts that the Application is deficient because it "does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emissions units" and further asserts that "[t]he responsibility to identify provisions in the CAAPP permit that should not be carried forward initially falls on US Steel as it is the CAAPP Permittee for the Granite City Works."

The Application was submitted for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NaNSR applicability evaluations relating to the Project implemented by

---

[226] US Steel does not need to provide a basis upon which the Illinois EPA could initiate a reopening of Permit 96030056 to address USEPA's revisions to 40 CFR 63 Subpart FFFFF. As acknowledged by this comment, under both the Clean Air Act and the Act, US Steel must comply the requirements of 40 CFR 63 Subpart FFFFF as they currently exist without consideration of the outdated provisions of Permit 96030056 that indicate that certain requirements do not apply during periods of startup, shutdown and malfunction. As a practical matter, a reopening of Permit 96030056 to specifically address these outdated provisions would only be needed if US Steel attempts to rely on the outdated provisions of Permit 96030056 to excuse violations of applicable standards during period of startup, shutdown or malfunction.

[227] For Denial Point 16, the provisions of the Act that are cited as the basis for denial of the Application are Sections 9(a), 39(a),* 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c) (v). The regulation that is cited as the basis of this denial point is 35 IAC 202.160(a).

*** Section 39(a) of the Act is cited as it provides the statutory standard for issuance of permits. In addition, this section is cited as it provides that when granting permits, the Illinois EPA may impose conditions as necessary to accomplish the purposes of the Act provided they are not inconsistent with Board rules. As discussed in the Revised Draft Denial Letter, Appendix A, p. 2, this second element of Section 39(a) is cited as a basis for denial as the Application does not include information that may be needed for the Illinois EPA to impose necessary conditions in a revision to Permit 95010001 as requested by the Application.**

National Steel. This application was not intended to address changes that are not directly relevant to that purpose. In addition, an application is pending to renew the CAAPP permit for the facility, which application was submitted by US Steel in November 2013, received by the Illinois EPA on December 3, 2013, and subsequently deemed complete by operation of law.

These assertions are without merit. Illinois EPA does not identify any provision of the Act or the Illinois Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, request changes to the facility's CAAPP permit other than those directly resulting from the requested revisions of the underlying construction permit. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws.

The comment does not show that the Application should not be denied. In rebuttal to Denial Point 17, this comment simply claims that denial based on this denial point would be improper because, "The Application was submitted for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NaNSR applicability evaluations relating to the Project implemented by National Steel [presumably, referring to the correction of errors in the original quantification of emissions]." However, US Steel's purpose for the Application is irrelevant to the denial of the Application on this denial point. That a separate application for renewal of Permit 96030056 is pending with the Illinois EPA is also irrelevant.[228]

What is relevant, as was discussed in the Draft Denial Letters, is that the Application requests that the revision of Permit 95010001 sought by the Application be subject to Integrated Processing. As such, pursuant to Subsection 39.5(13)(c)(v) of the Act, the Application effectively becomes a CAAPP application. To the extent that the Application would not address an administrative amendment of Permit 96030056 and does not address units that are now shutdown, the Application requests, by omission, that the Illinois EPA issue an amended CAAPP permit that would, on its face, continue to address units that are now shutdown, e.g., the two by-product recovery coke oven batteries that were shutdown in 2015 and associated by-product recovery equipment. As such, the Application requests a revision to

[228] This comment also observes that the Illinois EPA has not formally requested US Steel to provide information that remedies this deficiency in its application for renewal of Permit 96030056, as the Illinois EPA is authorized to do pursuant to Subsection 39.5(5)(g) of the Act. This fact does not affect US Steel's obligation under Subsection 39.5(5)(g) of the Act.

Permit 95010001 that would authorize issuance of an amended CAAPP permit that on contain blatant errors. This would be contrary to Subsection 39.5(5)(i) of the Act, which provides as follows for applicants for CAAPP permits.

> **Any applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPPP application or who has submitted incorrect information in a CAAPP application shall upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information to the Agency. …**
>
> **Illinois Environmental Protection Act, Subsection 39.5(5)(i).**

By means of the Draft Denial Letters, US Steel has been informed of this deficiency in the Application. However, US Steel has not undertaken action to remedy this deficiency.[229] Moreover, US Steel is the permittee for the Granite City Works. As such, US Steel should initiate actions to appropriately address the changes that it has made at its facility; the Illinois EPA should not initiate such actions on behalf of US Steel.

---

[229] Denial Point 17 does not require US Steel to make a revision to the Application detailing the emission units addressed by the current CAAPP permit that are now shutdown. Alternatively, US Steel could take the necessary action with an appropriate application for an administrative amendment or minor modification of the CAAPP permit. This would also enable issuance of an amended CAAPP permit pursuant to the Application that would no longer address units that have been shut down.

8A. General Responses to Certain Comments by US Steel, As Referred to by the Illinois EPA in Its Responses in Section 7

General Response 1: General Response to Comments As They Address Facts or Matters That Are Extraneous to the Planned Denial of the Application

In many of its comments, as addressed in this General Response 1, in addition to the other specific point(s) that are made by the comments, US Steel also makes observations or claims with regard to facts or matters that, even as they may be true, are appropriately considered extraneous to the planned denial of the Application. As such, as explained in this General Response, these "generic" comments did not show that the Application should not be denied.

Denial of the Application Would Be Improper Because the Illinois EPA Did Not Notify US Steel That the Application Was Deficient Before Beginning the Process for Denial of the Application

In a number of generic comments, US Steel observes that the Illinois EPA did not take certain actions before beginning the preparation of the Initial Draft Denial Letter. In particular, the Illinois EPA did not notify US Steel in writing that the Application was deemed incomplete and that certain information, as the Illinois EPA considered necessary, needed to be submitted as part of a new or revised application.[230] As US Steel's comments make this observation, the

---

[230] In particular, in its comments, US Steel references 35 IAC 201.158 in Part 201, "Permits and General Provision," and 35 IAC 204.1300 in Part 204, "Prevention of Significant Deterioration," which provide as follows:

> **Section 201.158 Incomplete Applications**
> **An application shall not be deemed to be filed until the applicant has submitted all information and completed application forms required by Section 201.152 or 201.157 of this Subpart, whichever is applicable, and procedures adopted and effective pursuant hereto. Provided, however, that if the Agency fails to notify the applicant within 30 days after the filing of a purported application that the application is incomplete and of the reasons the Agency deems it incomplete, the application shall be deemed to have been filed as of the date of such purported filing. The applicant may treat the Agency's notification that an application is incomplete as a denial of the application for purposes of review, pursuant to Section 40 of the Act [415 ILCS 5/40].**
>
> **Section 204.1300 Notification of Application Completeness to Applicants**
> **The Agency shall notify the applicant within 30 days after receipt as to the completeness of an application for a permit under this Part or any deficiency in the application or information submitted in such an application. In the event of such a deficiency, the date of receipt of the**

comments suggest that the Application should not be denied. However, these comments do not show that the Illinois EPA had to request information that was not provided in the Application or that was needed to correct deficiencies in the Application as a prerequisite to beginning the process of denying the Application. The comments certainly do not show that it would be improper for the Application to be denied due to the deficiencies in the Application that have been identified simply because US Steel was not notified of any such deficiencies within the 30 day timeframes in the cited rules.[231] Indeed, the cited rules could be considered a reason why the Application must be denied given that the Illinois EPA did not notify US Steek of deficiencies in the Application within 30 days of the date that the Application was received by the Illinois EPA.

Moreover, the fact that certain earlier actions did not occur also does not bar or block denial of the Application. The standard for review of a permit application under Section 39(a) of the Act, that is, whether permit requested by the application should be issued or the application should be denied, addresses the submitted permit application, without consideration of the actions that the Illinois EPA did or did not take before denying the application. In addition, if the Act's standard for issuance of a permit would not be met by an application, the Act does not provide that the requested permit must be issued even if an action specified by the Act was not taken, e.g., the denial letter did not identify the provisions of the Act or the Illinois Code that might be violated if the permit requested by the application were issued. In such circumstances, if the denial of an application were appealed to the Board, the Board would properly return or remand the application back to the Illinois EPA so that it could resume its review of the application. This further review could still result in preparation of an appropriate denial letter if the permit applicant did not supplement its application to address the substance of the issues that were identified in the denial letter that the Board found to be defective on procedural grounds.

---

application shall be the date on which the Agency receives all required information.

[231] As a practical matter, it is unrealistic to expect the Illinois EPA to identify all deficiencies in applications for air pollution control permits within 30 days given the often complicated nature of such applications and the workload of the Illinois EPA, Air Permit Section. At most, the cited rules should be considered to provide for an administrative determination for of the completeness of an application rather than technical completeness based on the review of the application by the professional staff of the Air Permit Section. Moreover, given the time required to prepare for and hold a public comment period on a draft of a permit or a permit denial letter, when a public comment period is held for a permit application, deficiencies in the application may not be identified until many months after it was received.

The Denial of the Application Would be Improper Because the Illinois EPA Has Not Adopted Procedures Pursuant to 35 IAC 201.152 Addressing the Deficiencies that Have Been Identified in the Application.

In a number of generic comments, US Steel observes that the Illinois EPA has not adopted procedures as provided for by the Board in 35 IAC 201.152,[232] that would specify that applications for state construction permits must include certain information that was not included BU US Steel in the Application. By these comments, it is suggested that since the Illinois EPA has not adopted such procedures, it would be improper for the Application to be found deficient and denied because certain information was not provided in the Application. However, the issue before the Illinois EPA is whether the Application meets the standard for issuance of a permit in Section 39(a) of the Act.[233] The fact that

---

[232] **In its entirety, 35 IAC 201.152 provides:**

> **Section 201.152 Contents of Application for Construction Permit**
> **An application for a construction permit shall contain, as a minimum, the following data and information: The nature of the emission unit and air pollution control equipment, including the expected life and deterioration rate; information concerning processes to which the emission unit or air pollution control equipment is related; the quantities and types of raw materials to be used in the emission source or air pollution control equipment; the nature, specific points of emission and quantities of uncontrolled and controlled air contaminant emissions at the source that includes the emission unit or air pollution control equipment; the type, size, efficiency and specifications (including engineering drawings, plans and specifications certified to by a registered Illinois professional engineer) of the proposed emission unit or air pollution control equipment; maps, statistics and other data reasonably sufficient to describe the location of the emission unit or air pollution control equipment. The Agency may waive the submission by the applicant of such engineering drawings, plans, specifications or such other portions of the above data or information as it shall deem inappropriate or unnecessary to the construction permit application. The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.**

[233] **It should be noted that the Act does not identify or prescribe the particular information that must be included in an application for a state air pollution control permit for it to be considered to provide proof that the relevant substantive requirements of the Act and the Illinois Code related to emissions would not be violated by the facility and/or equipment for which a permit is being requested. Similarly, except for rare instances, the Illinois Code does not address the particular information that must be included in an application for a state air pollution control permit for it to be considered to provide proof that the relevant substantive requirements of the Act and the Illinois Code would not be violated. Decisions about the information that should be included in an application are entrusted to the Illinois EPA and its**

the Illinois EPA has not adopted procedural rules regarding the required contents of state construction permit applications, as addressed by 35 IAC 201.152, is irrelevant. The Illinois EPA is not required to adopt such rules.[234] In 35 IAC 201.152, the Board simply

---

technical judgment. Even where the Illinois Code specifies information that must be included in an application to address an applicable requirement, it may be done in terms of what must be shown by the information that is required to be included, as well as in terms of the specific information that must be provided. For example, with respect to the BACT requirement of the PSD rules, 35 IAC 204.810 provides as follow:

> **Section 204.810 Source Information**
> **The owner or operator of a proposed major stationary source or major modification shall submit all information necessary to perform any analysis or make any determination required under this Part.**
>
> **a) With respect to a source or modification to which Sections 204.1100 ["Control Technology Review"] … apply, such information shall include:**
>
> **1) A description of the nature, location, design capacity, and typical operating schedule of the source or modification, including specifications and drawings showing its design and plant layout;**
>
> **2) A detailed schedule for construction of the source or modification; and**
>
> **3) A detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that BACT, as applicable, would be applied [emphasis added].**

[234] The Illinois Pollution Control Board (Board) has addressed whether the Illinois EPA is required to adopt procedures and the scope of such procedures in the context of the former program for Underground Storage Tank Remediation pursuant to Sections 22.18, 22.18a, 22.18b and 22.18c of the Act, which are now repealed. The Board found that a determination made by the Illinois EPA denying reimbursement for certain costs under this program was appropriate even though this subject was not addressed by the rules that the Illinois EPA had adopted. The Opinion and Order of the Board in the subject case, PCB 91-201, includes the following statements;

> **The Act "authorizes the Agency [Illinois EPA] to adopt reasonable and necessary rules for the administration of this Section." (Section 22.18(f).) The Agency has chosen not to promulgate rules pertaining to reimbursement but rather evaluates ach application on its own merits, on a case by case basis. (Pet. Br. at 39.) The evaluation of the application by the Agency is governed by the requirements of the statute.**
>
> **The guidance manual has no legal force or affect because it was not promulgated according to the requirements of the APA [Administrative Procedures Act]. Corrective action is an action to stop minimize, eliminate or clean up a release of petroleum, The Strubes have not shown that the**

recognizes the authority of the Illinois EPA to adopt such rules. Moreover, even if the Illinois EPA had adopted such rules it is unreasonable to expect that they would address all the matters that should be considered for the revision of Permit 95010001, as the Illinois EPA would address by denial of the Application.

Denial of the Application Would Be Improper Given Historic Actions by the Illinois EPA That Involved Permit 95010001

In certain generic comments, claims are made that the denial of the Application would be improper because of past actions taken by the Illinois EPA with regard to Permit 95010001. For example, several of these comments observe that the Illinois EPA did not require National Steel in the permit application that resulted in the initial issuance of Permit 95010001 in 1996 to provide certain supporting information or justification for the emission data provided in the Application, as submitted in October 2022. These comments suggest that it would be improper for the Application to be denied because it does not include such supporting information or justification for certain emission data that it contains. This is not the case and the absence of such information from the Application is an appropriate basis for the Application to be denied. These comments should be considered extraneous because they do not directly address the Application that US Steel has submitted.

In this regard, by the submittal of the Application, US Steel requested that the Illinois EPA make certain revisions to Permit 95010001. As revisions to this permit are requested, US Steel cannot simply rely on the Illinois EPA and its past actions to support or justify the revisions to Permit 95010001 that US Steel is now requesting. The Application, itself, must meet the standard in the Act for issuance of a revised permit. In this regard, US Steel's comments do not identify a provision of the Act that establishes a standard for the issuance of revisions of state permits that is different than the standard of issuance that generally applies for issuance of state permits. In other words, the Illinois EPA is not required to and should not perpetuate past decisions or past actions that are or may been erroneous when taking a new action. As recognized by the Board, when acting on a permit, the Illinois EPA must generally act appropriately based on the

---

replacement of the concrete at their station was a corrective action. The Agency did not inform the Strubes about the reimbursements for costs associated with repaving but requested that the bills be submitted for review. Therefor the Board finds that the Strubes are not eligible for reimbursement of the cost of replacement of concrete pursuant to the statute.

Fred M. Strube and Cynthia L. Strube v. Illinois Environmental Protection Agency, PCB 91-205, Order and Opinion of the Board, May 21, 1992, p.3, p.7.

application and the issues that are currently before it irrespective of how it may have previously acted.[235] For example, the fact that certain decisions with respect to Best Available Control Technology (BACT) under the PSD program were made almost 30 years ago when initially issuing Permit 95010001 to National Steel is irrelevant to the review of the Application. This is because the Application requests increases in the permitted emissions of these units such that new determinations of BACT now also need to be made.[236]

The Illinois EPA Could Pursue Resolution of the Issues Identified In the Draft Denial Without Denying the Application

In a number of generic comments, US Steel observes that the Illinois EPA could pursue resolution of the deficiency that is identified in the Draft Denial Letter by a means other than denial of the Application. For example, it could continue informal discussions with US Steel about the revisions of Permit 95010001 and resolution of the permit appeals current pending with the Pollution Control Board. Alternatively, the Illinois EPA could have asked US Steel to supplement or revise the Application to address the deficiencies in the Application that have been identified.

While the Illinois EPA could have chosen to continue to engage in further informal discussions with US Steel or to attempt to get

---

[235] For example, refer to the following statement by the Board in Chemrex, Incorporated v. Illinois Environmental Protection Agency, PCB 92-123, Order and Opinion, February 4, 1993. This statement formally confirms, as a matter of principle, that in its review of an application, the Illinois EPA is not constrained to the decision that was made for an earlier application.

> **…the Board believes that the Agency is entitled to change its position, rather than maintain consistency with an incorrect eligibility determination, in light of the fact that there is no statutory provision, regulation or case law that addresses the issue at hand.**
>
> **PCB 92-123, Opinion and Order, February 4, 1993, p. 7.**

[236] Based on certain past actions by the Illinois EPA, as mentioned by US Steel in its comments, US Steel may think that the level of information that was provided in the Application was reasonable, as is also observed in certain comments. (These observations are similar to incidental observations made in other comments that US Steel was not obligated to correctly guess as to how the Illinois EPA would exercise its judgment with respect to certain aspects of the requested revisions to Permit 95010001.)
However, these observations are clearly irrelevant to the denial of the Application. The Illinois EPA's review of the Application must consider whether the Application meets the Act's standard for issuance of a permit. The opinion of US Steel, the permit applicant, as to whether the level of information was "reasonable" or "appropriate" is irrelevant to whether the Application should or should not be denied.

deficiencies in the Application dealt with by US Steel by a means short of denial of the Application, this does not show that denial of the Application would be inappropriate. These generic comments do not point to a provision of the Act that requires the Illinois EPA to take such action on an application for state construction permit that it finds to be deficient prior to denying the application.[237] Indeed, these comments do not even show that denial of the Application would be unreasonable if one considers when issues with certain emission limits in Permit 951010001 were first identified.

[237] **While these comments acknowledge that the Illinois EPA has, "authority to requests additional documentation in conjunction with a construction permit application," (for example, see US Steel's Comment VI), the comments point to 35 IAC 201.152 as the basis for such authority. As discussed above, this rule recognizes that the Illinois EPA may adopt procedures that expound upon or further specify the required content of an application for a construction permit as also specifically addressed by this rule. This rule does not address the process whereby the Illinois EPA may request a permit applicant supplement or revised the application that has been submitted.**

8B. General Responses to Certain Comments by US Steel, as referred to by the Illinois EPA in its responses in Section 7

General Response 2: General Response to Comments Concerning Prescribed Emission Factors and Emission Determination Methodology

For various emission units, the Application requests that the revision to Permit 95010001 specify or "prescribe" the emission factors that US Steel must use on an ongoing basis to determine or calculate emissions for the purpose of demonstrating compliance with limitations in the permit for annual emissions. In addition, for the roof monitor for the blast furnace casthouse, the Application requests that the revised permit specify use of an "emissions determination methodology" that would yield specific emission factors for emissions of NOx and VOM. (To simplify this response, in the remainder of this response, this emissions determination methodology proposed by the Application will not be addressed separately but will instead be considered as being within the broad scope of the term emission factor.)

The emissions units and emission points for which the Application requests that the revision to Permit 95010001 prescribe emission factors are ones for which direct measurement of the rate of emissions by USEPA Reference Test Methods or, alternatively, material balance based on the amount of the pollutant precursor(s) in process materials, is not feasible. The Application does not request that the revised permit specify emission factors for emission units and emissions points whose circumstances are such that direct measurement of the rate of emissions is feasible.

For example, for the particulate emissions of the blast furnace casthouse, the Application proposes that the revision to Permit 95010001 prescribe the specific emission factors that are to be used to determine the uncaptured emissions from the casthouse. As these emissions occur through the roof monitor of the casthouse, rather than through the stacks of the particulate control devices serving the casthouse, these emissions are not amenable to quantitative measurement by established USEPA Reference Test Methods.[238] All calculations for the

---

[238] In the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Mills, 40 CFR 63 Subpart FFFFF, USEPA has recognized that the emissions through roof monitors on casthouses are not amenable to emission testing. This NESHAP does not set quantitative emission standards for the amount or mass of particulate emissions from the roof monitors on blast furnace casthouses. These emissions from the roof monitors are constrained with standards for the opacity of emissions. These standards also serve to indirectly address the effectiveness with which the particulate emissions from tapping of blast furnaces, as occurs in casthouses, must be captured and directed to particulate control devices pursuant to this NESHAP.

amounts of particulate emissions from the casthouse roof monitor must necessarily be made by use of emission factors that are developed or derived relying on something other than direct measurements of the emissions through the roof monitor.[239]

As the Application requests that the revision to Permit 95010001 prescribe emissions factors for the determination of the emissions of certain emission units or certain emission points, the Application requests a fundamental change in Permit 95010001 as it would address the emissions of these units or emission points. This change also has important consequence for the content of the Application. As delineated in Denial Points 8, 9 and 10, the Application is deficient as it does not contain the additional information that must necessarily accompany its request that the revised permit prescribe use of certain emission factors.[240] In particular, the Application does not provide information justifying the specific values of the emission factors that are proposed or would be generated. Moreover, the various comments that are made with respect to the emission factors that are proposed by the Application do not show that such information need not be included in

---

[239] It should also be understood that for units at the facility for which emission testing is performed, emissions factors must also be used to calculate emissions on an ongoing basis. This is because emission testing occurs periodically. On a routine basis other than when testing is actually being conducted, the emissions of such units must be calculated using emission factors developed from the results of the testing that is conducted.

However, as provided in the CAAPP permit for the facility, Permit 96030056, the "test-based" factors may be refined to address the actual operation of the emission units and their control devices. In particular, if the operation of a control device is impaired lowering its effectiveness, the emission factor used to calculate emissions during the period of impaired operation must be refined so that it reasonably reflects the actual effectiveness of the control device during such period.

[240] The three categories of emission factors that the Application requests be prescribed by revised Permit 95010001 are addressed in Denial Points 8, 9 and 10. In addition, Denial Point 8 generally addresses the deficiencies in the Application as it requests that revised Permit 95010001 prescribe certain emission factors.

Denial Point 8, after the initial general discussion, addresses deficiencies in the Application with respect to proposed emission factors that appear to directly reflect published emission factors. Denial Point 9 further addresses the deficiencies in the Application with respect to the emission determination methodology that is proposed for uncaptured emissions of NOx and VOM from the blast furnace casthouse. Denial Point 10 addresses the deficiencies in the Application with respect to certain proposed emissions factors that appear to be derived from published emissions factors using process-specific information. For example, for the Iron Pellet Screen, the Application proposes a particulate emission factor that is 85 percent of a factor for uncontrolled emission, presumably to account for the control measures that are present for this unit. However, the Application does not justify the use of 85 percent control efficiency for this unit.

the Application. Instead, they generally argue that the previous acceptance by the Illinois EPA in previous permit actions involving the emission factors that the Application now requests be prescribed is sufficient to show that use of the selected emission factors should be prescribed by the requested revised permit. In addition, these comments argue that it is responsibility of the Illinois EPA to draft the requested revision to Permit 95010001 with conditions that it judges to be suitable and appropriate. As such these comments relinquish any responsibility by US Steel to provide substantive support and justification in the Application for the emission factors that it proposes be prescribed.

Accordingly, as the Application does not provide substantive support for the emission factors that it proposes to now be prescribed by the requested revised permit, it is appropriate that the Application be denied for reasons as set forth in Denial Points 8, 9 and 10, as has been done. Moreover, as US Steel argues that the Illinois EPA is responsible for imposing conditions in the requested revised permit that the Illinois EPA deems suitable and appropriate, it is also proper for the Application to have been denied. This is because the judgment of the Illinois EPA is that the Application does not include information showing that the specific emission factors that the Application requested be prescribed are suitable or appropriate.

By way of explanation, as the Application requests that revised Permit 95010001 specify use of specific emission factors for certain units and emission points, the Application requests a fundamental change to how the emissions of those units and emission points would be addressed on an ongoing basis. This is because this permit currently does not prescribe the specific emission factors that US Steel must use on an ongoing basis to determine compliance with the emission limits set by this permit. In addition, rather than prescribing use of specific emission factors, the Illinois EPA made clear when issuing the CAAPP permit for the facility, Permit 96030056, that emission factors that do not understate actual emissions, essentially "appropriate emission factors," are to be used on an ongoing basis when calculating emissions of the units for which Permit 95010001 sets limitations.[241] This happens

---

[241] For Project-affected process units, Condition 5.13(a) of Permit 96030056, if not stayed, would provide that, "The emission factors used by the Permittee [US Steel] to determine compliance with these emission limits [the emission factor limits and annual emission limits from Permit 95010001 for process emission units as they are restated in Permit 96030056] shall not understate actual emissions." In this regard, the subsequent provisions in Condition 5.13 distinguishes between the emission factors for emissions units for which Permit 96030056 requires emissions testing and emission factors for units for which emission testing is not required. The further requirements imposed by Condition 5.13, if it were not stayed, for these two categories of factors are different because of what would be expected to result in a change in the factor that US

as Permit 96030056 restates the emissions limitations set by Permit 95010001, as these limitations are applicable requirements for purposes of the CAAPP. For the various Project affected units at the facility, the obligation to show that appropriate emissions factors are being used to calculate emissions is placed on US Steel.[242]

As discussed by the Illinois EPA in the introductory paragraphs of the discussion for Denial Point 8 in the Denial Letters, if Permit 95010001 is to be revised as requested by the Application, to now prescribe the emission factors that US Steel must use to calculate emissions from certain units and emissions points, it must be determined that the factors that would be prescribed should be considered representative of those emissions. In particular, as reflected in various determinations by USEPA cited in this discussion, the record supporting the issuance of such a permit must contain the basis or rationale for the Illinois EPA's determination that the emissions factors that are being prescribed would be appropriate, i.e., representatives of actual emissions. However, the responsibility to provide the basis or rationale for the emission factors that are proposed to be prescribed rests, at least initially, upon US Steel and the information that it provides in its application for revisions to Permit 95010001. This is because US Steel has requested the revisions to Permit 95010001 to prescribe the emission factors that are to be used on an ongoing basis for certain emission units and emission points. Notwithstanding the fact that the Application requests that certain emission factors be prescribed, the Application does not provide substantive support for why the specific values of the emission factors that are proposed would

---

Steel is using, i.e., the emissions measured in a periodic emission test or new information that becomes available about the emissions from an emissions unit or emission point, including new information published by USEPA.

Condition 5.13 of Permit 96030056 is, in fact, stayed pursuant to a May 2, 2013, Order of the Illinois Pollution Control Board (Board), which responded to a motion for stay of the effectiveness of appealed conditions made by US Steel in the permit appeal for Permit 96030056 (PCB 2013-053). However, this stay does not affect Condition 5.13(a) as it is also a public pronouncement by the Illinois EPA for how US Steel should determine emissions of Project-affected process units for purposes of addressing ongoing compliance with the limits on emissions set by Permit 95010001. That is, emissions shall not be determined simply based on an emission factor that may nominally address the emissions of a Project-affected process unit or emission point but, in reality, may understate the actual emissions of the unit or emission point.

[242] To facilitate review by the Illinois EPA and interested parties of the emission factors that US Steel is using to determine compliance with the relevant emission limitations, Permit 96030056 would also impose certain procedural requirements. For example, this permit would require US Steel to review the emission factors that it is using for units for which emission testing is not required on at least an annual basis (Condition 5.13(c)(ii)) and to inform the Illinois EPA if it updates the emission factors that it is using based on such review (Condition 5.13(d)(i)).

appropriately be set as prescribed factors by the revised permit. Instead, the Application simply identifies the purpose for which the proposed factor has been used earlier in the Application in the revised NSR applicability analyses for the Project.[243] This information is not sufficient to serve as a basis or rationale for the revision to Permit 95010001 to prescribe use of the proposed factors.

Moreover, with regard to the emission factors that the Application proposes be prescribed, US Steel's comments rejects responsibility for justifying the use of the specific factors that are proposed. The comments ignore the USEPA's Order concerning BP Amoco Chemical Company cited in Denial Point 8 (Denial Letters, Footnote 40). This decision concerning a Title V permit issued in Texas is relevant as it discusses what must be shown if a revision to Permit 95010001 is to be issued that would now prescribe use of certain emissions factors on an ongoing basis.[244] It is implicit in USEPA's decision that for the emissions units

---

[243] For example, when describing the requested changes to permit terms for PM and PM_{10} emissions, for the proposed prescribed emission factors for certain blast furnace operations, the Application simply states that:

> **Prescribed emission factors consistent with the approach described in Section 3 [Discussion of Permit Conditions used to Restrict PTE] are provided herein. USS Granite is proposing the following prescribed emission factors for the emission point for which emissions testing is not feasible [Footnote] 31. Each of these emission factors is the same as the corresponding emission factors used to calculate pre-project actual emissions as shown in Table 5-5 [Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM Emission Factors for Affected Emissions Units] and Table 5-6 [Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM_{10} Emission Factors for Affected Emissions Units].**
>
> **(a) For Blast Furnace Casthouse Roof Monitor, use PM emissions factor of 0.030 lb/ton and PM_{10} emission factor of 0.0153 lb/ton.**
> **(b) For Blast Furnace Charging, use PM emission factor of 0.0024 lb/ton and PM_{10} emissions factor of 0.0012 lb/ton.**
> **(c) For slag pits, use PM and PM_{10} emission factor of 0.00417 lb/ton. Application, 5-14, Section 5.5.1.2 Prescribed Emission Factors for Certain Blast Furnaces Operations.**
>
> **[Footnote][31] PM and PM_{10} emission factors are appropriately determined from the results of emissions testing per 40 CFR 63 Subpart FFFFF to determine PM and PM_{10} emissions rates for the Blast Furnace Casthouse baghouse and the Iron Spout baghouse.**
>
> **Application, Section 5.5.1.2, "Prescribed Emission Factors for Certain Blast Furnace Operation," pp. 5- 14 and 5-15.**

[244] When responding to a petition requesting that USEPA object to a Title V permit issued by the Texas Commission on Environmental Quality (TCEQ) as it addressed the emission factors that the permit allowed the source to use to

and emissions points for which the Application requests that Revised Permit 95010001 prescribe use of specific emission factors, the Application must provide a substantive, technical justification for the proposed factors. It is then incumbent upon the Illinois EPA to exercise its judgement to decide whether such justification should be considered adequate.

---

determine emissions of NOx and CO from certain fuel combustion units, the USEPA found the following, granting the petition on this point:

> **Instead of providing technical justifications, TCEQ's RTC [Response to Comments] redirected the public as follows: "The rationale for the emission factors and emission calculations is included in the application representations that were made during the NSR permit action that authorized these terms and conditions." RTC at 11. This cursory reference to an unspecified permit application is not enough to justify the sufficiency of monitoring [*], nor to adequately respond to significant public comments questioning the same. TCEQ's response leaves the public—and for that matter, the EPA—in the dark about where to look, and what to look for.{Footnote} [26] Moreover, a justification provided by a permittee in a permit application should not substitute for the judgement of the permitting authority (TCEQ) with responsibility for ensuring that a title V permit contains sufficient monitoring to ensure compliance.**
>
> > **[* As this response uses the term "monitoring," it refers to "periodic monitoring" as used in the federal operating permit program required by Title V of the Clean Air Act to refer to the collection of requirements for emission unit(s) imposed by such a permit to reasonably address compliance with applicable substantive requirement(s) that apply for the emissions of such unit(s). "Periodic monitoring" may include requirements such as requirements for periodic emission testing, operational instrumentation, certain work practices, recordkeeping, and reporting, as well as requirements for operational monitoring and emissions monitoring.]**

[Footnote][26] As the Petitioners suggest, this is no simple task for a permit like Permit No. 1176/PSDTX782, which has been revised numerous times. Although the 2013 version of this permit includes a date next to some permit terms indicating the last time that a permit term was revised, it is unclear whether the application associated with the initial establishment of the term, or the latest revision, or something in between, might contain the information that TCEQ deems relevant. Moreover, the 2020 version of this permit no longer includes these date references, further obscuring the location of any potentially relevant application representations.

Before the Administrator, United States Environmental Protection Agency: In the Matter of: BP Amoco Chemical Company, Texas City Chemical Plant, Galveston County Texas, Permit O1513 Issued by the Texas Commission on Environmental Quality; Petition No. VI-2017-6, Order Responding to Petition Requesting Objection to the Issuance of Title V Permit; Order Granting in Part and Denying In Part a Petition for Objection to Permit, July 20, 2021, p.18.

It should be understood that the Illinois EPA does not dispute that as related to the Project, it has accepted certain emission factors during past permitting actions. However, in the permits that were issued, the Illinois EPA did not prescribe the specific emissions factors that US Steel must use when calculating emissions of process units for purpose of compliance with applicable emissions limitations, as is now requested by the Application.[245] Moreover, the question of how compliance should be determined in practice with the emission factor limits and annual emission limits set by Permit 95010001 was not directly confronted until the 2010 time frame, almost 15 years after the initial issuance of Permit 95010001. This happened when the Illinois EPA began processing US Steel's initial application for a CAAPP permit for the facility. It was in this period that the Illinois EPA formalized its very straightforward position that compliance with the emission factor limits and annual emissions in Permit 95010001 was to be calculated using appropriate emission factors.

Finally, even if the Illinois EPA had prescribed emission factors in past permits, it would still be necessary during the issuance of the requested revisions to Permit 95010001 for there to be substantive information showing that any emission factors that would be prescribed by such revised permit would be appropriate. In other words, in the proceeding for revision to Permit 95010001, it would have to be shown either that the previously prescribed emissions factors should still be considered appropriate or, otherwise, that the new emissions factors that are being proposed to be prescribed by the revised permit would be appropriate.

---

[245] While some of US Steel's comments claim that the Illinois EPA has already prescribed the use of emission factors in Permit 95010001, these claims are not supported. The comments do not identify language in Permit 95010001 that suggests that the emissions factor limits set by this permit are anything but enforceable limitations. The comments do not explain why Permit 95010001 would prescribe emission factors for all Project-affected units and emission points rather than only for units and emission points for which emission testing is not feasible. Finally, if US Steel believed that the Illinois EPA considered that the subject provisions in Permit 95010001 prescribed the emission factors that US Steel must use to address limitations set for annual emissions by Permit 95010001, as claimed in its comments, why did US Steel file permit appeals with the Board challenging the emission factor limits in Permit 95010001 as they were or would be restated in Permit 96030056 (PCB 2013-053 and PCB 2013-062). Indeed, one of the reasons that US Steel filed these permit appeals is precisely because the Illinois EPA made clear in the subject permit proceedings that the provisions in Permit 95010001 addressing emissions of process units in terms of pounds/ton of production or pounds/ton of material handled, as they were present in the appealed permits, set limitations on emissions.

9. Attachment A: The Proper Approach, As Prepared by the Illinois EPA, to the Increase and Net Increase in the NOx Emissions of the Project with the Requested Revisions to Permit 95010001.

In this attachment, the Illinois EPA sets forth how the increase and net increase in the NOx emissions of the Project with the requested increases in the NOx emissions of the blast furnace casthouse and BOFs would properly be addressed. This attachment shows that if the applicability of NSR for NOx were properly evaluated, excluding the unrelated post-project decreases in NOx emissions, the Project would almost certainly be a major modification for NOx with the increases requested by the Application in the permitted NOx emissions of the blast furnace casthouse and the BOFs.

This attachment includes three tables with accompanying discussion. Table 1 addresses the increase in NOx emissions simply from the project itself. Table 2 addresses the net increase in NOx emissions from the Project also considering the contemporaneous increases and decreases in emissions that accompanied the Project. Table 3 also addresses the net increase in NOx emissions from the Project but describes how the post-project emission decreases should be disregarded in an appropriate analysis. The purpose of this table is to highlight the errors in the revised NSR analysis in the Application. As neither US Steel's comments nor the Application provide information for the NOx emissions of the Project as should have been permitted in 1996 if the NOx emissions of the emissions of the blast furnace casthouse and BOFs had been correctly quantified, these tables use a variable, "*p*", to represent the extent to which the permitted NOx emissions of the Project-affected fuel burning units and the Project would have been more than the baseline NOx emissions.[246] Likewise, because information was not provided for the decrease in NOx emissions that accompanied each of the three actions that lowered NOx emissions of Project-affected fuel burning units, variables, "*q*," "*r*," and "*s*," are used to represent these

[246] In Attachment A, the approaches taken by the Illinois EPA to estimating the NOx emissions of the Project-affected fuel burning units with the Project are more refined than those discussed in the Draft Denial Letters. The approaches now indicate that the increase in the NOx emissions of the Project-affected fuel burning units with the requested revisions to Permit 95010001 could be about 200 tons/year, rather than being in the range of 400 to 500 tons/year. (For example, refer to the revised Draft Denial Letter, Attachment 1, Footnote 11.) In any case, if one accepts that the Project involved an increase in the permitted annual NOx emissions of Project-affected fuel-burning units in the hundred tons, rather than a decrease in their emissions, as improperly claimed by the Application, it is apparent that the Application does not provide proof that the Project would not become a major modification for NOx with the requested revisions to Permit 95010001 to increase the permitted NOx emissions of certain furnaces.

decreases.

Table 1: Illinois EPA's Presentation for an Appropriate Revised Emissions Increase Analysis for the Project for NOx (NOx Emissions in Tons/Year)			
Emission Units	**Revised Baseline Emissions**	**Project Emissions with Requested Revised Limits**	**Increase in Emissions**
Blast Furnaces	**4.6**	**24.0**	**19.4**
BOFs and Other BOF Shop Operations	**179.8**	**400.0**	**220.2**
Continuous Casting Operations	**0.0**	**0.0**	**0.0**
Project-Affected Fuel Burning Units	**956.3**	**956.3 + *p***	***P***
Total	**1140.7**	**1,380.3 + *p***	**239.6 + *p***
Since the increase in NOx emissions is equal to or greater than the NSR significant emissions rate for NOx, 40 tons/year, contemporaneous changes in NOx emissions may be considered in Step 2 of the revised NSR applicability analysis for NOx to show that the net increase in emissions of the Project is less than significant.			

As already explained, in Table 1, the variable *p* is used to show that the value for the NOx emissions of Project-affected fuel burning units in the Application does not account for the increase in NOx emissions from such units with the use of more fuel, as is specifically allowed by Permit 95010001 to accompany production of more iron and steel as addressed by this permit. As a result, the overall NOx emissions of the Project and the increases in the emissions of the Project should also be increased by *p*. In this regard, US Steel has not provided information for the value of *p*, i.e., the upward adjustment to the NOx emissions of the Project-affected fuel burning units making the same corrections that were made in the proposed revisions to their baseline NOx emissions for the Project. For these units, the revised determination for baseline emissions now addresses emissions from use of COG. It also may make certain other corrections to the determination of baseline emissions. For example, the Application indicates that this revised determination addresses the fact that the original determination for baseline NOx emissions incorrectly "double-counted" NOx emissions from use of natural gas in continuous casting operations, which emissions were also being addressed with the emissions of the Project-affected fuel burning units. (Application, Section 6.2.2.7, p. 6-4.) However, as US Steel argues that, at least with respect to Project-affected fuel burning units, the revised NSR applicability analysis for NOx should be prospective in nature, US Steel has not submitted a revised value for the NOx emissions of these units with the

Project that would reflect the circumstances of the Granite City Works circa 1996 when Permit 95010001 was originally issued.

Table 2: Illinois EPA's Presentation for an Appropriate Revised Net Emissions Increase Analysis for NOx for the Project With Contemporaneous Period From January 1990 through January 1996 (Emissions in tons/year)		
Value for NOx Emissions Used in the Analysis/ Is the Net Increase in Emissions Significant?	**Emissions**	**Totals**
Emissions Increases and Decreases in the Contemporaneous Period		
Decrease from Blooming Mill Shutdown (April 1991)	**-217.8**	
Decreases from Batch Annealing Shutdown (December 1991)	**-8.7**	
Contemporaneous Increases & Decreases – Total		**-226.5**
Overall Revised Net Emissions Change of the Project		
Increase in Emissions from the Project (From Table 1)	**239.6 + *p***	
Contemporaneous Increases and Decreases in Emission	**-226.5**	
Total	**13.1 + *p***	**13.1 + *p***
Is the Increase Significant?	**Yes, as explained below**	

It is reasonable to expect that *p* is much greater than the amount that would be necessary for the Project to become a major modification for NOx with the requested increases in permitted NOX emissions of the blast furnaces and BOF.[247] For the net increase in NOx emissions of the

[247] **The Project was originally permitted for a net increase in NOx emissions of 38.3 tons/year. (Permit 95010001, issued May 30, 2012, Condition 41(c).) The Application requests that Permit 95010001 be revised to increase the permitted NOx emissions of the blast furnace casthouse and the BOFs by over 200 tons/year. However, the Application does not identify errors in the original permitting of the Project whose correction would lower the NOx emissions of the Project by a similar amount so as to make up for the requested increase in permitted emissions.**

In particular, for the continuous casting operations, the Application does propose corrections to the original emissions accounting for the Project for NOx. US Steel has determined that there are not "process emissions" from the caster molds, only NOx emissions from burning natural gas, contrary to what National Steel indicated in 1996 in its original application for the Project and provided for by Permit 95010001. However, this correction would not be sufficient to make up for the requested increase in the permitted NOx emissions of the blast furnace casthouse and BOFs. Based on National Steel's original application, the increase in process NOx emissions from the continuous caster molds was only about 29.2 tons/year, i.e., the difference between baseline emissions of 60.34 tons/year and emissions with the Project of 89.50 tons/year. (Application, Appendix C – Emission Calculations, Emissions Calculations

Project to become 40 tons/year, the NSR significant emission rate for NOx, *p* would only need to be 26.9 ton/year. (40 tons/year – 13.1 tons/year = 26.9 tons/year.)

Since the Application did not provide a revised determination for the potential/permittable NOx emissions of Project-affected fuel burning units with the Project circa 1996, the Illinois EPA has made estimates for the value of *p*. Based on these estimates, the Illinois EPA has concluded that the Application does not provide proof that the net increase in NOx emissions from the Project with the requested increases in permitted NOx emissions of the blast furnace casthouse and BOFs would be less than 40 tons/year, the NSR significant emissions rate for NOx. An estimate for *p* can be made from the information in the Application, including the copies of Permit 95010001 in Appendix D of the Application. Since production of iron by an integrated iron and steel mill is more fuel intensive than production of steel, requiring use of more fuel by the facility in Btu/ton produced, it should be expected that *p,* the increase in NOx emissions of the Project-affected fuel burning units with the Project, is proportional to the permitted increase in iron production. Permit 95010001 provides for an increase of about 50 percent in the production of iron.[248] The permitted NOx emissions from Project-affected fuel burning units from use of BFG and natural gas were originally about 664 tons/year (175.19 tons/year for natural gas + 488.48 tons/year for BFG = 663.67 tons/year). (Permit 95010001, issued January 25, 1996, Condition 22, Table 4.) This yields a value for *p* of about 220 tons/year {664 tons/year x (150% – 100%) ÷ 150% = 221.3, ~ 220 tons/year). If it is assumed, as was done during the original permitting

---

Included in the 1995 Construction Permit Application, Table 3-2: Granite City Division of National Steel, Netting Analysis Summary – NOx (originally dated 1/16/96).

> **Any NOx emissions from this operation [the continuous caster molds] are <u>due to combustion of natural gas</u> [emphasis added] and are already accounted for under gaseous fuel burning activities listed above [fuel burning emissions units]. Therefore, in the revised analysis, NOx emissions are not included from this operation.**
> **Application, Section 6.2.2.7, p. 6-4.**

[248] As explained in its introductory paragraph, Permit 95010001 provided for an increase in the permitted production of iron by the facility to 3,165,000 tons/year. The baseline iron production was 2,059.557 tons (Application Table 6-3). As such, Permit 9501001 addresses an increase in iron production of about 50 percent ({3,165,000 – 2,059,557} ÷ 2,059,557 = 0.537, ~ 50 percent). A similar calculation for production of steel shows an increase of 0.483, or again about 50 percent.

of the Project,[249] that the increase in production would be enabled solely by increased use of BFG, the resulting value for *p* is only about 160 tons/year {488.48 tons/year x (150% – 100%) ÷ 150% = 162.8, ~ 160 tons/year}. With either of these values for the increases in NOx emissions from the Project-affected fuel burning units, the decreases in emissions in the contemporaneous period (i.e., January 1990 through January 1996) are not sufficient to compensate for the requested increases in the permitted NOx emissions of the blast furnace casthouse and BOFs.[250]

Values for *p* can also be estimated from information in the Application for the corrected baseline NOx emissions for the Project-affected fuel burning units. In this regard, the Application indicates corrected baseline NOx emissions from these units of 494.73 tons/year from use of BFG and natural gas. The resulting value for *p* is 180 tons/year {494.73 tons/year x (150% – 100%) ÷ 100% = 247.4, ~ 245 tons/year}. This is noticeably greater than the values derived from the emissions limitations in Permit 95010001, i.e., 160 or 220 tons/year. This estimate also indicates that the Project would become a major NSR source for NOx with the increases in the permitted NOx emissions of the blast furnace casthouse and the BOFs that the Application requests.[251]

---

[249] The subsequent issuance of Construction Permit 98110038 in 1999, which provided for an increase in the permitted usage of and emissions from use of natural gas, raises doubts about the validity of this assumption.

[250] If one also assumes for these estimates, as was assumed for the original permitting of the Project, that the usage of COG by Project-affected fuel burning units would not change with the Project, the calculated increases in NOx emissions of the fuel burning units with the Project would be greater. This is because the increases in permitted production with the Project can only be achieved with increases in usage of BFG or natural gas, but not usage of COG. For example, if COG historically provided about 10 percent of the heat input to the Project-affected fuel burning units,* the increase in usage of natural gas and BFG, or BFG by itself, for the increase in permitted production should be expected to be about 7 percent greater than estimated above, i.e., about 170 or 235 tons/year. This is because the factor applied to the permitted emissions should be 35.7 percent, rather than 33.3 percent. {(150% - 100%) ÷ (100% - 10% + 50%) = 0.357; (150% - 100%) ÷ (100%) = 0.333; and 0.357 ÷ 0.333 = 1.0725, or about 7 percent greater.}

*** Information for the contribution of COG to the fuel usage of the Project-affected fuel burning units is provided in the information in the Application supporting the revised determination for the baseline emissions of the Project. (Application, Appendix B – Emission Calculations, Revised NOx PSD Net Emissions Increase Analysis.)**

[251] The Application indicates baseline NOx emissions from the blast furnace stoves, boilers, ladle drying-preheaters and BFG flares from use of BFG and natural gas of 494.7 tons/year (319.5 and 175.2 tons/year from, respectively, use of BFG and natural gas). (Application, Table 6.5, Pre-project Actual

Table 3: Illinois EPA's Presentation for the Application's Revised Net Emissions Increase Analysis for NOx for the Project With Contemporaneous Period From January 1990 through January 1996 (Emissions in tons/year)		
Value for NOx Emissions Used in the Analysis/ Is the Net Increase in Emissions Significant?	Emissions Totals	
Overall Net Emissions Change of the Project		
Increase in Emissions from the Project (From Table 1)	239.6 + *p*	
Contemporaneous Increases & Decreases (From Table 2)	-226.5	
Project Net Increase	13.1 + *p*	
Is the Increase Significant?	Yes, as already explained	
Post-Project "Non-Contemporaneous" Emission Decreases (After 1996)		
Decrease from shutdown of Boilers 1 – 10 (pursuant to C. Permit 06070023, orig. issued Jan. 2008)	-*q**	
Decrease from adding FGR systems to Boilers 11 & 12 (pursuant to C. Permit 10080022, orig. issued Feb. 2011)	-*r**	
Decrease from elimination of COG with the shutdown of the two by-product recovery coke oven batteries (shutdown February 2015)	-*s**	
Subtotal	-(*q* + *r* + *s*)	
Project Net Increase	239.6 + *p*	13.1 + *p*
Contemporaneous Increases & Decreases (From Table 2)	-226.5	
Post-Project Emissions Decreases (from above)	-(*q* + *r* + *s*)	
Total		13.1 + *p* - (*q* + *r* + *s*)
Is the Increase Significant?	Yes, as explained below	

As already discussed, the Application does not provide information for the decrease in NOx emissions from each of the post-project actions

---

Emissions and Summary of Proposed Changes to Pre-Project NOx Emissions Factors for Affected Emissions Units.) With the assumption that the increase in use of BFG and natural gas or only BFG to facilitate the permitted increase in production is in the same proportion as the permitted increase in iron production, the values for *p* that result are 245 tons/year {494.7 x (150% – 100%) ÷ 100%} = 247.37, ~ 245 tons/year; {319.5 x (150% – 100%) ÷ 100%} = 159.75, ~ 160 tons/year. These values for *p* are consistent with the values estimated using information in Permit 95010001, i.e., 160 and 245 tons/year compared to 160 and 220 tons/year. These estimates for *p* also indicate that the Project would become a major modification with the increases that the Application requests in the permitted NOx emissions of the blast furnace casthouse and the BOFs.

that the revised NSR applicability analysis in the Application implicitly relies upon. Indeed, the Application does not actually quantify the overall decrease in emissions that resulted from these actions. Accordingly, *q*, *r* and *s* are used, respectively, to represent the amount by which the three actions that have occurred at the Granite City Works acted to the NOx emissions of affected units.

This revised NSR applicability analysis does not show that the Project would not become a major project for NOx with the requested increases in permitted NOx emissions of the blast furnace casthouse and BOFs. While the Application claims, based on the analysis set forth in Table 6-9, that the net emissions increase for NOx would be a net increase of only 13.1 tons/year, that analysis is flawed. That analysis overlooks the increase in the NOx emissions for Project-affected fuel burning units with the Project. Then, it also improperly takes credit for decreases in NOx emissions that were not part of the Project, i.e., decreases that occurred after January 1996, which was the end of the contemporaneous period for the Project. With appropriate information for the increase in emissions from the Project, absent the post-Project decreases, the Project would still become a major modification for NOx with the requested increases in the permitted emissions of the blast furnace casthouse and BOFs, as previously shown in Table 2.

Copies of USEPA Determinations Addressing Relaxations of Limitations Established in Permits As Related to Applicability of New Source Review That Are Referred to by US Steel in Certain Comments and the Illinois EPA in Its Responses to Those Comments

APPENDIX 1.1

BOMBARDIER DETERMINATION

September 22, 2005

(A-18J)

Jeffrey C. Hanson, P.E., Chief
Permits and Stationary Source Modeling Section
Bureau of Air Management
Wisconsin Department of Natural Resources
101 South Webster Street
P.O. Box 7921
Madison, Wisconsin 53707

Dear Mr. Hanson:

I am writing in response to your July 28, 2005, letter requesting assistance from the United States Environmental Protection Agency (USEPA) in determining whether a relaxation of synthetic minor permit limits at Bombardier Motor Company of America (Bombardier) would be subject to non-attainment New Source Review (NAA NSR). Bombardier is located in Racine County, Wisconsin, which is designated as a moderate non-attainment area under the 8-hour National Ambient Air Quality Standard (NAAQS) for ozone which has a major source threshold of 100 tons per year (TPY) of volatile organic compounds (VOC). Prior to June 15, 2005, Racine County was designated as a severe nonattainment area under the 1-hour ozone standard and had a major source threshold of 25 TPY of VOC.

The Wisconsin Department of Natural Resources (WDNR) issued Bombardier a permit in 2001 under the 1-hour ozone standard that limited its potential emissions of VOC to less than 25 TPY to avoid classification as a major source and to avoid NAA NSR review that would require emission offsets and the application of Lowest Achievable Emission Reductions (LAER). Bombardier has now requested that the restrictions in its synthetic minor NSR permit be relaxed from 25 TPY to less than 100 TPY.

Wisconsin has a State Implementation Plan (SIP) approved NAA NSR program. This authority was approved by the USEPA on January 18, 1995, and became effective on February 17, 1995. (See 60 FR 3538.) Pursuant to this approval, the WDNR is responsible for issuing NSR related applicability determinations to sources based on Wisconsin's regulations, in compliance with its SIP. USEPA's NSR regulations for nonattainment areas are set forth at 40 CFR 51.165, 52.24 and part 51, Appendix S. The following is our position regarding the application of EPA's NAA NSR requirements.

The NAA NSR rules at 40 CFR §51.165(a)(5)(ii) state:

> At such time that a particular source or modification becomes a major stationary source or major modification solely by virtue of a relaxation in any enforceable limitation which was established after August 7, 1980, on the capacity of the source or modification otherwise to emit a pollutant, such as a restriction on hours of operation, then the requirements of regulations approved pursuant to this section shall apply to the source or modification as though construction had not yet commenced on the source or modification.

It is our view that if a stationary source becomes a major stationary source solely by virtue of a relaxation in any enforceable limitation on the capacity of the source, such as relaxation of a synthetic minor emissions cap, then the NAA NSR requirements apply to the source as though construction had not yet commenced on the source. USEPA's April 30, 2004, phase 1 8-hour ozone implementation rule (69 FR 23986) provides: "emission limitations and other requirements in NSR permits issued under 1-hour NSR programs will continue to be in force when the 1-hour NAAQS is revoked."

Bombardier's 25 TPY emissions limit was a requirement in a minor NSR permit, and the limit was taken to avoid application of major NAA NSR. Based on the language in the rule, the revocation of the 1-hour NAAQS should not allow relaxation of the permit limit without triggering major NSR.

The interpretation above was made in consultation with USEPA's Office of General Counsel and Office of Air Quality, Planning, and Standards.

If you have any further questions regarding this matter, please contact Susan Siepkowski of my staff at (312) 353-2654.

Sincerely,

/s/

APPENDIX 1.2

PSE & G DETERMINATION

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 2
290 Broadway
New York, NY 10007-1866

February 11, 2009

Mr. William N. Viola
Director, Power Generation PJM
PSE&G Fossil LLC
80 Park Plaza
Newark, NJ 07102-4194

Re: Request for PSD Applicability Determinations for
Burlington 12 and Kearny 12 Generating Stations

Dear Mr. Viola:

This is in response to your December 3, 2008 letter to me wherein you requested PSD non-applicability determinations for the proposed relaxation of certain operating and emissions limitations contained in the existing permits for the PSE&G Burlington and Kearny Generating Stations. Specifically, you are proposing relaxations that would enable you to increase the annual heat input and resultant emissions for 8 General Electric LM6000 combustion turbines (4 of these "peaking" units are located at each facility) to address proposed NJDEP regulations regarding nitrogen oxide emissions during High Electric Demand Days. Your letter states that the proposed relaxations would allow greater use of these LM6000 units instead of older, less efficient combustion turbines during these high demand days.

In its New Jersey Title V permits, PSE&G restricted the amounts of natural gas and fuel oil to limit the LM6000 units to approximately 15.4% annual capacity at the Burlington Station, and approximately 13.2% annual capacity at Kearny. These permit limits were established upon commencement of operation of the units (the years 2000 through 2001) so that the emissions from these projects would remain below the applicability threshold limits of New Jersey's non-attainment regulations of NJAC 7:27-18. The establishment of these limits also resulted in the non-applicability of the Burlington and Kearny projects to the federal PSD regulations of 40 CFR § 52.21. The proposal that is the subject of your December 3, 2008 letter is to increase the annual capacity at the Burlington Station to 18.6% and at Kearny to 16.8%.

In order to determine PSD applicability in this case, two specific, separate and independent tests must be performed: (1) the standard PSD applicability test pursuant to 40 CFR § 52.21 (a)(2)(ii) to determine whether a significant net emissions increase under a physical change or change in the method of operation would occur; and (2) the 40 CFR 52.21(r)(4) test which treats a modification "as though construction had not yet commenced on the source or modification." Each applicability test is to have its own

baseline period and contemporaneous period that will be different for each test. The general applicability review in accordance with the first citation above would subject a modification to the PSD requirements in those cases where a physical change or a change in the method of operation would result in a significant emissions increase of a regulated pollutant. In the subject case, the change in the method of operation is the increase in the permitted annual turbine capacities, from 15.4% to 18.6% at the Burlington Station and from 13.2% to 16.8% at Kearny. PSE&G performed such an applicability review, delineated in its December 3rd letter, in which it was asserted that the Burlington and Kearny Station projects are not PSD affected under 40 CFR § 52.21 (a)(2)(ii). However, in order for EPA to evaluate your determination, as you have requested, we will need additional information, including: (1) substantiations for all calculations provided such as how they were determined, and any and all assumptions made; and (2) more documentation on the contemporaneous emission increases and decreases, including calculations, assumptions, and the federal enforceability of the emission changes. This information is especially important relative to the "retired Burlington 10 unit," which may be outside of the contemporaneous period.

The second test, under 40 CFR § 52.21 (r)(4), has not been done. While you acknowledge in your December 3rd letter that EPA verbally communicated to your consultant our position that the aforementioned PSD provision would apply in this case, you have indicated that you disagree with this interpretation. In your letter, you state that PSE&G did not originally propose limits to these turbines with the intent of subsequently requesting minor annual capacity increases that would also avoid new source review, which you call "sham" permitting. It was also noted that at the time of initial permitting of these LM6000 turbines, PSE&G did not contemplate the need to relax the operational restrictions of the turbines within several years, and only requested the relaxations based on New Jersey's proposed high electric demand day regulations. Regardless, EPA remains of the opinion that the (r)(4) provision applies in this case. This PSD provision does not discuss intent; it simply states that any relaxation of an established limit that would make the project "major" would at that point in time make PSD applicable. That is, the (r)(4) provision must be considered for the life of any project for which enforceable limits were established such that any subsequent requests for a relaxation of the aforementioned limitations will necessitate their review within the originally-issued permits.

To fulfill your request that we verify your PSD applicability review of the annual heat input increases for 8 General Electric LM6000 combustion turbines at the PSE&G Burlington and Kearny Generating Stations, you must provide an applicability review pursuant to 40 CFR 52.21(r)(4). Such a review must delineate the emissions from the turbines that correspond to the entire 18.6% and 16.8% capacities, as well as the contemporaneous emissions changes based upon the time of the initial permitting (that is, contemporaneous from the commencement of construction of the units, during the years 2000 and 2001). Information and documentation as described above for the emission calculations and contemporaneous emission changes should be submitted to this office for our review to be made. In this case, EPA requests that PSE&G use the actual

commencement of construction date for the contemporaneous emission period rather than the projected date of construction that we presume was originally used.

Once the requested documentation is provided to this office, we will complete our PSD applicability review. If you have any questions regarding this letter, please call me at (212) 637 – 4074 or Mr. Gerald DeGaetano at (212) 637 – 4020.

Sincerely,

/ s /

APPENDIX 1.3

PFIZER DETERMINATION

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 2
290 BROADWAY
NEW YORK, NY 10007-1866

SEP 2 3 2015

Mr. Ramon Frontanes, Site Leader
Pfizer Pharmaceuticals LLC
Barceloneta Site, Rd. 2, KM 58.2
P.O. Box 628
Barceloneta, Puerto Rico 00617

Re: Prevention of Significant Deterioration (PSD) Non-Applicability- Pfizer Pharmaceuticals LLC's Proposed Modification

Dear Mr. Frontanes:

The U.S. Environmental Protection Agency's Region 2 Office (EPA) received Pfizer Pharmaceuticals LLC, Barceloneta Plant's (Pfizer) July 30, 2015, letter, in which it requested EPA's determination whether the PSD regulations codified under 40 CFR 52.21 will apply to Pfizer's proposed modification. Pfizer is proposing to remove an existing oil-fired Heat Recovery Steam Generator (HRSG) and install three new 11.5 MMBtu/hr liquified petroleum gas (LPG)-fired steam boilers. It is also requesting that its current PSD non-applicability related Nitrogen Oxide (NOx) potential to emit (PTE) emission limit be raised from 56 tons/year to 90 tons/year. Pfizer stated that it currently is and it will continue to remain a "synthetic minor" source for PSD and title V purposes; therefore, Pfizer maintains that the existing 56 tons/year NOx PTE limit required pursuant to its 1994 project cannot be considered a relaxation of an emission limit which would otherwise trigger a PSD review under 40 CFR § 52.21 (r)(4). Based on the review of the information Pfizer provided in its letter and in e-mails to EPA through September 1, 2015, it appears that Pfizer's proposed modification will not trigger PSD and that its current NOx limit may be revised from 56 tons/year to 90 tons/year.

Background

Prior to 1994, Pfizer, an active pharmaceutical ingredients manufacturing facility, operated two residual oil-fired (16.5 MMBtu/hour) boilers and four 255 HP fire engines. It did not have a PSD permit but at the time it was an existing major source for PSD applicability purposes because it was a "PSD source category" and its boilers' sulfur dioxide and process-related volatile organic compounds (VOC) PTE exceeded the 100 tons/year major source threshold. The NOx PTE at the time was 55 tons/year. In 1994, under its Utility Plant Expansion Project, Pfizer proposed to remove the two residual oil-fired boilers and install the following: 1) 5 new diesel generators (each with its own selective catalytic reduction (SCR) unit and all of these then connected downstream to a combined secondary SCR); 2) a 37.5 MMBtu/hour No. 2 oil-fired HRSG at the Engines' exhaust and 3) a 37.5 MMBtu/hour oil/LPG-fired steam boiler. Pfizer's PSD non-applicability analysis in 1994 indicated that its net change in sulfur dioxide emissions would be negative whereas its NOx net change in emissions would be 28.88 tons/year. Therefore, its NOx PTE was estimated at 54.44 tons/year. To avoid PSD, Pfizer proposed to limit its total combined fuel oil usage to 6.4 million gallons per year and operate each engine to no more than 7500 hours/year. On November 30, 1995, EPA determined that Pfizer's PSD non-applicability request was approvable and also asked that Pfizer limit its NOx PTE to 56 tons/year. EPA notes that

Electronic Filing: Received, Clerk's Office 06/12/2024 **PCB 2024-077

Pfizer's current non-applicability request is not proposing to revise any other operational limits required pursuant to EPA's 1995 determination.

The Puerto Rico Environmental Quality Board (EQB) issued a Construction Permit to Pfizer in 2002, which was revised in 2008, 2010, 2012 and 2014. The current EQB Construction Permit allows construction of 5 diesel generators, a 37.5 MMBtu/hr HRSG, a 37.5 MMBtu/hr oil/LPG boiler, and the 4- 255 HP engines. The permit also allows construction of new units which were not part of the original Utility Plant Expansion Project such as 4 fire engines, 3 thermal oxidizers (0.7, 0.1 and 0.1 MMBtu/hour), a 100 HP diesel generator, 3 gasoline generators (14 HP each) and 7 diesel generators (845 HP each). The 2002 permit limited each criteria pollutants' PTE to 90 tons/year and hazardous air pollutants' PTE to below 10/25 tons/year to keep the facility below the PSD/title V applicability's 100/25/10 tons/year thresholds. The permit further limits NOx PTE to 56 tons/year pursuant to EPA's 1995 non-applicability determination. These 2002 PTE limits have remained unchanged as of today despite subsequent changes to the permit in the years that followed to add more units. Pfizer is asking now to relax its PSD NOx limit to 90 tons/year in EQB's Construction Permit. It should be noted that Pfizer stated in its September 1, 2015, e-mail that the 3 gasoline (14 HP) and 7 (845 HP) diesel generators were permitted but never installed.

EPA Review

Pursuant to EPA's 1995 non-applicability determination, Pfizer completed its Utility Plant Expansion Project and operated the source at NOx PTE of 56 tons/year and process VOC emissions above 100 tons/year until 2002. There was no other change made to the Utility Plant during those years of operation. On October 2, 2002, EQB issued a Construction Permit to Pfizer limiting its PTE for all criteria pollutants, including VOC, to below 100 tons/year making the facility a "synthetic minor" source for title V and PSD purposes. The EQB permit also contained the original 1995 NOx PTE limit of 56 tons/year that had been requested by EPA in its PSD non-applicability section. Pfizer stated that it has continued to operate as a "synthetic minor" source for PSD and title V purposes since 2002. Its current proposal to remove the HRSG (37.5 MMBtu/hour) and replace it with three new LPG package boilers (11.5 MMBtu/hour each) will also not increase its 2002 PTE limits and Pfizer will continue to remain a "synthetic minor" source after the change.

EPA's review of the information indicates that Pfizer is not attempting to circumvent PSD applicability by requesting to increase the 1995 PSD non-applicability NOx PTE limit from 56 tons/year to 90 tons/year because the facility or the 1994 modification does not become a major stationary source or major modification solely by virtue of this NOx emission limit relaxation. In addition, the "synthetic minor" status has been maintained by Pfizer since 2002 and will continue to be maintained after the proposed modification. Furthermore, Pfizer is also not requesting any changes to its annual fuel and hours of operation restrictions put in place pursuant to the 1995 non-applicability determination. Therefore, Pfizer's request to revise the NOx PTE from 56 tons/year to 90 tons/year is approvable.

EPA notes, however, that the EQB permit authorized construction of 3 gasoline generators and 7 diesel generators that were never installed and are not expected to be constructed and, as such, must be removed from the EQB Construction Permit as a condition of this approval. EPA is not commenting on other specific changes that relate to the conditions in the Construction Permit that Pfizer is requesting in its July 30, 2015 letter since these changes are related to EQB's permit and EPA is asking EQB to take the lead on those discussions.

Please note that EPA's assessment of the proposed project is not final Agency action and is based on information solely provided by Pfizer. In the event that we learn of facts suggesting a different assessment of the project, EPA may revisit this issue, and invoke any necessary authorities under the Clean Air Act. However, we do not anticipate further action at this time. If you have any questions regarding this letter, please contact Mr. Umesh Dholakia at (212) 637-4023.

Sincerely,

Steven C. Riva, Chief
Permitting Section

Re: United States Steel Corporation—Granite City Works
Notice of Intent to Deny Application for Revision to
Construction Permit/PSD Approval (Permit Application No. 95010001)
ID No. 119813AAI

Dear Mr. Frost:

Attached to this letter are comments prepared by my client, U. S. Steel Corporation, in response to the referenced public notice posted to Illinois Environmental Protection Agency's internet website on December 8, 2023. The public notice indicates comments "must be postmarked by 11:59 pm, January 8, 2024." The comments attached to this letter are therefore timely submitted.

We appreciate the opportunity to submit comments on the Notice of Intent, as well as the agency's careful consideration of our comments.

Very truly yours,

RTP ENVIRONMENTAL ASSOCIATES, INC.

Colin M. Campbell
Principal

Comments of the United States Steel Corporation - Granite City Works

Revised Draft Denial Letter Dated December 8, 2023:
Notice of the Intent to Deny Application for Revision to Construction Permit/PSD Approval
Permit Application No. 95010001

While it is with great disappointment that U. S. Steel received Illinois EPA's notice of intent to deny the pending permit application, we respectfully request that the Agency reconsider its preliminary decision and work with U. S. Steel on resolving any outstanding issues. We also request to meet with Illinois EPA in the interest of reaching resolution considering many of the reasons that Illinois EPA raises in its proposed denial were not known to U. S. Steel until it received the notice (or very shortly beforehand) notwithstanding the parties met several times to discuss the permit application. U. S. Steel also notes that Illinois EPA did not notify U. S. Steel of any deficiency in the application or information submitted in such application pursuant to 35 Ill. Admin. Code 201.158 and 204.1300 or 415 ILCS 5/39.5(5). We are greatly disappointed that the Agency took this path, when many of the issues, as explained herein, could have been efficiently resolved if the Illinois EPA raised them during the years while the permit application was pending as is customary. U. S. Steel also notes that the permit application is for a revision to a previously issued PSD permit (as issued to National Steel Corporation in 1996) to a source that has been and continues to operate; and is not a request for a new major modification – and, therefore, the scope of the review is more limited and the process is substantially different than when compared to a major modification or a revision to a PSD permit for a source that has yet to operate.

U. S. Steel also respectfully notes that Illinois EPA does more than "clarify" its previous notice of intent to deny the application; but instead raises new bases for its objections. Instead of working with the applicant on addressing any concerns, Illinois EPA appears to be doubling down on its insistence to deny the permit. In response to comments, Illinois EPA's bases for intending to deny the permit have changed and have become a moving target. U. S. Steel respectfully notes that it would prefer to work with Illinois EPA collaboratively to address Illinois EPA's concerns and to work collaboratively on issuing a permit that complies with statutory and regulatory requirements; not searching for hypothetical and potential reasons why it should not be issued.

The PSD regulations are forward looking. However, in its proposed notice of intent to deny the permit, Illinois EPA is pursuing a path that would make U. S. Steel retroactively address all potential operating scenarios under the facility's prior ownership and footprint, for which U. S. Steel does not have the requisite information and for which U. S. Steel is not responsible. Such an approach is inconsistent with the Clean Air Act and legal precedent.

In Section I below, U. S. Steel addresses Illinois EPA's stated reasons for its proposed denial of the pending permit application In Sections II through XIII below, U. S. Steel addresses the denial points listed in Attachment 1 to the draft denial letter.

I. U. S. STEEL DISAGREES WITH ILLINOIS EPA REGARDING WHETHER ISSUANCE OF THE REQUESTED PERMIT REVISION WOULD VIOLATE PROVISIONS OF THE ILLINOIS

ENVIRONMENTAL PROTECTION ACT OR THE REGULATIONS OF THE POLLUTION CONTROL BOARD

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that Section 39(a) of the Illinois Environmental Protection Act *might be violated*. Section 39(a) states that "it shall be the duty of the Agency to issue …a permit upon proof by the applicant that the facility, equipment, vehicle, vessel, or aircraft will not cause a violation of this Act or of regulations hereunder." As set forth further herein, U. S. Steel maintains that its application demonstrates that the facility and equipment at issue in the application will not cause a violation of the Illinois Environmental Protection Act or the regulations thereunder. Therefore, it is Illinois EPA's duty, under the statute, to proceed with permit issuance.

For the various reasons set forth herein, U. S. Steel maintains that Illinois EPA is incorrect that any provisions of the Illinois Environmental Protection Act or the regulations thereunder would be violated if the permit were granted; where the Illinois EPA has asserted that information was not provided to the Agency, U. S. Steel is providing that information here, is directing the Illinois EPA to the information in the application, or describes why such information is not pertinent to the issues at hand. Accordingly, Illinois EPA should not issue the proposed permit denial. As stated herein, U. S. Steel stands ready to work with Illinois EPA to resolve any remaining concerns for permit issuance.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA has now preliminarily determined that subsections 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv), 39.5(13)(a), and 39.5(c)(v) of the Illinois Environmental Protection Act, pertaining to administrative amendments of Clean Air Act Permit Program ("CAAPP") permits, might be violated. U. S. Steel notes that, because the listed subsections of the Illinois Environmental Protection Act relate only to the CAAPP, it would be inappropriate to deny the application for a revision of the construction permit and PSD approval based on a failure to satisfy these statutory provisions, as discussed in Section XIII.A herein.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that subsection 39.5(5)(e) of the Illinois Environmental Protection Act might be violated. This provision requires a certification of truth, accuracy, and completeness. This is not a valid basis for denial of the permit application for the reasons discussed in Section III herein.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that 35 Ill. Adm. Code Sections 203.128 and 204.560 might be violated. The cited rule provisions are definitions, not affirmative requirements, and cannot be violated.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that 35 Ill. Adm. Code Sections 201.160, 203.601, 203.602, 204.1100, 204.1110, 204.1120 and 204.1130 might be violated. These claims, which relate to the Prevention of Significant Deterioration ("PSD") and Nonattainment New Source Review ("NNSR") programs under the federal Clean Air Act, are without merit for the reasons discussed in Sections VI through VIII below.

II. THE PERMIT APPLICATION SATISFIES 35 ILL. ADM. CODE SECTION 201.159

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the pending permit application "does not include a signed certification for the truth, accuracy and completeness of this application as

it was actually submitted in October 2022, as required by 35 IAC 201.159" and that "the 2022 application includes a photocopy of an earlier certification, dated February 25, 2020, which was submitted with a prior application." These assertions are incorrect in several respects.

First, the agency misrepresents the requirements of the cited rule provision, which are as follows. There is no requirement for a certification of truth, accuracy, and completeness.

> All applications and supplements thereto shall be signed by the owner and operator of the source, or their authorized agent, and shall be accompanied by evidence of authority to sign the application.

Second, the application that the agency refers to as the "2022 application" is actually a construction permit application submitted on March 2, 2020. This permit application includes a completed 199-CAAPP form, with a certification signed and dated February 25, 2020, and a completed 197-FEE form, with a check for the application fee of $23,000 and a certification signed and dated February 25, 2020.

A supplement to the permit application was submitted in October 2022. As required by 35 Ill. Adm. Code Section 201.159, the supplement was signed by Michael Patton, the General Manager of the Granite City Works. No application fee was provided, as is appropriate for a supplement to a pending application for a construction permit.

Furthermore, U. S. Steel notes that, while Illinois EPA had the permit application supplement for months, and virtually met with U. S. Steel to discuss the pending permit application and the supplement, the Agency never requested such a new signature or certification.

III. U. S. STEEL PROVIDED A SIGNED CERTIFICATION OF TRUTH, ACCURACY, AND COMPLETENESS FOR THE PERMIT APPLICATION SUPPLEMENT SUBMITTED IN OCTOBER 2022

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the pending permit application "does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022" and that such a certification is required by Section 39.5(5)(e) of the Illinois Environmental Protection Act. This is not a valid basis for denial of the permit application for the following reasons.

As noted in Section II above, the agency mischaracterizes the October 2022 submittal as a new or separate permit application, as it is merely a supplement to the permit application submitted in March 2020. In the transmittal letter for the supplement, and for administrative convenience U. S. Steel suggested that Illinois EPA refer to the supplement rather than to the initial submittal from March 2020 because, as requested by Illinois EPA staff following review of the initial permit application submittal, the sections of the permit application were reordered.[1] The cited provision of the Illinois Environmental Protection Act requires that each submitted permit application include a certification, but it does not expressly require a separate certification for each supplement to a permit application.

[1] For example, the sections summarizing changes to CO emissions and presenting proposed Best Available Control Technology ("BACT") determinations for CO emissions were sections 3 and 4 of the initial permit application and were sections 4 and 8 of the supplement, and these sections were cross-referenced in sections 1 and 2 of each submittal.

Nonetheless, and without waiving any rights or defenses, U. S. Steel provided to Illinois EPA in September 2023 a new certification of the truth, accuracy and completeness of the supplement that was submitted in October 2022. Accordingly, even if Illinois EPA's interpretation of Section 39.5(5)(e) of the Illinois Environmental Protection Act were correct and a separate certification is required for each supplement to a pending permit application, that requirement was satisfied prior to the proposed denial and this claimed deficiency cannot form a valid basis for denial of the permit application. Furthermore, this issue could easily have been avoided if Illinois EPA simply made a request to certify the supplement, which we subsequently completed, yet Illinois EPA inexplicably asserts that this was not sufficient, baselessly claims the application is under a cloud, and further asserts that the certification or application is somehow fraudulent (Per Illinois EPA, "[t]hus, even if the certification had been submitted as a supplement to the 2022 application, its truthfulness and validity would be questionable.") U. S. Steel is unable to respond to these assertions because, frankly, they are absurd and are without merit. U. S. Steel has worked collaboratively with Illinois EPA in responding to inquiries and requests.

IV. PURPORTED FAILURE TO BE CONSISTENT WITH PENDING BOARD APPEALS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the application must be denied because it does not individually address all items that are currently under appeal with the Illinois Pollution Control Board. In particular, Illinois EPA claims, "the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62." Quite strikingly, Illinois EPA cites to no Board order or regulatory or statutory citation to support its assertion. This is for good reason, as there is none. The assertion is without merit. Although it is logical that Illinois EPA might inquire about contested provisions in the appeals before the Board that may appear to be absent in the application, the absence of such mention is not grounds for denying the permit application. Furthermore, the permit application submitted in March 2020 and supplemented in October 2022 has been pending for nearly four years, during which time Illinois EPA and U. S. Steel met in person and virtually on several occasions to discuss the PSD permit revisions, yet only in the proposal to deny the permit application did U. S. Steel learn of Illinois EPA's apparent contention that U. S. Steel was obligated to address individually in its permit application all items that are currently under appeal with the Illinois Pollution Control Board. U. S. Steel's understanding from these discussions was that, with satisfactory issuance of the revised permit, the pending appeals could be dismissed in their entirety. U. S. Steel would be pleased to discuss Illinois EPA's concerns in the context of the appeal before the Board, but the Agency cannot claim these differences as a basis to deny the permit application.

V. PURPORTED INCONSISTENCY BETWEEN THIS PERMIT APPLICATION AND THE PERMIT APPLICATION SUBMITTED IN 2008 REQUESTING REVISIONS RELATING TO SO_2 EMISSIONS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the application must be denied because it "is inconsistent with" a separate permit application submitted in 2008.

Unfortunately, the Illinois EPA has not acted on the 2008 application. That application was submitted in accordance with the Consent Decree between U. S. Steel and the Illinois EPA. (*See, People of the State of Illinois v. United States Steel Corporation*, No. 05-CH-750, Third Judicial Circuit, Madison County.) The 2008 application was submitted based on limited information that was available at the time, and subsequent information indicates that when averaged over the year, the emission factor in

the existing permit is appropriate. This topic was discussed with the Illinois EPA as the permit application submitted in 2020 was pending; and the Illinois EPA did not object to this development at the time. To now claim that this discrepancy serves as a basis to deny the PSD application is disingenuous. U. S. Steel cannot simply withdraw the 2008 permit application at this time but would do so following issuance of the revised PSD permit, pursuant to the permit application submitted in 2020 and supplemented in 2022, and termination of the Consent Decree. U. S. Steel has indicated it would work with Illinois EPA on that process and remains committed and willing to do so.

In its explanation of how the claimed inconsistency between the permit applications submitted in 2008 and 2020 purportedly represents a deficiency in the permit application submitted in 2020, Illinois EPA asserts that the more recent permit application "does not meet the standards for issuance of a construction permit" because it does not "show compliance with the SO_2 emission limits for burning BFG that are currently in Permit 95010001." U. S. Steel admits that the permit application submitted in 2020 and supplemented in 2022, which does not request any changes to any SO_2 emission limits, does not include a demonstration of compliance with the referenced SO_2 emission limits, nor does it include demonstrations of compliance with any of the dozens of other emission limits that apply to the Granite City Works and are unrelated to the present application. There is no provision in the Illinois Environmental Protection Act or the regulations thereunder requiring that an application for a construction permit include such compliance demonstrations.

VI. THE PERMIT APPLICATION IS SUFFICIENT AS TO THE PSD AIR QUALITY IMPACTS ANALYSIS FOR CARBON MONOXIDE

The Production Increase Project was a major modification under the preconstruction PSD permitting program because it involved physical and operational changes that would result in a significant net increase in emissions of carbon monoxide (CO). National Steel Corporation, then the owner and operator of Granite City Works, submitted a PSD permit application for this project in 1995. Illinois EPA determined that this PSD permit application included all necessary information and granted PSD approval for the project in conjunction with issuance of Permit No. 95010001 on Jan. 25, 1996. One of the key requirements of the preconstruction PSD permitting program, which Illinois EPA determined had been satisfied by National Steel Corporation's 1995 permit application, is an air quality impact analysis—a demonstration by the applicant that the project will not cause or contribute to a violation of any national ambient air quality standard for CO. 40 CFR § 52.21(k).

As explained in the permit application submitted by U. S. Steel in March 2020 and supplemented in October 2022, recent information suggests that some of the emissions data relied upon by Illinois EPA in issuing Permit No. 95010001 in 1996 are not representative. Therefore, during informal discussions between Illinois EPA and U. S. Steel, the parties agreed that corrective updates to these data and to the CO air quality impact analysis are appropriate. The pending permit application includes such updated analysis.

In Attachment 1 to the draft denial letter, Illinois EPA indicates that a basis for the denial of the permit application is that the updated CO air quality impact analysis "cannot be relied upon because the inventory for the CO emissions of the source with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered." In particular, Illinois EPA indicates it has "concern" there may be some CO emissions from the Basic Oxygen Furnace Shop Roof Monitor which are not reflected in the air quality impact analysis and also

suggests that the analysis should "consider the CO emissions of the former by-product coke oven batteries at the source." In addition, Illinois EPA asserts that the ambient background CO concentration data used by U. S. Steel, gathered by Illinois EPA during the period of three calendar years from 2016 through 2018, are "not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted."

None of the concerns listed by Illinois EPA are deficiencies warranting denial of the permit application. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a request for revision of a PSD approval include any of the listed information, nor does the agency point to even an application form or guidance document suggesting that such information be provided. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[2] but that was not done here.

As it relates to the possibility of CO emissions from the Basic Oxygen Furnace Shop Roof Monitor, U. S. Steel responds further as follows: Illinois EPA's prior determination that the Production Increase Project would not cause or contribute to a violation of any national ambient air quality standard for CO was based on the agency's assumption that there are no CO emissions from this point. In the pending permit application, U. S. Steel did not request any changes to existing permit terms relating to this emission point. Illinois EPA has neither requested that U. S. Steel's updated CO air quality impacts analysis include any emissions from this emission point, nor has the agency provided a quantitative estimate of those emissions. In the absence of such a request, U. S. Steel had no reasonable basis to conclude that the agency had reconsidered its prior determination as relating to CO emissions from the Basic Oxygen Furnace Shop Roof Monitor; it was therefore reasonable for U. S. Steel to conclude that its updated CO air quality impacts analysis, with revisions to the CO emission rates only for those emission points where the parties agreed that National Steel Corporation's modeled rates should be corrected, was sufficient for the purpose of requesting revisions to the permitted CO emissions from certain combustion units burning blast furnace gas and/or natural gas and affected by Production Increase Project.

As it relates to historical CO emissions from the by-product coke oven batteries that were operated by National Steel Corporation at the time the PSD approval was granted by Illinois EPA in 1996, U. S. Steel responds further as follows: It is unclear to U. S. Steel whether this observation relates to the demonstration that was approved by Illinois EPA in 1996 or to the demonstration submitted by U. S. Steel in March 2020 and supplemented in October 2022. If the former, then U. S. Steel notes that those emissions were, in fact, included.[3] If the latter, then U. S. Steel notes that it is not requesting PSD approval or other authorization for CO emissions from by-product coke oven batteries and that there is no basis for considering emissions under a counterfactual scenario in evaluating whether a requested change will cause or contribute to a violation of any national ambient air quality standard.[4]

---

[2] *See, e.g.,* 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[3] *See, e.g.,* permit application supplement submitted by National Steel Corporation Jan. 16, 1996, at Table 5-8.

[4] This is one of several instances where Illinois EPA appears to be asserting that the present permit application is deficient because it does not address a set of facts and circumstances that may have existed at some point in history but do not exist

Finally, as it relates to the use of 2016-2018 background CO concentration data, U. S. Steel responds further as follows: These data were the most current quality-assured data available at the time of U. S. Steel's submittal of the pending permit application in March 2020 and use of these data was approved by Illinois EPA following its review of U. S. Steel's dispersion modeling protocol in February 2020. U. S. Steel agrees that the 2016-2018 background CO concentration data are less current now than they were at the time of permit application submittal. Currentness of air quality data is one aspect of the permit application review process that is ensured by compliance with the procedural requirements relating to timely processing of permit applications.[5]

VII. THE PERMIT APPLICATION IS SUFFICIENT AS TO BEST AVAILABLE CONTROL TECHNOLOGY

A. Introduction

The pertinent provision of the PSD rule governing the required contents of the permit application pertaining to establishment of Best Available Control Technology ("BACT") is a requirement to include in the application:

> A detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that best available control technology would be applied. 40 CFR § 52.21(n)(1)(iii).[6]

It is undisputed that the permit application includes estimates of the CO emissions from the casthouse and the blast furnace stoves as well as a detailed description of the systems of continuous emission reduction that U. S. Steel plans to use to control these emissions.

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the application "lacks necessary information" for the agency to make BACT determinations for the casthouse and the blast furnace stoves.

B. CO Emissions from Blast Furnace Casthouse

For the casthouse, as discussed in Section 8.2.3 of the permit application, the only control options identified by U. S. Steel for potential consideration in a BACT determination by Illinois EPA are add-on air pollution control equipment options—specifically, installation and use of a capture system and some type of incinerator. Illinois EPA asserts that this part of the permit application is deficient because it provides neither an explanation of "why process-related control options are not available" nor, with respect to the literature search conducted by U. S. Steel that did not identify any process-related control options for CO emissions from blast furnace casthouses, "documentary support for the review of available control options that was conducted." It is unclear to U. S. Steel how it would be helpful to Illinois EPA's BACT determination to have copies of reports that contain no pertinent

---

presently or in the future. To the extent that Illinois EPA is making such claims, they are without merit, as the requested approval is forward-looking, *i.e.*, is based on the applicable regulations and other circumstances as they exist or will exist at the time of permit issuance. 42 U.S.C. § 7410(j). *See, e.g., United States v. EME Homer City Generation, L.P.*, 727 F.3d 274 (3rd Circuit, 2013)

[5] *See,* 35 Ill. Adm. Code Section 201.158 (providing that a permit application shall be deemed to have been filed 30 days after submittal if Illinois EPA has not notified the applicant that it is incomplete) and 42 U.S.C. § 7475(c) (requiring final action on a PSD permit application not later than one year after filing).

[6] *See, also,* the current PSD rule at 35 Ill. Adm. Code Section 204.810(a)(3).

information, and it is even more unclear how U. S. Steel might be expected to know, without receiving from Illinois EPA a request for specific additional information, which reports containing no pertinent information would be most valuable for this purpose. As to the first of the purported deficiencies listed by Illinois EPA—the failure to explain why no process-related control options are available for controlling CO emissions from the blast furnace casthouse—U. S. Steel notes that Illinois EPA is familiar with the chemical reaction that is intentionally forced to occur in the casthouse as an inherent part of the ironmaking process.[7] Having not received from Illinois EPA a request for specific additional information, U. S. Steel had no way to know that it was necessary to explain in the permit application that the partial combustion of coke inevitably yields carbon monoxide as a reaction product.

U. S. Steel also notes that, as it pertains to CO emissions from the casthouse, U. S. Steel has not requested any changes to its current permits and is currently subject neither to any numeric emission limitations nor to any work practice requirements other than those in 40 CFR part 63, subpart FFFFF. U. S. Steel did not include any information pertaining to BACT for CO emissions from the casthouse in the initial permit application submitted in March 2020; at the request of Illinois EPA, although under no obligation to do so,[8] U. S. Steel voluntarily provided a proposed BACT analysis for CO emissions from the casthouse in the permit application supplement submitted in October 2022. Illinois EPA's proposed denial of the permit application will simply ensure the status quo is maintained, *i.e.*, that U. S. Steel is not subject to any limitations on CO emissions from the casthouse.

C. CO Emissions from Blast Furnace Stoves

In the permit application it submitted in 1995, National Steel Corporation made the following proposal:

> Therefore the BACT recommendation for control of CO emissions from the blast furnace stoves is the maintenance of good combustion practices.[9]

As described in Section 8.1 of the permit application, Illinois EPA reviewed this proposal and agreed with it, determining that work practices constitute BACT for CO emissions from the blast furnace stoves at Granite City Works.

As discussed in Section 8.2.1.1 of the permit application, this determination is consistent with the PSD rule requirements, which expressly provides for a PSD permit to prescribe work practices to satisfy the BACT requirement where the permitting authority "determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible." 40 CFR § 52.21(b)(12).[10]

---

[7] *See, e.g.,* "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 4 ("The charge materials (iron ore, coke, limestone and other flux material) are fed into the furnace at the top through a double-bell lock system. Heated air is blown into the furnace through nozzles or tuyeres near the bottom of the furnaces. In the furnaces, the coke undergoes partial combustion to carbon monoxide providing the heat to melt the charge as well as reducing the iron ore to elemental iron.")

[8] *See, e.g., U.S. v. Midwest Generation, LLC,* 781 F. Supp. 2d 677 (N.D. Ill. 2011)(holding that source owner's obligations with respect to BACT are limited to those imposed in a PSD permit).

[9] *See,* permit application supplement submitted by National Steel Corporation Oct. 30, 1995, at p. 4-11.

[10] *See, also,* the current PSD rule at 35 Ill. Adm. Code Section 204.280.

In 2013, when issuing the CAAPP permit for the Granite City Works, Illinois EPA again determined that work practices suffice for purposes of demonstrating compliance with the applicable requirements of Permit No. 95010001.[11]

In Section 8.2.2.6 of the permit application, in the discussion of step 5 of the proposed BACT analysis for CO emissions from the blast furnace stoves, U. S. Steel stated as follows:

> USS Granite City is proposing work practice requirements rather than numeric limits as BACT. Numeric emission limitations are not proposed because direct measurement of emissions—*i.e.*, use of U.S. EPA reference test methods—is not feasible for any of the fuel emissions units subject to the BACT requirements for CO emissions. In particular, for the stack serving the blast furnace A stoves, there is no sampling port,[45] and for the stack serving the blast furnace B stoves there is no sampling port satisfying the location requirement in U.S. EPA Reference Method 1.[46] Each stack is refractory lined and is believed to be approximately one hundred years old.
>
> For the reasons presented above, numeric CO emission standards are not feasible for the blast furnace stoves.

Footnote 45. For the one-time exhaust gas sampling event discussed in footnote 19 of this permit application, USS Granite City inserted a sampling probe into the stack through a pipe used to inject steam into the stack.

Footnote 46. Appendix A-1 to 40 CFR part 60.

In Attachment 1 to the draft denial letter, Illinois EPA makes the following assertion:

> Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. For example, the application does not include diagrams for the existing ductwork of the stoves to address whether the configuration of this ductwork would accommodate installation of test ports at a location that would satisfy USEPA Reference Method 1. The application also does not show how the refractory lining on the stacks or their age, approximately one hundred years old, would present significant technical challenges and costs so that the installation of test ports at a suitable location should be considered infeasible. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

With respect to both Illinois EPA's general suggestion that "further support" is needed and its list of specific examples, Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance

[11] *See*, CAAPP Permit No. 96030056 at Condition 7.4.12.b, stipulating that compliance with all applicable requirements for the stoves and certain other processes are demonstrated by meeting "the work practices, testing, monitoring, recordkeeping, and reporting requirements in Sections 7.4 and 5 of this permit;" note that the permit does not include any testing, monitoring, recordkeeping, or reporting requirements specific to the blast furnace stoves.

document suggesting that such documentation or additional explanation be provided. Notably, the documentation provided in the permit application supplement submitted in October 2022 regarding infeasibility of emissions testing is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. U. S. Steel's permit application includes all information required by the applicable permitting rules—including the PSD rule—relating to BACT for CO emissions from the blast furnace stoves at Granite City Works. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[12] but that was not done here.

D. Emissions Associated with Combustion of Coke Oven Gas

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it "does not demonstrate that prior to February 2015, when the by-product recovery coke oven batteries at the Granite City Works were shut down and [coke oven gas] ceased to be available, BACT was being utilized for the SO_2 and CO emissions from use of [coke oven gas] in the stoves." U. S. Steel acknowledges that the BACT determination made by Illinois EPA in 1996, in response to the permit application submitted by National Steel Corporation in 1995, may have been deficient in this regard. Nonetheless, Illinois EPA's assertion that any such historical deficiency is relevant to U. S. Steel's pending permit application is entirely without merit.[13]

VIII. PSD AND NNSR APPLICABILITY WITH RESPECT TO NO_X EMISSIONS

A. Illinois EPA's Claims Are Based on Emissions Increases Previously Authorized

Attachment 1 to the draft denial letter suggests that the permit application is deficient because it does not include or otherwise address the substantive requirements of the PSD and NNSR programs with respect to NO_X emissions. However, in its evaluation of whether the Production Increase Project would become a major modification, Illinois EPA improperly considers emissions and emissions increases that were authorized by Illinois EPA at the time Permit No. 95010001 was issued to National Steel Corporation but will not occur in the future. As shown in the following table, the net NO_X emissions increase from the Production Increase Project authorized by Illinois EPA prior to U. S. Steel's ownership, during the period when National Steel Corporation owned and operated the Granite City Works, is greater than that with the revisions proposed by U. S. Steel.

Permit Date	Permitting Authority	Owner/Operator	Net NO_X Emissions Increase (TPY)
Jan. 25, 1996	Illinois EPA	National Steel Corporation	38.3
Jan. 5, 1999	Illinois EPA	National Steel Corporation	70.1
Pending	Illinois EPA	U. S. Steel	- 237.3 (decrease)

In summarizing its review of the updated NO_X net emissions increase ("netting") analysis provided in the permit application, Illinois EPA conspicuously avoids using the controlling language of the source

[12] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[13] *See, e.g., U.S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677 (N.D. Ill. 2011)(holding that source owner's obligations with respect to BACT are limited to those imposed in a PSD permit).

obligation provisions, discussed in detail in Section VIII.B below, but rather states that the application "does not show that the Project would still not be a major modification for NO_X." With this ambiguous language, Illinois EPA appears to be attempting improperly to shift to U. S. Steel a burden that is not U. S. Steel's. U. S. Steel has demonstrated in the permit application that the Production Increase Project would not become a major modification solely by virtue of the relaxations and other revisions requested by U. S. Steel. This is the only demonstration required of U. S. Steel as it relates to applicability of the PSD and NNSR programs with respect to NO_X emissions. Illinois EPA complains that the permit application submitted by U. S. Steel in 2020 and supplemented in 2022 "does not show that the actual NO_X emissions of the subject units in the period from 1996 to the present have not exceeded" the emission rates now proposed by U. S. Steel, but U. S. Steel has no obligation under the rules to make such a showing.[14]

Illinois EPA's improper claims regarding U. S. Steel's obligations with respect to PSD and NNSR with respect to NO_X emissions are contrary to law. The claim that Illinois EPA makes here—that the permits for the Granite City Works must obligate U. S. Steel to comply with the substantive requirements of these major NSR programs because of emissions increases that may have occurred many years ago, prior to U. S. Steel's ownership—is the same claim previously made by the State of Illinois made and rejected by both the U.S. District Court for the Northern District of Illinois and the U.S. Court of Appeals for the 7th Circuit. [15,16]

B. Source Obligation

Under the PSD and NNSR programs as in effect at the time of the Production Increase Project, where the project involved changes to existing emissions units that are so significant that the emissions unit was deemed not to have begun normal operation, the post-change actual emissions of that unit are assumed equal to its potential to emit. 40 CFR § 52.21(b)(21).[17] The major modification applicability test was therefore based on a comparison of the pre-project actual emissions and the post-project potential to emit of the emissions unit or group of units. 40 CFR §§ 52.21(b)(2)-(3). An emissions unit's potential to emit is its maximum capacity to emit a pollutant under its physical and operational design. 40 CFR § 52.21(b)(4). Limitations on the capacity to emit a pollutant are treated as part of the design of an emissions unit or group of units if the limitation or the effect it would have on emissions is legally enforceable and enforceable as a practical matter. Where the potential to emit of a unit or

[14] Illinois EPA appears to suggest it has already been determined the Production Increase Project as authorized prior to U. S. Steel's ownership of the Granite City Works was a major modification. Attachment 1 to the draft denial letter at footnote 3 (asserting that an analysis of alternatives would have been required of National Steel Corporation "if it had been recognized in 1996 that the Project was a major modification for NO_X"). U. S. Steel is unaware of any such final determination or adjudication.

[15] *See, U.S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677 (N.D. Ill. 2011)(holding that, where a facility should have been subjected to BACT and other substantive requirements of the major NSR permitting programs due to modifications implemented by a prior owner, Section 9.1(d) of the Illinois Environmental Protection Act does not obligate a subsequent owner to come into compliance with those requirements).

[16] Illinois EPA is well aware of the case law, as in recent years the agency has repeatedly issued construction permits for the very emissions units that were the subject of that decision. *See, e.g.*, Construction Permit No. 15030051, issued Oct. 16, 2015 (authorizing operation of the modified units and not imposing BACT or other major NSR obligations); Construction Permit No. 15030051, revised July 15, 2016 (same); Construction Permit No. 15030051, revised May 9, 2017 (same); Construction Permit No. 15030051, revised July 9, 2020 (same).

[17] Except as noted, all citations to the applicable PSD rules herein are to the federal PSD rule as codified and in effect at the time of issuance of Permit No. 95010001 in 1996; where the corresponding provision of the then-effective NNSR rule is equivalent, separate citations are not provided.

group of units is governed by enforceable limitations rather than by the unrestricted physical capacity of that unit or those units, and where those limitations were necessary to a determination that a project was not a major modification, the term "synthetic minor" is commonly used to describe the project and the associated limitations.

As explained in detail in Section 2.2.4 of the permit application, the PSD and NNSR rules provide that after-the-fact PSD or NNSR permitting is required when a project becomes a major modification "solely by virtue of a relaxation in" a synthetic minor limitation. 40 CFR § 52.21(r)(4).[18] These "source obligation" provisions effectively require updated PSD and NNSR applicability analyses in situations where the applicant proposes to relax a synthetic minor limitation in a permit.

Applicability analyses performed in order to determine whether the source obligation provisions apply in conjunction with a requested relaxation are prospective, not retrospective. All of the facts as they will exist at the time of the requested relaxation are considered in the updated emissions increase calculations; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.[19]

The updated NO_X emissions increase calculations presented in the permit application fully conform to and satisfy the source obligation provisions of the PSD and NNSR rules. U. S. Steel's prospective calculation of potential NO_X emissions from the certain fuel combustion units affected by the Production Increase Project includes zero emissions from Boilers 1 through 10, which accurately represents the future potential to emit of those boilers because they no longer exist; does not include the greater NO_X emission rates of Boilers 11 and 12 prior to the required retrofit of flue gas recirculation in those boilers; and includes zero emissions from combustion of coke oven gas as fuel, which accurately represents the future emissions of units that previously burned coke oven gas because coke oven gas is no longer an available fuel at the facility. As discussed further in Sections VIII.C and VIII.E below, if Illinois EPA revises Permit No. 95010001 with the requested relaxations and other changes to the limitations in the permit currently in effect, the Production Increase Project will not become a major modification solely due to those relaxations.

C. NO_X Emissions Associated with a Facility Configuration No Longer Authorized or Under a Counterfactual Hypothetical Are Immaterial to the "Source Obligation" Demonstration

Contrary to the plain language of the source obligation provisions, Illinois EPA suggests that the updated NO_X netting analysis provided in the permit application is deficient because it reflects the prospective reality for the fuel combustion units at the Granite City Works, not any counterfactual

[18] *See, also,* the current PSD rule at 35 Ill. Adm. Code Section 204.850.

[19] *See, e.g.*, letter from S.C. Riva, U.S. EPA, to R. Frontanes, Pfizer Pharmaceuticals LLC (Sept. 23, 2015), conveying U.S. EPA's non-applicability determination for proposed relaxation of synthetic minor limitations that had been imposed in 1994 in order to establish synthetic minor status with respect to NO_X emissions from a project that involved installation of five diesel generators and two boilers. The synthetic minor limitations imposed in 1994 established the combined potential to emit NO_X from the seven new units at 56 tons per year; if the combined potential to emit had been 65 tons per year or more, the project would have been a major modification. U.S. EPA's 2015 applicability determination allowed relaxation of the limitations such that the new potential to emit would be 90 tons per year; the agency's source obligation analysis relied on the fact that other facts had changed during the intervening time period and it gave no consideration to the fact that, had the combined potential to emit been 90 tons per year historically, the project would have been a major modification.

hypothetical. Illinois EPA theorizes that "the NO_X emissions of fuel burning units allowed by Permit 95010001 must necessarily be more than the baseline emissions" and that "the future NO_X emissions of the fuel burning units for purposes of any revised netting analysis should be expected to be substantially greater than their baseline emissions."[20] For purposes of the source obligation analysis, this is plainly untrue, as the total baseline NO_X emissions of these units are 956 tons per year and the total maximum future emissions are 706 tons per year. The draft denial letter does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring an applicant to anticipate, address, or refute the unsupported expectations of Illinois EPA staff as part of the construction permit approval process.

D. Project Emissions Increases and Net Emissions Increases

By definition, the net emissions increase from a project is the sum of two values: The increase in actual emissions from the project and "[a]ny other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable." 40 CFR § 52.21(b)(3)(i).

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that "additional decreases in NO_X emissions that would now be proposed to be relied upon" by U. S. Steel are not contemporaneous and otherwise creditable.[21] This preliminary determination is erroneous for three reasons.

First, to the extent that Illinois EPA's analysis includes separate calculations of increases and decreases based on specific fuels and changes in fuels, those calculations are inconsistent with the PSD and NNSR rule requirements. As described previously, the major modification applicability test requires a comparison of the pre-project actual emissions of the emissions unit or group of units with the post-project actual emissions (or potential to emit) of that emissions unit or group of units; the applicable definition of actual emissions does not provide for a calculation that considers only some portions of the units' emissions. For the certain fuel combustion units affected by the Production Increase Project, the change in actual NO_X emissions is properly calculated as the total post-project actual NO_X emissions, regardless of the fuel or fuels being burned to generate those emissions, minus the total pre-project actual NO_X emissions, regardless of the fuel or fuels that were burned to generate those emissions. This is the basis for the values shown in Table 6-8 of the permit application.

Second, the emissions changes at issue are at certain fuel combustion units affected by the Production Increase Project. Emissions changes at these emissions units must be included in the calculation of the emissions increase that will occur as a result of the project, under the first clause in the definition of

[20] Attachment 1 to the draft denial letter at footnote 11. *See, also,* Attachment 1 at pp. 5 and 11, suggesting that the updated applicability analysis should include "'future' NO_X emissions" greater than zero from Boilers 1 through 10, notwithstanding the fact that those boilers are prohibited from operating currently and in the future; at p. 5, suggesting that the updated applicability analysis should include greater NO_X emission rates from Boilers 11 and 12 based on the configuration of those boilers as they existed at the time the Production Increase Project was implemented by National Steel Corporation, notwithstanding the fact that the Boilers are prohibited from operating at those emission rates currently and in the future; at p. 5, suggesting that the updated applicability analysis should include greater NO_X emission rates from Boilers 11 and 12 and from the blast furnace stoves based on the use of coke oven gas as fuel in those units, notwithstanding the fact that coke oven gas is not an available fuel at the facility currently or in the future. Each of these suggestions is demonstrably inconsistent with the current and future operation of the Granite City Works and is not properly considered in the source obligation analysis.

[21] Attachment 1 at p. 4.

the term "net emissions increase."[22] Therefore, it was proper to include the emissions changes at the certain fuel combustion units affected by the Production Increase Project in the updated calculation of the NO_X emissions increase from the project, -10.7 tons per year, as calculated in Table 6-8 of the permit application and as shown in Table 6-9 of the permit application. These tables are repeated here for the convenience of the reviewer:

Table 6-8. NO_X Project Emissions Increase Analysis

	NO_X Pre-Project Actual Emissions (TPY)	**Proposed Revised NO_X Emissions Caps (TPY)**	**NO_X Change (TPY)**
Blast Furnace Operations	4.6	24.0	19.4
BOF Shop	179.8	400.0	220.2
Continuous Casting Operations	0.0	0.0	0.0
Certain Fuel Burning Units	956.3	706.0	-250.3
Total	1140.7	1130	-10.7

Table 6-9. Updated Net Emissions Increases for NO_X for the 1996 Project

		NO_X
Start of Contemporaneous Period		Jan 1990
End of Contemporaneous Period		Jan 1996
Project Emissions Increases		239.6
Significant Emission Rates		40
Whether Significant?		Yes
Project Emissions Changes (includes decreases at the fuel combustion units)		-10.7
Contemporaneous Emissions Increases	Date	
Installation of #8 Galvanizing Line	Mar-1996	n/a
Contemporaneous Emissions Decreases		
Blooming Mill Shutdown	Apr-1991	-217.8
Batch Annealing Shutdown	Dec-1991	-8.7
Net Emissions Increase		**-237.3**
Whether Significant?		No

Third, even if the contribution of the certain fuel combustion units affected by the Production Increase Project were properly considered as among the other decreases under the second clause of the definition rather than a contribution to the emissions increase from the project under the first clause of the definition, it is not relied upon for the non-applicability determination. The net NO_X emissions increase from the project as presented in Table 6-9 of the permit application is -237.3 tons per year; even if the decrease of 250.3 tons per year as calculated by Illinois EPA is omitted from the calculation, the net emissions increase is 13 tons per year (-237.3+250.3), which is less than the significant level of 40 tons per year and therefore sufficient to demonstrate that the Production

[22] Contrast this with the emissions changes at the blooming mill and galvanizing line shown in Table 6-9. Because these are emissions units not affected by the Production Increase Project, increases and decreases in actual emissions at these units are among the other changes that are considered under the second clause in the definition.

Increase Project would not become a major modification solely by virtue of the relaxations requested by U. S. Steel. The calculations under this hypothetical scenario are illustrated in the following tables.

Table 6-8a. NO_X Project Emissions Increase Analysis

	NO_X Pre-Project Actual Emissions (TPY)	**Proposed Revised NO_X Emissions Caps (TPY)**	**NO_X Change (TPY)**
Blast Furnace Operations	4.6	24.0	19.4
BOF Shop	179.8	400.0	220.2
Continuous Casting Operations	0.0	0.0	0.0
Certain Fuel Burning Units	956.3	706.0	0.0*
Total	1140.7	1130	239.6*

* This Table 6-8a shows a counterfactual hypothetical where the NO_X emissions decrease of 250.3 TPY from the fuel combustion units is not counted because it is determined not to be a creditable or contemporaneous decrease.

Table 6-9a. Updated Net Emissions Increases for NO_X for the 1996 Project

		NO_X
Start of Contemporaneous Period		Jan 1990
End of Contemporaneous Period		Jan 1996
Project Emissions Increases		239.6
Significant Emission Rates		40
Whether Significant?		Yes
Project Emissions Changes (excludes decreases at the fuel combustion units)		239.6*
Contemporaneous Emissions Increases	Date	
Installation of #8 Galvanizing Line	Mar-1996	n/a
Contemporaneous Emissions Decreases		
Blooming Mill Shutdown	Apr-1991	-217.8
Batch Annealing Shutdown	Dec-1991	-8.7
Net Emissions Increase		**13.1**
Whether Significant?		No

* This Table 6-9a shows a counterfactual hypothetical where the NO_X emissions decrease of 250.3 TPY from the fuel combustion units is not counted because it is determined not to be a creditable or contemporaneous decrease.

E. Substantive Requirements of the PSD and NNSR Programs Are Not Applicable with Respect to NO_X Emissions

Because the Production Increase Project would not become a major modification with respect to NO_X emissions solely by virtue of the relaxations requested by U. S. Steel, the substantive requirements of the PSD and NNSR programs[23] are not required elements of the permit application and the fact that these requirements are not addressed in the permit application is not a valid basis for application denial.

[23] 35 Ill. Adm. Code Sections 203.601, 203.602, 204.1100, 204.1110, 204.1120 and 204.1130.

IX. THE PERMIT APPLICATION INCLUDES ALL REQUIRED INFORMATION PERTAINING TO PRE-PROJECT (BASELINE) AND POST-PROJECT (FUTURE) NO_X EMISSIONS CALCULATIONS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient in that it omits certain information that is purportedly necessary for Illinois EPA to validate the PSD/NNSR non-applicability determinations. As explained below, these assertions are without merit.

A. Volume of Coke Oven Gas Combusted During the Pre-Project Baseline Period

In Attachment 1 to the draft denial letter, Illinois EPA states that the updated calculations of the NO_X emissions change resulting from the Production Increase Project include the difference between the pre-project and post-project actual emissions from certain combustion units and that the calculation of pre-project actual NO_X emissions rates for some of these combustion units includes consideration of NO_X formed from combustion of coke oven gas, among other fuels. These statements are correct.

Illinois EPA then asserts that the pre-project coke oven gas usage rates used in calculating these emission contributions "are not accompanied by any documentation or explanation," suggesting that it is not enough to identify the quantity of coke oven gas consumed in each type of affected combustion unit. With respect to an "explanation," this assertion is incorrect. The permit application includes extensive discussion of the use of coke oven gas as fuel during the pre-project baseline period.[24]

With respect to additional documentation or further explanation, Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular documentation or explanation in conjunction with a historical operational rate or emissions rate, nor do they point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. Notably, the documentation provided for coke oven gas in the permit application supplement submitted in October 2022 is indistinguishable from the documentation provided with respect to other fuels, both in the permit application supplement submitted in October 2022 and in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. In all cases, what was provided was a table of usage values, with no primary source documents such as strip charts, because it is neither required nor customary to provide such documents. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[25] but that was not done here.

B. NO_X Emission Factor for Use of COG in Boilers 11 and 12:

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that Table 6-4 in the permit application indicates the emission factor used in calculating the amount of NO_X formed from combustion of coke oven gas in the boilers during the pre-project baseline period is based on emissions testing performed at a coke oven battery.

[24] *See, e.g.*, pp. 2-4, 4-2, 5-5, and 11-2 of the body of the permit application. Additional information is provided in the appendices to the application.

[25] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

The emission factor basis listed in Table 6-4 of the permit application is a scrivener's error. The error was pointed out to U. S. Steel by Illinois EPA's permit application reviewer by telephone in January 2023. The factor is actually based on emission testing performed at Boiler #12, which is one of the boilers that is the subject of the calculation. This fact was conveyed to Illinois EPA's permit application reviewer by telephone in January 2023.

C. Emission Factor for Use of Natural Gas in Ladle Preheaters

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the calculations presented in the permit application in support of the pre-project actual NO_X emissions from certain fuel combustion units affected by the Production Increase Project, U. S. Steel used a single emission factor for all such units, including ladle preheaters. This statement is correct.

Illinois EPA then asserts that the permit application "does not show that it is appropriate to utilize this emissions factor for ladle preheaters." Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular documentation or justification for the emission factors used to estimate historical emissions, nor do they point to even an application form or guidance document suggesting that such documentation or justification be provided. Notably, for a period of nearly thirty years, the emission factor at issue has been used consistently for all purposes pertaining to the permitting of the Production Increase Project and has been both accepted and prescribed by Illinois EPA for that purpose.[26] In light of Illinois EPA's repeated acceptance of and reliance on this emission factor for calculating NO_X emissions from combustion of natural gas in ladle preheaters in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application submitted in March 2020 and supplemented in October 2022.

D. Emissions from Use of Natural Gas on the Continuous Casting Lines:

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the calculations presented in the permit application in support of the pre-project actual NO_X emissions from emissions units affected by the Production Increase Project, U. S. Steel indicated there is no NO_X formation from the continuous casting operation other than from combustion of natural gas and, because all natural gas consumption in the continuous casting operation is accounted for elsewhere, U. S. Steel did not account for any additional pre-project actual NO_X emissions from the continuous casting operation. Illinois EPA's statements in this regard are correct.

Illinois EPA then asserts that U. S. Steel's failure to double-count the pre-project actual NO_X emissions from the continuous casting operation is "problematic." This assertion is incorrect. U. S. Steel's election not to overstate the pre-project actual NO_X emissions from emissions units affected by the Production Increase Project is the correct and appropriate approach, as it best represents the

[26] *See, e.g.,* "Calculation Sheet" prepared by Jim Ross of Illinois EPA, Dec. 5, 1995 (summarizing Illinois EPA's review of the construction permit application submitted by National Steel Corporation and received by Illinois EPA on Jan. 3, 1995) at p. 12; permit application supplement submitted by National Steel Corporation Jan. 16, 1996, at p. 3-2; Construction Permit No. 95010001 as issued Jan. 25, 1996, at Table 4 (prescribing use of this factor for ladle preheaters and certain other combustion units); Construction Permit No. 95010001 as revised Dec. 17, 2012, at Table 4 (same).

increases in actual emissions resulting from the project, consistent with the requirements of the PSD and NNSR rules. However, the manner in which U. S. Steel presented in the permit application the natural gas usage rates and associated NO_X emissions contributions during the pre-project baseline period gas is unclear, and that lack of clarity appears to have caused confusion on the part of Illinois EPA's reviewer. The lack of clarity and the correctness of the total pre-project actual NO_X emissions from natural gas consumption in certain fuel combustion units affected by the Production Increase Project is explained below.

Following are the natural gas usage rates during the pre-project baseline period as listed in Table 3-2 of the permit application submitted by National Steel Corporation in 1995[27] and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996.

Source Description	Emission Factor	Base Year Throughput	Actual Emission	Projected Throughput	Projected Emission
Boiler House 1 (Blrs 1-10) – NG	306 lb/MMcf	361 MMcf	55.23 TPY	included below	
Boiler #11 – NG	306 lb/MMcf	226 MMcf	34.58 TPY	included below	
Boiler #12 – NG	306 lb/MMcf	218 MMcf	33.35 TPY	included below	
BOF Preheaters/Dryers – NG	306 lb/MMcf	283 MMcf	43.30 TPY	included below	
Continuous Caster #1 & #2 – NG	306 lb/MMcf	57 MMcf	8.72 TPY	included below	
Natural gas usage	306 lb/MMcf	1,145 MMcf	inc. above	1,145 MMcf	175.19 TPY

The total natural gas usage in the affected units during the pre-project baseline period is 1,145 million cubic feet per year, including 805 million cubic feet per year from the boilers and 340 million cubic feet per year from the BOF shop and the continuous casting operations. The total associated NO_X contribution during the pre-project baseline period is 175.19 tons per year, including 123.17 tons per year from the boilers and 52.02 tons per year from the BOF shop and the continuous casting operations. National Steel Corporation's projection of the total post-project natural gas usage in the affected units, including the continuous casting operations, was the same as the pre-project amount: 1,145 million cubic feet per year. The total NO_X emissions increase from the Production Increase Project as shown in Table 3-2 of the permit application submitted by National Steel Corporation in 1995 is 238.8 tons per year.

Illinois EPA included in Permit No. 95010001 a limit on total post-project natural gas usage and a limit on total post-project NO_X emissions contribution from this natural gas usage. The limits are 1,145 million cubic feet per year and 175.19 tons per year, respectively.[28] These limits precisely match the values that were presented in Table 3-2 of the permit application submitted by National Steel Corporation in 1995 and that included natural gas usage in the continuous casting operations. Illinois EPA also included in the permit a list of the fuel combustion units to which these limits apply.[29] Likely inadvertently, Illinois EPA omitted the continuous casting operations from this list of fuel combustion units. It is undisputed that Illinois EPA accepted and relied upon both the pre-project baseline information and the projections presented in Table 3-2 of the permit application submitted by

[27] *See*, permit application supplement submitted by National Steel Corporation Jan. 16, 1996, at Table 3-2.
[28] *See, e.g.*, Construction Permit No. 95010001 as issued Jan. 25, 1996, at Special Condition 21 and Table 4.
[29] *Ibid* at Special Condition 21, Special Condition 35, and Table 4.

National Steel Corporation in 1995: The total NO_X emissions increase authorized in the construction permit issued in 1996 is 238.8 tons per year,[30] which precisely matches the value presented in the 1995 permit application.

In the permit application submitted by U. S. Steel in March 2020 and in the supplement submitted in October 2022, the total natural gas usage in the affected units during the pre-project baseline period is documented as 1,145 million cubic feet per year, including 805 million cubic feet per year from the boilers and 340 million cubic feet per year from the BOF shop. The total associated NO_X contribution during the pre-project baseline period is documented as 175.19 tons per year, including 123.17 tons per year from the boilers and 52.02 tons per year from the BOF shop. Consistent with the approach taken by Illinois EPA in drafting Permit No. 95010001, and perpetuating what was likely an inadvertent error, U. S. Steel omitted the continuous casting operations from the list of fuel combustion units burning natural gas and contributing to the total associated NO_X contribution during the pre-project baseline period but included the contribution of the continuous casting operations. However, emissions associated with natural gas combustion in this operation were properly accounted for both in pre-project baseline and the post project emission for the project affected units.

E. Post-Project NO_X Emissions

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it does not include supporting information related to the maximum future NO_X emissions of 706 tons per year from the certain fuel combustion units affected by the Production Increase Project, such as "the maximum annual amounts of fuels burned in these units" and "the emission factors used to calculate annual emissions." As discussed in detail in Section XII.J herein, U. S. Steel included all of this information in the construction permit application submitted in March 2020 but omitted it from the permit application supplement submitted in October 2022 based on Illinois EPA's informal comments regarding the initial submittal. Notably, the permit application at issue does not request a new construction permit; instead, it requests revision of an existing permit, which existing permit has since 1999 limited the maximum NO_X emissions from the fuel combustion units to 706 tons per year. Because the permit application requests no change in the maximum NO_X emissions from the fuel combustion units, U. S. Steel reasonably assumed that no additional information was needed with respect to this calculation. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[31] but that was not done here.

X. THERE ARE NO QUANTIFIABLE FUGITIVE EMISSIONS OF NO_X OR VOM FROM THE BASIC OXYGEN FURNACES

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application "does not address uncaptured emissions" of NO_X and VOM from the basic oxygen furnaces and that the emissions calculations presented in the permit application reflect an assumption "that all emissions of these pollutants from the basic oxygen furnaces are now captured" and routed to atmosphere through the electrostatic precipitator or baghouse. Illinois EPA also acknowledges that such uncaptured

[30] *Ibid* at Special Condition 42.c and Table 6.
[31] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

emissions, if they exist, are not significant and that, if estimated quantities of such uncaptured emissions were added to the calculations supporting the PSD/NNSR non-applicability demonstrations, would yield smaller (rather than greater) emissions increases.

With one minor exception, Illinois EPA's general statements characterizing the emissions increase calculations presented in the permit application, as summarized above, are correct. The minor exception is this: The permit application does not reflect an assumption that there are zero uncaptured emissions of NO_X and VOM from the basic oxygen furnaces but rather reflects the conclusion that, if there are any such uncaptured emissions, those emissions are fugitive emissions[32] and are not quantifiable. Fugitive emissions are counted for purposes of PSD and NNSR applicability determinations only to the extent that such emissions are quantifiable.[33]

Although Illinois EPA presents speculation regarding possible fugitive emissions of NO_X and VOM from the basic oxygen furnaces, that speculation is not a sufficient basis to determine that such emissions exist and are quantifiable. Neither U. S. Steel nor Illinois EPA has not identified any evidence of such quantifiable emissions in the literature or in the permitting records of other iron and steel mills.

The fact that there are fugitive particulate matter emissions from basic oxygen furnaces is not indicative of the formation of NO_X or VOM emissions. The capture system serving the secondary baghouse at Granite City Works is a large ventilation system that is generally evacuating the space around the basic oxygen furnace vessels during the charging, refining, and tapping operations. The primary mechanism for formation of particulate matter during charging and tapping is the oxidation of molten metal. This formation mechanism cannot be expected to result in the formation of NO_X or VOM.

XI. THE PERMIT APPLICATION INCLUDES ALL REQUIRED INFORMATION PERTAINING TO PRE-PROJECT (BASELINE) PARTICULATE MATTER EMISSIONS CALCULATIONS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient for the following reason:

> With regard to baseline particulate emissions, the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not provide needed supporting information for the "corrected" determinations of baseline particulate emissions of

[32] Fugitive emissions are "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." 40 CFR § 52.21(b)(20). The emissions capture systems serving the basic oxygen furnaces satisfy the stringent requirements of 40 CFR part 63, subpart FFFFF, which reflects U.S. EPA's determination of the maximum degree of reduction in emissions that is achievable for these operations. 42 U.S.C. § 7412(d)(2). It is indisputable that these capture systems reflect the state of the art and that, to the extent there are any uncaptured emissions of NO_X or VOM, those emissions could not reasonably be captured or controlled and thus are fugitive emissions.

[33] *See, e.g.,* 40 CFR § 52.21(i)(4)(vii)(exempting a project from PSD permitting requirements if it would be major "only if fugitive emissions, to the extent quantifiable, are considered" and it would occur at a source that is not in a listed source category); *see, also,* 45 *Fed. Reg.* 52676 at 52692 (Aug. 7, 1980)(EPA explains that it is declining to extend the exemption the exemption at § 52.21(i)(4)(vii) to the listed source categories, such as iron and steel mills, but stated, "EPA emphasizes, however, that fugitive emissions from a source in one of the listed categories will only be included in threshold calculations 'to the extent quantifiable'").

> these operations as it is not accompanied by detailed calculations for the emissions from handling each material.

The assertion regarding a deficiency in the permit application is, for two reasons, without merit. First, Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Second, Illinois EPA's characterization of these pre-project (baseline) emission rates as "corrected" is erroneous: These are the values presented in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. U. S. Steel made no change to these values and is not in possession of information that would allow such change. In light of Illinois EPA's acceptance of and reliance on these values during that prior permitting action, which preceded U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the present permit application. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[34] but that was not done here.

XII. THE PERMIT APPLICATION INCLUDES ALL REQUIRED INFORMATION RELATING TO POST-PROJECT ACTUAL EMISSIONS OF PM, PM_{10}, NO_X, AND VOM AND TO ENFORCEABLE LIMITATIONS ON POTENTIAL TO EMIT THESE POLLUTANTS

A. It Is Feasible to Establish Enforceable Emission Caps for Groups of Emissions Units and Emission Points as Proposed in the Permit Application

As correctly described by Illinois EPA in Attachment 1 to the draft denial letter, U. S. Steel's permit application proposes that PM, PM_{10}, NO_X, and VOM emissions be subject to annual emission caps covering groups of related emissions units and emission points. For the blast furnace operations and the BOF shop, the proposed groupings include emission points with significant emissions, such as the BOF electrostatic precipitator stack, and minor emission points such as the iron spout baghouse stack. U. S. Steel's permit application also proposes approaches to making these emission caps enforceable as a practical matter, as would be required if these emission caps were to serve as synthetic minor limitations.[35]

In Attachment 1 to the draft denial letter, Illinois EPA asserts that there may be alternative groupings of emissions units and emission points that could be subjected to enforceable emission caps or other limitations:

> It would be reasonable and appropriate for both the annual emissions of the casthouse and the annual emissions of the two basic oxygen furnaces to be directly limited separately from the emissions of any other units.
> *

[34] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[35] See discussion of synthetic minor limitations in Section VIII.B herein.

> *
> Alternatively, limits specifically for the emissions of the casthouse for the blast furnaces and the basic oxygen furnaces, i.e., the principal units at the facility for iron and steel production, could be accompanied by group limits for the overall emissions of these principal units and the other, "non- principal" units in these areas of the facility. For example, limits could be set for both emissions of the casthouse and for the emissions of the casthouse, charging of the blast furnaces, and the slag pits. Attachment 1 at 18-19.

U. S. Steel agrees with Illinois EPA generally that there are potentially suitable groupings other than those proposed in U. S. Steel's permit application and that the approach suggested by Illinois EPA in Attachment 1 is likely permissible under the applicable permitting rules.

It is unclear whether Illinois EPA's discussion of other potentially suitable groupings of other emissions units and emission points is intended to explain Illinois EPA's proposed denial of the permit application.[36] If it is so intended, U. S. Steel disagrees that this represents a valid basis for such denial. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

B. Particulate Matter Emissions Associated with a Facility Configuration No Longer Authorized Are Immaterial to the "Source Obligation" Demonstration

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application does not include information associated with emissions from the handling of coal and coke at the by-product coke oven batteries that were permanently shut down in 2015. This statement is correct.

Illinois EPA then asserts that this omission represents a deficiency in the permit application because these emissions should be included in the total post-project actual emissions quantity as used in determining whether PSD and NNSR permitting requirements apply. This assertion is without merit. Although this information may be relevant to an evaluation of whether the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel Corporation prior to U. S. Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs, it is not relevant to the "source obligation" analysis and demonstration that are required here. As discussed in Section VIII.B above, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.

[36] Notably, Illinois EPA has not claimed that the groupings and approaches proposed by Illinois EPA would result in permit conditions that are not enforceable as a practical matter or that are otherwise impermissible under the applicable rules.

C. The Permit Application Includes All Required Information Relating to Quantifying Emissions of NO_X and VOM from the Blast Furnace Casthouse Roof Monitor

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed NO_X and VOM emission caps, U. S. Steel proposed that emissions of these pollutants from the Blast Furnace Casthouse Roof Monitor be calculated as 5.3% of the measured emission rate from the Blast Furnace Casthouse Baghouse. (This value reflects the assumption that the emissions from the baghouse represent 95.0% of the total emissions from the casthouse and the uncaptured and unmeasured emissions represent 5.0% of the total: 5% ÷ 95% = 5.3%.)

Illinois EPA then asserts that U. S. Steel's permit application does not demonstrate that the proposed methodology would yield calculated emission rates that are representative of actual emissions from the Blast Furnace Casthouse Roof Monitor under all conditions; in particular, Illinois EPA asserts, the proposed methodology might underestimate actual emissions if the capture efficiency is less than the assumed 95%. Finally, Illinois EPA suggests that prescribing specific emission rates for NO_X and VOM in the permit can reasonably be expected to be more representative than the ratio approach proposed by U. S. Steel.

It is unclear whether these assertions in Attachment 1 to the draft denial letter are intended to support Illinois EPA's proposed denial of the application. If these assertions are so intended, U. S. Steel disagrees that this is a valid basis for denial of the application. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

U. S. Steel agrees that the potential problem identified and discussed by Illinois EPA—that an actual capture efficiency of less than 95% would not be reflected in the calculation methodology proposed by U. S. Steel—exists as a theoretical matter. U. S. Steel contends that this scenario is effectively prohibited, as operation of the blast furnace casthouse capture system is subject to stringent requirements under 40 CFR part 63, subpart FFFFF, particularly § 63.7790(b). Thus, if it were left to U. S. Steel to decide on appropriate compliance demonstration methods for inclusion in the revised construction permit, the proposed 5.3% ratio approach would be used. However, U. S. Steel recognizes that this decision is within the judgment and discretion of Illinois EPA.

D. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Blast Furnace Casthouse Roof Monitor

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Blast Furnace Casthouse Roof Monitor be calculated using prescribed emission factors of 0.030 lb per ton of iron and 0.0153 lb per ton of iron, respectively. Each of these proposed emission factors is derived

from the pre-control PM emission factor of 0.6 lb per ton of iron published by U.S. EPA.[37] Specifically, the PM emission factor is based on an assumed 95% capture efficiency (*i.e.*, 5% of the pre-control emissions are emitted to atmosphere through the roof monitor; 5% × 0.6 = 0.030). The PM_{10} emission factor is based on an assumed particle size distribution where the PM_{10} emission rate is equal to 51% of the PM emission rate (51% × 0.030 = 0.0153), again based on data published by U.S. EPA.[38]

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to these emission factors because the application "does not include relevant supporting information," "only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency," and therefore does not demonstrate that the proposed emission factors would yield calculated emission rates that are representative of actual emissions from the Blast Furnace Casthouse Roof Monitor.

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the permit application regarding the emission factors at issue is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. The assumption of 95% capture efficiency for the blast furnace casthouse at Granite City Works has been consistently applied by Illinois EPA for many years.[39]

A brief recap of the history of U. S. Steel's approach with respect to this issue is in order. In the construction permit application submitted in March 2020, U. S. Steel proposed PM and PM_{10} emission factors of 0.031 lb per ton of iron and 0.0155 lb per ton of iron, respectively. These emission factors have been prescribed by Illinois EPA for this purpose for decades.[40] Among Illinois EPA's informal comments regarding that permit application submittal, Illinois EPA's permit application reviewer correctly pointed out that these historically assumed emission factors are slightly higher than the values that would result from correctly calculating the emission factors using Illinois EPA's historic assumptions of 0.6 lb per ton pre-control, 95% capture efficiency, and 51% PM_{10}:PM ratio. Illinois EPA's permit application reviewer also stated that the agency's records do not appear to contain an explanation for this discrepancy. Accordingly, the permit application reviewer suggested that U. S. Steel use the revised and corrected emission factors in the permit application supplement submitted in October 2022, which U. S. Steel did.

[37] *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 4th Ed. U.S. EPA, Research Triangle Park, NC. Section 7.5, "Iron and Steel Production," Table 7.5-2, "Particulate Emission Factors for Iron and Steel Mills," May 1983.

[38] *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 5th Ed. U.S. EPA, Research Triangle Park, NC. Section 7.5, "Iron and Steel Production," Table 7.5-2, "Size Specific Emission Factors," January 1995.

[39] *See, e.g.*, "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 41.

[40] *See, e.g.*, Construction Permit No. 95090167 issued Sept. 15, 1995; Construction Permit No. 95010001 issued Jan. 25, 1996.

In light of Illinois EPA's repeated acceptance of and reliance on the assumption of 95% capture efficiency in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, and in light of the informal suggestion by Illinois EPA's permit application reviewer to correct the emission factor calculations in the manner described above, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[41] but that was not done here.

Alternatively, if Illinois EPA now believes there are insufficient data to quantify the capture efficiency of the state-of-the-art capture system employed at the blast furnace casthouse at Granite City Works, and that the fugitive emissions[42] from the Blast Furnace Casthouse Roof Monitor are therefore not quantifiable, then those emissions should be omitted from the analyses performed by Illinois EPA to determine whether the source obligation provisions apply in conjunction with the permit revisions requested by Illinois EPA. Fugitive emissions are counted for purposes of PSD and NNSR applicability determinations only to the extent that such emissions are quantifiable.[43]

E. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Slag Pits

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Slag Pits be calculated using a prescribed emission factor of 0.00417 lb per ton of hot metal.

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to this emission factor because the application "does not include relevant supporting information" and therefore does not demonstrate that the proposed emission factor would yield calculated emission rates that are representative of actual emissions from the Slag Pits.

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code

[41] *See, e.g.,* 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[42] Fugitive emissions are "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." 40 CFR § 52.21(b)(20). The emissions capture systems serving the blast furnace casthouse satisfy the stringent requirements of 40 CFR part 63, subpart FFFFF, which reflects U.S. EPA's determination of the maximum degree of reduction in emissions that is achievable for these operations. 42 U.S.C. § 7412(d)(2). It is indisputable that these capture systems reflect the state of the art and that, to the extent there are any uncaptured emissions of PM_{10} or PM, those emissions could not reasonably be captured or controlled and thus are fugitive emissions.

[43] *See, e.g.,* 40 CFR § 52.21(i)(4)(vii)(exempting a project from PSD permitting requirements if it would be major "only if fugitive emissions, to the extent quantifiable, are considered" and it would occur at a source that is not in a listed source category); *see, also,* 45 *Fed. Reg.* 52676 at 52692 (Aug. 7, 1980)(EPA explains that it is declining to extend the exemption the exemption at § 52.21(i)(4)(vii) to the listed source categories, such as iron and steel mills, but stated, "EPA emphasizes, however, that fugitive emissions from a source in one of the listed categories will only be included in threshold calculations 'to the extent quantifiable'").

requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the permit application regarding the emission factor at issue is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. The emission factor of 0.00417 lb per ton for the Slag Pits at Granite City Works has been consistently applied by Illinois EPA for decades.[44] The summary of the derivation of that factor as provided by U. S. Steel in the permit application is simply a paraphrasing of Illinois EPA's description.[45]

In light of Illinois EPA's repeated acceptance of and reliance on this emission factor in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[46] but that was not done here.

F. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Continuous Casting Operation

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Caster Mold, Slab Cutoff, and Slab Ripping operations be calculated using prescribed emission factors.

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to these emission factors because the application does not supporting information "sufficient to show that the emission factors that are proposed as prescribed factors are representative."

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or

---

[44] *See, e.g.*, Construction Permit No. 95090167 issued Sept. 15, 1995; Construction Permit No. 95010001 issued Jan. 25, 1996.

[45] *See, e.g.*, "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 42, stating as follows:

> Emission Factor: 0.00417 lbs/ton of iron
> Origin of EF: Calculated from EPA Assessment of Atmospheric Emissions from Quenching of Blast Furnace Slag. Also, AP-42, Table 13.2.4-4, Fugitive Uncontrolled emissions.
> Summation of the following emission factors:
> a. Slag Quenching = 0.0026 lbs/ton iron,
> b. Slag Digging = 0.00157 lbs/ton iron.

[46] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the permit application regarding the emission factors at issue is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. These PM/PM_{10} emission factors for the continuous casting operation at Granite City Works have been consistently prescribed by Illinois EPA for this purpose for many years.[47]

In light of Illinois EPA's repeated acceptance of and reliance on these emission factors in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application submitted in March 2020 or the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[48] but that was not done here.

G. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Iron Pellet Screen

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Iron Pellet Screen be calculated using a prescribed emission factor of 0.00131 lb per ton of material. As explained in the permit application, the proposed emission factor is derived from the PM_{10} emission factor of 0.0087 lb per ton of material published by U.S. EPA for crushed stone screening,[49] with application of an 85% control efficiency. Specifically, the PM emission factor is based on an assumed 95% capture efficiency (*i.e.*, 5% of the pre-control emissions are emitted to atmosphere through the roof monitor; 5% × 0.6 = 0.030).

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to this emission factor because the application "does not include relevant supporting information," particularly with respect to the proposal to use an emission factor for PM derived from an emission factor published by U.S. EPA for PM_{10}, and therefore does not demonstrate that the proposed emission factor would yield calculated emission rates that are representative of actual emissions from the Iron Pellet Screen.

---

[47] *See, e.g.,* "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 47; Construction Permit No. 95090167 issued Sept. 15, 1995; Construction Permit No. 95010001 issued Jan. 25, 1996.

[48] *See, e.g.,* 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[49] *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42),* 5th Ed. U.S. EPA, Research Triangle Park, NC. Section 11.19.2, "Crushed Stone Processing and Pulverized Mineral Processing," Table 11.19.2-2, "Emission Factors for Crushed Stone Processing Operations," updated Aug. 2004. A control efficiency of 85% was applied for this operation 7.5, "Iron and Steel Production," Table 7.5-2, "Particulate Emission Factors for Iron and Steel Mills," May 1983.

The listing of the PM_{10}-derived emission factor as the proposed, prescribed factor for PM emissions was a scrivener's error in the permit application; U. S. Steel's intent was to propose that Illinois EPA prescribe use of the corresponding PM emission factor of 0.00375 lb per ton of material as shown in Table 5-5 of the permit application supplement submitted in October 2022. Nonetheless, the assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any proposed emission quantification methods for fugitive emissions, nor does the agency point to even an application form or guidance document suggesting that such a proposal be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate, including recordkeeping requirements and other compliance demonstration methods; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

H. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Mag Lime Silo

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that U. S. Steel proposed in the permit application that emissions of PM and PM_{10} from the Mag Lime Silo be included in the permit conditions relating to demonstration of compliance with the proposed PM and PM_{10} emission caps, and further proposed that emissions of these pollutants from the Mag Lime Silo be calculated using a prescribed emission rate of 0.009 lb per hour.

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to this emission factor because the application does not include supporting information demonstrating that the proposed emission rate of 0.009 lb per hour is representative of actual emissions from the Mag Lime Silo.

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any proposed compliance demonstration methods, nor does the agency point to even an application form or guidance document suggesting that such a proposal be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate, including recordkeeping requirements and other compliance demonstration methods; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters. Here, it is noteworthy that U. S. Steel voluntarily proposed that emissions from the Mag Lime Silo be subject to limits where it had no obligation to do so. Illinois EPA's proposed denial of the permit application will simply ensure the status quo is maintained, *i.e.,* that U. S. Steel is not subject to any limitations on emissions from this emissions unit.

I. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Basic Oxygen Furnace Shop Roof Monitor

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Basic Oxygen Furnace Shop Roof Monitor be calculated using prescribed emission factors that are lower than the emission factors used by National Steel Corporation in the permit application submitted in 1995 and by Illinois EPA in the permit issued in 1996. Illinois EPA characterizes U. S. Steel's proposal as follows:

> For PM, an emission factor of 0.01986 pounds/ton is proposed as a prescribed factor, compared to the current emission factor limit of 0.0987 pounds/ton; for filterable PM_{10}, an emission factor of 0.0296 pounds/ton is proposed, compared to the current emission factor limit of 0.06614 pounds/ton.

This misstates U. S. Steel's proposal as presented in Section 5.5.2.2 of the permit application:

> For BOF Shop Roof Monitor, use PM emission factor of 0.0296 lb/ton and filterable PM10 emission factor of 0.0198 lb/ton.

Illinois EPA's mischaracterization of U. S. Steel's proposed emission factors for the Basic Oxygen Furnace Shop Roof Monitor is likely a scrivener's error in Attachment 1 to the draft denial letter.

Illinois EPA acknowledges in Attachment 1 to the draft denial letter that the emission factors proposed by U. S. Steel are representative of the current configuration of the Basic Oxygen Furnace Shop, but then asserts that U. S. Steel's permit application is deficient as relating to these emission factors because "those prescribed factors would not be representative of emissions before the new baghouse system was installed" and further asserts that "particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}."

These assertions are without merit. Although this information may be relevant to an evaluation of whether the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel Corporation prior to U. S. Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs, it is not relevant to the "source obligation" analysis and demonstration that are required here. As discussed in Section VIII.B above, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.

J. The Permit Application Includes Adequate Explanation of Projected Post-Project Actual Emissions from Fuel Combustion Units and Does Not Diminish Illinois EPA's Authority to Impose Enforceable Limits

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application represents the maximum total post-project actual NO_X emissions from certain fuel combustion units affected by the

Production Increase Project will be 706 tons per year and that the application also requests elimination of the gaseous fuel usage limits for these units. These statements are correct.

Illinois EPA then asserts that the permit application is deficient because it "does not explain why actual NO_X emissions of the subject units would not exceed this amount going forward if the permit were revised" as proposed. This assertion is without merit. The explanation is provided in Table 6-7 of the permit application supplement submitted in October 2022: The maximum potential emissions of the affected fuel combustion units are less than 706 tons NO_X per year.

Illinois EPA further asserts as follows:

> While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed above, this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the 2022 application does not show that new limits for fuel usage and emissions would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shutdown. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown. (Internal footnote omitted.)

A brief recap of the history of U. S. Steel's approach with respect to this issue is in order. In the construction permit application submitted in March 2020, U. S. Steel expressly requested enforceable emission caps for emissions of NO_X and other pollutants from the fuel combustion units affected by the Production Increase Project and provided emission calculations supporting these proposed emission caps. Among Illinois EPA's informal comments regarding that permit application submittal, Illinois EPA's permit application reviewer correctly pointed out that enforceable emission caps are superfluous and unnecessary where the maximum potential emissions of the affected unit or units is less than or equal to the emission caps under consideration. Accordingly, in the permit application supplement submitted in October 2022, U. S. Steel omitted the express request for enforceable emission caps for the affected fuel combustion units.

Notwithstanding this history, it remains the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. If Illinois EPA is not persuaded that the future actual emissions from the fuel combustion units affected by the Production Increase Project will be less than or equal to the values represented in the permit application in the absence of enforceable limits on fuel usage in, or an enforceable emission caps for, these units, then the agency undisputedly has the discretion and authority to impose such limits in the permit. The permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters. That should be especially true where, as here, the agency conveys its preliminary judgment, the applicant revises its permit application to be consistent with that representation, and then the agency vacillates.

With regard to Illinois EPA's suggestion that the limits the agency is now considering may need to "address fuel burning units other than the Project-affected units currently addressed by the permit,"

such as the slab reheat furnaces and cogeneration boiler at the Granite City Works, U. S. Steel disagrees that such limits would be appropriate. As these emissions units were not among the units affected by the Production Increase Project, the emissions from these units are not relevant to the "source obligation" analysis and demonstration that are required here, as discussed in Section VIII.B above.

XIII. THE PERMIT APPLICATION INCLUDES ALL INFORMATION NECESSARY FOR INTEGRATED PROCESSING UNDER THE CAAPP OR, IN THE ALTERNATIVE, ANY DEFICIENCIES DO NOT FORM A BASIS FOR DENYING THE CONSTRUCTION PERMIT APPLICATION

A. Claimed Deficiencies in the Permit Application As Related to Integrated Processing Under the CAAPP Do Not Form a Basis for Denying the Construction Permit Application

As correctly noted by Illinois EPA in the draft denial letter, U. S. Steel requested that the revised construction permit be subjected to "integrated processing," as provided by subsections 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act, which would allow the changes to Permit No. 95010001 to be incorporated into the facility's CAAPP permit using the administrative amendment process.

Numerous purported deficiencies in the permit application listed by Illinois EPA in Attachment 1 to the draft denial letter are claimed to be deficient only because of the request for integrated processing. U. S. Steel generally does not agree with Illinois EPA regarding these claimed deficiencies, as discussed in Sections XIII.B through XIII.I below. In addition, U. S. Steel emphasizes that none of these issues would form a valid basis for denying the construction permit application; even if Illinois EPA were correct that these deficiencies would prevent the use of integrated processing, that would only provide a valid basis for denial of the request for integrated processing of the revised construction permit and associated revisions of the CAAPP permit.

B. The Permit Application Includes All Necessary Information Relating to General Provisions in the CAAPP Permit Governing Selection of Emission Factors

In Attachment 1 to the draft denial letter, Illinois EPA states that Permit No. 95010001 does not specify how emissions are to be quantified for purposes of demonstrating compliance with the permitted emission caps and that, in the absence of such compliance demonstration requirements, Illinois EPA imposed monitoring and recordkeeping requirements in the facility's CAAPP permit sufficient to assure compliance with applicable emission limits as required by subsection 39.5(7)(p) of the Illinois Environmental Protection Act. These statements are correct.

Illinois EPA then asserts that the pending permit application does not request revisions to Permit No. 95010001 "that would enable revisions to the CAAPP permit for the Granite City Works, Permit 96030056, to be made by administrative amendment." This assertion is incorrect. U. S. Steel requested that the construction permit be subjected to "integrated processing," which requires that Illinois EPA process the permit application and draft the permit using a program that "meets procedural and compliance requirements substantially equivalent to those" imposed in the CAAPP program. Although this request was stated generally, and the permit application did not specify with precision the monitoring and recordkeeping requirements to be imposed in the revised construction permit and the amended CAAPP permit, that approach is appropriate: It is the responsibility of Illinois

EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters. Inherently subsumed in a request for integrated processing is an implied request that Illinois EPA satisfy its mandate to draft a permit or permit revision that includes the minimum elements of a CAAPP permit—including monitoring, reporting, and recordkeeping requirements sufficient to assure compliance with applicable emission limits—and to remove or revise conflicting or redundant permit terms.

C. The Permit Application Includes All Required Information In Conjunction with the Request for Changes to Emission Point Naming

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the permit application, U. S. Steel requested that the emission point currently identified as "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" in Permit No. 95010001 be renamed and identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." This statement is correct.

Illinois EPA then asserts that, for the following reasons, the pending permit application is deficient.

> However, the application does not actually identify the specific units that would be addressed by the proposed new term. In this regard, the application is not accompanied by an itemized list of the equipment and activities that would be covered by this new term or a diagram that identifies this equipment and activities. US Steel's request also does not explain how the requested revision to Permit 95010001 would do what has generally been requested as the proposed new term would refer to a "Material Handling Tripper." As the 2022 application requests changes to terminology in Permit 95010001, the changes should act to better identify the emissions units that would be addressed, improving the specificity and clarity of the revised permit.[51, 52]
>
> [51] For example, the proposed new term would not make clear that the basic oxygen furnace shop actually has two ladle stirring stations and one ladle metallurgy furnace, all served by Baghouse 2.
>
> [52] The requested change to the terminology for these emissions unit(s) is also problematic as it would refer to a control device, Baghouse 2, rather than to the equipment or activities that generate emissions. Applied literally, the proposed term would only address captured emissions; it would not address the uncaptured emissions, which elude capture for control by the baghouse.

This assertion is without merit. As an initial matter, U. S. Steel has not characterized the listed item as an emissions unit, regardless of naming convention. It is an emission point, and that is how U. S. Steel correctly characterized it in the permit application. The only condition in Permit No. 95010001 that applies to this emission point is a particulate matter emission limit of 12.8 tons per year, which applies solely to the emission point and not separately to "the equipment or activities that generate emissions." Any uncaptured emissions from that equipment or activities are routed to atmosphere through the Basic Oxygen Furnace Shop Roof Monitor. Those emissions are subject to the separate emission limits for the item referenced as "BOF Roof Monitor." This is consistent with the overall structure of Permit No. 95010001, which was issued by Illinois EPA many years prior to U. S. Steel's ownership, in which the emission limits for non-fugitive emissions are applicable to emission points (e.g., "Casthouse Baghouse," "Iron Spout Baghouse," "BOF ESP Stack") rather than emissions units.

A similar change to the item naming was effected by Illinois EPA in 2013 when issuing the CAAPP permit for the Granite City Works, where the agency referred to this emission point (i.e., the item to which the particulate matter emission limit of 12.8 tons per year is applicable) as "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)."[50]

The "list of the equipment and activities that would be covered by this new term" – *i.e.*, Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility – is precisely the same as the list of the equipment and activities that are currently covered by the term "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" as used in Permit No. 95010001 and by the term "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)" in the facility's CAAPP permit. U. S. Steel reasonably concluded that Illinois EPA would understand this fact because the permit application requested and enumerated only discrete changes to Permit No. 95010001, none of which related to reconfiguring the equipment and activities venting to this emission point. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a straightforward request for revision of the name of an emission point be accompanied by a list of the equipment and activities venting to that emission point, nor does the agency point to even an application form or guidance document suggesting that such information be provided. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[51] but that was not done here.

Notwithstanding all of the above, it remains the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. If Illinois EPA wishes to revise the permit to "improv[e] the specificity and clarity of the revised permit better" or to "identify the emissions units that would be addressed" by a particular emission limit, Illinois EPA has the discretion and authority to make such revisions. The permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

D. The Permit Application Includes All Required Information Relating to the Steel Slag Removal Station and the Handling Operation for Raw Materials Used in Ladle Metallurgy

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the permit application, U. S. Steel "does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS." Although U. S. Steel did not request any permit revisions with respect to this item that it considers to be substantive, the absolute statement is incorrect, as U. S. Steel indicated in the permit application that this item should be renamed as "Baghouse 1 for Material Handling." This revision was suggested by U. S. Steel for two reasons: First, renaming this item based on the emission point rather than the emitting activity is more consistent with the naming convention generally used in Permit No. 95010001, as discussed in Section XIII.C above. Second, the historical naming of this item is misleading, as this baghouse does not serve to control emissions from any slag removal operation; the steel slag removal station at Granite City Works is not served by any capture system or baghouse.

[50] *See,* CAAPP Permit No. 96030056 at Condition 7.5.6.g.
[51] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

The requested renaming is consistent with the approach taken by Illinois EPA in Attachment 3 of the CAAPP for the facility, which refers to this item as “Baghouse #1.”

Illinois EPA then asserts that the pending permit application is deficient in two respects relating to the steel slag removal station (i.e., the activity identified as “deslagging station” in historical permitting documents). This assertion is without merit as discussed below.

First, Illinois EPA states that the permit application “does not explain why this steel deslagging operation should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the basic oxygen furnace shop.” U. S. Steel has claimed neither that the steel slag removal station should not appropriately be categorized as slag skimming nor that it should not be addressed with the other slag skimming operations in the basic oxygen furnace shop. Plainly, U. S. Steel was under no obligation to offer, as part of the permit application or otherwise, a justification for a claim that it was not making.

Second, Illinois EPA states that the permit application “does not request revisions to Permit 95010001 to facilitate amendment of the CAAPP permit to appropriately address the emissions of this deslagging station and the associated material handling system.” Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, include a request for revisions “to facilitate amendment of the CAAPP permit” for the facility. It is the responsibility of Illinois EPA to draft both a construction permit and a CAAPP permit with conditions it judges to be suitable and appropriate. The permit applicant has no obligation to reflect in the permit application a correct guess as to what revisions to one permit would be viewed by the permitting authority as facilitating revisions to another permit.

E. The Permit Application Includes All Required Information Relating to the Ladle Drying Preheaters

In Attachment 1 to the draft denial letter, with respect to the Ladle Drying Preheaters, Illinois EPA states that the permit application is deficient because U. S. Steel “does not request any changes to Permit 95010001 to maintain consistency with the approach to these units in the CAAPP permit.”

This assertion is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, include a request for revisions “to maintain consistency with the approach to these units in the CAAPP permit” for the facility. It is the responsibility of Illinois EPA to draft both a construction permit and a CAAPP permit with conditions it judges to be suitable and appropriate. The permit applicant has no obligation to reflect in the permit application a correct guess as to what revisions to one permit would be viewed by the permitting authority as maintaining consistency with another permit.

F. The Permit Application Includes All Required Information Relating to Identification of the CAAPP Permit to be Administratively Amended Following Integrated Processing of the Construction Permit Application

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application is deficient because it "does not identify the version of the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, Permit 96030056, that would be eligible for administrative amendment" under the integrated processing provisions. Relatedly, Illinois EPA asserts that U. S. Steel "has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006."

These assertions are without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, specify the "version" of the CAAPP permit for the facility that should be amended. It is solely the responsibility of Illinois EPA to make revisions and amendments to CAAPP permits in conformance with applicable rules and laws.

Regarding whether U. S. Steel has initiated the process of incorporating the provisions of Permit No. 11050006 into the facility's CAAPP permit, U. S. Steel responds further as follows: In November 2013, U. S. Steel submitted an application to renew the CAAPP permit for Granite City Works. In this permit application, U. S. Steel expressly requested that Illinois EPA incorporate the conditions of Permit No. 11050006 into the CAAPP permit and noted that "the Basic Oxygen Furnace process described in the CAAPP permit condition 7.5 needs to be updated with the new secondary baghouse added as part of the Emission Reduction Project (Construction Permit No. 11050006)."[52] That application was deemed complete by operation of law in January 2014.[53] Illinois EPA retains authority to request additional information in conjunction with a CAAPP permit application,[54] but the agency has not done so.

G. The Permit Application Includes All Required Information Relating to the Relationship Between Fugitive Dust Control Measures Required by Permit No. 95010001 and Requirements of 35 Ill. Adm. Code Part 212

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application is deficient because it "does not make clear the relationship between these requirements established by permit [relating to emissions of fugitive dust from roadways, parking areas, and open access areas] and state regulatory requirements for fugitive emissions in 35 IAC Part 212 Subpart K."

This assertion is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, specify the relationship between existing permit terms and applicable rule requirements. It is the responsibility of

[52] *See*, CAAPP permit renewal application at pp. 2-1 and 4-1.
[53] *See*, subsection 39.5(5)(f) of the Illinois Environmental Protection Act ("Unless the Agency notifies the applicant of incompleteness, within 60 days of receipt of the CAAPP application, the application shall be deemed complete.").
[54] *See*, subsection 39.5(5)(g) of the Illinois Environmental Protection Act ("If after the determination of completeness the Agency finds that additional information is necessary to evaluate or take final action on the CAAPP application, the Agency may request in writing such information from the source with a reasonable deadline for response.").

Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws.

H. The Permit Application Includes All Required Information Relating to Applicable Provisions of 40 CFR Part 63 Subpart FFFFF

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it "does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020." Relatedly, in Attachment 1, Illinois EPA makes the observation:

> These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the 2022 application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the basic oxygen furnaces and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate.

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, include suggested bases upon which Illinois EPA might reopen the facility's CAAPP permit. It is solely the responsibility of Illinois EPA to reopen the CAAPP permit where the agency determines that the permit must be revised or revoked to assure compliance with all applicable requirements.[55]

U. S. Steel generally agrees with Illinois EPA's observation regarding the relevance of the NESHAP requirements and responds further as follows: The applicable requirements of the NESHAP as currently codified are legally enforceable, and the monitoring, testing, recordkeeping, and work practice requirements of that rule provide a sound technical basis for demonstration of compliance with particulate matter emission limits, regardless of whether Illinois EPA satisfies the mandate to reopen the CAAPP permit where such reopening is required to assure compliance with all regulatory requirements.

I. The Permit Application Includes All Required Information Relating to Equipment that is Listed in the CAAPP Permit and Has Been Permanently Shut Down

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it "does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emissions units" and further asserts that "[t]he responsibility to identify provisions in the CAAPP permit that should not be carried forward initially falls on US Steel as it is the CAAPP Permittee for the Granite City Works."

[55] *See*, subsection 39.5(15)(a)(iv) of the Illinois Environmental Protection Act.

These assertions are without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, request changes to the facility's CAAPP permit other than those directly resulting from the requested revisions of the underlying construction permit. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws.

The pending permit application was submitted for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NNSR applicability evaluations relating to the Production Increase Project implemented by National Steel Corporation. This application was not intended to address changes that are not directly relevant to that purpose.

In November 2013, U. S. Steel submitted an application to renew the CAAPP permit for Granite City Works. That application was deemed complete by operation of law in January 2014.[56] Illinois EPA retains authority to request additional information in conjunction with the CAAPP permit application,[57] but the agency has not done so.

[56] *See*, subsection 39.5(5)(f) of the Illinois Environmental Protection Act ("Unless the Agency notifies the applicant of incompleteness, within 60 days of receipt of the CAAPP application, the application shall be deemed complete.").
[57] *See*, subsection 39.5(5)(g) of the Illinois Environmental Protection Act ("If after the determination of completeness the Agency finds that additional information is necessary to evaluate or take final action on the CAAPP application, the Agency may request in writing such information from the source with a reasonable deadline for response.").

DENIAL OF AN APPLICATION FOR REVISIONS TO A CONSTRUCTION PERMIT/PSD APPROVAL[1] (REVISED DRAFT[2])

(Draft December 2023)

U.S. Steel Granite City
Attn: Krista Armentrout – Environmental Manager
1951 State Street
Granite City, Illinois 62040

Permit/Application No.: 95010001 I. D. No.: 119813AAI
Date Permit Originally Issued: January 25, 1996
Date Application for Revisions Received: October 7, 2022
Subject of Permit: Production Increase
Location: Granite City Works, Southeastern Granite City

The Illinois EPA has reviewed your above referenced application for revisions to the above-referenced construction permit/Prevention of Significant Deterioration (PSD) approval (Permit 95010001) issued for the above referenced project. The permit application is DENIED because, if a revision to Permit 95010001 were issued as requested by this application, it might violate various Sections of the Illinois Environmental Protection Act (Act) and various p*rovisions* in Illinois' regulation pursuant to the Act. The Sections of the Act that might be violated include Sections 9(a), 9(b)(2), 9.1(d), 39(a), 39.5(5)(e), 39.5(7)(a), 39.5(5)(i), 39.5(10)(a)(iv) and 39.5(13)(c)(v). The provisions of the relevant Illinois regulations, i.e., Subtitle B of Title 35 of the Illinois Administrative Code (IAC), that might be violated include 35 IAC 201.152, 201.159, 201.160(a), 203.123, 203.128, 203.201,. 203.203(b), 203.208, 203.301, 203.302, 204.280, 204.330, 204.400, 204.550, 204.560. 204.810, 204.1100(c), 204,1110, 204.1130 and 270.401(f).

The specific Sections of the Act and the specific provisions of the Illinois Administrative Code that may not be met if Permit 95010001 were to be revised as requested by this application are detailed in the Listing of Denial Points, Attachment 1 of this permit denial. For each Denial Point, Attachment 1 also describes the information that this application did not provide and the specific reasons why the Act and might be violated if a revised permit were issued as requested, with accompanying explanation and discussion.

[1.] In this application, US Steel requests that the revision of Permit 95010001 be processed with "Integrated Processing," as is provided for by Sections 39.5(13)(a) and (c)(v) of the Act. Integrated Processing would allow changes to the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, as would be set forth in the revised permit, to subsequently be made by means of an Administrative Amendment of the CAAPP permit.

[2.] This revised draft denial letter takes the place of the initial draft denial letter, which was made available for public review and comment beginning in July 2023. This revised denial letter more clearly sets forth the specific laws, rules and reasons that would be the basis for the Illinois EPA's proposed denial of this application.

(This footnote would not be included later in any denial that would be issued by the Illinois EPA.)

This permit denial has two appendices. Appendix A lists the various sections of the Act that are cited in Attachment 1 as the statutory basis for this denial letter, with description and, in some cases, general explanation why the section might be violated if Permit 95010001 were to be revised as requested by this application. Appendix B lists the various provisions in Subtitle B of Title 35 of the Illinois Administrative Code that are cited in Attachment 1 as the regulatory basis for this denial letter, with description and, in some cases, general explanation why the provision might be violated if Permit 95010001 were to be revised as requested by this application.

Before taking action to deny the above-referenced application, the Illinois EPA held a public comment permit on a draft of a proposed permit denial letter in accordance with 35 IAC Part 252, as provided for by 35 IAC 252.105(b).

If you have any questions on the denial of this application, please call Jason Schnepp or Minesh Patel at 217/785-1705.

U.S. Steel Granite City (I. D. No. 119813AAI)
Permit/Application No. 95010001
Application for Revisions to the Permit Received on October 7, 2022
Draft of Permit Denial Letter December 2023

ATTACHMENT 1: LISTING OF DENIAL POINTS

1. THE REVISED NETTING ANALYSIS FOR THE PROJECT FOR NITROGEN OXIDES (NOx) DOES NOT FULFILL RELEVANT REQUIREMENTS OF NEW SOURCE REVIEW (NSR) FOR SUCH ANALYSES

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d) and 39(a)*. (Note: The significance of asterisks that accompany certain Sections of the Act is explained in Appendix A.)

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 Illinois Administrative Code (IAC) 201.160(a), 203.201, 203.203(b), 203.208**, 203.301, 203.302, 204.550**, 204.810, 204.1100(c), 204.1110 and 204.1130. (Note: The significance of asterisks that accompany certain provisions of the Illinois Administrative Code is explained in Appendix B.)

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not show that the Production Increase Project (Project) would still not be a major modification for emissions of nitrogen oxides (NOx) for purposes of New Source Review (NSR) with the increases in NOx emissions that are requested to address errors in the initial permitting of the Project. In particular, the application requests an increase in the permitted NOX emissions of the basic oxygen furnaces (BOFs) of more than 200 tons/year. The netting analysis for NOx in the application, which addresses the Project with the requested increases in NOx emissions, is flawed so cannot be relied upon to show that the increases in permitted NOx emissions would not result in the Project being a major modification. The revised NSR applicability analysis is flawed as, contrary to applicable rules, it relies upon decreases in NOx emissions from actions that were neither contemporaneous with the Project nor creditable as they were not required by Permit 95010001. These decreases resulted from the later shutdowns of ten older boilers at the facility and the much later shutdown of the two by-product recovery coke oven batteries at the facility, as coke oven gas (COG) ceased to be available for use in Project-affected fuel burning units. The incongruous conclusion of the revised NSR applicability analysis is that the Project was accompanied by an overall decrease in the NOx emissions of Project-affected fuel burning units rather than an increase in NOx emissions as would be expected from an increase in production of iron by the blast furnaces.

As the Project would become a major modification for NOx with the requested increase in permitted NOx emissions, the Project would become subject to Nonattainment New Source Review (NaNSR) (35 IAC Part 203, Major Stationary Sources Construction and Modification (MSSCAM)) for NOx. NOx is regulated as a precursor to the formation of ozone in the atmosphere and, in 1996, the Granite City Works was in an area designated nonattainment for ozone air quality. (This area is still nonattainment for ozone.) As the Project would become a major modification for NOx with the requested increase in permitted NOx emissions, the Project would also become subject to Prevention of Significant Deterioration or PSD (35 IAC Part 204) for NOx. NOx is also regulated as a precursor to the formation of nitrogen dioxide (NO_2) in the atmosphere and, in 1996, the facility was in an area designated attainment or unclassified for NO_2 air quality. (This area is still attainment or unclassified for NO_2.) However, as related to the NOx emissions of the Project as now requested by the 2022 application, the application does not address the substantive requirements of MSSCAM or PSD for a major modification, much less show that these requirements are fulfilled. The application does not show that for the Project-affected emissions units for which the Lowest Achievable Emission Rate (LAER) and Best Available Control Technology (BACT) should have originally been required for NOx, LAER and BACT are present as required, respectively. by MSSCAM and PSD. For NOx, the application also does not address the requirement of MSSCAM that a major project be accompanied by emission offsets to counterbalance the increase in emissions of the nonattainment pollutant from the project. The application also does not include an analysis for the impact of the project on NO_2 air quality, as required by PSD.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Section 9.1(d) of the Act and the substantive requirements of 35 IAC Part 203 and Part 204 for a major modification (the requirements for LAER, BACT and emission offsets for NOx and an air quality impact analysis for NO_2) would be violated if a revision to Permit 95010001 were issued that increased the permitted NOx emissions of the Project as requested by the 2022 application. This is because the revised NSR applicability analysis for the Project for NOx improperly relies upon decreases in NOx emissions that are neither contemporaneous nor creditable to claim that the Project would continue to not be a major modification for NOx with the increases in permitted NOx emissions that are being requested.

Discussion

Overview

For NOx emissions, the 2022 application for revisions to the Construction Permit 95010001 for the Production Increase Project (Project)[1] does not address or show fulfillment of the substantive requirements of the Prevention of Significant Deterioration (PSD) and Nonattainment New

[1] Permit 95010001 was initially issued in January 1996 for a "Production Increase" at the Granites City Works. It provides for increases in the allowable production rates of iron from 2,372,500 to 3,165,000 tons per year and of steel from 2,774,000 to 3,580,000 tons per year. This permit was preceded by Construction Permit 9209014, a permit for increases in production issued in September 1992. That permit provided for increases in the permitted production rate on a monthly average basis for iron from 5,600 to 6,500 tons per day (equivalent to production of 2,372,500 tons per year) and for steel from 6,900 to 7,600 tons per day (equivalent to production of 2,774,000 tons per year).

Source Review (NaNSR) programs related to impacts on air quality, i.e., air quality analysis for impacts on NO_2 air quality per 35 IAC 204.1130 and emission offsets for NOx per 35 IAC 203.302. For the blast furnaces and blast furnace stoves, i.e., the emission units that underwent physical modifications with the Project, the 2022 application also does not show fulfillment of the BACT and LAER requirements, respectively of PSD (35 IAC 204.1100) and NaNSR (35 IAC 203.301) for NOx emissions.[2, 3] This showing is necessary because Permit 95010001 is currently based on the net increase in NOx emissions from the Project not being significant so that the Project is not a major modification for NOx.[4] The 2022 application requests that the Project be permitted for additional NOx emissions but does not show that the Project would still not be a major modification for NOx if the permit were revised as requested. As the Project would become a major modification for NOx with the requested revisions to Permit 95010001, the 2022 application must show for NOx that the relevant substantive requirements of PSD and NaNSR are fulfilled for the Project. It would not be appropriate for a revised permit to be issued with increases in permitted NOx emissions as requested by the current application if this application does not also show that the applicable substantive requirements of PSD and NaNSR would be met for the Project for NOx.

In this regard, the 2022 application requests that the permitted NOx emissions of the casthouse on the blast furnaces and the basic oxygen furnaces be increased by 19.4 and 220.2 tons/year, respectively, for an overall increase of 239.6 tons/year. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.)[5] The revised netting analysis for the Project for NOx in the 2022 application suggests that this increase would be accompanied by decreases in the NOx emissions of certain other units. With these accompanying decreases, the net increase in NOx emissions from the Project with the requested revised permit would continue to not be significant.[6] The requested increase in the permitted NOx emissions of the blast furnaces and

[2] The basic oxygen furnaces, at which the largest increase in permitted NOx emissions is requested, were not physically modified and would not become subject to requirements for BACT or LAER for NOx even if the Project were a major modification.

[3] The 2022 application also does not include an analysis of alternatives. This analysis would have been required to be included in the original application for the Project if it had been recognized in 1996 that the Project was a major modification for NOx. It is beyond the scope of the revisions of Permit 95010001 that are now requested to address the fact that such an analysis was not originally part of the construction permit application for the Project.

[4] Under the PSD program, the significant emission rate for NOx is 40 tons/year; under NaNSR, since Granite City is not in an area that is classified as serious, severe or extreme nonattainment for ozone air quality, the significant emissions rate for NOx is also 40 tons/year. An increase in NOx emissions or, if the source elects to evaluate the net increase in emissions, a net increase in NOx emissions from a project that is equal to or greater than this rate is considered significant. (35 IAC 204.660 and 35 IAC 203.209.)

[5] In the 2022 application, the increases in the NOx emissions of the blast and basic oxygen furnaces reflect proposed corrections to baseline emissions, as well as increases in the permitted emissions with the project. For the blast furnaces, the application indicates that baseline NOx emissions should be lowered from 15.6 to 4.6 tons/year. For the basic oxygen furnaces, baseline NOx emissions should be raised from 46.94 to 179.8 tons/year. (2022 application, Table 6-5, “Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units.”)

[6] When a netting analysis that showed a project would not be a major modification is found to have understated emissions of certain new or modified emission units, the next step is usually to examine

basic oxygen furnaces, 239.6 ton/year combined, would not result in the Project becoming a major modification for NOx. For this purpose, the 2022 application indicates that the overall decrease in NOx emissions from Project-affected fuel burning units would now be 250.3 tons/year, comparing their revised baseline NOx emissions of 956.3 tons/year and future NOx emissions of 706 tons/year. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) However, the 2022 application does not identify the specific decreases in NOx emissions that occurred at different groups of Project-affected fuel burning units. Instead, the 2022 application simply indicates that the future NOx emissions of the Project-affected fuel burning units, overall, would not exceed 706.0 tons/year.

This netting analysis for NOx in the 2022 application cannot be relied upon for issuance of a revised permit for the Project as requested by US Steel. The application does not include relevant information showing that additional decreases in NOx emissions that would now be proposed to be relied upon would be contemporaneous and creditable for permitting of the Project. For emission decreases to be relied on for the purpose of a netting analysis, 35 IAC 204.550 and 203.208 provide that the decreases must be contemporaneous and creditable. This necessitates information for how the additional decreases in NOx emissions addressed in the revised netting analysis for NOx were created and how the amounts of the decrease were quantified. Most significantly, the 2022 application does not show that certain decreases in NOx emissions that it would rely upon should be considered contemporaneous with the Project. A revised permit cannot be issued for the Project that relies upon “post-project” emissions decreases, which occurred after the Project, to show that the Project with the requested increases in NOx emissions of the furnaces, should still not be considered a major modification. This is critical because changes that are unrelated to the Project have occurred at certain fuel burning units after the initial issuance of Permit 95010001. The 2022 application proposes to rely upon the decreases in NOx emissions due to these changes, which decreases were not and could not have been relied upon by the original permit for the Project. These decreases in emissions would be relied upon by the revised netting analysis as the analysis does not account for and exclude the emissions decreases from these changes from the analysis. (In addition, as will be addressed separately below, the 2022 application does not include appropriate support for certain units for the quantification of NOx emissions in the revised netting analysis.)

Application Relies on Emission Decreases That Are Not Contemporaneous

As related to the requirement of the NSR rules that decreases in emissions relied upon for netting be contemporaneous, the 2022 application indicates baseline NOx emissions of 131.8 and 123.2 tons/year from the use of blast furnace gas (BFG) and natural gas, respectively, in Boilers 1

whether the project should still not be considered a major modification. The revised netting analysis for this purpose may consider adjustments such as reductions in the permitted emissions of other new or modified units involved in the project. It may also consider additional emission decreases that were not relied upon by the original netting analysis but could have been as they are contemporaneous and creditable. As this reexamination of a project shows that it still would not be considered a major modification with appropriate adjustments to the netting analysis, an appropriately revised construction permit may be issued that is based on the project continuing to not be a major modification.

through 12. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) Boilers 1 through 12 are the twelve boilers at the source in 1996 that were addressed by Permit 95010001. Ten of these boilers, Boilers 1 through 10, were shut down in 2009.[7] The 2022 application does not show that NOx emissions of these ten boilers, as existed in the period prior to 2009, were considered in the "future" NOx emissions with the Project of at most 706 tons/year from the Project-affected fuel burning units. In addition, with regard to Boilers 11 and 12, the two remaining old boilers at the source that continue in operation, flue gas recirculation systems have been installed on these boilers pursuant to Construction Permit 10080022, issued in January 2011. These systems were installed to control NOx emissions to facilitate compliance with 35 IAC 217.164. The 2022 application does not show that the revised netting analysis for NOx does not rely on the lower NOx emissions from Boilers 11 and 12 that are now being achieved with the new control systems, rather than their NOx emissions as previously existed with the Project in the period before these control systems were installed.

The application also indicates baseline NOx emissions of 461 tons/year from use of coke oven gas (COG) in the blast furnace stoves and Boilers 11 and 12.[8] In 2015, US Steel shut down the two by-product recovery coke oven batteries at the Granite City Works. COG ceased to be available for use in the stoves or Boilers 11 and 12. However, COG was available for use in the stoves and these boilers in 1996. As related to the Project, the 2022 application does not show that the revised netting analysis for NOx would not rely upon decreases in the NOx emissions of the stoves and boilers due to the elimination of COG, which did not occur until 2015.[9]

[7] The shutdown of Boilers 1 through 10 was required by Condition 2.6(a) of Construction Permit 06070023, which was originally issued in July 2006. This permit addresses construction of a cogeneration boiler at the facility that would be designed to produce both high-pressure steam to generate electricity and lower pressure process steam. This boiler has been constructed and is in operation. The permitting of this new boiler relied upon contemporaneous decreases in NOx emissions from several actions, most notably, a decrease of 558.9 tons/year from addition of low NOx burners to four reheat furnaces. The permitting of the new cogeneration boiler also relied on a 33.41 tons/year decrease in NOx emissions from the shutdown of Boilers 1 through 10 as this eliminated use of natural gas by these boilers. The related application for emissions decreases that were contemporaneous with the new boiler did not rely on any decreases in the NOx emissions of these boilers from use of COG and BFG. This is because "…the boilers shutdowns will not result in any change in the amount of BFG and COG combusted at the Facility." (Application 06070022, Section 3.3.1. "Boilers 1 through 10 Shutdown Emission Calculations," p. 3-7.) The reliance of Permit 06070023 on emission decreases from the shutdown of these boilers is a further impediment to reliance on these decreases in a revised netting analysis for the Project.

[8] For Project-affected boilers, the 2022 application indicates that baseline NOx emissions from usage of COG are addressed only for Boilers 11 and 12. (2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units.") This is likely erroneous since the application for Permit 06070022 indicates that Boilers 1 through 10 also had the ability to use COG.

[9] The 2022 application does reflect increased use of natural gas by Project-affected fuel burning units. The application explains that with the shutdown of the by-product coke oven batteries, COG is no longer available and more natural gas may need to be used (e.g., 2022 application, Section 6.3, Post-Project NOx Emissions Limitations"). Permit 95010001 currently limits annual use of natural gas by the Project-affected fuel burning units to 1,346 million cubic feet. The revised netting analyses in the 2022

In summary, for purposes of applicability of NSR, the NOx emissions allowed from the Project in 1996 that would be permitted with the requested revisions to the permit could be substantially higher than indicated in the 2022 application.[10] This application does not show that this would not be the case such that the Project would not become a major modification for NOx with the requested increases in the permitted emissions of the blast furnaces and the basic oxygen furnaces. The timing of actions that have resulted in decreases in NOx emissions of fuel burning units after 1996 is critical when considering applicability of NSR to the Project with the requested revisions to Permit 95010001. As the decreases in NOx emissions from certain actions cannot be considered or would be smaller, the net increase in NOx emissions of the Project would be greater. In this regard, it must be assumed that the "future NOx emissions" indicated in the 2022 application reflect maximum actual NOx emissions beginning in 2023, with the requested revisions to Permit 95010001. The application does not suggest that these future NOx emissions are the emissions that should have been allowed by the permit back in 1996 when the permit was issued and the Project commenced.[11]

---

application are based on a post-project annual natural gas usage of up to 1,980 million cubic feet (e.g., Tables 5-7, 6-6 and 7-3).

The decreases in NOx emissions that resulted from the shutdown of the coke oven batteries and elimination of COG in 2015 are contemporaneous with any increases in NOx emissions due to the accompanying use of more natural gas. However, these emissions decreases are not contemporaneous relative to the Project, which was undertaken in 1996. In addition, an application for revisions to Permit 95010001 is not an appropriate venue to address the use of more natural gas due to the shutdown of the coke oven batteries. The Project involved increases in production of iron and steel. The Project-affected fuel burning units do not include four slab furnaces that also used COG and now must use more natural gas. Lastly, the consequences of the shutdown of the coke oven batteries on the facility's NOx emissions, including the consequences for the slab reheat furnaces, are the subject of a separate construction permit application, Application 15030001, received March 5, 2015, which application is still pending.

[10] It should be noted that for purposes of applicability of NSR, for the same reasons that the 2022 application understates the net increase in emissions of NOx from Project-affected fuel burning units, the application also understates the increases or net increases in emissions of the Project for purposes of NSR for particulate matter (PM), particulate matter$_{10}$ (PM_{10}) and volatile organic material (VOM), i.e., pollutants other than NOx for which the requested revised permit for the Project would rely upon the increase or net increase in emissions not being significant.

[11] With the requested revisions of Permit 95010001, it is unclear how the "future NOx emissions" of fuel burning units indicated in the 2022 application are NOx emissions that could have been allowed by this permit in 1996. The future NOx emissions of affected fuel burning units indicated in the 2022 application are less than the baseline NOx emissions, i.e., proposed future emissions of 706 tons/year compared to the claimed baseline of 956 tons/year. However, the Project did not include any elements that would lower the NOx emissions of fuel burning units. Rather, the production of more iron and steel would be accompanied by increased utilization of the blast furnace stoves and boilers as more blast air and steam are generally needed for blast furnaces to produce more iron. Accordingly, in 1996, the NOx emissions of fuel burning units allowed by Permit 95010001 must necessarily be more than the baseline emissions, as this permit addresses a project that involves use of more BFG and natural gas by Project-affected fuel burning units. (Use of COG was not expected to be affected by the Project because production of COG was constrained by the design and operation of the existing coke oven batteries, which were not being modified as part of the Project.)

Indeed, the future NOx emissions of the fuel burning units for purposes of any revised netting analysis should be expected to be substantially greater than their baseline emissions. If one assumes that the increases in emissions would be proportional to the permitted increase in iron production, future NOx emissions of the fuel burning units would be expected to increase by roughly 40 percent. If the baseline

2. THE DETERMINATION OF BASELINE NOx EMISSIONS IN THE REVISED NETTING ANALYSIS CANNOT BE INDEPENDENTLY CONFIRMED

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d) and 39(a)*.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152**, 201.152*** and 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include data and information supporting the determinations of baseline NOx emissions for certain emissions units in the revised NSR applicability analysis for NOx. In this regard, it is noteworthy that the revised NSR applicability analysis does more than seek increases in permitted NOx emissions of the blast furnace casthouse and BOFs to correct errors in the original application for the Production Increase Project. As explained in the discussion below, the revised NSR applicability analysis now also addresses NOx emissions from burning coke oven gas (COG) in Project-affected units, which the Illinois EPA did not require be addressed in 1996. For the continuous casting operations, the analysis also takes a different approach to use of natural gas and associated NOx emissions. Lastly, the analysis does not reflect a reevaluation of the NOx emission factor used for ladle preheaters. For these units, an emissions factor for use of natural gas in boilers, which likely is not appropriate for the simpler burner systems in preheaters, continues to be used.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* As there are deficiencies in the data and information that is provided in the 2022 application for the baseline NOx emissions of fuel burning units, the revised NSR applicability analysis cannot be relied upon. Separate from Denial Point 1 concerning reliance on NOx emission decreases that are not contemporaneous and creditable, deficiencies in the emission data presented in this analysis are also a reason why this analysis cannot serve as proof that the Production Increase Project would not become a major modification for NOx under NSR with the increases in permitted NOx emissions that are now being requested. Likely or possible deficiencies in the emission data in the revised NSR applicability analysis for NOx in the application need to be resolved or corrected before any revised version of Permit 95010001 is issued that would be based upon a revised NSR applicability analysis for the Project.

---

emissions of these units should have been 956 tons/year, as indicated in the 2022 application, this suggests future emissions of these units with the Project should be about 1,340 tons/year (956 tons/year x 1.4 = 1.338 ~ 1,340 tons/year). Alternatively, absent any decreases in NOx emissions from the twelve boilers and the discontinuation of COG, and disregarding increased use of natural gas in place of COG, the NOx emissions from the Project-affected fuel burning units for purposes of NSR applicability, as of 1996, would be on the order of 1,420 tons/year (Proposed future emissions of 706 tons/year + 131.8 tons/year attributable to use of BFG by the boilers + 123.2 tons/year attributable to use of natural gas by the boilers + 461 tons/year from the discontinuation of the use of COG in the stoves and Boilers 11 and 12 ~ 1,420 tons/year). If so, the calculated change in NOx emissions from Project-affected fuel burning units for purposes of NSR applicability would be a net increase on the order of 460 tons/year (1,420 – 956 = 464), rather than a net decrease of about 250 tons/year.

Discussion

The new determination of baseline NOx emissions of Project-affected fuel burning units provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not show that all Project-affected fuel burning units have been addressed. For units that are addressed, the application does not show that appropriate emission factors and operating data have been used to estimate emissions. As specific concerns exist with the determination of baseline NOx emissions for certain emission units, as discussed below, concerns exist with the determination of the overall baseline NOx emissions for the Project.

Baseline Usage of Coke Oven Gas (COG)

As already discussed, the use of coke oven gas (COG) in Project-affected fuel burning units is introduced in the 2022 application for revisions to Permit 95010001.[12] This application does not include supporting documentation or explanation for the baseline usage of COG utilized in the revised netting analysis. The annual usage of COG in the blast furnace stoves (374 million cubic feet/year) and in boilers (2,211 million cubic feet/year) is simply presented in the revised netting analysis for NOx. (2022 application, Appendix B - Emission Calculations, USS Granite City - 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis). The indicated usages of COG are not accompanied by any documentation or explanation.

Emission Factor for Use of COG in Boilers 11 and 12:

For COG, the 2022 application utilizes a NOx emission factor for Boilers 11 and 12[13] of 404 pounds/million cubic feet of COG.[14] The application states that this factor is based on emission testing conducted on the stack of A Coke Battery (2022 application, Table 6-4. "NOx Emission Factors for Fuel Burning"). The application does not show that it is appropriate to utilize an

[12] It should be noted that the introduction in the revised netting analysis for the Project of NOx emissions from use of COG in Project-affected fuel burning units is not acknowledged in the section of the 2022 application in which historical production and operating rates are discussed. Section 6.2.1 of the application, "Historical Throughput Rates," states that "The pre-project actual emissions were calculated using the same production and operating rates as the 1995 Application shown in Table 6-3 [Pre-Project Production and Operating Rates for NOx]." This statement is clearly not accurate as the usage of and NOx emissions from COG were not quantified in the 1995 application. Moreover, Table 6-3 does not include information for the historical or baseline usage of COG.

[13] In the 2022 application, there is an inconsistency in the information for the baseline NOx emissions of boilers. In Table 6-5, "Pre-project Actual Emissions and Summary of Changes to Pre-Project NOx Emissions Factors for Affected Emissions Units," baseline NOx emissions of Boilers 1 through 10 do not appear to be addressed since this table shows that baseline emissions are provided for B11 and B12 (Boilers 11 and 12). In Appendix B, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis, baseline NOx emissions appear to be provided for all boilers, as information is shown as being for "boilers."

[14] For the stoves, the revised netting analysis utilizes a lower NOx emission factor of 80 pounds/million cubic feet of COG. The application states that this factor is based on an emission test for which the date is unknown (2022 application, Table 6-4, p. 6-3). As this factor is identical to the NOx emission factor in USEPA's WebFIRE database for burning COG in industrial boilers, this factor can be considered appropriate. (USEPA, Clearinghouse for Inventories & Emission Factors, Emission Factors & AP42, WebFIRE, with search conducted using the term "coke oven gas" in the field under Select options under Source Classification Code. .

emission factor developed from the results of emission testing on the combustion stack of a coke oven battery to calculate emissions of a boiler. There are significant differences between combustion of COG as occurs at coke ovens and combustion of fuel in a boiler. At a fundamental level, a combustion stack emits the products of combustion from the heating of coke ovens to the high temperature needed to convert coal into coke. Regenerative heat exchangers are utilized to efficiently achieve this temperature. Boilers 11 and 12 emit the products of combustion from burning fuel to achieve the temperature needed convert water into process steam.[15]

Emission Factor for Use of Natural Gas in Ladle Preheaters:

For use of natural gas, the 2022 application utilizes a single emission factor for NOx emissions from all Project-affected fuel burning units. This factor, 306 pounds/million cubic feet of natural gas reflects the results of emission testing conducted on Boiler 12 when using natural gas. The application does not show that it is appropriate to utilize this emissions factor for ladle preheaters, which are different types of emissions units than boilers. Moreover, the revised netting analysis for NOx in the application erroneously indicates that the estimated baseline NOx emissions of ladle preheaters were "Revised to use current AP-42 emission factor." (2022 application, Appendix B, Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) The current AP-42 NOx emission factor for small boilers (<100 million Btu/hour heat input) without low NOx burners or flue gas recirculation is only 100 pounds/million cubic feet of natural gas. (USEPA, *Compilation of Air Pollutant Emission Factors*, AP-42, Table 1.4-1.)

Emissions from Use of Natural Gas on the Continuous Casting Lines:

Unlike the original application, the 2022 application does not directly address NOx emissions associated with use of natural gas in continuous casting operations.[16] In this regard, this application states:

> The pre-project actual emissions for the Continuous Caster Mold – Caster #1 and Caster 2 process, as presented by National Steel Corporation in the 1995 Application listed NOx emissions from this operation. USS Granite City evaluated this analysis and determined that there is no NOx formation from this operation. Any NOx emissions from this operation are due to combustion of natural gas and are already accounted for under the gaseous fuel burning activities listed above [Section 6.2.2.1, Fuel Burning Emissions Units

[15] Application 15030001, the pending application for a construction permit for use of more natural gas with the shutdown of the by-product coke oven batteries, utilizes an emission factor for use of COG of 80 pounds/million cubic feet for baseline NOx emissions of Boiler 12. This is the NOx emission factor in FIRE for use of COG in boilers. This factor is much lower than 404 pounds/million cubic feet, the factor for COG used in the 2022 application for the baseline emissions of Boilers 11 and 12.

It should be noted that Application 15030001 does not include a NOx emission factor for Boiler 11 for COG. This is likely because Boiler 11 did not use COG in the baseline period used for Boilers 11 and 12 (January 2013 through December 2014) for the net increase analysis in this application.

[16] As reflected in Permit 95010001, the original permitting of the Project accounted for NOx emissions of 89.5 tons/year from Caster Molds – Casting but did not account for any NOx emissions from Slab Cut-Off and Slab Ripping, for which only particulate emissions were addressed.

Emissions (Revised)]. Therefore, in the revised analysis, NOx emissions are not included from this operation.

2022 application, Section 6.2.2.7, "Continuous Caster Mold Process Emissions (Revised)."

This is problematic for several reasons. First, the 2022 application does not address the NOx emissions of the natural gas-oxygen torches used in the slab cutting and slab ripping processes, which are part of the continuous casting lines.[17] Second, as the application indicates that NOx emissions are present from the mold processes on the casting lines, the application does not show that the same NOx emission factor is appropriate for this use of natural gas as utilized for ladle preheaters or, alternatively, separately account for the NOx emissions from use of natural gas in the casting process. Lastly, the 2022 application does not identify either the caster processes or the torches as units whose use of natural gas and resulting NOx emissions would be addressed with the emissions of other Project-affected fuel burning units (e.g., 2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units").

[17] Alternatively, if NOx is not formed by the torches given they are supplied with oxygen, the application does not confirm that usage of natural gas by the torches was not considered when the baseline NOx emissions from use of natural gas in Project-affected fuel burning units were determined.

3. THE APPLICATION LACKS INFORMATION FOR THE ACTUAL NOx EMISSIONS OF PROJECT-AFFECTED FUEL BURNING UNITS (LACK OF INFORMATION RELEVANT TO NETTING)

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152***, 201.160(a), 203.123, 203.128, 203.208*, 204.400, 204.550* and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The revised Netting Analysis for NOx in the 2022 application does not show that the value for the maximum future NOx emissions from certain fuel burning units, 706 tons/year, in aggregate, is appropriate for purposes of NSR. That is, the 2022 application does not show that 706 tons/year represents the post-project NOx emissions of these units as could have been addressed when Permit 95010001 was originally issued in 1996 if emissions from burning of COG in these units when operating at the levels of iron and steel production that were permitted had been considered. The 2022 application also does not show that the actual NOx emissions of the subject units in the period from 1996 to the present have not exceeded 706 tons/year. In other words, the application does not show that a value for future NOx emissions of the subject units of 706 tons/year does not really represent "future" emissions beginning at the present time. Otherwise, the value for future NOx emissions in the application improperly takes credit for reductions in the NOx emissions of the Production Increase Project (Project) that were not originally part of the Project. When the Project was initially issued in 1996, the NOx emissions from use of blast furnace gas (BFG) and natural gas in 12 boilers at the Granite City Works was addressed. When revaluating applicability of NSR for the Project for NOx with the increases in permitted emissions requested by the application, it is not appropriate to only address the potential NOx emissions of the two boilers that now remain. Although the other ten boilers are now shutdown, they were operating and emitted NOx in 1996. Similarly, in 1996, coke oven gas (COG) was used as a fuel and burned at the facility. With the shutdown of the two by-product recovery coke oven batteries at the facility, COG is no longer being produced. The NOx emissions of the fuel-burning units that formerly burned COG are now lower than they were in 1996 since natural gas is used to make up for the heat input to the units previously provided by COG. (Compared in terms of pounds of NOx per million Btu of fuel heat input, the NOx emissions from use of natural gas as a fuel are generally lower than those from use of COG.) However, when revaluating applicability of NSR for the Project for NOx with the increases in permitted emissions now requested, it is not appropriate to evaluate the NOx emissions of the units that formerly used COG as they now exist and to ignore the fact that in 1996 these units did use COG and their potential NOx emissions were higher. Again, as touched on in Denial Point 1, the difficulty is not that the future NOx emissions of the subject units may be lower compared to

what may have been possible for their permitted NOx emissions in 1996. The difficulty is that the revised NSR applicability analysis for NOx in the 2022 application attempts to rely on this "post-project" reduction in the NOx emissions of these units to make up for the increases in permitted NOx emissions of the blast furnace casthouse and BOFs that are requested.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* It would be improper for the Illinois EPA to issue a revision to Permit 95010001 that is based on the NSR applicability analysis for NOx in the 2022 application that is not consistent with the provisions of the NSR rules governing such analyses. This would be the case if the value/proposed limitation for maximum future NOx emissions of the subject units in the application was relied upon for issuance of a revision to Permit 95010001 and this value/proposed limitation does not reflect the potential emissions from the subject units with the Project, as required by 35 IAC 203.208 and 204.550 In other words, it would be improper for a revised permit to be issued that reflects current circumstances for the subject units if this reflects NOx emissions that are lower than could have properly been allowed in 1996.

Discussion

The 2022 application does not include a demonstration that the actual NOx emissions of Project-affected fuel burning units would not have exceeded the "future amount" or post-project emissions indicated in the revised netting analysis for the Project for NOx since Construction Permit 95010001 was issued if the production of iron and steel by the source was at the levels allowed by this permit.

3A. THE APPLICATION LACKS INFORMATION FOR THE ACTUAL NOx EMISSIONS OF PROJECT-AFFECTED FUEL BURNING UNITS (LACK OF SUPPORTING INFORMATION)

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

!. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*, *201.152****,35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The amount in the 2022 application for the maximum future NOx emissions from certain fuel burning units, 706 tons/year, in aggregate, is not accompanied by supporting information but is simply presented. The application does not explicitly list the various units whose NOx emissions are being addressed and describe the nature of the various units relative to the emissions of NOx from burning fuel in the units. Data is not provided for the maximum annual amounts of fuels burned in these units. Data is also not provided for the emission factors used to calculate annual emissions, the sources or basis of those factors, and why those factors should be considered representative of the NOx emissions of the various types of units that are being addressed.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include information that is necessary to allow the Illinois EPA to rely upon the future maximum NOx emissions of the subject units, presumably the fuel burning units affected by the Production Increase Project, being no more than the stated amount, or issue a revised permit that limits NOx emissions to the stated amount. The missing information is needed so that the Illinois EPA and other interested parties can independently review the methods, data and calculations by which the representation in the 2022 application for maximum future NOx emissions of the subject units was determined. This information is also necessary if the Illinois EPA is to place appropriate conditions in a revised permit requiring US Steel to track the NOx emissions of the subject units, so as to verify that that the future NOx emissions do not exceed the amount stated in the application or other appropriate amount. In this regard, it is significant that the emissions of many of the Project-affected fuel burning units at the facility, i.e., the blast furnace stoves, the BFG gas flares, and various process heaters, cannot be directly determined because these units are not amenable to emission testing.
Note that this denial point addresses the lack of supporting information for the maximum future NOx emissions of the subject units that is stated in the 2022 application. Denial Point 3, above,

addresses the time period that should be reflected in the determination of maximum future emissions for purposes of evaluating applicability of NSR.

(A further discussion is not provided for this denial point, as it was not present in the Initial Draft Denial Letter. Following the close of the public comment period on the Initial Draft Denial Letter, the Illinois EPA realized that the 2022 application is also deficient as the value it provides for future NOx emissions of Project-affected fuel burning units is not accompanied by supporting information.)

4. FOR THE BASIC OXYGEN FURNACES, THE 2022 APPLICATION DOES NOT ADDRESS THE POTENTIAL FOR UNCAPTURED EMISSIONS OF NOx, VOLATILE ORGANIC MATERIAL (VOM) AND CARBON MONOXIDE (CO) THROUGH THE ROOF MONITOR FOR THESE FURNACES

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*** and 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include information for the uncaptured emissions of NOx, volatile organic material (VOM)_ and carbon monoxide (CO) for the BOFs that occur through the roof monitor on the BOF shop, i.e., the building in which the BOFs are located. The existences of emissions of NOx, VOM and CO from the BOFs is well-established from testing of the stacks of the control systems for the particulate emissions of the BOFs. This testing shows emissions now occur through both the older ESP control system for the BOFs and the baghouse that was installed within the last ten years to improve control of particulate emissions from charging and tapping of the BOFs. These control systems may capture most of the emissions of the BOFs, achieving overall capture efficiencies that engineering design suggests may approach 100 percent. However, the 2022 application does not contain technical or engineering information showing that all emissions of the BOFs are now being captured and no emissions occur through the roof monitor or other openings in the BOF shop. Complete capture of the emissions of the BOF is also not required by applicable regulations. For example, under the National Emission Standards for Hazardous Air Pollutants for Integrated Iron and Steel Manufacturing Facilities ("Iron and Steel NESHAP" or "NESHAP"), 40 CFR 63 Subpart FFFFF, Table 1, the opacity of emissions from the roof monitor and other openings in the BOF shop at the facility is only limited to no more than 20 percent, on a 3-minute average.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information addressing uncaptured emissions of NOx, VOM and CO from the BOFs, the 2022 application would not provide complete information about the emissions of the BOFs. For NOx, absent information for these uncaptured emissions, if US Steel were to submit a corrected, revised NSR applicability analysis to show that the Project would not be a major modification for NOx with increases in permitted emissions as requested, that analysis would not be complete. For VOM, for which the 2022 application also requests an increase in permitted emissions, the revised NSR applicability analysis to support such a revision is not complete. For CO, for which revisions to the PSD approval provided by Permit 95010001 are requested for emission units other than the BOFs, the updated air quality impact analysis for

CO required under the PSD rules would not reflect a complete emissions inventory for the existing sources of CO emissions at the Granite City Works.

Discussion

For the basic oxygen furnaces, consistent with the original permitting of the Project, the 2022 application only quantifies stack emissions of NOx, VOM and CO. For these furnaces, the application does not address uncaptured emissions of these pollutants. (For these furnaces, the 2022 application does address uncaptured emissions of particulate and lead[18] for which Permit 95010001 limits emissions of these pollutants from the "BOF [Basic Oxygen Furnace] Roof Monitor," (Permit 95010001, Condition 18 and Table 2, Item 2)).

The revised netting analyses for NOx and VOM in the 2022 application assume that all emissions of these pollutants from the basic oxygen furnaces are now captured. That is, with the installation of the new baghouse control system on the furnaces to improve control of particulate emissions from the charging and tapping processes, all NOx and VOM emissions of these furnaces that originally were not captured and were emitted through the roof monitor now are captured and are emitted through the stack on the baghouse system. For example, as related to emissions of NOx, the application explains,[19, 20]

> At the time of the 1995 Application, the BOF Shop did not include a baghouse to capture secondary emissions. Secondary emissions were released to the atmosphere through the BOF Shop roof monitor. No information was available at the time about the NOx emissions from the BOF Shop roof monitor. Since then, the BOF Shop includes a capture system for secondary emissions that are routed to a baghouse. NOx emissions testing for the BOF Shop

[18] The uncaptured lead emissions of the basic oxygen furnaces are summarily addressed by the 2022 application. In Section 2.2, this application states that changes to the current limits for lead emissions set by Permit 95010001 are not requested. As such, this application acknowledges the current limits for lead emissions in Permit 95010001, including the limits for uncaptured emissions from these furnaces that are emitted through the roof monitor (Permit 95010001 Condition 18 and Table 2, Item 2). Revisions to these limits are not requested.

[19] The 2022 application addresses uncaptured emission of VOM of the basic oxygen furnaces in a similar manner in Part 7 of the application. Refer to the second Section 7.2.2.1 in the application on p. 6-4, "BOF Baghouse – Secondary Emissions (New)."

[20] As reflected in this excerpt, the 2022 application refers to the NOx and VOM emissions of the baghouse system as "secondary emissions." This is inconsistent with the meaning of this term under the NESHAP for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, which only restricts this term to emissions of particulate matter. It is also misleading as it does not distinguish between captured and uncaptured emissions and suggests that capture of these emissions with a baghouse is sufficient to eliminate concerns for the existence of uncaptured emissions.

In this regard, as defined at 40 CFR 63.7852, "*Secondary emissions* mean **particulate matter** emissions (emphasis added) that are not controlled by a primary emissions control system, including emissions that escape from open and closed hoods, lance hole openings, and gaps or tears in the primary emission control system." For secondary emissions, 40 CFR 63 Subpart FFFFF recognizes the existence of both captured or stack emissions and uncaptured emissions, as would occur through a roof monitor. For basic oxygen furnaces, as well as setting emission limits for particulate emissions from primary control systems, this NESHAP also sets separate emission limits for 1) the particulate matter emissions from a control device used for the collection of secondary emissions, and 2) the opacity of secondary emissions that exit any opening in the furnace shop or other building housing a basic oxygen furnace.

> baghouse completed in the 2019-2020 time frame shows an average NOx rate of 0.0075 lb/ton for the BOF Shop Baghouse Stack. USS Granite City added the BOF Shop secondary NOx emission baseline based on the result of the stack test for the BOF Shop Baghouse stack.
>
> 2022 application, Section 6.2.2.6. "BOF Baghouse – Secondary Emissions (New)."

This assumption made by the 2022 application for uncaptured emissions of NOx and VOM of the basic oxygen furnaces, i.e., that all emissions that were formerly uncaptured are now emitted through the baghouse system, is not appropriate. At a fundamental level, the application does not include any support for this assumption. A rigorous analysis for and quantification of the uncaptured emissions of NOx and VOM from these furnaces is warranted as these emissions were overlooked in the original permitting for the Project.[21]

Then, the data for NOx and VOM emissions from the baghouse stack, which is now available from testing of the baghouse, does not support this assumption and, if anything, shows that this assumption is unsound. This is because this testing does not address the level of capture being achieved by the baghouse system. Rather it shows that there are emissions of these pollutants from charging and tapping and, as such, data for the uncaptured emissions of these pollutants is also appropriate. In this regard, the results of emission testing for the NOx and VOM emissions from the new baghouse system on these furnaces, as cited by the application, indicate more than negligible levels of emissions. (2022 application, Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase

[21] In the original permitting of the Project, the uncaptured emissions of NOx and VOM from the basic oxygen furnaces appear to have been considered negligible. This was likely because the emissions of NOx and VOM of the furnaces were all attributed to the refining process, rather than to charging and tapping. During the refining step in a basic oxygen furnace, oxygen is injected into the molten iron charged to a furnace, which removes carbon from the iron by oxidation, converting the iron into steel. The oxidation of the carbon also provides heat to facilitate the melting of the scrap metal that is also charged to the furnace, so molten metal in the appropriate temperature range can be tapped from the furnace.

In 1996, the basic oxygen furnaces were only controlled by the electrostatic precipitator (ESP) system. While the ESP system only reduces or controls emissions of particulate and not emissions of NOx or VOM, the ESP system does capture NOx and VOM from these furnaces. As the capture efficiency for particulate emissions from refining is assumed to be at least 99.9 percent, it was also reasonable to assume that the ESP system also would achieve at least 99 percent capture for NOx and VOM. With these assumptions, i.e., that NOx and VOM are only generated during the refining step and at least 99.9 percent capture of these emissions is achieved by the ESP system, given the limits on emissions of NOx and VOM from the stack of the ESP set by Permit 95010001, i.e., 69.63 and 10.74 tons/year, respectively, the uncaptured emissions of NOx and VOM from these furnaces would have been projected to be no more than 0.07 and 0.01 tons/year, respectively,. (For example, for NOx, 69.63 tons/year ÷ (99.9 ÷ 100.0) x (100.0 – 99.9) ÷ 100.0 = 0.07 tons/year.) For purposes of determining applicability of NSR to the Project. the increases in NOx and VOM emissions of the furnaces with the Project would be less because these calculations for uncaptured emissions address all emissions of the furnaces, both baseline emissions and the increases in emissions from the Project.

Even with the correction to the emission data for the basic oxygen furnaces indicated in the 2022 application, <u>if</u> all NOx and VOM emissions of these furnaces were actually attributable to the refining step, uncaptured NOx and VOM emissions would still be very small. For example, the potential NOx emissions from the stack of the ESP are now shown to be 380.0 tons/year. With capture of at least 99.9 percent of the NOx by the ESP system, the potential uncaptured NOx emissions from these furnaces would still only be an additional 0.38 tons/year.

Analysis and Revised VOM PSD Net Emissions Increase Analysis.) For NOx, the application indicates baseline captured emissions of 179.8 tons/year, of which, based on the measured emissions from the new baghouse system, as much as 5.1 percent, i.e., 9.1 tons/year, would have been uncaptured in 1996; captured VOM emissions are 26.6 tons/year, of which as much as 15.8 percent, i.e., 4.2 tons/year, would have been uncaptured emissions in 1996. However, instead of assuming that all NOx and VOM emissions are now captured, it would not be unreasonable to assume that the new baghouse system improved capture of the emissions from charging and tapping such that the levels of captured emissions from the baghouse stack and the uncaptured emissions through the roof monitor are now identical.[22, 23]

Finally, the assumption that all NOx and VOM emissions of these furnaces is now captured is inconsistent with the approach taken in the 2022 application to the particulate and lead emissions of these furnaces, for which it is assumed that there are uncaptured emissions that still occur through the roof monitor. In particular, the 2022 application requests that the revised permit establish prescribed emission factors for the particulate emissions of the basic oxygen furnaces

[22] It is reasonable to assume that the new baghouse that was installed to improve control of particulate emissions from charging and tapping of the basic oxygen furnaces reduced these emissions to less than half of their previous amounts. For example, the nominal control efficiency for charging and tapping went from 95 percent with only the ESP control system to 97.5 percent with the addition of the baghouse system. With this assumption, the potential NOx and VOM emissions from the baghouse stack from charging and tapping would be estimated to be about the same as the potential uncaptured emissions from charging and tapping that still occur through the roof monitor, with both being about 2.5 percent of the total emissions from the furnaces. The remainder of the NOx and VOM emissions from charging and tapping continue to occur through the ESP stack (95 percent of the total emissions of the furnaces).

[23] With this assumption, the potential NOx emissions of the basic oxygen furnaces with the Project would become 420.4 tons/year, rather than 400.0 tons/year (400.0 tons/year x (100% + 5.1%) ÷ 100% = 420.4 tons/year. The potential VOM emissions of these furnaces with the Project would become 52.1 tons/year, rather than 45.0 tons/year (45.0 tons/year x (100% + 15.8%) ÷ 100% = 52.1 tons/year.

that occur through the roof monitor.[24] For example, for pre-project actual emissions of the roof monitor, Section 5.2.2.7 of the application explains the following, [25]

> Prescribed emissions factors consistent with the approach described in Section 3 [Discussion of Permit Conditions Used to Restrict PTE] are provided herein. USS Granite City is proposing prescribed emission factors for the BOF Shop Roof Monitor for which emissions testing is not feasible.[Footnote 33] For BOF Roof Shop Monitor, use PM emissions factor of 0.0296 lb/ton and filterable PM_{10} emission factor of 0.0198 lb/ton.
>
> Footnote 33: PM and PM_{10} emissions factors are appropriately determined from the results of emission testing per 40 CFR 63 Subpart FFFFF to determine PM and PM_{10} emission rates for the BOF ESP and baghouse, Desulf/Soda Ash and Hot Metal Charging Baghouse, Slag Skimming Baghouse, and Baghouse 2 for Argon Stirring and Ladle Metallurgy.
>
> 2022 application, Section 5.5.2.2. "Prescribed Emission Factors for Certain BOF Shop Operations."

[24] The 2022 application requests that Permit 95010001 be revised to set "prescribed emission factors" for the emissions of certain emissions units or their uncaptured emissions (e.g., the uncaptured particulate emissions of the basic oxygen furnaces, which are also referred to as the emissions through the roof monitor of the basic oxygen furnace shop). For those units or emission points, the prescribed emission factors would effectively replace the provisions currently in Permit 95010001 that address emissions in pounds/ton of input or production or in pounds/hour. For convenience, these provisions in the permit are generally referred to as "emission factor limits." The usage of this term extends to the provisions of the permit that address emission of lead that are in pounds per hour. In this regard, in Permit 95010001, Table 2, these limits for lead emissions are listed under the heading of "Emission Factor," along with the limits in pounds per ton of production for emissions of other pollutants.

Unlike the emission factor limits currently in Permit 95010001, which the Illinois EPA considers to be directly enforceable against US Steel, prescribed emissions factors that would be established in a revision to Permit 95010001 would not be enforceable. Instead, prescribed emission factors would be specific values for emission rates that US Steel would have to use for normal operation when determining compliance with the limits on annual emissions set by the revised permit. The appropriateness of the various prescribed emissions factors that are selected would be a matter that would be considered during the processing of the revisions to Permit 95010001. Given the role of prescribed emission factors in determining compliance with annual emission limits set by the permit, it is expected that prescribed emission factors would only be set for units for which emissions testing is not feasible or is not warranted given the low levels of annual emissions predicted by engineering analysis and calculations. It is also expected that, as it is practical to do so, prescribed emission factors would be conservative, reflecting the maximum rates of emissions that could occur during the routine, compliant operation of emissions units.

[25] For pre-project actual emissions of particulate matter of the basic oxygen furnace through the roof monitor, Section 5.2.2.7 of the 2022 application explains the following,

> The BOF roof monitor actual emissions were calculated using the information from AP-42 Chapter 12.5 and AIRS (Aerometric Information Retrieval System) database. For pre-change actual PM and PM_{10} emissions, National Steel used 90% capture efficiency during the charging and tapping steps and 99% capture efficiency during the refining step for BOP operations. A detailed description of the baseline roof monitor PM and PM_{10} emission factors is provided in Appendix C of the 1995 Application. For the BOF operations, per particle size distribution in AP-42 Table 12.5-2, 67% of PM is PM_{10}. No changes are necessary for this emission factor.
>
> 2022 application, Section 5.2.7.7, BOF Roof Monitor Emissions (No Change)

The fact that there are emissions of NOx and VOM from the basic oxygen furnaces that now occur from the stack of the new baghouse system but were previously not captured and were not originally quantified raises concern that similar circumstances are present for emissions of CO. [26] In this regard, the 2022 application requests various revisions to Permit 95010001 to correct issues that are posed for the original permitting of the Project with respect to CO emissions, but the application does not propose any such revisions for the basic oxygen furnaces or explain why such revisions are not needed.[27]

[26] For the basic oxygen furnaces, uncaptured emissions of CO should generally be expected to be much greater than the uncaptured emissions of NOx or VOM because the permitted stack emissions of CO of these furnaces are much greater. In this regard, Permit 95010001 limits the CO emissions from the stack of the ESP system for these furnaces to 16,097 tons/year. (The 2022 application does not request an increase in this limit.) If only 99.9 percent capture of CO is assumed by the ESP system, the potential uncaptured CO emissions of these furnaces would be 16.1 tons/year. (16,097 tons/year ÷ {99.9 ÷ 100.0} x {100.0 – 99.9} ÷ 100.0 = 16.1 tons/year CO.) Of course, the capture efficiency of the ESP system for CO could be higher than the efficiency for NOx or VOM if CO is only formed during the refining step when oxygen is actually being injected into the furnace and not during the entire refining step. However, one approach to the revision of Permit 95010001 would be to conservatively assume that the capture efficiency of the ESP system for CO is the same as its capture efficiency for particulate.

[27] The application also does not suggest that it would be inappropriate for any revised permit to simply limit the stack emissions of CO from the basic oxygen furnaces, addressing the combined stack emissions of the ESP and the new baghouse, to the current limits for the CO emissions of the furnaces in Permit 95010001, which limits currently apply only to emissions from the stack of the ESP.

5. THE EMISSION INVENTORY FOR THE SOURCE USED IN THE AIR QUALITY ANALYSIS FOR CARBON MONOXIDE (CO) OMITS CERTAIN CO EMISSIONS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152***, 201.160(a), 204.330, 204.1110 and 204.1130.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The "Air Quality Modeling Report," Appendix C of the 2022 application, which provides the "Source Impact Analysis" required under PSD, is deficient because it does not address certain CO emissions of units that are at or were at the Granite City Works. In particular, the uncaptured CO emissions of the blast furnace cast house and the BOFs (i.e., the emissions that occur from the roof monitors and other openings in structures) are not addressed. The CO emissions of the two by-product recovery coke oven batteries formerly at the Granite City Works, which were in operation in 1996, are also not addressed.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* As the source impact analysis in the 2022 application does not address certain CO emissions, it does not fully address the impact of the Production Increase Project, with increases in permitted CO emissions as now requested, on ambient air quality for CO. This analysis also does not address the impact of the Project on CO air quality as would have been determined in 1996 if the Project had been permitted for more CO emissions, as is now being requested by the 2022 application.

Discussion

The results of the analysis of the impacts of the Project on ambient air quality for carbon monoxide (CO) cannot be relied upon because the inventory for the CO emissions of the source with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered. The 2022 application includes an air quality analysis because the Project was originally permitted as a major modification for CO under the Prevention of Significant Deterioration (PSD) program and the application requests revisions to Permit 95010001 to increase the CO emissions for which the Project is permitted.[28] To support

[28] The 2022 application requests that Permit 95010001 be revised to address an additional 25,334 tons/year of CO. This would include emissions of 320 tons/year of CO from the casthouse on the blast furnaces, for which CO was not addressed in the original permitting for the project (2022 application, Section 4.4, p. 4-4) . This would also include an additional 25,014 ton/year from Project-affected fuel burning units, other than Boilers 1 through 10, which are now retired (2022 application, Sections 4.2 and 4.3, pp. 4-2 and 4-3). For the fuel burning units, US Steel has determined that the emission factors for CO

this request, an air quality analysis for CO must be part of the application pursuant to Illinois' PSD rules, 35 IAC 204.1130, Air Quality Analysis, since the request involves revisions to the provisions in Permit 95010001 that involve the Project as it is a major modification for CO under the PSD program.

Uncaptured Emissions from the Casthouse on the Blast Furnaces

The air quality analysis in the 2022 application does not address the uncaptured emissions of the casthouse (2022 application, Appendix C – Air Quality Modeling Report, Table for "US Steel Granite City Volume Source Inputs"). The application indicates potential CO emissions of 13.6 tons/year from the roof monitor on the casthouse on the blast furnaces (2022 application, Section 4.4). These "uncaptured" CO emissions, which are not captured by the baghouse systems on the casthouse, must be addressed in the air quality analysis submitted to support revisions of Permit 95010001 to provide for more CO emissions from the Project.

Uncaptured Emissions from the Basic Oxygen Furnaces

The air quality analysis in the 2022 application does not address uncaptured emissions of the basic oxygen furnaces. (2022 application, Appendix C – Air Quality Modeling Report, Table for "US Steel Granite City Volume Source Inputs.") As discussed earlier, the 2022 application does not address uncaptured emissions from these furnaces. The application also does not explain why uncaptured emissions would not be present as the application does not show 100 percent capture of the emissions of these furnaces by the control systems for emissions of particulate. As there are uncaptured CO emissions from these furnaces, these emissions must also be addressed in the air quality analysis submitted to support revisions of Permit 95010001 to accommodate additional CO emissions from the Project.

By-product Coke Oven Batteries

The 2022 application does not explain why the air quality analysis in the application should not consider the CO emissions of the former by-product coke oven batteries at the source. These batteries were in operation when the Project was originally permitted in 1996 and did not cease operation until 2015. Accordingly, the analysis does not address CO ambient air quality with the Project as would have been predicted by the original air quality analysis for the Project if it had addressed the additional CO emissions now being requested for the Project. On the other hand, the analysis addresses CO emissions of emission units that did not exist in 1996, as this analysis addresses the emissions of the heat recovery coke ovens adjacent to the Granite City Works, which were built and are now operated by Gateway Energy & Coke. [29]

utilized in the original permitting of the Project, particularly the emission factor for blast furnace gas used in the blast furnaces stoves, understated CO emissions.

[29] The modelling in the air quality analysis did address certain newer units, which came into operation after the Project in 1996. In particular, the analysis addressed the CO emissions of the new coke oven batteries adjacent to the Granite City Works that are owned and operated by Gateway Energy & Coke. However, modeling of the CO emissions of new units would only compensate for the CO emissions of existing units if the new batteries were direct, in-kind replacements of the shutdown units, which is not the case. This is not the case. The batteries that were shut down by US Steel were by-product recovery batteries. They recovered chemicals from the off-gas from the coking process (e.g., benzene, toluene and naphthalene, with the gas then used as fuel for heating the coke ovens and in certain other units at the source. Gateway's batteries are heat recovery batteries, in which the off-gas from coking is combusted in

the ovens and the heat is used to make steam and generate electricity. Moreover, the new batteries and the old batteries both operated for a period of several years before US Steel shut down its batteries.

5A. ISSUES WITH THE BACKGROUND AIR QUALITY USED IN THE AIR QUALITY ANALYSIS THE EMISSION INVENTORY FOR THE SOURCE USED IN

(Note: In the Initial Draft Denial, this denial point, Denial Point 5A, was not addressed separately but was instead addressed as part of Denial Point 5. This deficiency is now being addressed separately for ease of understanding. This deficiency relates to the value for background ambient air quality used in the CO air quality analysis rather than deficiencies in the inventory of sources (i.e., the compilation of emissions units and emission data) used in the dispersion modeling in the air quality impact analysis for CO.)

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d) and 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 204.330, 204.1110 and 204.1130.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The "Air Quality Modeling Report," Appendix C of the 2022 application, which also provides the "Air Quality Analysis" required under PSD, is deficient. As related to baseline ambient air quality for CO, this report does not address baseline ambient air quality as existed at the time that the Production Increase Project was initially permitted. It also does not address ambient air quality as it presently exists. Rather, a value for background air quality from ambient monitoring conducted in 2016 through 2018 is used. This does not represent either air quality in the period before the Project was initially permitted or air quality at the present time. While the monitoring station in East St. Louis that was the source for the value selected for background air quality ceased operation in 2019, the Missouri Department of Natural Resources continues to conduct ambient monitoring for CO at a site in St. Louis. (In this regard, the 2022 application, p. 4-5, indicates that "There are many existing ambient CO monitors within the 100 miles of the facility (Figure 4).") The 2022 application does not justify use of a value for background ambient air quality that is not representative of the period when the Project was initially permitted. Then, if this can be justified, the 2022 application does not explain why it is appropriate to use a value for background air quality taken from ambient monitoring conducted over five years ago.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested*: Because of the issues with the value for baseline air quality used in the "Air Quality Modeling Report" in the 2022 application, as discussed above, it would not be proper to rely on the results of this report to issue a revised permit what would provide for increases in permitted CO emissions as requested by the 2022 application.

Discussion

In addition [to the deficiency addressed in Denial Point 5], the air quality analysis in the application uses a value for CO background air quality on an 8-hour average that is based on ambient air quality data collected for a three year period consisting of 2016, 2017 and 2018. As such the value used for background air quality is not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted.[30]

[30] Under the PSD program, the air quality analysis for a project whose modelled maximum impact(s) by itself on air quality for a pollutant are above certain specified concentration(s) or "significant impacts levels" under the PSD program must also consider "background air quality." This accounts for the contribution to ambient air quality of mobile sources (e.g., cars, trucks and buses) and of other sources (e.g., residential and commercial heating), which contribution cannot be determined as part of the computerized dispersion modelling for discrete emission units performed as part of the analysis. The air quality analysis in the 2022 application shows that the maximum air quality impact of the Project with the requested increases in CO emissions would continue to be above the significant impact level for CO on an 8-hour average. (In the original air quality analysis, the Project's impacts were significant for CO on both a 1-hour and an 8-hours average.) The value for background in the current air quality analysis is based on data collected at an ambient air monitoring station in East St. Louis operated by the Illinois EPA. If US Steel shows that the air quality analysis for the revision to Permit 95010001 should address current ambient air quality for CO, the value for background air quality in the analysis should be updated. Since the Illinois EPA discontinued ambient monitoring for CO at its East St. Louis monitoring station in 2020, the new value for background would likely need to be based on data collected at an appropriate monitoring station in Missouri operated by the Missouri Department of Natural Resources.

It should be noted that the values for background used in the original air quality analysis were likely conservative, as they were based on data from a now retired monitoring station in Granite City that was less than a third of a mile from the Granite City Works. Given the location of that station, the ambient air quality data collected at that station may have included the contribution to air quality of units for which modelling was also conducted, so that the original analysis effectively counted the impacts of those units twice. Thus, it is reasonable for the current air quality analysis to use value(s) for background air quality based on data collected at a monitoring station other than the one that was originally used.

6. SCOPE OF PROPOSED GROUP EMISSION LIMITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not show that certain proposed collections of emission units for the "group limits" for annual emissions of particulate, NOx and VOM that are generally requested are appropriate. In this regard, the 2022 application does not propose limitations that would only apply to the annual emissions of particulate of the casthouse for the two blast furnaces. The application also does not propose limitations that would apply only to the annual particulate emissions of the two BOFs. These are principal emission units at the Granite City Works. For the casthouse, the 2022 application does not show that that it would be unreasonable or inappropriate for Permit 95010001 to continue to have limitations for annual emissions of particulate that are directly enforceable independent of emissions of the other, lesser units involved in production of iron (i.e., the charging of the blast furnaces and slag pit operations). (As the application does not indicate any NOx or VOM emissions from these lesser operations, it is unclear whether group limits are actually being requested for blast furnace operations for NOx and VOM.) Similarly, for the BOFs, the 2022 application does not show that it would be unreasonable or inappropriate for Permit 95010001 to continue to have limitations for annual particulate emissions that are directly enforceable independent of the emissions of other, lesser units involved in making steel (i.e., the removal of sulfur from the molten iron, the skimming of the resulting slag from the surface of the iron in the ladle, and the ladle metallurgy operations after the BOFs). (The application does not actually indicate any NOx emissions from these lesser operations; for VOM, the only lesser unit identified with emissions is the skimming of slag.) While the 2022 application points to three construction permits for facilities issued by other permitting authorities as support for the proposition that limitations on annual emissions that apply to both principal units and lesser units are appropriate, the 2022 application does not show that the circumstances of the Granite City Works are such that those other permits should serve as precedents for the requested revisions of Permit 95010001. Variability in utilization or activity was an inherent aspect in the basic design or purpose of those three facilities and led to the approach to the emissions limitations that were set for those facilities. In this regard, one facility involved a fleet of sea-going vessels engaged in exploration for petroleum. The second facility, "the first of its kind," would be developed to make fuel ethanol from processed municipal waste and sewage sludge. (It may also be relevant that the construction permit for this facility, and as well as the permit for a fleet of vessels that would conduct offshore exploration for petroleum, both limited emissions so that the facilities would not be major sources for purposes of NSR.) The third facility was being developed as a peaking power plant, to operate mainly when other

sources of electricity, including wind and solar power, could not fully satisfy the demand for electricity. Moreover, this last permit sets limitations for the annual emissions of a group of identical generating units. As such, this permit does not provide support for setting limitations for a collection of disparate emission units. In summary, the 2022 application does not request revisions to Permit 95010001, that would continue to separately limit the annual particulate emissions of the blast furnace casthouse and the annual emissions of the two BOFs by themselves.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* If a revision to Permit 95010001 were issued without limits that independently apply to the emissions of the blast furnaces casthouse and to the emissions of the two BOFs, the 2022 application would not show the limits on annual emissions established in such revised permit would serve to restrict the emissions of the casthouse and the two BOFs as a practical matter. In this regard, as US Steel is applying for revisions to emission limits that are currently in Permit 95010001, it is obliged in its application to adequately explain and justify the revisions to the current emission limits that it is requesting. The three permits cited by US Steel in the 2022 application do suggest that permit limitations for the annual emissions of emission units that are accompanied by appropriate operational and/or emissions monitoring may now be considered acceptable as being enforceable as a practical matter without associated emission factor limits, i.e., limits on emission of pollutant(s) in pounds per ton of production or throughput, pounds per million Btu fuel heat input or pounds per hour. However, these permits do not show that the stringency of the current limits for the annual emissions of principal emissions units at the Granite City Works, a facility with substantial emissions in an urban area, should generally be relaxed by setting revised limits that would now apply to emissions of both principal unit(s) and other lesser units, as is proposed by the 2022 application.

Discussion

The application does not show that the proposed collections of emission units for the requested group limits for annual emissions of particulate, NOx and VOM are appropriate.[31, 32] In particular, the application does not propose limits that would only apply to the annual emissions of the casthouse on the blast furnaces and to the annual emissions of the two basic oxygen furnaces. These are principal emission units at this facility. It would be reasonable and appropriate for both the annual emissions of the casthouse and the annual emissions of the two basic oxygen furnaces to be directly limited separately from the emissions of any other units. The construction permits issued by permitting authorities in other jurisdictions cited in the application as support for

[31] For PM, PM_{10}, NOx and VOM (i.e., pollutants other than sulfur dioxide (SO_2), carbon monoxide (CO) and lead), the 2022 application requests that the revised permit not include the provisions in Permit 95010001 that the Illinois EPA considers would limit emissions of individual "processes" in pounds/ton of production or throughput and in tons/year. These provisions were set to ensure that the Project would not be a major modification for purposes of New Source Review (NSR). The removal from Permit 95010001 of the "emission factor limits" which limit emissions of various process operations relative to their production or throughput, would facilitate resolution of two permit appeals filed by US Steel with the Illinois Pollution Control Board (PCB), PCB 2013-53 and PCB 2013-62. Both appeals indirectly address the emission factor limits in Permit 95010001. PCB 2013-53 concerns the revised Clean Air Act Permit Program (CAAPP) permit for the facility (Permit 96030056) issued in 2013. US Steel appealed this permit as it repeats the emission factor limits as originally set by Permit 95010001. PCB 2013-62 concerns the construction permit for the addition of the baghouse system to improve control of particulate emissions from charging and tapping of the BOFs, Permit 11050006, as reissued in 2013. For the BOFs, this permit also repeats the emission factors limits for the BOFs set by Permit 95010001. US Steel appealed the subject emission factor limits in these permits because, prior to issuing the revised CAAPP permit for the facility in 2013, the Illinois EPA had explicitly explained that the provisions in the permit containing emission factors were considered to constitute enforceable limits on emissions. This was done in the Illinois EPA's "Statement of Basis for a Planned Revision of the Clean Air Act Permit Program (CAAPP) Permit for: U. S. Steel Corporation, Granite City Works, 20th and State Streets, Granite City, Illinois," of March 2011, pages 20 through 26. That these provisions set enforceable limits was then recognized by the USEPA in the Administrator's subsequent order of December 3, 2012, "In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056," Petition Number V-2011-2, pages 7 through 9).

[32] With regard to the current limits for the annual emissions of PM, PM_{10}, NOx and VOM of individual processes, the 2022 application requests "group limits" for the annual emissions of groups of related emission units. For example, the application requests that the revised permit limit the overall emissions of a group of units that includes the casthouse for the blast furnaces and other, ancillary units involved in production of iron. The permit currently sets separate limits for the emissions of the casthouse, the emissions from charging the blast furnaces, and the emissions from slag pit activities. Unlike the current limits for annual emissions, which apply on a calendar year basis, the proposed new limits for annual emissions would be rolled monthly, restricting emissions over each consecutive 12 month period. The requested limits would theoretically be less stringent than the current limits as US Steel could potentially compensate for any "overage" of emissions by unit(s) in a group of units with lower levels of emissions from other units in the group.

Incidentally, in these appeals, US Steel only challenges the emission factor limits for "processes," such as the casthouse, the basic oxygen furnaces, continuous casting operations, and discrete material handling operations. These appeals do not challenge the emission factor limits for fuel burning units affected by the Project. Those limits do not restrict the emissions of individual units or groups of similar units. Instead, they separately restrict the emissions from use of different fuels, i.e., blast furnace gas, natural gas and oil.

emission limits that apply to groups of emission units do not show that the annual emissions of the casthouse and the basic oxygen furnaces should not both continue to be limited individually.[33]

In this regard, the 2022 application points to USEPA policy and practice concerning how the potential emissions of a source may be restricted (2022 application, Section 3, "Discussion of Permit Conditions used to Restrict PTE [Potential to Emit]). The application shows that USEPA has found that construction permits may be issued that restrict potential emissions by means of limits on annual emissions that are practically enforceable. Accordingly, the current provisions in Permit 95010001 that limit emissions of process units in pounds/ton of production of throughput, which apply on a short-term rather than annual or long-term basis, are not essential to restrict potential emissions. In addition, the application points to several construction permits issued outside of Illinois since 2000 for which the permitting authority determined that annual emission limits that apply to groups of emission units that are practically enforceable were determined to be sufficient to restrict potential emissions without need for accompanying limits that address emissions on a short-term basis.[34, 35] However, the 2022 application does not show that the

[33] In light of the construction permits issued by other permit authorities cited by the application as support for group limits, it would seem acceptable for a revised permit to set group limits for the emissions units or operations that do not qualify as principal units. For example, for the production of iron, a revised permit could set limits for the overall emissions from charging the blast furnaces and the slag pits. Alternatively, limits specifically for the emissions of the casthouse for the blast furnaces and the basic oxygen furnaces, i.e., the principal units at the facility for iron and steel production, could be accompanied by group limits for the overall emissions of these principal units and the other, "non-principal" units in these areas of the facility. For example, limits could be set for both emissions of the casthouse and for the emissions of the casthouse, charging of the blast furnaces, and the slag pits.

[34] The 2022 application, Appendix E - "Copies of EPA Determinations," contains two decisions by the USEPA's Environmental Appeals Board (EAB):

- The 2012 decision of the EAB for an Outer Continental Shelf (OCS) Permit to Construct and Title V Air Quality Operating Permit issued by Region 10 of USEPA to Shell Offshore, Inc. (USEPA, EAB, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2012).
- The 2018 decision of the EAB for a PSD permit issued by the Department of Environmental Quality for Pima County, Arizona, to Tucson Electric Power (USEPA, EAB, *In Re Tucson Electric Power*, PSD Appeal No. 18-02, Order Denying Review, Decided December 3, 2018).

[35] In a footnote, the 2022 application also refers to the USEPA's order responding to a petition to object to a Title V permit issued for a facility in Middletown, New York proposed by Masada (USEPA, Order, May 2, 2001, *In the Matter of Orange Recycling and Ethanol Production Facility, Pencor-Masada Oxynol, LLC*, Permit ID: 3-3309-00101/00001, Issued by the New York State Department of Environmental Conservation, Petition No.: II-2000-07.) As explained by US Steel in the application, in this order, the USEPA upheld the,

> …use of annual emission caps with a rolling cumulative total methodology and rejected petitioners' "concerns that the permit appears to rely on after-the-fact monitoring, rather than engineering practices, test data or vendor guarantees" to establish restrictions on PTE. U. S. EPA based its findings on the fact that "[i]f the source has no room to operate under the PTE emission limiting cap, it must cease operation or face a violation" and that "all PTE limits rely on after the fact monitoring of some kind."
>
> 2022 application, Footnote 11.

specific circumstances of the Project are such that the current limits for annual emission of the principal emission units should be replaced with group limits that apply to the combined emissions of principal emission units and other lesser emission units.[36] The circumstances of the Granite City Works are not the same as those presented by the cited permits. US Steel's Granite City Works is a manufacturing facility at which iron is produced from iron ore in blast furnaces and steel is produced from molten iron and scrap metal in basic oxygen furnaces. The processes that generate emissions at the Granite City Works are different than the oil-fired engines that are generally addressed by the permit for Shell Offshore and the natural gas-fired engines addressed by the permit for Tucson Electric. The permit for Shell Offshore, Inc., addresses a marine drilling unit, the "Kulluk," and an associated fleet of support vessels that may be used during July through November of each year to conduct exploratory drilling operations in areas of the Beaufort Sea north of Alaska. The permit for Tucson Electric Power addressed a new peaking electrical generating facility with ten engine-generating units at Tucson Electric's Irvington Station. The utilization of the individual generating units in the new facility would vary from day to day and season to season as the use of the units would be tied to the inability of other electrical generating facilities to meet the demand for electricity.[37]

---

[36] For the casthouse on the blast furnaces, Permit 95010001 currently sets separate limits for the emissions of various pollutants from the casthouse baghouse (i.e., the main baghouse for the casthouse), the iron spout baghouse, and the roof monitor (uncaptured emissions). If Permit 95010001 were to be revised, it would be reasonable for each pollutant for which emissions are limited, other than CO, for the permit to restrict the overall emissions of the pollutant from the casthouse, rather than to individually limit the stack emissions of each control system and uncaptured emissions. The application also does not suggest that it would be inappropriate for any revised permit to simply limit the stack emissions of CO from the BOFs.

For the basic oxygen furnaces, the current permit separately addresses emissions of particulate and lead from the stack of the ESP and the roof monitor (uncaptured emissions.) For these furnaces, it would also be reasonable in a revised permit to set limits for different pollutants for the overall emissions of the pollutant from these furnaces. In particular, the revised permit would not set limits specifically for the emissions of the new baghouse system that was installed to improve control of particulate emissions from charging and tapping of these furnaces. Instead, the revised permit would address emissions that occur from this baghouse with limits for different pollutants for the overall emissions of these furnaces.

[37] At the Shell Off-Shore and Masada facilities, variability of utilization or operation of different emission units was a consideration in the permitting of these facilities. In its response to comments on the draft permit for Shell Offshore, USEPA Region 10 explains,

> The commenters are correct that EPA guidance does express a general preference for shorter time periods rather than 12-month rolling limits. See 1989 PTE Guidance at 9. As the commenter acknowledges, however, EPA has also recognized that longer rolling limits are appropriate for sources with substantial and unpredictable variations in emissions, as well as for those sources that curtail operation during part of a year on a regular seasonal cycle. Id. at 9 – 10. Such is the case here. Shell's planned exploratory operations are atypical as compared to other sources because emission units consist of multiple engines and generators with variable emission on the Kulluk and a fleet of numerous support vessels. Operations will vary from hour-to-hour, day-to-day month-to-month, and season-to-season based on factors such as the number of wells drilled, the activity being undertaken (drilling mud cellar lines, other drilling activity, or activity that does not involve drilling), the depth of wells drilled, whether emergency engines are being run for testing, and ice conditions. Given the variability in operations, and thus emissions expected from the source, and after considering a full

7. INADEQUATE JUSTIFICATION FOR ELIMINATION OR REVISION OF CURRENT LIMITS FOR PROJECT-AFFECTED FUEL BURNING UNITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

---

range of options for limiting the source's potential to emit, Region 10 determined that it was appropriate to establish longer-term rolling limits.

USEPA, Region 10, "Response for Comments for Outer Continental Shelf Permit to Construct and Title V Air Quality Operating Permit: Conical Drilling Unit Kulluk," October 2011, p. 26.

In the USEPA's order for Masada of April 8, 2002, USEPA observes that,

Masada's operations will have significant fluctuations due [sic] the variability of the processed waste, making an operating parameter-based PTE limit less appropriate. The emissions-based PTE limit discussed below recognizes this fact and provides Masada with operational flexibility accordingly. Moreover, Masada will be measuring its emissions on a real-time basis using CEMS [continuous emissions monitoring systems], obviating the need to limit and monitor operating parameters as a surrogate for emissions.[Footnote 6] Thus the petitioners have not demonstrated that it was inappropriate for the NYSDEC [New York State Department of Environmental Conservation] to restrict Masada's emissions directly, rather than its operation or production.

Although it is generally preferable that PTE limitations be as short-term as possible (e.g., not to exceed one month), EPA guidance [USEPA, "Guidance on Limiting Potential to Emit in New Source Permitting," June 13, 1989] also allows permits to be written with longer term limits if they are rolled (meaning recalculated periodically with updated data) on a frequent basis (e.g., daily or monthly). The 1989 guidance recognizes that such longer rolling limits may be appropriate for sources with 'substantial and unpredictable annual variation in production." 1989 Guidance at 9.

Footnote 6. This is consistent with prior EPA practice in appropriate circumstances. See e.g., Memorandum entitled "3M Tape Manufacturing Division Plant, St. Paul, Minnesota," from John Rasnic to David Kee, dated July 14, 1992 ("a federally enforceable emission limit may be used …to limit the potential to emit as long as a continuous emissions monitor (CEM) or an acceptable alternative is used."); and Memorandum entitled "Policy Determination on Limiting Potential to Emit for Koch Refining Company Clean Fuels Project," from John Rasnic to David Kee, dated March 13, 1992 ("Use of an emission limit to restrict potential to emit …is acceptable provided that emissions can be and are required to be readily determined or calculated.")

USEPA, Order, April 8, 2002, "*In the Matter of Orange Recycling and Ethanol Production Facility, Pencor-Masada Oxynol, LLC*, Permit ID: 3-3309-00101/00003, Issued by the New York State Department of Environmental Conservation," Petition No.: II-2001-05, p. 6)

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency*: The 2022 application does not include information that would support revisions to Permit 95010001 to revise or eliminate current limitations for usage of fuels by the Project-affected fuel burning units, as is requested by the application. With regard to the elimination of the current limitations, the 2022 application does not quantitatively demonstrate that this would not result in an increase in the potential emissions of the subject units. This is of particular concern as Permit 9501001 does not limit the usage of COG, which was not quantitatively addressed in 1996 during the initial permitting of the Production Increase Project. Moreover, with the shutdown in 2015 of the two by-product recovery coke oven batteries at the facility, more natural gas must now be used as fuel in certain subject units (e.g., the blast furnace stoves), to replace the COG that was previously used. With regard to the revisions of the current limitations, the 2022 application does not include information that would be necessary for the Illinois EPA to set values for revised limitations that would be appropriate. As discussed above in Denial Point 3A, the 2022 application does not include the data and calculations underlying the representations in the 2022 application for future maximum emission of the Project-affected fuel burning units. This data would include the maximum usages of fuels as would be needed for the Illinois EPA to appropriately set revised limitations for future usages of fuel.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would eliminate or revise the current limitations in Permit 95010001 for the usage of fuel by Project-affected fuel burning units.

Discussion

The justification provided in the 2022 application for revisions to Permit 95010001 to eliminate or revise limits on usage of fuel and, presumably, emissions by Project-affected fuel burning units is not adequate. Although this application indicates that the revised permit should not contain the limits for usage of natural gas and BFG currently set by Permit 95010001, it does not propose any new limits in their place.

> USS Granite City is also requesting revision/elimination of gaseous fuel usage limits for project-affected combustion units. In 2015, USS Granite City shutdown its by-product coke oven batteries. This eliminated the ability to use coke oven gas (“COG”) as a fuel at the mill. In addition, ten of the twelve boilers at the time of the Project in 1996 have been retired. These actions have greatly reduced the emissions from fuel combustion in project-affected emissions units and obviate the need to preserve limits to restrict PTE of the remaining units.
>
> 2022 application, Section 2.2.3, p. 2-4.

This rationale is deficient because it does not consider that the 2022 application also requests that the revised permit address an increase in the usage of natural gas at the facility as a consequence of the shutdown of the by-product coke oven batteries. While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed

above,[38] this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the 2022 application does not show that new limits for fuel usage and emissions would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shutdown. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown.

[38] It is noteworthy that the 2022 application does not address what an appropriate limit for usage of COG would have been in Permit 95010001 if the permit had originally addressed use of COG by Project-affected fuel burning units. In the absence of such information, it is unclear how the shutdown of the two by-product coke ovens at the facility and elimination of COG led to decreases in NOx emissions relative to the limits for NOx emissions of fuel-burning units set by Permit 95010001.

8. THE APPLICATION DOES NOT SHOW THAT EMISSION FACTORS THAT ARE PROPOSED AS PRESCRIBED FACTORS FOR CERTAIN UNITS WOULD BE REPRESENTATIVE

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* Relative to the revisions to Permit 95010001 that are requested to establish certain "prescribed emission factors," the 2022 application does not include information justifying the future use of such proposed factors for the purpose of determining compliance with the revised limitations for the emissions of the project that are requested. In particular, the 2022 application does not include information showing that the proposed factors should be considered representative, accurate and appropriate. For example, for the uncaptured emissions of particulate of the BOFs, which occur through the roof monitor and, possibly, other openings in the BOF shop building, the application does not include any explanation for the emission factors that are proposed as prescribed emission factors. These factors are lower than the factors that were used for the calculations in the application for the baseline emissions of uncaptured particulate from the BOFs. This is generally reasonable as improvements have been made that have improved capture and control of the particulate emissions of the BOFs and should lower uncaptured emissions. Notably, a baghouse control system has been installed to improve control of emissions from charging and tapping the BOFs. However, the 2022 application does not explain how the proposed prescribed factors were developed. It also does not lay out the practices for control of particulate emissions of the BOFs that would accompany the proposed factors.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would determine future emissions of the subject emission units and emission points based on the factors proposed in the 2022 application. The 2022 application does not show that the proposed prescribed factors would appropriately be relied upon for the purpose of enforceably limiting the future emissions of the emission units and emission points for which they are proposed.

Discussion

To calculate baseline emissions of certain emission units for which emission testing is not feasible or practical, the 2022 application necessarily relies on use of emission factors that are

not based on source-specific emissions testing. Likewise, for the ongoing determination of the emissions of these units, the application requests that revised Permit 95010001 "prescribe" or specify the emission factors that are to be used. As explained in the 2022 application, where a permit relies on a limit on annual emissions or an "annual emission cap" to restrict potential emissions, USEPA policy and precedent provide that:

> Where the permit prescribes an emission factor to be used in conjunction with operational data in demonstrating compliance [with an annual emission cap], the permitting authority should describe the basis for its determination that the emission factor is representative.
>
> 2022 application, Section 3, p. 3

This summary of relevant USEPA policy in the 2022 application is consistent with the statements made by the EAB and the Administrator of USEPA in various orders responding to petitions that request it object to Title V permits or, in Illinois, CAAPP permits), issued by a permitting authority. In its decision in *Shell Offshore, Inc.*, the EAB also considered the use of prescribed emission factors in the permit that was appealed. The EAB did not object to this practice. It found that the use of prescribed emission factors may be appropriate for a permit to prescribe use of specific emission factors published by USEPA in its *Compilation of Air Pollutant Emission Factors* (AP-42) for certain emission units for the purpose of determining emissions for purposes of compliance with annual emission limits set by the permit.[39]

> The Region explained in the record its rationale, based on the Region's technical expertise and applied in certain limited circumstances, for supplementing source-specific emission factors derived for most of the emission units or groups of emission units with either AP-42 emission factors, or factors derived from source test data Shell submitted to the Region in support of two separate, previously OCS [Outer Continental Shelf] PSD permits authorizing Shell to conduct exploratory activities in the Chukchi and Beaufort Seas using the *Discover* drillship.
>
> USEPA, Environmental Appeals Board, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2013.

For US Steel, Granite City Works, the USEPA specifically addressed the use of emission factors for determining compliance with emission limits in an order of December 3, 2012. Note that relative to prescribed emission factors, the USEPA's finding, as is provided below, should be considered *dicta*. This is because the permit that was the subject of the appeal did not provide for use of prescribed emission factors. In addition, as the order addresses the possibility of using of

[39] The EAB did observe that it is preferable that compliance with emission limits set by a permit be determined using source-specific emission factors, as would be developed by emissions testing required by the permit. The EAB did not address prescribed emission factors from sources other than AP-42 since the permit that was appealed only prescribed use of emission factor from AP-42. Given the general nature and limited scope of AP-42, the EAB's decision should not be interpreted to preclude use of emissions factors from source other than AP-42. There are emission units and pollutants for which use of prescribed emissions is appropriate for which emission factors are not present in AP-42 or better emission factors are available from other sources.

prescribed emission factors in terms of the actions that the Illinois EPA would need to take when issuing a permit that prescribed emission factors, the order serves to identify the underlying information that a source must provide in an application if it seeks a permit that would provide for use of prescribed emission factors is sought. The Illinois EPA would then be responsible for assuring that the emission factors that are prescribed would be appropriate and sufficient for compliance or noncompliance with the associated emission limits to be reasonably determined.[40,]

> …IEPA [Illinois EPA] must include in the permit itself the monitoring methodology for determining compliance with these limits [emission factor limits and annual emission limits]. If using emission factors, IEPA must propose the actual emission factors in the permit or supporting permit record, and provide supporting documentation for the accuracy and appropriateness of these emission factors, such as historical source test data or other available information. If source test data are not readily available for a specific emission unit, as IEPA asserts, other sources of emission factors (including published literature and material and energy balances) must be reviewed and cited for acceptable emission factors before issuing the permit.
>
> USEPA, Order Responding to Petitioner's Request that the Administrator Object to Issuance of State Operating Permit, Petition Number V-2011-2, *In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056*, Petition Number V-2011-2, dated December 3, 2012, p. 12.

<u>Roof Monitor on the Basic Oxygen Furnace Shop – Particulate Emissions:</u>
The 2022 application does not include support for the particulate emission factors that are proposed as prescribed factors for the roof monitor on the basic oxygen furnace shop (i.e., the uncaptured emissions from these furnaces). The application does include support for the <u>baseline</u>

[40] In an order concerning a Title V permit issued by the Texas Commission on Environmental Quality (TCEQ), the Administrator of USEPA stated the following when addressing the use of emission factors in the permit:

> …Moreover, the justification provided by a permittee in a permit application should not substitute for the judgment of the permitting authority (TCEQ) with responsibility for ensuring that a Title V permit contains sufficient monitoring to ensure compliance. If TCEQ wishes to adopt and incorporate an applicant's technical justification for specific monitoring into the current Title V permit record, it must, at minimum, identify specifically where such a justification is to be found (just as it would be required to do it if [sic]wished to incorporate by reference a requirement located elsewhere.)
>
> USEPA, Administrator, Order Responding to Petition Requesting Objection to the Issuance of Title V Operating Permit, Petition No. VI-2017-6, *In the Matter of BP Amoco Chemical Company, Texas City Chemical Plant, Galveston County, Texas, Permit No. 01513*, dated July 20, 2021, p. 18.

particulate emission rates for the roof monitor on the basic oxygen furnace shop.[41, 42] However, the permitting of the Project in 1996 relied upon various changes that were made to improve capture and control of emissions of particulate from the basic oxygen furnaces and decrease the uncaptured emissions of particulate. For example, a fourth section was added to the ESP in 1995, increasing the volume of air that it could handle. As such, the baseline particulate emission rates of the Project are not representative of future emissions with the Project. Moreover, the emission factors actually proposed in Section 5.5.2.2 in the 2022 application are lower than emission factor limits now contained in Table 2 of Permit 95010001 for the roof monitor on the basic oxygen furnace shop. For PM, an emission factor of 0.0296 ~~0.01986~~ pounds/ton is proposed as a prescribed factor, compared to the current emission factor limit of 0.0987 pounds/ton; for filterable PM_{10}, an emission factor of 0.0198 0~~.0296~~ pounds/ton is proposed, compared to the current emission factor limit of 0.06614 pounds/ton. The 2022 application does not show that the emission factors for the roof monitor on the basic oxygen furnace shop that are proposed as prescribed emission factors in Section 5.5.2.2 of the application are representative.[43]

Caster Mold, Slab Cutoff/Ripping Processes in Continuous Casting:
For the caster mold, slab ripping and slab ripping processes on the continuous casting lines, prescribed emission factors are proposed in Section 5.5.3 of the 2022 application that are identical to the baseline particulate emission rates for these emission units as generally discussed in Section

[41] The baseline emission rates for the roof monitor are based on emissions factors from AP-42 for uncontrolled emission with application of 90 and 99 percent capture efficiencies for the refining process and the charging and tapping processes, respectively, being provided by the ESP control system on the furnaces in the baseline period before 1996 (2022 application, Section 5.5.2.2). While the application cites to Appendix C in the original application for the Project as support for these values for capture efficiency, this appendix only uses these assumed values of capture efficiency when calculating baseline emission rates for the Project. This appendix does not actually provide technical support for these values for capture efficiency being representative of the levels of capture efficiency that were achieved for particulate emissions of the basic oxygen furnaces in the baseline period for the Project. Appendix C also does not provide support for the higher levels of capture efficiency (95% and 99.9%) that it uses for operation and emissions for the basic oxygen furnaces with the Project.

[42] It should generally be noted that the sections of the 2022 application that provide the explanation or basis for the emission factors used in the application are not the sections in which prescribed emission factors are proposed for certain units. The basis for the different emission factors is typically provided earlier in the application in the sections of the application where baseline emission rates are addressed. For example, the particulate emission rates or factors for the roof monitor on the blast furnace casthouse are discussed in Section 5.2.3.3 (2022 application, p. 5-3); the proposed prescribed emission factors for this emission point, which are the same numerically, are provided later in Section 5.5.1.2 without further discussion (2022 application, p. 5-14 and 5-15).

[43] The emission factors that the 2022 application proposes to be prescribed for particulate emissions from the roof monitor on the basic oxygen furnaces may be appropriate at the present time given the installation of a baghouse control system on these furnaces. Nonetheless, for a revised permit to be issued that prescribes emission factors for emission from the roof monitor, the application must show that those factors are representative with the emission control measures that are required by the permit. It must also be recognized that those prescribed factors would not be representative of emissions before the new baghouse system was installed and operation of this system was required. As such, particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}.

5.2.2.11, 5.2.2.13 and 5.2.2.14 of the application. In these sections, the application explained that these emission factors reflect emission factors from a report prepared by the Illinois EPA in 1991, i.e., "Illinois EPA 1991 EIS PM/PM_{10}." This is not sufficient to show that the emission factors that are proposed as prescribed factors are representative. In this regard, the statement that these factors were taken from a historic report prepared by the Illinois EPA does not show that this report included information showing why these factors should be considered representative and can be prescribed by a revised permit.

Mag-Lime Silo:

For the Mag-Lime Silo, a prescribed emission rate of 0.009 pounds/hour is proposed (2022 application, Section 5.5.4.2). As explained in the application, this unit, which stores the reagent used in desulfurization of iron in the basic oxygen furnace shop, was overlooked in the original permitting of the Project (2022 application, Section 5.4.4 and Footnote 34, p. 5-16 and 5-17). US Steel elected not to address its baseline emissions in the revised netting analyses for PM and PM_{10} because emissions are low, i.e., potential annual emissions less than 0.1 tons. However, the application does not include calculations explaining how US Steel determined that potential particulate emissions of this unit are less than 0.1 tons/year, much less information showing that a prescribed emission rate of 0.009 pounds/hour should be considered representative of the emissions of this unit.[44]

[44] The application also does not explain how US Steel determined that the potential annual particulate emissions of the Mag-Lime Silo are less than 0.1 tons. In this regard, the application does not include calculations that identify any assumptions about operation of this unit or the control of its emissions made by US Steel when calculating the potential emissions of this unit. For example, for particulate matter, was the outlet emission rate of the filter that is part of this unit assumed to be less than the regulatory limit of 0.03 grains per dry standard cubic foot pursuant to 35 IAC 212.308 and 212.313?

9. FOR THE ROOF MONITOR OF THE CASTHOUSE, THE APPLICATION DOES NOT SHOW THAT THE METHODOLOGY THAT IS PROPOSED TO BE PRESCRIBED FOR THE DETERMINATION OF NOx AND VOM EMISSIONS WOULD BE REPRESENTATIVE

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a). 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* Relative to the revision to Permit 95010001 that is requested to establish a certain "prescribed emission determination methodology" for the uncaptured NOx and VOM emissions of the blast furnace casthouse, the 2022 application does not include information justifying the future use of such proposed methodology for the purpose of determining compliance with the revised limitations for the NOx and VOM emissions of the blast furnace casthouse that are requested. In particular, the 2022 application does not include information showing that the proposed methodology should be considered representative, accurate and appropriate. In this regard, the 2022 application does not show that changes in the levels of captured NOx and VOM emissions, as measured by emission testing, would be due to actual changes in the overall level of NOx emissions from the casthouse rather than other causes. For example, changes in the levels of measured NOx or VOM emissions could be due to changes in the manner of operation of either the iron making/tapping processes or the baghouse control systems as they function to capture NOx and VOM emissions. Changes in the levels of measured emissions could also be due to the variation in the results of emission testing that may be present with the applicable reference test methods.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would determine future uncaptured NOx and VOM emissions of the blast furnace casthouse based on the methodology proposed in the 2022 application. The 2022 application does not show that the proposed prescribed methodology would appropriately be relied upon for the purpose of addressing the future uncaptured NOx and VOM emissions of the blast furnace casthouse.

Discussion

For the NOx and VOM emissions of the roof monitor on the casthouse on the blast furnaces (i.e., uncaptured emissions, which do not pass through a control device), the 2022 application proposes a prescribed emission calculation methodology that involves the results of emission testing for the main baghouse for the casthouse and an assumed capture efficiency of 95 percent.[45] For example, for NOx emissions from the roof monitor, the application requests that,

> Prescribed emissions factors consistent with the approach described in Section 3 [Discussion of Permit Conditions Used to Restrict PTE] are provided herein. USS Granite City is proposing a prescribed emissions calculation methodology for NOx emissions from the blast furnace casthouse roof monitor based on application of 95% capture emissions to the NOx stack test result for the blast furnace casthouse baghouse.
>
> 2022 application, Section 6.5.1.2, Prescribed Emission Factors for Blast Furnaces Operations, p 6-9.

The application does not show that the "proposed methodology" would result in NOx and VOM emissions rates for the roof monitor that would be representative. In this regard, the proposed methodology would yield emission rates for the roof monitor that would be related directly to the measured emissions of the main baghouse on the casthouse. However, it would not address the effect of variation in capture efficiency on emissions. That is, with the proposed methodology, if emissions from the baghouse measured by a particular test were "lower," the calculated emission rate of the roof monitor would also be lower. The methodology would not address a situation in which the emissions measured by testing are lower because the capture efficiency of the baghouse system during testing was also lower. In this situation, there would actually be more emissions through the roof monitor. As such, unlike specific emission rates for NOx and VOM that would be prescribed in a revised permit, the "proposed methodology" would not address the NOx and VOM emissions from the roof monitor in a way that can reasonably be considered to be representative on an ongoing basis.[46, 47]

---

[45] With the proposed methodology, the NOx or VOM emission rate for the uncaptured emissions of the casthouse would be derived from the emission rate of the main baghouse measured by periodic testing using the following formula:

[{Measured rate of the baghouse (lbs/ton) ÷ 0.95} x 0.05] = Calculated rate for the monitor (lbs/ton)

[46] This issue would not be present with an appropriate prescribed emission factor. As such, a factor would not change based on the results of periodic testing, the factor could be reviewed when processing the application to confirm that it was conservatively developed so as to be representative on an ongoing basis.

[47] Section 7.5.1.2 of the 2022 application, which addresses the proposed calculation methodology for the VOM emissions from the roof monitor on the casthouse, erroneously refers to the results of emissions testing of the main baghouse system on the casthouse for NOx rather than testing for VOM.

10. THE APPLICATION DOES NOT INCLUDE NECESSARY SUPPORT FOR THE EMISSION FACTORS THAT ARE PROPOSED AS PRESCRIBED FACTORS FOR CERTAIN UNITS.

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a), 203.123, 203.128, 204.400 and 204.560.

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* Relative to the revisions to Permit 95010001 that are requested to establish certain "prescribed emission factors" as specifically proposed by the 2022 application, the application does not include information justifying the future use of such proposed factors for the purpose of determining compliance with the revised limitations for the emissions of the Project-affected units that are requested. In particular, as the proposed factors are derived from emissions factors developed by USEPA, the 2022 application does not include information showing that the factors that were derived and are now proposed should be considered representative, accurate and appropriate. For example, for the blast furnace casthouse, the application proposes a prescribed emission factors for uncaptured emissions of particulate that are based on factors in USEPA's *Compilation of Air Pollutant Emission Factors*, AP-42, and achievement of at least 95 percent capture efficiency by the particulate control systems on the casthouse (i.e., 5 percent of the particulate emission being uncaptured). However, as support for reliance on these systems achieving at least 95 percent capture efficiency, the application only refers to a single memorandum by USEPA staff and a consultant.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include necessary information to allow a revised permit to be proposed for the Project, much less issued, that would determine future emissions of the subject emission units and emission points based on the factors proposed in the application. The application does not show that the proposed prescribed factors would appropriately be relied upon for the purpose of enforceably limiting the future emissions of the emission units and emission points for which they are proposed.

Discussion

The 2022 application does not include relevant supporting information for certain emission factors used in the application, as follows. Absent this information the Illinois EPA cannot assess whether the prescribed emission factors proposed for these units should be considered representative.

Blast Furnace Casthouse Roof Monitor:
The prescribed particulate emission factors proposed for the roof monitor on the blast furnace casthouse (i.e., the uncaptured emissions from the casthouse) are identical to the baseline emission rates. These rates are based on emission factors from AP-42 for uncontrolled emissions with application of a 95 percent capture efficiency for the baghouse control systems on the casthouse. The application only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency (2022 application, Section 5.2.3). Further support is needed for a prescribed emission factor based on achievement of 95 percent capture.

Slag Pits:
For particulate emissions from quenching of slag, the 2022 application does not include a copy of the "EPA assessment" that is the basis of the emission factors and material showing how the selected emission factors were derived from this assessment. For emissions from transfer of slag, the application does not include a copy of the calculations by which the emission factors were developed from the formulas provided in AP-42, Section 13.2.4. The application also does not address whether the emission factors rely on control by the application of water or the presence of residual moisture and, if so, the basis for the assumed levels of control efficiency. (2022 application, Section 5.2.2.5, p 5-4).

Iron Pellet Screen:
For the Iron Pellet Screen, the proposed prescribed emission factor for PM and PM_{10} emissions is identical to the baseline emission rates (2022 application, Section 5.2.2.16). While the emission factor for uncontrolled emissions for screening of crushed stone in Table 11-19.2-2 in AP-42 is identified as the basis of this emission rate, a control efficiency of 85 percent is applied, reducing the factor that is actually used to 15 percent of the cited AP-42 factor. The application does not describe the means by which the particulate emissions of this screen are controlled or reduced to show that 85 percent control of particulate emissions is achieved for the Iron Pellet Screen.[48]
In addition, AP-42 lists two emission factors for screening of crushed stone, one for PM and one for PM_{10}. The emission factor for PM is about three times the factor for PM_{10} (0.025 pounds/ton ÷ 0.0087 pounds/ton = 2.87, ~ 3). The 2022 application does not show that for screening of iron ore pellets, an emission factor that was developed for PM_{10} is directly transferable to PM emissions.

[48] The CAAPP permit, Condition 7.4.2 indicates that the Iron Pellet Screen is not served by emission control equipment.

11. THE DETERMINATIONS OF PARTICULATE EMISSIONS FROM HANDLING OF COKE, IRON PELLETS AND LIMESTONE ARE NOT SUPPORTED AND CANNOT BE CONFIRMED

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*,35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* For handling of coke, iron pellets and limestone, the baseline emissions of particulate matter (PM) and particulate matter-10 (PM-10) provided in the 2022 application are both 17.2 tons/year. The information for baseline emissions from handling these materials is not accompanied by supporting information. The application does not explicitly list the various units whose emissions are being addressed and describe the nature of the various units relative to their emissions of PM and PM-10. Data is not provided for the annual amounts of various materials that were handled by these units. Data is also not provided for the emission factors used to calculate annual emissions, the sources or basis of those factors, and why those factors should be considered representative of the emissions of the various types of units being addressed.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include the necessary information to allow a revised permit to be proposed for the Project, much less issued, that would restrict future PM and PM-10 emissions of the subject units. The issuance of a revised permit with limitations for the future emissions of these units that are practically enforceable necessarily requires that the application include supporting information as discussed above. For example, the Illinois EPA needs information on how baseline emissions were determined to confirm that the baseline emissions were reasonably determined. This information is also needed to determine what limitations on emissions should be set in the revised permit and if the permit should require any specific practices to assure emissions are controlled to levels relied upon in the calculations of baseline emissions. Finally, this information is needed so appropriate permit conditions can be developed setting forth how compliance with the limitations is to be demonstrated.

Discussion

With regard to baseline particulate emissions, the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not provide needed supporting information for the “corrected” determinations of baseline particulate emissions of

these operations as it is not accompanied by detailed calculations for the emissions from handling each material. (2022 application, Table 5-5. "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM Emissions Factors for Affected Emission Units" and Table 5-6, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM_{10} Emissions Factors for Affected Emission Units.")[49]

With regard to emissions with the Project, the 2022 application does not include information for particulate emissions from handling of coke, iron pellets and limestone. Since the by-product coke oven batteries were not shut down until 2015, emission information is needed for handling of coal for the period of operation with the Project before the batteries were shut down. Likewise for coke, emission information is needed to address handling of coke before US Steel constructed the conveyor system to receive coke directly from the heat recovery coke production facility built by Gateway.[50]

[49] Tables 5-5 and 5-6 do refer to "Table F-3 of the 1995 application" for these material handling operations. A copy of this table is provided in Appendix B of the 2022 application. However, this table only appears to address PM_{10} emissions, for which it provides annual emissions in tons/year. This table does not include calculations and background information showing how the annual emissions of PM_{10} were determined. Finally, the data for annual emissions of material handling operations appears to rely on the "PM10 SIP" requiring a 90 percent reduction from uncontrolled emissions without providing any support for this assumption.

[50] As this new system was constructed as part of a different project, i.e., the construction of the Gateway facility, rather than the Production Increase Project, US Steel should not address emissions that are specifically associated with this new system.

12. THE REQUESTED CHANGES TO THE GROUPING OF UNITS IN THE PERMIT FOR CONSISTENCY WITH THE GROUPINGS OF UNITS IN THE CAAPP PERMIT WOULD NOT ADDRESS ALL DIFFERENCES IN THE GROUPINGS OF UNITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152* and 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application requests certain changes to Permit 95010001 because the areas or sections of the CAAPP permit for the Granite City Works, Permit 96030056, in which certain emission units are addressed are not the same as those in Permit 95010001. Most notably, in Permit 95010001, discrete material handling and processing operations are addressed with the units with which they are associated. For example, handling of fluxes and alloy materials for the BOFs is addressed with the provisions of the permit for the BOF Shop. In the CAAPP Permit, handling of fluxes and alloy materials for the BOFs and other discrete material handling and processing operations are addressed in a separate section of the permit (Section 7.1) rather than with Blast Furnace Operations (Section 7.4), the BOF Shop (Section 7.5), or Continuous Casting Operations (Section 7.6). While it is reasonable for Permit 95010001 to be revised so that the placement of units in this permit is the same as their placement in the CAAPP permit, several concerns are posed by the specific changes to Permit 95010001 that are requested to accomplish this. In particular, the 2022 application requests that Permit 95010001 be revised to address the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" with other ancillary operations in the BOF Shop, rather than with the Continuous Casting Operations. This change would be appropriate as these units would be placed with other units that are subject to the Iron and Steel NESHAP, 40 CFR 63 Subpart FFFF, as they are BOF Shop ancillary operations. However, the application also requests that the permit be revised to refer to these units as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." This change would not be appropriate as it would refer to the baghouse serving these units and its emissions rather than to the units themselves and their emissions. The application also does not request any changes to Permit 95010001 for the "Deslagging Station and Material HS [Handling System]." In the CAAPP permit, these units are currently addressed twice, both with the discrete material handling operations (Section 7.1) and with continuous casting operations (Section 7.6). More importantly, the placement of these units in Permit 95010001 should be directed by the emission standards that apply to these units. These units would be appropriately addressed with BOF Shop Operations (Section 7.5) as they entail either a "skimming station" or "ladle metallurgy" for purposes of the Iron and Steel NESHAP. Finally, for "Ladle Drying/Preheating," the application does not request revisions to Permit 95010001 although the CAAPP permit addresses these emission units both with BOF Shop Operations (Section 7.5) and with other Project-affected fuel burning units (Condition 5.6.2(a)(ii)). In Permit 95010001, these units are currently only addressed as Project-affected fuel burning units.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* As related to the location in permits where certain emission units are addressed, the 2022 application does not request all revisions that are known to be appropriate to Permit 95010001, and, by means of Integrated Processing of the revisions to Permit 95010001, are appropriate to the CAAPP permit for the facility. For certain units, the application would not address differences in where the units are addressed by the two permits and the related emission standards and requirements that may apply to those units. As related to the naming of units, the Applicant requests a change that is improper as well as unnecessary. As such, if Permit 95010001 were revised with the placement of units in the permit shifted as requested by the 2022 application, it would preclude Integrated Processing of the revised permit. This is because the revision of Permit 95010001 would otherwise allow discrepancies or errors in the provisions for certain units in the current CAAPP permit, which have now been identified and are within the potential scope of the revisions to Permit 95010001, to be perpetuated by the amendments to the CAAPP permit that would be authorized.

Discussion

As addressed in Section 2.2.2 of the 2022 application, US Steel generally requests changes to the organization of Permit 95010001 because the areas or sections of the CAAPP permit in which certain units are addressed are different than those in Permit 95010001. Most notably, in Permit 95010001, discrete material handling and processing operations are addressed with either the blast furnace operations, operations in the basic oxygen furnace shop or the continuous casting operations, based upon the area with which they were considered to be associated. In the CAAPP permit, these discrete material handling and processing operations are generally addressed in a separate section of the permit, Section 7.1, "Material Handling and Processing Operations." In addition, in the CAAPP permit, the "Argon Stirring Station and Material Handling Tripper" was addressed with units in the basic oxygen furnace shop in Section 7.5 of the CAAPP permit rather than with the continuous casting operations as in Permit 95010001.

While it is reasonable for there to be consistency in the groupings or categorization of emission units in Permit 95010001 and the CAAPP permit, as generally requested by US Steel, several concerns are posed, as discussed below, by the specific changes to Permit 95010001 that have been requested.

Requested Changes for the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)"**:**

As explained in Section 11.1.2 of the 2022 application, US Steel requests that the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" now be addressed in Permit 950100001 with operations in the Basic Oxygen Furnace Shop. The application also requests that this unit be identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." However, the application does not actually identify the specific units that would be addressed by the proposed new term. In this regard, the application is not accompanied by an itemized list of the equipment and activities that would be covered by this new term or a diagram that identifies this equipment and activities. US Steel's request also does not explain how the requested revision to Permit 95010001 would do what has generally been requested as the proposed new

term would refer to a "Material Handling Tripper." As the 2022 application requests changes to terminology in Permit 95010001, the changes should act to better identify the emission units that would be addressed, improving the specificity and clarity of the revised permit.[51, 52]

Absence of A Request for Revisions for the "Deslagging Station and Material HS"**:**
The 2022 application does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS (Handling System).[53] These emission units are currently addressed in Permit 95010001 with continuous casting operations (Permit 95010001, Condition 20 and Table 3). In the CAAPP permit, a "Steel Deslagging Station" is identified as one of the continuous casting operations (CAAPP permit, Condition 7.6.2(a)).[54] The 2022 application does not explain why this steel deslagging operation should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the basic oxygen furnace shop. In this regard, for the argon stirring station, US Steel does explain in Section 11.1.2 of the 2022 application that this station should be addressed with operations in the basic oxygen furnace shop rather than with continuous casting operations. This is because this station is a "BOPF shop ancillary operation" for purpose of the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF (2022 application, Section 11.1.2). US Steel does not explain why the current placement in Permit 95010001 of the steel deslagging station with continuous casting is appropriate and this station should not also be addressed with other BOPF shop ancillary operations. Alternatively, US Steel does not request that this station be addressed with other

[51] For example, the proposed new term would not make clear that the basic oxygen furnace shop actually has two ladle stirring stations and one ladle metallurgy furnace, all served by Baghouse 2.
[52] The requested change to the terminology for these emission unit(s) is also problematic as it would refer to a control device, Baghouse 2, rather than to the equipment or activities that generate emissions. Applied literally, the proposed term would only address captured emissions; it would not address the uncaptured emissions, which elude capture for control by the baghouse.
[53] For example, in Section 5.2, the 2022 application does not identify any updates or revisions to the pre-project actual emissions of the steel deslagging station and associated material handling system. Likewise, Appendix B – Emission Calculations does not identify any changes from the 1996 netting analyses that involve these units (Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis and Revised PM10 PSD Net Emissions Increase Analysis).
[54] The presence of a deslagging station that is physically located in the continuous casting building is indicated in the pending application for renewal of the CAAPP permit. This application indicates that the particulate emissions of this station are controlled.

> Deslagging Station:
> Molten steel from the BOF is transferred directly from the BOFs to the continuous casting building. The first operation carried out in this building is the skimming of slag from the surface of the molten steel. Slag removed by this operation is skimmed into slag pots for disposal. Baghouse #1 is used to control emissions from this process.
>
> CAAPP Renewal Application, Appendix D: Process Descriptions, Section 7.6 Continuous Casting, Deslagging Station, p. D-56.

BOPF shop ancillary operations.[55] Slag skimming is one of the operations that 40 CFR 63.7852 defines as being "Basic oxygen process furnace shop ancillary operations."[56, 57]

For the "Deslagging Station and Material HS," the 2022 application also does not request revisions to Permit 95010001 as the CAAPP permit currently limits particulate emissions of this operation twice, once as a continuous casting operation and again as a material handling operation. In this regard, the CAAPP permit limits the particulate emissions of a "Deslagging Station and associated Material Handling System (Condition 7.6.6(a). As indicated by a reference in this condition, the CAAPP permit also limits emissions of a "Material HS and Deslagging Station" (Condition 7.1.6(b)(i)) in Section 7.1 of the CAAPP permit, where discrete material handling and processing operations are addressed. The 2022 application does not request revisions to Permit 95010001 to facilitate amendment of the CAAPP permit to appropriately address the emissions of this deslagging station and the associated material handling system. In the absence of such revisions, the current CAAPP permit would suggest that the revised netting analyses for particulate should address the emissions of these units twice, once as deslagging and once as material handling. On the other hand, if Permit 95010001 would address emissions of these units in this way, the consolidated emission limits for continuous casting and discrete material handling operations would be inappropriate as emissions of the deslagging station and the associated material handling system would be accounted for twice.[58]

---

[55] The proper categorization of this steel deslagging station is important when considering US Steel's request for consolidation of the emission limits currently set by Permit 95010001. As a general matter, any new, "consolidated" limits set by a revised permit must be developed to apply to sensible groupings of units. The groupings of units should facilitate identification in the revised permit of the regulatory requirements that apply to various units. This is especially true as the consolidated limits would rely on certain applicable regulatory requirements, e.g., the work practices and operational monitoring requirements under 40 CFR 63 CFR Subpart FFFFF, to assure consistent operation of emission units so as to keep short-term emissions at or below the established emission rates for the units.

[56] For this steel deslagging station, there is a potential compliance issue relative to the NESHAP, 40 CFR 63 Subpart FFFFF. The CAAPP permit indicates that the emissions of this station are not controlled (CAAPP permit, Condition 7.6.2). On the other hand, if its emissions are controlled by Baghouse 2, the direct applicability of the NESHAP to this station becomes a minor matter. This is because Baghouse 2 is directly subject to requirements of 40 CFR 63 Subpart FFFFF as it controls emissions from "ladle metallurgy." Ladle metallurgy is defined by 40 CFR 63.7852 as "… a secondary steelmaking process that is performed typically in a ladle after initial refining in a basic oxygen furnace to adjust or amend the chemical and/or mechanical properties of steel. This definition does not include vacuum degassing."

[57] It is also noteworthy that as the steel deslagging station is identified as a continuous casting operation by Permit 95010001, the permit applies 35 IAC 212.458(b)(8), which sets a limit of 5 percent, 6-minute average, for the opacity of emissions from the various continuous casting operations (Permit 95010001, Condition 19). However, Permit 95010001 omits the introductory language for this standard that provides that it does not apply to fugitive emissions. The introductory language is present in the CAAPP permit, which addresses the standards that apply to both fugitive and non-fugitive emissions of continuous casting operations (Permit 96030056, Conditions 7.6.3((b), (b)(ii) and (c)).

[58] If there was not actually a material handling system associated with the steel deslagging station, this could be readily addressed in the application for revisions of Permit 95010001. The application could acknowledge the error in the original application, as reflected in the permit that was issued, accompanied by an accurate diagram for the deslagging station as it existed in 1995 and as it now exists. In this regard,

For “Ladle Drying/Preheating,” Absence of Any Request for Changes**:**
For “Ladle Drying/Preheating,” the 2022 application does not request any changes to Permit 95010001 to maintain consistency with the approach to these units in the CAAPP permit. In Permit 95010001, these emission units are addressed with other Project-affected fuel burning units (Permit 95010001, Table 4, Certain Fuel Combustion Units). In the CAAPP permit, these units are addressed in Section 7.5 as “Basic Oxygen Processes” with other units in the Basic Oxygen Furnace Shop, as well as elsewhere in the permit with other Project-affected fuel burning units (e.g., Conditions 5.6.2((ii) and (iii)). In addition, the CAAPP permit sets a limit for the total NOx emissions of the BOF Shop (Condition 7.5.6(b)). In the absence of appropriate changes to the CAAPP permit, since the ladle drying/preheating takes place in the basic oxygen furnace shop, the limit for the NOx emissions of the basic oxygen furnace shop would apply to the sum of the NOx emissions of the basic oxygen furnaces and the ladle dryers/preheaters.

it is perhaps noteworthy that Permit 95010001 does not identify the material(s) that are handled by the material handling operations associated with the steel deslagging station.

13. THE 2022 APPLICATION DOES NOT REQUEST REVISIONS TO PERMIT 95010001 AND, INDIRECTLY, TO THE CAAPP PERMIT THAT WOULD ALSO BE NECESSARY AS THIS APPLICATION REQUESTS THAT THE REVISED PERMIT PRESCRIBE EMISSION FACTORS FOR CERTAIN UNITS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not request that the revision to Permit 95010001 add condition(s) generally setting forth how compliance with annual emission limitations set by Permit 95010001 is to be determined. While revisions are requested to establish certain "prescribed emission factors" and "prescribed emission determination methodology," the application does not request related revisions to Permit 95010001 to generally address the procedures that are to be followed when determining compliance with the limitations on annual emissions set by Permit 95010001. In this regard, it is noteworthy that, if it were not stayed, Condition 5.13 of the CAAPP permit for the Granite City Works, Permit 96030056, would address the general procedures for how compliance with limitations on annual emissions set by Permit 95010001 is to be determined. (That condition is currently stayed following an appeal to the Pollution Control Board, PCB 2013-53.) That condition would generally require that compliance with limitations on annual emission be determined using "appropriate emission factors." However, that condition does not address nor would it provide for use of prescribed factors or methodology to determine compliance with limitations on annual emissions, as is being requested by the 2022 application.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* If a revised version of Permit 95010001 were issued that provided for use of prescribed emission factors and methodology without condition(s) generally setting forth how compliance with limitations for annual emissions in Permit 95010001 is to be determined for emission units which the permit establishes prescribed emission factors and methodology (similar to CAAPP Condition 5.13 as it currently addresses use of appropriate emission factors), the limitations on annual emissions in the revised permit would not be enforceable as a practical matter. In this regard, at this time, CAAPP Condition 5.13, which addresses the use of appropriate emission factors in determining compliance with annual emission limitations, cannot be relied upon for this purpose. As well as currently being stayed, that condition only provides for use of appropriate emission factors. It does not provide for the use of prescribed emissions factors or prescribed emission determination methodologies. Moreover, in the absence of a request in the 2022 application for suitable condition(s) generally addressing how compliance with limitations on annual emissions is to be determined, the

application does not show that the revision to Permit 95010001 that is requested would meet the criteria for Integrated Processing, as the application also specifically requests. That is, the 2022 application would not show that the request for a revised permit would provide for compliance requirements substantially equivalent to those provided for by the CAAPP since the application does not request that the revised permit include requirements substantially equivalent to those that would have been provided by CAAPP Condition 5.13 if it were not stayed.

Discussion

The 2022 application does not request revisions to general provisions in Permit 95010001 that would enable revisions to the CAAPP permit for the Granite City Works, Permit 96030056, to be made by administrative amendment to allow prescribed emission factors to be used to determine ongoing emissions of certain emission units. In this regard, the CAAPP permit currently provides that "appropriate emission factors" shall be used when determining emissions to evaluate compliance with the emission limits for process units set by Permit 95010001. Permit 95010001 does not specify how emissions are to be determined for this purpose, much less specify that, for certain emission units and pollutants, prescribed emission factors are to be used.[59] Accordingly, the procedures to determine compliance with the emission limits set by Permit 95010001 were established in the CAAPP permit for the Granite City Works. This was necessary because the emission limits set by Permit 95010001 are applicable requirements under the CAAPP. The procedures that were established in the current CAAPP permit do not provide for the use of prescribed emission factors. Rather, the CAAPP permit generally requires US Steel to use "appropriate emission factors," i.e., emission factors that do not understate emissions, with the primary responsibility for the appropriateness of the factors that are used placed on US Steel.[60] The CAAPP permit also provides for recordkeeping and reporting by US Steel so that the Illinois EPA and interested parties can know and may review for the emission factors that are being used. However, the 2022 application simply requests revisions to Permit 95010001 to require use of prescribed emission factors for certain units. The application does not address the fact that the CAAPP permit currently does not accommodate the use of prescribed emission factors to calculate emissions but instead requires use of "appropriate emission factors."[61]

[59] Condition 39(a) of Permit 95010001 did require "one-time testing" for various pollutant for certain emission units within 270 days of the date that this permit was initially issued. Additional time was subsequently provided to complete testing for the particulate emissions of a boiler when burning blast furnace gas. Unfortunately, the permit did not require testing of the NOx and VOM emissions of the BOFs. That testing was subsequently required by the CAAPP permit issued for the facility.

[60] This approach is consistent with a basic principle of the Title V permit program, as reflected in the CAAPP, that the responsibility for showing compliance with applicable air pollution control requirements for a facility lies with the source or Permittee for the facility, and not with the permitting authority.

[61] It should also be noted that in PCB 2013-53, the appeal that is pending before the Pollution Control Board for CAAPP permit 96030056, US Steel challenged Condition 5.13, General Procedures for Certain Permit Limits on Emissions. Condition 5.13 is relevant to the requested revisions of Permit 95010001 as it specifies procedures by which compliance is to be generally determined with the emission factor limits and annual emission limits set by Permit 95010001for process units. In addition to not proposing revisions to Permit 95010001 to accommodate use of prescribed emissions factors, the 2022 application does not address related revisions to Condition 5.13 of Permit 96030056 to potentially facilitate resolution of PCB 2013-53 as Condition 5.13 is challenged in this appeal.

14. THE 2022 APPLICATION DOES NOT ADDRESS THE AMENDMENT TO THE CAAPP PERMIT AUTHORIZED BY CONSTRUCTION PERMIT 11050006, AS IS RELEVANT FOR THE REQUESTED INTEGRATED PROCESSING OF THE REVISION TO PERMIT 95010001

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application was not accompanied by an application for an administrative amendment to incorporate changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are authorized by Construction Permit 11050006, issued April 1, 2013. That construction permit addresses the baghouse control system installed on the BOFs to improve control of the particulate emissions of these furnaces from charging and tapping. As that construction permit was subject to Integrated Processing, it provides for certain changes to then be made in the CAAPP permit to the requirements for the BOFs as needed to accommodate the use of both this new baghouse control system and the existing electrostatic precipitator (ESP) system for control of emissions. However, US Steel has not initiated a revision to the CAAPP permit to incorporate changes as authorized by Permit 11050006 by submitting an application for an administrative amendment of the CAAPP permit.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent the administrative amendment of the CAAPP permit as authorized by Construction Permit 11050006, as the 2022 application requests Integrated Processing, the application requests that revision of Permit 95010001 authorize changes to the current CAAPP permit. As such, the application effectively requests that separate from the revisions that are specifically requested by the application, the Illinois EPA reissue a CAAPP permit that, as related to the BOFs, contains provisions that are no longer accurate. For example, the description of the BOFs in CAAPP Conditions 7.5.1 and 7.5.2 does not indicate the use of the baghouse control system on the BOFs; only the ESP system is addressed. In addition, CAAPP Condition 7.5.5-1 does not address the corrective action procedures for baghouses required by 40 CFR 63.7800(b)(4). The addition of the baghouse system would be appropriately addressed in the CAAPP permit by the earlier amendment authorized by Construction Permit 11050006. As such, it would be contrary to the CAAPP to authorize further revisions to the CAAPP permit by means of Integrated Processing, as is requested by the 2022 application, without first making the revisions to the CAAPP permit authorized by Permit 11050006. Otherwise, the amendment of the CAAPP permit authorized by means of the revision of Permit 95010001 would be deficient. For the BOFs, as such a CAAPP permit, would not address certain applicable requirements, the

permit would not contain provisions to assure compliance with all applicable requirements. It would also continue to include requirements that, as addressed by Permit 11050006, would have become obsolete with the addition of the baghouse control system.

Discussion

The 2022 application does not identify the version of the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, Permit 96030056, that would be eligible for administrative amendment pursuant to the Integrated Processing of the revisions to Permit 95010001 that are requested. This is relevant because the Illinois EPA has already issued a construction permit with Integrated Processing, i.e., Construction Permit 11050006, issued April 1, 2013. This permit addresses the addition of a baghouse system to improve control of particulate emissions of the basic oxygen furnaces from charging and tapping of the furnaces. With the addition of this new system, the furnaces have three points of emissions, i.e., the new baghouse, the historic ESP, and the roof monitor on the furnace shop.[62] Certain work practices that were required by Permit 95010001 for control of particulate emissions of the furnaces with only an ESP system conflicted with the use of the baghouse system or would no longer be appropriate when emissions were also controlled with the new system. To address the fact that these work practices were also present in the CAAPP permit for the facility, Construction Permit 11050006 was subject to Integrated Processing and allowed certain changes to be made to the CAAPP permit by administrative amendment.[63] This was intended to enable use of the new baghouse system for improved control of particulate emissions in compliance with the CAAPP permit without the need for a subsequent permit proceeding to modify the CAAPP permit. However, US Steel has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006.[64]

Section 39.5(13)(a) of the Illinois Environmental Protection Act provides that "The Agency shall take final action **on a request** for an administrative permit amendment within 60 days after **the**

[62] The new baghouse system required a construction permit because this system would affect the requirements that then existed for control of particulate emissions of the basic oxygen furnaces, including their emissions of lead. For purposes of NSR, the construction permit was issued based on the new baghouse system being a project that would reduce the emissions of particulate and lead from these furnaces rather than increase these emissions. The permit was also based on this new system not increasing the emissions of other pollutants from these furnaces. As such, the construction permit for the new baghouse system, Permit 11050006, did not set limits for emissions from the baghouse system. This permit also did not lower the existing limits for the emissions of the basic oxygen furnaces.

[63] To address the changes to the CAAPP permit that would be needed for use of the new baghouse system, Permit 11050006 provides for replacement of Section 7.5 of the CAAPP permit, which addresses the basic oxygen furnace shop, including the basic oxygen furnaces, in its entirety. The new version of Section 7.5 addresses the basic oxygen furnace shop with the new baghouse system. Given the extent of the changes to Section 7.5 that were needed to accommodate addition of a baghouse to the particulate control system for the basic oxygen furnaces, this approach was taken to Permit 11050006 to provide accuracy, clarity and simplicity in the revisions to the CAAPP permit that were being authorized.

[64] The 2022 application does address the addition of the baghouse control system for the basic oxygen furnaces as related to the emission of the furnaces. US Steel does not propose separate limits set for the individual emission points for these furnaces. Instead, the application requests that the revised permit set overall limits for the emissions from the control systems of the basic oxygen furnaces.

receipt of the request." (Emphasis added.) Accordingly, in the absence of a formal request from US Steel to the Illinois EPA to initiate the administrative amendment of the CAAPP permit contemplated by Permit 11050006, the 2022 application can only request Integrated Processing to allow administrative amendments of the current CAAPP permit, as has actually been physically issued by the Illinois EPA.[65, 66]

[65] The timing of the physical issuance of a revised CAAPP permit by the Illinois EPA is critical as a procedural matter because it starts the period within which the Permittee may appeal such action to the Pollution Control Board. Moreover, in PCB 2013-62, US Steel has already appealed certain elements of the changes to the CAAPP permit that are addressed by the administrative amendment to the CAAPP permit authorized pursuant to Permit 11050006.

Given this appeal, the Illinois EPA would not "reinstate" those provisions when issuing the amended CAAPP permit. Instead, it is expected that the amended CAAPP permit would contain notes that explain that the appealed provisions continue to be present in the that existing CAAPP permit as they were appealed. Nevertheless, it is possible that US Steel would appeal those notes in the amended permit as they would acknowledge the continued existence of the appealed provisions.

[66] Concerns are posed by certain conditions in existing Construction Permit 11050006 and the related amendments to CAAPP Permit 96030056 that it authorizes. The 2022 application is not accompanied by a request for changes to Permit 11050006 or a proposal for how to address these concerns so that they would not be perpetuated in the amended CAAPP permit. One concern is that the deadlines in Permit 11050006 for performing emission testing on the new baghouse and completing certain other actions were based on the basic oxygen furnaces being in routine use once the construction of the new baghouse system was completed. The permit did not contemplate the over two yearlong interruption in production that began in December 2015. US Steel undertook this interruption in production in response to the poor markets for domestic steel at that time. As such, although failures to meet certain deadlines in Permit 11050006 likely were reasonable, it is not clear that they would be excused as being due to *force majeur* (i.e., event(s) that could not reasonably be anticipated or controlled by the source).

The other concern with existing Construction Permit 11050006 and the related amendments to CAAPP Permit 96030056 is that they overlook the role of the existing ESP control system in controlling particulate emissions from charging and tapping of the basic oxygen furnaces. Instead, Permit 11050006 incorrectly indicates that the new baghouse system will control emissions from charging and tapping of the furnaces and the existing ESP system will control emissions from the refining process. In fact, the new baghouse system was constructed to improve control of emissions from charging and tapping, with capture hoods to collect particulate emissions that are not captured by the hoods that serve the ESP system. This is perhaps most clearly shown in the 2010 Memorandum of Understanding between US Steel and the Illinois EPA (MOU) as this MOU addresses improvement in the control of emissions from charging of the furnaces. Section 4(d) of the MOU acknowledges the presence of the existing control for charging with the ESP. It also indicates that control of emissions from charging could be improved by ducting either some or all of these emissions to a new baghouse system. In any case, the errors in the description of the new baghouse system for the basic oxygen furnaces in Permit 11050006 should also be corrected so that erroneous information is not perpetuated in the amendments to the CAAPP permit.

15. THE 2022 APPLICATION WOULD NOT CLARIFY THE RELATIONSHIP BETWEEN FUGITIVE DUST CONTROL MEASURES REQUIRED BY PERMIT 95010001 AND MEASURES REQUIRED BY 35 IAC PART 212 SUBPART K

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* As related to practices to reduce emissions of fugitive dust from roadways, parking areas and open areas at the Granite City Works and certain public roadways near this facility, the 2022 application does not propose revisions to clarify the interplay between the associated recordkeeping and reporting that are required by Permit 95010001 and the associated recordkeeping and reporting that are required by Board rules. In this regard, except for Condition 25, Permit 95010001 does not address the Board's rules for control of emissions of fugitive dust. (Condition 25 addresses 35 IAC 212.316(e)(1), which limits the opacity of emissions from roadways and parking areas at the facility to no more than 5 percent, average of four vehicle passes, 3 opacity readings for each pass.) While the CAAPP permit for the facility addresses requirements in Board rules for control of fugitive dust, it is unclear whether the requirements for recordkeeping and reporting in 35 IAC 212.316(g) are applicable for the public roadways for which specific measures to reduce emissions of fugitive dust are required by Permit 95010001. This is because Condition 7.13.9(a) in Part 7.0 of the CAAPP permit, which contains "Unit Specific Conditions for Specific Emission Units," provides that the requirements of 35 IAC 212.316(g) apply for "… any fugitive particulate matter emission unit subject to 35 IAC 212.316," without further elaboration on whether public roads are subject to 35 IAC 212.316. However, Condition 5.3.2(c)(ii) in Part 5.0 of the CAAPP permit, which contains "Overall Source Conditions," explicitly applies the requirements for Fugitive Particulate Matter Operating Programs, 35 IAC 212.309, 212.310 and 212.312, to the public roadways for which measures to reduce emissions of fugitive dust are required. Accordingly, for the subject public roadways, the CAAPP permit indirectly indicates that the requirements of 35 IAC 212.316(g) also apply.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent clarifying information as described above, the 2022 application does not include the necessary information to allow a revision to Permit 95010001 to be proposed, much less issued, for the Project with Integrated Processing, as is also requested by the application. This is because the amendment of the CAAPP permit that would be authorized by means of the requested revision of Permit 95010001 would be deficient. For roadways, parking areas and other open areas, such an amended CAAPP permit, would not clearly delineate the standards for opacity of emissions pursuant to Board rules that apply to the different

categories of emission units (e.g., 5 percent for roadways and parking areas at the facility, 10 percent for storage piles, and 20 percent for the on-site landfill). In addition, if provisions of 35 IAC 212.316 should not be applied to public roadways, as they are not part of the Granite City Works, such an amended CAAPP permit would improperly perpetuate errors in the current CAAPP permit regarding applicability of Board rules.

Discussion

For roadways, parking areas, and open access areas, Conditions 23, 24, 26, 27, 28, 29 and 30 of Permit 95010001 require implementation of control measures for emissions of fugitive dust. The 2022 application does not make clear the relationship between these requirements established by permit and state regulatory requirements for fugitive emissions in 35 IAC Part 212 Subpart K.[67] In particular, Condition 29 requires daily recordkeeping for the implementation of required measures for on-site dust control. However, it does not address the relationship between these permit-mandated records and the recordkeeping required by 35 IAC 212.316(e)(2).[68] At the same time, Permit 95010001 does address one requirement of 35 IAC Part 212 Subpart K as Condition 25 restates the requirement of 35 IAC 212.316(e)(1), which provides that the opacity of fugitive particulate matter emissions from any roadway or parking area at the Granite City Works shall not exceed 5 percent.[69] That Permit 95010001 does not currently deal with regulatory

[67] Incidentally, the CAAPP permit for the Granite City Works appears to erroneously apply the requirements of 35 IAC Part 212 Subpart K, to the requirements for off-site dust control in Permit 95010001. These regulatory requirements, including that subject sources must be operated under the provisions of an operating program designed to significantly reduce fugitive particulate matter emissions, are applicable to US Steel for sources of fugitive dust at the Granite City Works. However, 35 IAC 212.302 appears to provide that the various emission standards and control requirements in 35 IAC Part 212 Subpart K, other than the general standard for the opacity of fugitive emissions in 35 IAC 212.301, apply for emission units for fugitive dust at certain types of facilities, including manufacturing facilities. Accordingly, these regulatory requirements would not apply to off-site roadways and the compliance procedures for the control measures for off-site roadways should instead be established by permit.

[68] For example, for roadways and parking areas at a steel mill in Granite City (i.e., the Granite City Works), 35 IAC 212.316(g)(2) requires the owner or operator to keep the following detailed records related to the application of control measures for these units:

> 35 IAC 212.316(g)(2) …
>
> D) For each application of water or chemical solution to roadways by truck: the name and location of the roadway controlled, application rate of each truck, frequency of each application, width of each application, identification of each truck used, total quantity of water or chemical used for each application and, for each application of chemical solution, the concentration and identity of the chemical;
> E) For application of physical or chemical control agents: the name of the agent, application rate and frequency, and total quantity of agent, and, if diluted, percent of concentration, used each day;
> F) A log recording incidents when control measures were not used and a statement of explanation.

[69] In Condition 31, Permit 95010001 also refers to 35 IAC Part 212 Subpart U, which also addresses fugitive emissions. For certain facilities, including the Granite City Works, it requires that the owner or operator prepare a contingency measure plan for reductions in particulate emissions that could be implemented in the event of an exceedance of the NAAQS for PM10, 24-hour average. Incidentally, Illinois has never needed to implement the contingency plans required by 35 IAC Part 212 Subpart U.

requirements for fugitive dust is an issue as Integrated Processing of a revision of this this permit requires that the compliance procedures in the revised permit be consistent with those required by the CAAPP.

16. THE 2022 APPLICATION DOES NOT ADDRESS CHANGES TO THE CAAPP PERMIT THAT ARE NEEDED DUE TO REVISIONS TO 40 CFR 63 SUBPART FFFFF, AS COULD BE EXPEDITED BY INTEGRATED PROCESSING OF PERMIT 95010001

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a) .

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not address or identify changes to Permit 95010001 and, by means of Integrated Processing of the revision to Permit 95010001, the changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are appropriate as a result of certain revisions of the Iron and Steel NESHAP, 40 CFR 63 Subpart FFFFF. Those revisions, which took effect in January 2022, provide that the emission standards in 40 CFR 63 Subpart FFFFF apply at all times. The prior exemptions from these standards for a subject unit during periods of startup, shutdown and malfunction no longer apply. The provisions of 40 CFR 63 Subpart FFFFF are relevant to Permit 95010001 as it directly or indirectly relies on these rules for the compliance procedures that accompany the permit limitations for the particulate emissions of the NESHAP-subject units, as needed to make those limitations enforceable as a practical matter. For the BOFs, Permit 95010001 directly relies on 40 CFR 63 Subpart FFFFF as Condition 9 refers to applicable provisions of 40 CFR 63 Subpart FFFFF for the work practices, opacity limits, operational limits, emission testing, operational monitoring, recordkeeping and reporting that are required. For the blast furnace casthouse and units other than the BOFs that are subject to 40 CFR 63 Subpart FFFFF, the applicable compliance provisions of this NESHAP are currently indirectly relied upon as those requirements are addressed in the CAAPP permit for the facility,. (For the BOFs, the CAAPP permit also addresses the applicable compliance procedures of 40 CFR 63 Subpart FFFFF.)

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent explicit recognition in the 2022 application of the recent revisions to 40 CFR 63 Subpart FFFFF, the version of Permit 96030056 that would be authorized by means of the Integrated Processing of revised Permit 95010001 could continue to reflect the historic version of 40 CFR 63 Subpart FFFFFF, prior to the revisions related to startup, shutdown and malfunction. For example, the current CAAPP permit addresses provisions of 40 CFR 63 Subpart FFFFF that required startup, shutdown and malfunction plans that were removed in the revision of these rules. (Refer to CAAPP Condition 7.4.5-2(a) for the “affected blast furnaces and casthouses [sic]” and CAAPP Condition 7.5.5-2(a) “for BOF [sic].”) This would be an impediment to Integrated Processing of a revision to Permit 95010001 if the revised permit would not provide for compliance requirements that are substantially equivalent to those

required by the CAAPP. It would clearly be contrary to the compliance requirements of the CAAPP if for the casthouse and the BOFs, the amended CAAPP permit that would be authorized be issued by means of Integrated Processing would still include provisions of the historic version of 40 CFR 63 Subpart FFFFF that have ceased to apply.

Discussion

The 2022 application does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020. (85 Federal Register, pages 42,074 – 42,130, July 13, 2020). Among other revisions to 40 CFR 63 Subpart FFFFF, USEPA acted to remove exemptions from the emission and opacity limits in this NESHAP for periods of startup, shutdown and malfunction (SSM). Accordingly, effective January 12, 2022, the emission and opacity limits of this NESHAP became applicable at all times. The requirements of this NESHAP that formerly dealt with SSM ceased to be applicable. Notably, subject sources would no longer be required to keep startup, shutdown and malfunction plans detailing the procedures for operating and maintaining subject emission unit(s) during periods of SSM, as had been required by 40 CFR 63 Subpart FFFFF as it had applied 40 CFR 63.6(e)(3) in the general provisions of the NESHAP regulations to subject sources,

These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the 2022 application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the basic oxygen furnaces and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate. This reliance occurs as the emission limits that are set or would be set by a revised permit would be restated in the CAAPP permit for the Granite City Works, Permit 96030056. The provision currently in CAAPP Permit 96030056 that reflect the exceptions to the requirements of 40 CFR 63 Subpart FFFFF for SSM create a break or interruption in this reliance on the NESHAP for purposes of enforceability of permit limits for emissions, even if the actual nature and effect of this break or interruption is uncertain. Any concern over such interruptions would be eliminated if the former provisions of the NESHAP regulations, which USEPA acted to strike in July 2020, were also no longer present in the CAAPP permit.[70]

[70] From a legal and practical perspective, the continued presence of the former provisions of 40 CFR 63 Subpart FFFFF in the CAAPP permit would be problematic. Would US Steel have to maintain startup, shutdown and malfunction plans as related to particulate emissions of NESHAP-subject units relative to permit limits for particulate emissions? Would the continued presence of these provisions in the CAAPP permit throw Integrated Processing of Permit 95010001 into question as the compliance procedures that would accompany the limits for particulate emissions in revised Permit 95010001 would not be consistent with the procedures required by the CAAPP? Would US Steel and the Illinois EPA have to delineate and then implement a secondary version of the compliance procedures that would deal with emissions of particulate from NESHAP-subject units during SSM events?

17. THE 2022 APPLICATION DOES NOT ADDRESS CHANGES TO THE CAAPP PERMIT THAT HAVE RESULTED FROM SHUTDOWN OF EMISSION UNITS, AS IS RELEVANT FOR THE REQUESTED INTEGRATED PROCESSING OF THE REVISION TO PERMIT 95010001

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency: T*he 2022 application does not identify or address changes to the CAAPP permit for the facility, Permit 96030056, that result from the permanent shutdown of certain emission units at the facility. US Steel has also not taken other action to initiate issuance of a revision of Permit 96030056 that would remove provisions for emission units that are now permanently shutdown. In this regard, for example, Permit 96030056 currently includes provisions addressing the two by-product recovery coke oven batteries at the facility that were permanently shut down in 2015.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information in the 2022 application or other appropriate action by US Steel, as addressed above, the application does not include the necessary information to enable a revision to Permit 95010001 to be issued with Integrated Processing. This is because the application would not show that such a revision to Permit 95010001 would meet the criteria for Integrated Processing, as is specifically requested by the application. That is, the 2022 application would not show that the revisions to Permit 95010001 would provide for procedural and compliance requirements in Permit 96030056 that are substantially equivalent to those provided for by the CAAPP. The application would not support subsequent amendment of Permit 96030056 by means of Integrated Processing that would remove provisions for units that are now shutdown. Instead, absent an appropriate request, the application, would only support issuance of an amended CAPPP permit that would include the current provision for units that are now shut down. In this regard, the Integrated Processing of a construction permit only allows for subsequent amendments to a CAAPP permit as provided for by the construction permit. The Illinois EPA is not given independent authority to revise a CAAPP permit to remove provisions for units that are now shut down but are not otherwise the subject of the construction permit application.

Discussion

The 2022 application does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emission units, as generally addressed by Condition 9.11 of the CAAPP permit.

> Condition 9.11 Permanent Shutdown
> This permit only covers emission units and control equipment while physically present at the indicated source location(s). Unless this permit specifically provides for equipment relocation, this permit is void for the operation or activity of any item of equipment on the date it is removed from the permitted location(s) or permanently shutdown. …

While the 2022 application acknowledges that the by-product coke ovens at the Granite City Works have been shut down, this application does not separately address the consequences for the current CAAPP permit. The shutdown of these batteries was accompanied by the shutdown of coal and coke handling operations, the coke by-products plant, the handling of coke by-products, and possibly certain wastewater treatment processes.[71, 72] In addition, although not shut down, Boilers 11 and 12, Ladle Dryer/Preheaters and Slab Reheat Furnaces are no longer able to use COG as fuel since COG is no longer produced at the facility. As such, provisions in the CAAPP permit that identify or address the use of COG in these units are no longer necessary.[73] It would be improper for the revised version of the CAAPP permit authorized by means of the Integrated Processing of a revision to Permit 95010001 to still physically include provisions that should no longer be present in the revised CAAPP permit given the permanent shutdown of the emission units that were subject to those provisions.[74] The responsibility to identify provisions in

---

[71] The elimination of COG also affected the applicability of emission standards to certain units. For example, 35 IAC 212.458(b)(23) is no longer applicable, to ladle dryers/preheaters, contrary to what is stated in Condition 7.5.3-1 of the CAAPP permit.

[72] US Steel's current application for renewal of CAAPP Permit 96030056, which was received by the Illinois EPA on December 3, 2013, also does not address shut down of the by-product coke oven batteries and other related operations at the facility. This application only acknowledges that changes to the CAAPP permit will be needed in the future to address the addition of the baghouse to the particulate control system for the basic oxygen furnaces when construction of the baghouse is complete.

> The existing equipment descriptions for the individual processes at GCW (Granite City Works) in the CAAPP permit sections 7.1 to 7.4 and 7.6 to 7.13 are generally accurate. However, the Basic Oxygen Furnace process described in the CAAPP permit condition 7.5 will eventually need to be updated with the new secondary baghouse added as part of the Emission Reduction Project (Construction Permit No. 11050006) once construction is complete.
>
> Application for Renewal of CAAPP Permit 95030056, Section 2.2.2, "Process Changes."

[73] Irrespective of whether certain provisions in the CAAPP permit related to use of COG are still necessary, Condition 5.6 of the CAAPP permit limits the SO_2 emissions of these units from use of COG. (This condition restates limits from Federally Enforceable State Operating Permit 94120017, originally issued December 12, 1994.) The absence of COG does not act to excuse US Steel from required recordkeeping and periodic reporting for emissions of SO_2 and PM_{10} from these units from use of COG (CAAPP permit, Conditions 5.9(e) and 5.10.3). It also does not excuse US Steel from required operational monitoring for the use and sulfur content of COG (CAAPP permit, Conditions 5.6(a) and 7.3.9(f)). In this regard, the emission units addressed by CAAPP Condition 5.6, which are addressed by these requirements for operational monitoring, recordkeeping and reporting, have not been shut down.

[74] A fundamental requirement of the CAAPP is that applications for CAAPP permits must be truthful, accurate and complete. In this regard, Section 39.5(5)(e) of the Environmental Protection Act provides that "Each submitted CAAPP application shall be certified for truth, accuracy, and completeness by a

the CAAPP permit that should not be carried forward initially falls on US Steel as it is the CAAPP Permittee for the Granite City Works.[75] Moreover, as the 2022 application requests Integrated Processing of the requested revisions to Permit 95010001, the subsequent revisions to the CAAPP permit that would be authorized by the revisions to Permit 95010001 must fulfill the requirement that a CAAPP permit issued for a source accurately identify or address the emission units that constitute the source is being permitted.

responsible official in accordance with applicable regulations." Section 10(a)(i) of the Act provides that one of the standards of issuance for a CAAPP permit by the Illinois EPA is that "… the applicant has submitted a complete and certified application for a permit, permit modification, or permit renewal consistent with subsection 5 and 14 of this Section [Section 39.5 of the Act], as applicable, and applicable regulations." The requirement for an application to be truthful, accurate and complete is applicable to US Steel's current request for revisions to Permit 95010001 as it includes a request for Administrative Amendment to the CAAPP permit for the Granite City Works by means of Integrated Processing under the CAAPP. The scope of this requirement's applicability is not limited to only certain types of CAAPP applications, such as applications for initial CAAPP permits or renewals of CAAPP permits.

[75] As US Steel is the Permittee for a CAAPP source, it must periodically report compliance or noncompliance with each of the requirements set forth in the CAAPP permit. If US Steel believes that it is "in compliance" with regard to certain requirements in the CAAPP permit because those requirements have been affected by Condition 9.11 of the CAAPP Permit, it is appropriate for US Steel to request appropriate changes to the CAAPP permit by means of an appropriate application for amendment or modification of the CAAPP permit. This is especially true as certain requirements in the CAAPP permit that relate to use of COG apply to emission units that have not been shut down.

18. THE EVALUATION OF BEST AVAILABLE CONTROL TECHNOLOGY (BACT) IN THE 2022 APPLICATION FOR CARBON MONOXIDE (CO) IS NOT SUFFICIENT AND DOES NOT ADEQUATELY SUPPORT US STEEL'S PROPOSAL FOR BACT

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were ranted as requested:* Sections 9(a), 9(b)(2), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*, 201.152***, 201.160(a), 204.280, 204.330, 204.810, 204.820 and 204.1100(c).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* For the blast furnace casthouse, for which BACT for CO must now be set as it has been realized that the casthouse emits CO, the BACT demonstration in the 2022 application does not show that options for BACT for CO other than add-on control devices were considered. For the blast furnace stoves, for which BACT for CO must now be reevaluated as increases in permitted emissions are requested, the application is not accompanied by diagrams and cost data supporting the claim that it is not feasible to conduct emission testing by USEPA reference methods for the CO emissions of the stoves. This information is necessary for the stoves if BACT for CO is to not be set as a numerical standard. (The 2022 application requests that the revised permit recognize CO emissions from the casthouse of about 300 tons/year, of which about 100 tons/year would be the increase from the Production Increase Project; the requested increase in permitted CO emissions from burning blast furnace gas (BFG) in the blast furnace stoves is almost 10,000 tons/year, with an overall increase, also considering the BFG flares and boilers, of more than 20,000 tons/year.) For both the casthouse and the blast furnace stoves, the BACT demonstrations in the application do not include descriptions or documentation for the investigations that were conducted into available options for control of CO.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as addressed above, the BACT demonstrations in the 2022 application for CO are not complete. They do not show that BACT would be utilized for CO with changes in permitted CO emissions of the Project as requested by the application. As such, they cannot be relied upon to conclude that BACT is utilized for CO for the casthouse and blast furnace stoves, much less, for the Illinois EPA to set appropriate requirements as BACT for CO in a revision to Permit 95010001.

Discussion

The evaluation of Best Available Control Technology (BACT) for CO in Section 8 of the 2022 application lacks necessary information to support US Steel's proposal for BACT for CO for the emissions units for which this must be determined or redetermined under the PSD program as a consequence of the requested revisions to Permit 95010001. The evaluation addresses BACT for

CO for the casthouse for which BACT must now be determined as it is now recognized that the casthouse emits CO. It also addresses BACT for CO for the blast furnace stoves as the 2022 application requests that the revision of Permit 95010001 allow for more emissions of CO from these units.

The Scope of the Evaluation

As explained in the 2022 application, consistent with the definition of BACT in Section 169(3) of the Clean Air Act (42 US Code Section 7479(3)) and as confirmed by USEPA guidance, a determination of BACT must consider options to control or reduce emissions of an emission unit besides add-on control devices.

> In the BACT analyses herein, the term "available" is used, consistent with U.S. EPA guidance to refer to any control strategy that is potentially applicable to the source type in question (i.e., a technology or control option that has a practical potential for application to the source category in general). These may include fuel cleaning, inherently lower polluting processes, and end of pipe control devices. All identified control strategies that are not inconsistent with the fundamental purpose and basic design of the proposed [sic] facility are listed in this step.
>
> 2022 application, Section 8.2.1.4, "Available Control Options," p. 8-4.

For the casthouse, when identifying control options, the BACT evaluation only identifies end-of-pipe or "add-on control" control options. The evaluation does not identify other process-related control options such as work practices (2022 application, Section 8.2.3.3). In contrast, for the blast furnace stoves, the evaluation identifies both add-on control options and a process-related control option. i.e., "Work Practice Standards, including good combustion practices" (2022 application, Section 8.2.2.3). The evaluation does not explain why process-related control options are not available for the casthouse.[76]

Support Provided for the Scope of the BACT Evaluation

[76] Incidentally, with regard to the blast furnace stoves, the evaluation does not explain why "good combustion practices" are considered to be a type of work practice standard rather than a separate control option. In Section 8.2.2.6 "Step 5 - Establish CO BACT," the evaluation proposes operational monitoring for temperature and oxygen levels to confirm operation of the stoves for efficient combustion of fuel, thereby maintaining CO emissions within the level that is achievable given the nature of the physical and operational design of the stoves. The evaluation also separately proposes the less prescriptive practices that are more often considered to constitute good combustion practices. For example, Section 8.2.2.6 also proposes to, "Conduct annual adjustment and tune-up to include, **at a minimum**, inspecting, adjusting, cleaning, or replacing instrumentation and operational control system components and inspecting the air-to-fuel ratio control system and adjusting as **appropriate** for **proper** operation." [Emphasis added.]
Moreover, this statement of what would constitute "good combustion practices" for the stoves would be problematic as it would not be enforceable given the various qualifications, as highlighted, on the actions that are required actions to be taken.

For both the casthouse and the blast furnace stoves, the BACT evaluation in the 2022 application is not accompanied by supporting documentation for the investigation that was conducted into available control options. Instead, the evaluation simply states that a review of available control options was conducted. For example, for the casthouse, the evaluation states:

> Based on a review for BACT determinations in U.S. EPA's RBLC (RACT/BACT/LAER Clearinghouse) database and other literature, the control options that are potentially available to control CO emissions from the blast furnace casthouse are:
>
> - Capture system and thermal incineration and
> - Capture system and catalytic incineration.
>
> 2022 application, Section 8.2.3.3, p. 8-8.

When a BACT evaluation is submitted, it may be appropriate or necessary[77] for the application to also include documentary support for the review of available control options that was conducted. In this regard, BACT evaluations commonly include copies of information from the RBLC that is potentially relevant to the determination of BACT that must be made. Further explanation is also provided if some of that information is not considered applicable to the units that are the subject of the BACT determination. Likewise, as there is relevant information in the literature, especially as it is addresses available control options for the subject pollutant, copies of that information should be included in a BACT evaluation. This information enables the Illinois EPA, the USEPA and interested parties to confirm that the review of available control options for a BACT evaluation was thorough and can be relied upon to have reasonably identified potentially available control options for BACT.

Support Provided for Work Practices As BACT for the Blast Furnace Stoves

For the blast furnace stoves, the BACT evaluation for CO in the 2022 application is not accompanied by supporting documentation to support the claim that it is infeasible to measure their CO emissions so that BACT should not be set as a numerical emission standard.[78]

---

[77] For the 2022 application, this information is considered necessary. BACT determinations for the CO emissions of casthouses for blast furnaces and blast furnace stoves are uncommon. The Illinois EPA does not have the ability based simply on its own experience and knowledge to confirm that the potential control options for CO BACT were reasonably identified in the BACT evaluations in the application.

[78] The definition of BACT at 35 IAC 204.280 provides that:

> If the Agency [Illinois EPA] determines that technological or economic limitations on the application of measurement methodology to a particular emission units would make the imposition of an emission standard infeasible, a design, equipment, work practice, operational standard or combination thereof, may be prescribed instead to satisfy the requirement for the application of BACT. Such standard shall, to the degree possible, set further the emission reduction achievable by implementation of such design, equipment, work practice or operation, and shall provide for compliance by means that achieve equivalent results.

> USS Granite City is proposing work practice requirements rather than numeric limits as BACT. Numeric emission limitations are not proposed because direct measurement of emissions --*i.e.*, use of U.S. EPA reference test methods—is not feasible for any of the fuel emissions units subject to the BACT requirements for CO emissions. In particular, for the stack serving the blast furnace A stoves, there is no sampling port,[45] and for the stack serving the blast furnace B stoves there is no sampling port satisfying the location requirement in U.S. EPA Reference Method 1.[46] Each stack is refractory lined and is believed to be approximately one hundred years old.
>
> For the reasons presented above, numeric CO emission standards are not feasible for the blast furnace stoves.
>
> Footnote 45. For the one-time exhaust gas sampling event discussed in footnote 19 of this permit application, USS Granite City inserted a sampling probe into the stack through a pipe used to inject steam into the stack.
> Footnote 46. Appendix A-1 to 40 CFR part 60.
>
> 2022 application, Section 8.2.2.6 “Step 5 – Establish CO BACT,” p. 8-7.

Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. For example, the application does not include diagrams for the existing ductwork of the stoves to address whether the configuration of this ductwork would accommodate installation of test ports at a location that would satisfy USEPA Reference Method 1. The application also does not show how the refractory lining on the stacks or their age, approximately one hundred years old, would present significant technical challenges and costs so that the installation of test ports at a suitable location should be considered infeasible. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

19. THE APPLICATION DOES NOT ADDRESS BACT FOR SULFUR DIOXIDE (SO_2) AND CO FROM USE OF COKE OVEN GAS (COG) IN THE BLAST FURNACE STOVES

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9.1(d), 39(a)* and 39(a)**.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.152*, 201.152***, 201.160(a), 204.280, 204.330, 204.810 and 204.1100(c).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include demonstrations of BACT for sulfur dioxide (SO_2) and CO from the burning of coke oven gas (COG) in Project-affected fuel burning units.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not allow a revision to Permit 95010001 to be issued for the Production Increase Project (Project)that considers baseline emissions from burning COG. This is because the application does not provide the demonstrations of BACT that is required as the Project is a major modification for SO_2 and CO under PSD. In this regard, unlike the initial permitting of the Project, the 2022 application now quantifies emissions of particulate, NOx and VOM from burning COG and these emissions are included in revised determinations of baseline emissions. (In 1996, the Project was permitted as a major modification for SO_2 and CO but did not quantitatively address emissions from burning COG.) If emissions from burning of COG are to be relied upon for the issuance of a revised permit, the 2022 application must also address the BACT requirements of PSD for the SO_2 and CO emissions from use of COG, as would have been applicable in 1996, when the Project commenced. The fact that the by-product recovery coke batteries at the Granite City Works were shutdown in 2015 and COG is no longer available at the facility, does not alter the applicable requirements under PSD that must be satisfied. PSD would be violated if a revised permit were issued for the Project based on revised NSR applicability analyses that considered use of COG, as contained in the 2022 application, absent demonstrations that the Project utilized BACT for emissions of SO_2 and CO from use of COG.

Discussion

The 2022 application does not demonstrate that Best Available Control Technology (BACT) was utilized as an aspect of the Project for the SO_2 and CO emissions of the blast furnace stoves, as required under the PSD program (e.g., 35 IAC 204.1100(c)). In this regard, unlike the original application, the 2022 application addresses emissions from use of coke oven gas (COG) as fuel in certain Project-affected units. (Refer to the revised netting analyses for the Project for particulate, NOx and VOM and in the 2022 application.) As the 2022 application now addresses emissions of certain pollutants from burning of COG in fuel-burning units, including the blast

furnace stoves, this application must also address the related consequence for emissions of SO_2 and CO under the PSD program from burning COG in the stoves. SO_2 and CO are pollutants for which the Project is a major modification subject to PSD. However, the 2022 application does not address BACT for SO_2 and CO as applied to use of COG in the stoves. As such, the 2022 application does not demonstrate that prior to February 2015, when the by-product recovery coke oven batteries at the Granite City Works were shut down and COG ceased to be available, BACT was being utilized for the SO_2 and CO emissions from use of COG in the stoves.

With respect to CO, it is relevant that the BACT demonstration in the 2022 application focuses on CO emissions from burning of fuels other than COG. For fuel burning units, the 2022 application states that “CO emissions of these units result primarily from incomplete combustion during the firing of BFG and natural gas.” This ignores the historic contribution of COG to the CO emissions of the stoves prior to February 2015. The 2022 application also does not state that, as of February 2015, it was no longer necessary to address CO emissions from use of COG because COG was no longer produced and available for use.

20. AS RELATED TO SO_2 EMISSIONS FROM USE OF BFG, THE 2022 APPLICATION IS INCONSISTENT WITH A PENDING 2008 APPLICATION

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 9(b)(2)), 9.1(d), 39(a)*, 39(a)** and 39(a)***.

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* As related to emissions of sulfur dioxide (SO_2) from burning blast furnace gas (BFG), the 2022 application is inconsistent with and conflicts with an earlier application for revisions to Permit 95010001 that was received on February 8, 2008 (the "2008 application"). For the emissions of SO_2 from burning of BFG, the 2008 application requests increases in the emissions that are allowed by Permit 95010001. The 2022 application does not request such increases and does not request any changes to Permit 95010001 related to SO_2 emissions. The 2022 application does not even address the 2008 application to explain why the revisions to Permit 95010001 requested by the 2008 application are no longer needed. US Steel has also not taken other actions that would act to resolve the conflict between the 2022 application, which is being addressed in this proceeding, and the earlier 2008 application, which is still pending. For example, US Steel has not requested withdrawal of the 2008 application. In this regard, it is noteworthy that the approach taken in the 2022 application to SO_2 emissions from burning BFG is different from the approach that is taken for NOx, VOM and particulate. For example, for the BOFs for NOx and VOM, the 2022 application requests revisions to Permit 95010001 to increase permitted emissions so as to facilitate future compliance.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* The conflict between the 2008 application and the 2022 application is an impediment to revision of Permit 95010001 as requested by the 2022 application. Absent resolution of this conflict, either by appropriate information or request in the 2022 application or by other appropriate action by US Steel, the 2022 application should not be considered to show compliance with the SO_2 emission limits for burning BFG that are currently in Permit 95010001. As such, the 2022 application does not meet the standards for issuance of a construction permit.

Discussion

In 2008, US Steel applied for revisions to Permit 95010001 to increase permit limits for the sulfur content of BFG and the SO_2 emissions resulting from the use of BFG. That application (the 2008 application) was received on February 4, 2008. The 2022 application is inconsistent with and conflicts with the 2008 application. As such, these applications, as they currently exist, cannot be processed by the Illinois EPA absent appropriate action by US Steel on one or both of these applications, e.g., changes to the 2022 application so that it requests the same revisions to SO_2 emission limits for use of BFG as the 2008 application. In this regard, the 2022 application "… does not request any changes to the emission limits for SO_2 and lead emissions established in the Construction Permit 95010001." (2022 application, p. 2-2.) The 2008 application does request changes to the provisions of the permit for SO_2., as it is an "Application to modify to correct the emission factors used to develop the original application and permit in light of newly identified information on emissions and emission factors." (October 2008 application, p. 1-1.)

In particular, in the 2008 application:

> …US Steel seeks to revise the Production Increase Permit (95010001) to account for US Steel's revised method for calculating the SO_2 emissions from BFG combustion. This will increase the total allowable SO_2 emissions on an annual basis from combustion of BFG in the Production Increase Permit.
>
> 2008 application, pp. 2-2 and 2-3

The 2008 application specifically requests that the SO_2 emission factor limit for BFG be increased from 6.65 to 16.00 pounds/million cubic feet of gas burned. With the revised emission factor, the permitted SO_2 emissions from use of the 185,030 million cubic feet of BFG per year, as allowed by the permit, would increase from 615.22 to 1480.24 tons/year. However, the 2022 application provides that the limits for SO_2 for use of BFG should be unchanged. As such, the 2022 application indicates that for use of BFG the requested revised permit should continue to limit SO_2 emission to 6.65 pounds/million cubic feet burned and 615.22 tons/year.

Moreover, the existence of the 2008 application suggests that the revisions to SO_2 emission limits that it requested were needed at the time of that application. The 2022 application does not show that this was not the case, as it does not address historic SO_2 emissions from use of BFG to show that an SO_2 emission factor of 6.65 pounds/million cubic feet was appropriate when Permit 95010001 was originally issued in 1996 and that annual SO_2 emissions have never exceeded 615.22 tons/year.

21. AS RELATED TO EMISSION LIMITS FOR SO_2, LEAD AND CO, THE 2022 APPLICATION IS INCONSISTENT WITH PENDING BOARD APPEALS

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 9(a), 39(a)*, 39(a)**, 39(a)***, 39.5(5)(i), 39.5(7)(a), 39.5(10)(a)(iv) and 39.5(13)(c)(v).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.160(a).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* For various processes, the 2022 application does not request or propose appropriate changes to the current emission factor limits in Permit 95010001 for SO_2, lead and CO to resolve pending permit appeals (PCB 2013-52 and PCB 2013-62). For these pollutants, Permit 95010001 sets emission factor limits for the blast furnace casthouse and the slag pits for SO_2; for the BOFs for lead and CO; and for desulfurization and reladling for lead. Alternatively, the 2022 application does not indicate that the inclusion of the current emission factor limits in a revised permit is not expected to result in another appeal as these limits are now considered acceptable. For the BOFs for CO, the application also does not indicate that the current emission factor limit, which applies only to the stack emissions from the electrostatic precipitator (ESP), would still be considered acceptable if applied to stack emissions. That is, the current limit would still be acceptable if it applied in aggregate to the CO emissions from the stack of the ESP and the stack of the baghouse, which was subsequently installed to improve control of the particulate emissions of the BOFs (Construction Permit 11050006). This change would be appropriate as particulate emissions of the BOFs are now addressed by two control systems. (Besides particulate, these systems capture emissions of CO and other pollutants from the BOFs but only act to reduce particulate and lead emissions.)

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* Absent information as described above, the 2022 application does not include information necessary for the Illinois EPA to include conditions in a revised permit to prevent noncompliance with certain current emission factor limits that apply to the subject processes. As the subject limits, as they are or, in the case of PCB 2013-62, would be present in the CAAPP permit, are currently the subject of appeals, it is reasonable for these limitations for the review of the application to be based on compliance not being achieved. Moreover, absent information as described above, the 2022 application does not show that, as the subject limits are appealed and could be stayed in any revised CAAPP permit, these limits should be considered to still meet the substantive requirements of the CAAPP. Finally, it is noteworthy that for the subject processes for the various emission factor limits for PM, PM-10, NOx and VOM, the application does request revisions to the emission factor limits. For those requested revisions, the 2022 application, page 2-3, explains that "USS Granite City anticipates that these revisions will

enable settlement of the permit appeals currently before the Board because they involve provisions of the permit addressing emission factors."

Discussion

As already mentioned, the 2022 application does not request any changes to the emissions limits for SO_2 and lead currently set by Permit 95010001. The application states, "This permit application also does not request any changes to the SO_2 and lead emission limits in Construction Permit No. 950100001, so SO_2 and lead emissions will not be discussed further." [2022 application, Section 2.2, "General Description of Requested Permit Revisions." p. 2-2.][79, 80, 81] For CO, the 2022 application does request that the revised permit address emissions of CO from

[79] In Section 3 of the application, in which support for elimination of emission factor limits and use of group limits is generally provided, the application only addresses limits for particulate, NOx and VOM. For example, the application states that,

> The approach proposed by USS Granite City with respect to the PM, PM_{10}, NOx and VOM emissions caps to be used in any revised Construction Permit No. 95010001, including the proposed revisions to certain emission limitations, compliance demonstration requirements, and other permit conditions as discussed in detail in Sections 5 through 7 of the permit application ["Proposed Changes to Permit Terms for PM and PM_{10} Emissions Increases Analyses," "Proposed Changes to Permit Terms for NOx Emission Increases Analysis, and "Proposed Changes to Permit Terms for VOM Emission Increases Analyses," respectively] is consistent with policy and precedent and will improve the enforceability of the PTE limitations in Construction Permit No, 95010001. In particular, USS Granite City emphasizes that removal of certain conditions and provisions addressing emissions individual emission units or emission points, including both limits on annual emissions and provisions emission addressing emissions factors will not result in impairment of the enforceability of the PTE limitations.
>
> 2022 application, Section 3, "Discussion of Permit Conditions Used to Restrict PTE [Potential to Emit]," 3-3.]

[80] For process operations, Permit 95010001 currently limits SO_2 emissions from the casthouse and slag pits associated with the blast furnaces in pounds per ton of iron produced and tons per year. For the casthouse, the SO_2 emissions of the main baghouse for the casthouse, the baghouse for the iron spouts at the casthouse, and the uncaptured emissions from the casthouse are limited, respectively, to 0.2006, 0.0073, and 0.0104 pounds per ton of iron produced. The SO_2 emissions of the slag pits are limited to 0.0100 pounds per ton of iron produced. (Permit 95010001, Condition 5 and Table 1.)

Although the emission factor limits for the SO_2 emissions of the casthouse are not identified as Best Available Control Technology (BACT) by Permit 95010001, these limits are considered to be the determination of BACT for SO_2 and should have been identified as such in this permit. BACT is required for the casthouse for SO_2 because the Project was a major modification for SO_2 under the PSD program, as is stated in this permit. Accordingly, as Project included physical changes to the blast furnaces to increase their production capability, BACT is required for the SO_2 emissions of the casthouse.

[81] For operations in the basic oxygen furnace shop, Permit 95010001 currently limits lead emissions in pounds per hour and tons per year. For the basic oxygen furnaces, the lead emissions from the ESP stack and roof monitor are limited to 0.01934 and 0.0129 pounds per hour, respectively. The lead emissions from desulfurization and hot metal transfer are limited to 0.0133 pounds per hour. (Permit 95010001, Condition 18 and Table 2.) The permit does not address the lead emissions of the basic oxygen furnaces that are now captured and controlled by the new baghouse system nor does the 2022 application request any revisions to the permit to address the lead emissions of these furnaces that now occur from the stack of the baghouse.

the casthouse and raise the limits for CO emissions of Project-affected fuel burning units.[82] However, the application does not request revisions to the emission limits currently in Permit 95010001 for the CO emissions of the basic oxygen furnaces, i.e., the limits in pounds per ton of steel produced and in tons per year for the CO emissions of these furnaces through the ESP stack.[83,] As such, the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62, as it does not propose revisions to current permit limits for emissions of SO_2, CO and lead. As previously discussed, in these appeals, US Steel challenged all emission factor limits set by Permit 95010001 for individual process operations. US Steel has not amended these appeals so that they only address emission factor limits for PM, PM_{10}, NOx and VOM and no longer address the t emission factor limits that are set for SO_2, CO and lead. In addition, in the 2022 application, US Steel does not explain why the emission factor limits in Permit 95010001 for SO_2, CO and lead that were appealed are no longer considered to be objectionable. That is, US Steel would not again challenge those limits as it has already done in PCB 0013-53 and PCB 0013-62 if a revision to Permit 95010001 were issued that continued to include the current emission factor limits.[84]

With regard to the CO emissions of the basic oxygen furnaces, the 2022 application also does not request revisions to Permit 95010001 as the current permit only addresses CO emissions from the "BOF ESP Stack." The application does not request that these limits be revised so that they address all stack emissions of the basic oxygen furnaces, e.g., CO emissions from both the stack of the new baghouse system and the stack of the ESP system. Moreover, as the 2022 application does not propose such revisions to the current limits for CO emissions of these furnaces, the application effectively requests a relaxation of the current limits. This is because the revised permit would not address the CO emissions of these furnaces that now occur through the baghouse stack. That is, the limits in the revised permit would not account for any CO emissions that are no longer being captured with the ESP system and are instead now being emitted from the baghouse system.[85]

---

[82] In the original application for Permit 95010001, the casthouse was not identified as a source of CO and information for CO emissions was not provided. The application also requests certain updates to the limits for CO emissions from use of blast furnace gas and natural gas in Project-affected fuel burning units to reflect new information for the CO emissions from burning these fuels.

[83] Permit 95010001 currently limits CO emissions of the basic oxygen furnaces through the ESP stack to 8.993 pounds per ton of liquid steel produced and 16,097.47 tons/year. (Permit 95010001, Condition 18, Table 2, Section 1, BOF ESP Stack.) The permit does not address CO emissions that are now captured by the new baghouse system and emitted from its stack or any uncaptured CO emissions, which occur through the roof monitor.

[84] If the subject emission factor limits were included in a revised permit, the Illinois EPA could explain that, if these limits in the revised permit were stayed pursuant to an appeal to the Pollution Control Board, the limits would continue to be enforceable pursuant to Permit 95010001 as issued before the revision of the permit and any appeal of the revised permit to the Board.

[85] The 2022 application also does not request revisions to Permit 95010001 to address uncaptured CO emissions of the basic oxygen furnaces or otherwise address the uncaptured CO emissions of these furnaces. This is not consistent with the approach taken for the casthouse on the blast furnaces. For the casthouse, the application requests that the revised permit limit the overall emissions of CO from the stacks on the control systems serving the casthouse. The application also includes information for the overall CO emissions of the casthouse, including other captured emissions and uncaptured emissions.

22. THE 2022 APPLICATION DOES NOT INCLUDE A SIGNED CERTIFICATION FOR THE ACCURACY AND COMPLETENESS OF THE APPLICATION

Overview of This Denial Point, with Information As Required or Specified by Section 39(a) of the Act for Denial of a Permit

1. *The Sections of the Act which may be violated if a revised permit were granted as requested:* Sections 39(a)* and 39.5(5)(e).

2. *The provision of the regulations under the Act which may be violated if the revised permit were granted as requested:* 35 IAC 201.159 and 270.401(f).

3. *The specific type of information, if any, which the Agency deems the applicant did not provide the Agency:* The 2022 application does not include a certification for the truth, accuracy and completeness of the application, as submitted on October 7, 2022. The certification in the 2022 application is a photocopy of an earlier certification dated February 25, 2020, that accompanied a prior application received on March 2, 2020, several years earlier. That certification cannot serve as the required certification. Also note that the 2022 application replaced the prior 2020 application. The transmittal letter accompanying the 2022 application states that, "Due to the nature of revisions throughout this application, the Illinois EPA should refer to this application for permit processing."

   The 2022 application also was not signed as required by 35 IAC 201.159. Even if Integrated Processing had not been requested so that the procedural requirements of the CAAPP were not applicable, the application still did not meet the procedural requirements for construction permit applications because the application was not signed.

   With respect to the "certification" and "signature" provided in US Steel's Comments responding to the Initial Draft Denial Letter, this was not sufficient to correct these omissions. First, this material, which is dated September 8, 2023, was an attachment to those comments and was not submitted as a supplement to the 2022 application. Second, the certification is not accompanied by an errata or other material correcting erroneous information in the application as either identified by the Illinois EPA in the Initial Draft Denial or identified by US Steel when

---

As discussed in Section 8.2.3.7 of this permit application [BACT Evaluation for Blast Furnace Casthouse], USS Granite City is proposing a CO BACT emission limit of 70 lb/hr based on total emissions of these two baghouses [main casthouse baghouse and iron spout baghouse], assuming 95% capture efficiency for the capture system associated with the cast baghouse, as discussed in Section 5.2.3 of this permit application {A&B Blast Furnace Casthouse Roof Monitor Emissions PM_{10} Revised], the fugitive CO emissions from the casthouse roof monitor are 3.1 lb/hr. Total CO emissions from the casthouse roof monitor, including both baghouse and fugitive emissions are 73.1 lb/hr and 320 tons per year ("TPY").

2022 application, Section 4.4, "Updated CO Emissions Information for Blast Furnace Casthouse."

developing its response to the Initial Draft Denial. Thus, even if the certification had been submitted as a supplement to the 2022 application, its truthfulness and validity would be questionable. The fact that the 2022 application was not certified and signed puts the entire application under a cloud.

4. *A statement of specific reasons why the Act and the regulations might not be met if a revised permit were granted as requested:* The 2022 application does not include the certification required by the Act, the Illinois EPA's regulations, and the Board's regulations.

Discussion

The 2022 application does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022, as required by 35 IAC 201.159 and Section 39.5(5)(e) of the Illinois Environmental Protection Act. In its place, the 2022 application includes a photocopy of an earlier certification, dated February 25, 2020 ~~2022~~, which was submitted with a prior application (2022 application, "Appendix A – Application Forms (Copies of Previously Submitted Versions)"). However, the 2022 application is a revision of the earlier application and US Steel intends the 2022 application to replace the earlier application submitted in March 2020 in its entirety (2022 application, Cover Letter). Accordingly, the 2022 application must include a new certification for its truth, accuracy and completeness.

Appendix A: Listing of Sections of the Illinois Environmental Protection Act (Act) That Are Cited for the Different Denial Points Detailed in Attachment 1 As Sections of the Act Which May Be Violated If a Revised Permit Were To Be Granted As Requested by the 2022 Application

Note: The text of the Act (415 ILCS 5) is available on a website for Illinois Compiled Statutes maintained by the Illinois General Assembly: https://www.ilga.gov/legislation/ilcs/ilcs3.asp?ActID=1585&ChapterID=36

Section 9(a): General prohibition against air pollution as it provides that no person shall "Cause or threaten to allow the discharge or emission of any contaminant into the environment in any State … so as to violate regulations or standards adopted by the Board (Pollution Control Board) under this Act." For various denial points in the Denial Letter, this general provision of the Act is cited as a provision of the Act that may be violated if a revised construction permit were issued as requested in the 2022 application as such permit would threaten to allow violations of Board regulations.

Section 9(b)(2): Prohibition against violating conditions imposed by air pollution control permits. The introductory language of Section 9 and Subsections 9(b) and 9(b)(1) of the Act provide that, "No person shall … Construct, install and equipment, facility … of any type designated by the Board … without a permit granted by the Agency unless otherwise exempt by this Act or Board regulations…." For persons with permits, the prohibition against violating permit conditions is in Subsection 9(b)(2), serving to provide that no such person shall operate any equipment or facility, "In violation of any conditions imposed by such permit."

Section 9.1(d): Prohibition against violations of certain sections of the federal Clean Air Act, including Section 165 (Prevention of Significant Deterioration (PSD)) and Section 173 (Permit Requirements for Nonattainment New Source Review Programs).

Section 39(a)*: Standard under the Act for issuance of permits. The designation "Section 39(a)*" or "39(a)*" is used to refer to the second clause of the first sentence in Section 39(a) of the Act. This clause provides that "…it shall be the duty of the Agency to issue a permit upon proof by that the applicant that the facility, equipment, vehicle vessel, or aircraft will not cause a violation of this Act or regulations thereunder." In the Denial Letter, this provision of the Act is routinely cited as a provision that may be violated because the 2022 application does not include proof that the Act or air pollution control regulations would not be violated if a revised permit were issued as requested by the application.

Section 39(a)**: Permit procedures under the Act. The designation "Section 39(a)**" or "39(a)**" is used to refer to the fifth sentence of Section 39(a) of the Act as it addresses imposition of conditions on permits. In particular, this sentence provides that in granting permits, "In granting permits, the Agency

may impose such other conditions as may be necessary to accomplish the purposes of this Act, and as are not inconsistent with the regulations promulgated by the Board hereunder." (As addressed below, this Section of the Act also provides that the Illinois EPA may impose reasonable conditions in a permit related to an applicant's compliance history as necessary to correct, detect or prevent noncompliance.) For various points in the Denial Letter, this provision of the Act is cited as one that may be violated because the 2022 application does not include information that may be needed for the Illinois EPA to impose necessary permit conditions in a permit that would be revised as requested by the application.

Section 39(a)***: Permit procedures under the Act. The designation "Section 39(a)***" or "39(a)***" is used to refer to the fourth sentence of Section 39(a) of the Act as it provides, "In granting permits, the Agency may impose reasonable conditions in a permit specifically related to an applicant's past compliance history with this Act as necessary to correct, detect or prevent noncompliance." (As discussed above, the Act also provides that permits may include conditions as may be necessary to accomplish the purposes of the Act and as are not inconsistent with Board regulations.) For certain points in the Denial Letter, this provision of the Act is cited as one that may be violated because the 2022 application does not include information that may be needed for the Illinois EPA to impose conditions to enable or facilitate future compliance.

Section 39.5(5)(e): A paragraph in Subsection 39.5(5) of the Act, "Applications and Completeness," in Section 39.5 of the Act, "Clean Air Act Permit Program." This provision requires that "Each submitted CAAPP application shall be certified for truth, accuracy and completeness by a responsible official in accordance with applicable regulations [i.e., 35 IAC 270.102 and the definition of "responsible official at Subsection 39.5(1) of the Act]. This provision is applicable for the review of the 2022 application as US Steel requests in this application that the processing of the revised permit that is requested be subject to Integrated Processing. As a consequence, the procedural and substantive requirements of Section 39.5 of the Act apply to the 2022 application pursuant to Section 39.5(13)(c)(v) of the Act, which provides the authorization for Integrated Processing of a construction permit.

Section 39.5(5)(i): A paragraph in Subsection 39.5(5) of the Act, "Applications and Completeness," in Section 39.5 of the Act. As already explained, the procedural and substantive requirements of the CAAPP are applicable to the Illinois EPA's review of the 2022 application as US Steel has requested that this application and any resulting revised permit prepared pursuant to this application be subject to Integrated Processing. The first sentence in this provision requires that:

> Any applicant who fails to submit any relevant facts necessary to evaluate the subject source and its CAAPP application or has submitted incorrect information in a CAAPP application shall, upon becoming aware of such failure or incorrect submittal, submit supplementary facts or correct information to the Agency."

For several denial points, Subsection 39.5(5)(i) of the Act is identified as a provision of the Act that might be violated if a revised permit were issued as requested by the 2022 application because it does not include "relevant information" necessary for the evaluation of the application. That is, as

related to the particular applicable requirements, the application lacks information addressing the requirements, the information in the application addressing the requirement is insufficient, or the information in the application supports a finding that the requested revisions might not comply with the requirements. Note that as Subsection 39.5(5)(i) of the Act would not be satisfied by an application, a CAAPP permit cannot be issued pursuant to such application. This is because Subsection 39.5(10)(a)(iv), one of the standards for issuance of a CAAPP permit, would also not be satisfied.

Section 39.5(7)(a): A paragraph in Subsection 39.5(7) of the Act, "Permit Content," in Section 39.5 of the Act. This paragraph requires that "All CAAPP [Clean Air Act Permit Program] permits shall contain limitations and conditions and other enforceable terms and conditions, including but not limited to operational requirements, and schedules for achieving compliance at the earliest reasonable date, which are or will be required to accomplish the purposes and provisions of this Act and to assure compliance with all applicable requirements [emphasis added]." For various points in the denial letter, this provision is cited as a provision of the Act that may be violated because the 2022 application does not include information that may be needed for the Illinois EPA to impose necessary permit conditions in a revised version of Permit 95010001 that would be revised as requested by the application. This provision is relevant to the Illinois EPA's review of the 2022 application as US Steel has requested that the application and any resulting permit be subject to Integrated Processing. As provided by Sections 39.5(13)(a) and (a)(iv), as listed below, this makes the application subject to substantive requirements of the CAAPP. It is also noteworthy that, absent Integrated Processing, any revised construction permit that is issued pursuant to the 2022 application would not resolve US Steel's pending appeal of the current CAAPP permit for the Granite City Works (PCB 2013-53) or the related appeal of Construction Permit 11050006 (PCB 2013-62). Resolution of these appeals would require a separate CAAPP permit application and a permit proceeding to revise the CAAPP permit. Moreover, the revised CAAPP permit that would result from the CAAPP proceeding would not necessarily reflect the terms and conditions established in the earlier revision of Permit 95010001. As such, resolution of these appeals could require two more permit proceedings, i.e., a proceeding to modify the CAAPP permit and another proceeding for revisions to Permit 95010001 to address issues identified during the modification of the CAAPP permit.)

Section 39.5(10)(a)(iv): A paragraph in Subsection 39.5(1) of the Act. As Subsection 39.5(5)(i) of the Act would be violated if a revised permit were issued as requested, the 2022 application also would not satisfy Subsection 39.5(10)(a)(iv) of the Act, one of the standards for issuance of a permit under the CAAPP. This is because this application would not include all "relevant information." Subsections 39.5(10)(a) and (a)(iv) of the Act provide that:

> The Agency shall issue a CAAPP permit, permit modification, or permit renewal if all of the following conditions are met:
>
> …

(iv) The Agency has received a complete application and if necessary, has requested and received additional information from the application consistent with Subsection 5 of this Section and applicable regulations.

Section 39.5(13)(c)(v): Paragraphs (a) and (c)(v) in Subsection 39.5(13) of the Act, "Administrative Permit Amendments," in Section 39.5 of the Act. The designation "Section 39.5(13)(c)(v)" or "39.5(c)(v)" are used to refer to these paragraphs. These paragraphs contain the authorization for the Integrated Processing of a construction permit so as to allow the related revisions to the CAAPP permit to be made by administrative amendment, thereby avoiding the need for a subsequent modification of the CAAPP permit by either a minor or significant modification, as appropriate. These paragraphs of Subsection 39.5(10)(c) of the Act provide:

c. For purposes of this Section [Section 39.5 of the Act] the term "administrative amendment " shall be defined as a permit revision that can accomplish one or more of the changes described below:

…

v. Incorporates into the CAAPP permit the requirements from preconstruction review permits under a USEPA-approved program [i.e., Illinois construction permit program for sources of emissions and air pollution control equipment], provided the program meets procedural and compliance requirements substantially equivalent to those contained in this Section [emphasis added].

For various denial points in the denial letter, these paragraphs are cited as provisions of the Act that may be violated because the 2022 application is not sufficient for the Illinois EPA to impose necessary permit conditions in a new version of Permit 95010001 that would be revised as requested by the 2022 application. That is, this application does not include information that is necessary to enable such a revised permit to meet the compliance requirements, i.e., the substantive requirements, that must be satisfied by a CAAPP permit. For example, for certain emissions units, the Application requests that Permit 95010001 be revised to prescribe the actual emission factors that are to be used to determine compliance with limitations on annual emissions set by this permit. However, the application does not provide the supporting information that USEPA has found necessary for a permitting authority, e.g., the Illinois EPA, to set "prescribed emission factors" when issuing a Title V Permit. Similarly, the 2022 application requests certain revisions to the organization and terminology in Permit 95010001 for consistency with the CAAPP permit. However, the application does not request all such revisions that may be appropriate to reasonably achieve consistency in the organization and terminology of these permits.

Appendix B: Listing of Provisions in Subtitle B of Title 35 of the Illinois Administrative Code (IAC) That Are Cited for the Different Denial Points Detailed in Attachment 1 As Provisions Which May Be Violated If a Revised Permit Were To Be Granted As Requested by the 2022 Application

Note: The text of Illinois' regulations for control of air pollution (Illinois Administrative Code (IAC), Title 5, Subtitle B: Air Pollution, are available on a website maintained by the Board: https://pcb.illinois.gov/SLR/IPCBandIEPAEnvironmentalRegulationsTitle35

35 IAC Part 201, Permits and General Provisions

35 IAC 201.152*, Contents of Application for Construction Permit
This rule requires that applications for construction permits include certain data and information. The designation "201.152*" is used to refer to this rule as it requires this data and information to include "information concerning processes to which the emission unit or air pollution control equipment is related.

35 IAC 201.152**, Contents of Application for Construction Permit
This rule requires that applications for construction permits include certain data and information. The designation "201.152**" is used to refer to this rule as it requires this data and information to include "the quantities and types of raw materials to be used in the emission source or air pollution control equipment."

35 IAC 201.152***, Contents of Application for Construction Permit
This rule requires that applications for construction permit include certain data and information. The designation "201.152**" is used to refer to this rule as it requires this data and information include "… the nature, specific points of emissions and quantities of uncontrolled and controlled air contaminant emissions at the source that includes the emission unit or air pollution control equipment …."

35 IAC 201.159, Signatures
This rule requires applications for air pollution control permit submitted to the Illinois EPA to be signed. It provides that, "All applications and supplements thereto shall be signed by the owner and operator of the source, or their authorized agent, and shall be accompanied by evidence of authority to sign the application."

35 IAC 201.160(a)(1), Standards for Issuance
In 35 IAC 201.160(a) and (a)(1), the Pollution Control Board (Board) restates the standard of issuance in Section 39(a) of the Act for the Illinois EPA to issue a permit as applied specifically to air pollution control construction permits. This rule provides:

a) No construction permit shall be granted unless the applicant submits proof to the Agency that:

1) The emission unit or air pollution control equipment will be constructed or modified to operate so as not to cause a violation of the Act or of this Chapter [Title 35, Subtitle B, Chapter I)];

35 IAC Part 203, Major Stationary Sources Construction and Modification

(35 IAC Part 203 is potentially of concern for the Production Increase Project for emissions of NOx, VOM and particulate. This is because, in 1996, when Permit 95010001 was initially issued for this project, the Granite City Works was in areas that were designated nonattainment for the National Ambient Air Quality Stands (NAAQS) for ozone (emissions of NOx and VOM) and particulate matter (emissions of $PM_{2.5}$). The Granite City Works is still in an area that is designated nonattainment for ozone.)

35 IAC 203.123, Federally Enforceable (Definition)
This definition provides that "Federally Enforceable" means enforceable by the United States Environmental Protection Agency [USEPA].” This definition is cited as a basis for certain denial points as the 2022 application requests revisions to Permit 95010001 to set limitations that would take the place of limitations currently in Permit 95010001. However, the application does not include information showing that these proposed limitations should be considered enforceable as a practical matter.

35 IAC 203.128, Potential to Emit (Definition)
This definition of “potential to emit” is cited as a basis for denial points as related to the role of permit limitations, as distinguished from the physical and operational design of a stationary source, in restricting the potential emissions of emission units. 35 IAC 203.128, along with 35 IAC 203.122, are cited as a basis for denial as the 2022 application does not show that certain emission limitations that are proposed, which would replace emission limitations currently in Permit 95010001, should be considered enforceable as a practical matter. In this regard, the second sentence of this definition of “potential to emit” provides that:

Any physical or operational limitation on the capacity of the source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design only if the limitation or the effect it would have on emissions is federally enforceable [emphasis added].

35 IAC 203.201, Prohibition
This provision requires an entity that would undertake a project that is "major" for a pollutant in an area that is designated a nonattainment area for the pollutant to comply with the substantive requirements of 35 IAC Part 203 for that pollutant. The various substantive requirements are then addressed later in Subpart C of 35 IAC Part 203. In this regard, the first two sentences of 35 IAC 203.201 provide:

> In any nonattainment area, no person shall cause or allow the construction of a new major stationary source or major modification that is major for the pollutant for which the area is designated a nonattainment area, except as in compliance with this Part [Part 203]for that pollutant. In areas designated nonattainment for ozone, this prohibition shall apply to new major stationary sources or major modifications of sources that emit volatile organic materials or nitrogen oxides.

As the revised NSR applicability analysis for NOx in the 2022 application does not show that the Production Increase Project would not have been a major modification for NOx with the increases in permitted NOx emissions that are being requested, 35 IAC 203.201 is cited as a basis for denial of this application. This is because the application also does not show that the substantive requirements of 35 IAC Part 203 would be fulfilled as the Project is now a major modification. For example, the 2022 application does not address the requirement in 35 IA3.302 that, as related to the role of emissions of NOx on air quality for ozone, an entity undertaking a major project for NOx in an ozone nonattainment area must provide emission offsets for NOx to compensate for the effect of the project's NOx emissions on ozone air quality.

35 IAC 203.203(b), Construction Permit Requirements and Application
For major projects that would be subject to 35 IAC Part 203, this rule sets forth the information that a permit application must contain. This rule provides that:

> Applications for construction permits required under this Section shall contain sufficient information to demonstrate compliance with 35 Ill. Adm. Code 201 [Permits and General Provisions] and the requirements of this Part [Part 203] including, but not limited to, Subpart C [Requirements for Major Stationary Sources in Nonattainment Areas, including the requirements for the Lowest Achievable Emission Rate (LAER) and the requirement to provide emission offsets].

35 IAC 203.208*, Net Emissions Determination – The Increase in Emissions from a Project
Among other aspects of "netting," this rule sets forth how the increases in emissions from a project should be addressed if a source elects to rely on netting with contemporaneous emissions decreases to show that a project would not be a major modification under 35 IAC Part 203. The first paragraph of this rule, referred to as "35 IAC 203 208*" is cited as a basis for denial of the 2022 application as the revised NSR applicability analysis for NOx in the application, which should address NOx emissions of the Production Increase Project, with the increases in permitted NO_X emissions that are now being requested. For certain units, this analysis does not show that the increases in NOx emissions from the Project have been properly addressed. For a project, itself, this rule provides that the increase in actual emissions due to the project should be addressed. However, since the amount of this increase should be determined during permitting,

i.e., before the project is implemented and the modified units begin normal operation with the project, 35 IAC 203.104(c) further provides that the Illinois EPA shall presume that the potential emissions of units with the project are equivalent to their actual emissions for purposes of permitting. (The circumstances are similar for permitting for a project that was improperly constructed without first obtaining a construction permit. This is because such source cannot rely on permit limitations in lieu of potential emissions absent enforceable limitations.) In particular, the first sentence in 35 IAC 203.208 provides:

> A net emissions increase is the amount by which the sum of any increase in actual emissions from a particular physical change or change in method of operation at a source [emphasis added], and any other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable, exceeds zero.

35 IAC 203.208**, Net Emissions Determination - The Contemporaneous Time Period and Creditability of Emission Decreases

As discussed above, 35 IAC 203.208 lays out the requirement for a NSR Applicability Analysis if a source elects to rely on netting to show that a project would not be a major modification under 35 IAC Part 203. 35 IAC 203.208(a) and (c)(1), referred to as 35 IAC 203.208**, are also cited as a basis for denial of the 2022 application. This is because the revised NSR applicability analysis for NOx in the application, which addresses NOx emissions with the increases in permitted emissions that are being requested for certain units, would improperly rely on certain decreases in NOx emissions that are neither contemporaneous nor creditable. This is contrary to 35 203.208(a) and (c), which do not allow credit in the revised NSR applicability analysis for NOx based on decreases in emissions due to the shutdown of Boilers 1 through 10 and, due to the shutdown of the two by-product recovery coke oven batteries at the Granite City Works, coke oven gas (COG) no longer being available for use in Project-affected fuel burning units.as a fuel. These actions and the accompanying emission decreases occurred after the implementation of the Production Increase Project and were not contemplated by Permit 95010001. In particular, the introductory paragraph in 35 IAC 203.208 and paragraphs 35 IAC 203.208(a) and (c)(1) provide:

> A net emissions increase is the amount by which the sum of any increase in actual emissions from a particular physical change or change in method of operation at a source, and any other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable, exceeds zero. The following steps determine whether the increase or decrease in emissions is available.
>
> a) Except for … [alternative provisions for projects in in serious and severe ozone nonattainment areas], an increase or decrease in actual emissions is contemporaneous only if it occurs between the date that an increase from a particular change occurs and the date five years before a timely and complete application is submitted for the particular change. …
>
> …

c) A decrease in actual emissions is creditable to the extent that:

1) It is federally enforceable at and after the time that actual construction on the particular change begins;

35 IAC 203.301, Lowest Achievable Emission Rate
For a project that is a major modification subject to 35 IAC Part 203, 35 IAC 203.301 sets forth the requirements for a permit application related to Lowest Achievable Emission Rate (LAER) for the emissions units for which LAER is required. 35 IAC 203.301(c) sets forth the requirement that LAER be demonstrated for such emission units. (Ongoing operation of LAER-subject units to comply with LAER is required by 35 IAC 203.601 once a permit is issued setting forth what LAER is for those units.) For the emission units and pollutant(s) for which LAER is required, 35 IAC 203.301(d) explicitly requires that the application include a detailed showing that the emission limitations proposed for the LAER-subject units would constitutes LAER. In this regard, these rules provide that:

c) Except as provided in subsection (e) or (f) below [Alternative provisions for projects ozone nonattainment areas that are classified as serious or severe nonattainment] the owner or operator of a major modification shall demonstrate that the control equipment and process measures applied to the major modification will produce LAER. This requirement applies to each emissions unit at which a net increase in emissions of the pollutant has occurred or would occur as a result of a physical change or change in the method of operation.

d) The owner or operator shall provide a detailed showing that the proposed emission limitations constitute LAER. Such demonstration shall include:

1) A description of the manner in which the proposed emission limitation was selected, including a detailed listing of information resources,

2) Alternative emission limitations, and

3) Such other reasonable information as the Agency may request as necessary to determine whether the proposed emission limitation is LAER.

35 IAC 203.302(a), Maintenance of Further Reasonable Progress and Emission Offsets
For a major project that is subject to 35 IAC Part 203 for a pollutant, this rule sets forth the basic requirement that project be accompanied by emission offsets. Emission offsets are enforceable reductions in the emissions of the subject pollutant, usually by existing source(s) other than the source at which the project would take place, that affect the quality of the ambient air that the emissions of the subject pollutant from the project would affect. The role of the offsets is to counterbalance the effect of the emissions of the subject pollutant from the project on ambient air quality that exceeds the applicable National Ambient Air Quality Standard. In this regard, 35 IAC 203.302(a) provides that:

a) The owner or operator of a new major source or major modification shall provide emission offsets equal to or greater than the allowable emissions from the source or the

net increase in emissions from the modification sufficient to allow the Agency to determine that the source or modification will not interfere with reasonable further progress as set forth in Section 173 of the Clean Air Act (42 U.S.C. 7401 et seq.).

35 IAC Part 204, Prevention of Significant Deterioration

(35 IAC Part 204 is of concern or potential concern for the Production Increase Project for emissions of NOx, SO_2, CO and lead. This is because, when Permit 95010001 was initially issued, the Granite City Works was in various areas that were designated attainment or unclassified, rather than nonattainment, for the NAAQS for CO, SO_2 and lead. It was also in an area designated as attainment or unclassified for the NAAQS for nitrogen dioxide (NO_2). The areas in which the Granite City Works is located are still designated attainment or unclassified for these pollutants. (After the NAAQS for lead was revised in 2008, an area that includes the Granite City Works was then designated nonattainment for lead in 2010. This area was later redesignated to attainment for lead in 2018.)

35 IAC 204.280, Best Available Control Technology (BACT) (Definition)
This definition reflects USEPA's guidance at 40 CFR 51.166(b)(12) for the meaning of this term. It is noteworthy that this definition provides that BACT is to reflect the maximum degree of reduction of emissions for the unit(s) and pollutant(s) for which it is required as determined to be achievable ".. through production processes or available methods, systems and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of such pollutant." As such, in addition to the use of add-on air pollution control equipment, both a BACT demonstration and a BACT determination must consider approaches to reducing emissions other than tradition air pollution control equipment. In addition, this definition provides that while it is preferred that BACT be codified in a permit as an emission limitation or a limitation for visible emissions, "If the Agency determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible, a design, equipment, work practice, operational standard, or combination thereof, may be prescribed instead to satisfy the requirement for the application of BACT."

35 IAC 204.330, Complete (Definition)
For an application for a permit for a major project subject to PSD [Prevention of Significant Deterioration], this definition provides that, "'complete' means, that the application contains all of the information necessary for processing the application."

35 IAC 204.400, Federally Enforceable (Definition)
This definition of "federally enforceable" in 35 IAC Part 204 is similar to the definition at 35 IAC 203.123. This definition also expressly identifies certain limitations that are, by definition, considered enforceable by USEPA (e.g., "…requirements within the SIP, any permit requirements established under 40 CFR 52.21… or this Part [Part 204} or under regulations approved under 40 CFR 51 Subpart I …, including operating permits issued under a USEPA-approved program that is incorporated into the SIP and expressly requires adherence to any permit issued under such

program"). However, it does not provide that limitations in a construction permit are still federally enforceable even if they are not enforceable as a practical matter.

35 IAC 204.550*, Net Emissions Increase (Definition) – The Increase in Emissions from a Project
This provision, which is similar to at 35 IAC 203.208, "Net Emissions Determination," sets forth how the increases in emissions from a project should be addressed if a source elects to rely on netting to show that a project would not be a major modification under 35 IAC Part 204. 35 IAC 204.550(a)(1), referred to as 35 IAC 204.550*, is cited as a basis for denial of the 2022 application as the revised NSR applicability analysis for NOx in the application, which addresses NOx emissions with the increases in permitted emissions that are now being requested for certain units, does not show that certain increases in emissions from the project have been properly addressed. For a project itself, this rule, which did not become effective until October 12, 2021 (86 Federal Register 50459), provides that the increase in actual emissions due to the project should be addressed. However, the application does not address post-project actual emissions. As such, 35 IAC 204.600(a)(4) provides that the potential emissions of units with the project are to be used as their actual emissions for purposes of evaluating applicability of PSD. In 1996, when the Production Increase Project was initially permitted, the requirements for Net Emission Determinations and Net Emission Increase, under the NaNSR and PSD programs respectively, were essentially identical.

35 IAC 204.550**, Net Emissions Increase (Definition) - The Contemporaneous Time Period and Creditability of Emission Decreases
As discussed above, 35 IAC 204.550 lays out the requirement for a NSR Applicability Analysis if a source elects to rely on netting to show that a project would not be a major modification under 35 IAC Part 204. 35 IAC 204.550(b)(2)) and (e)(2), referred to as 35 IAC 203.208**, are also cited as a basis for denial of the 2022 application. This is because the revised NSR applicability analysis for NOx in the application, which addresses NOx emissions with the increases in permitted emissions that are being requested for certain units, would improperly rely on certain decreases in NOx emissions that are neither contemporaneous nor creditable. This is contrary to 35 204.208(b)(2)) and (c)(2), which do not allow credit in the revised NSR applicability analysis for NOx based on decreases in emissions due to the shutdown of Boilers 1 through 10 and the elimination of coke oven gas (COG) with the shutdown of the by-product recovery coke oven batteries at the facility. These actions and the resulting emission decreases occurred after the implementation of the Production Increase Project and were not contemplated by Permit 95010001. In particular, the introductory paragraph in 35 IAC 204.550(b) and (b)(2) and 35 IAC 204.550(e) and (e)(2) provide:

> b) An increase or decrease in actual emissions is contemporaneous with the increase from the particular change only if it occurs between:
>
> …
>
> 2) The date that the increase from the particular change occurs.
>
> e) A decrease in actual emissions is creditable only to the extent that:
>
> …

2) It is enforceable as a practical matter at and after the time that actual construction on the particular change begins;

35 IAC 204.560, Potential to Emit (Definition)
This definition of "potential to emit" is cited as a basis for denial points as related to the role of permit limitations, as distinguished from the physical and operational design of a stationary source, in restricting the potential emissions of emission units. 35 IAC 204.560, along with 35 IAC 204.400, are cited as a basis for denial as the 2022 application does not show that certain emission limitations that are proposed, which would replace emission limitations currently in Permit 95010001, should be considered enforceable as a practical matter. In this regard, this definition of "potential to emit" provides that:

> "Potential to emit" means the maximum capacity of a stationary source to emit a pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is federally enforceable or legally and practicably enforceable (emphasis added) by a state or local air pollution control agency. Secondary emissions do not count in determining the potential to emit of a stationary source.

35 IAC 204.810(a)(3), Source Information
This rule, with the introductory language in 35 IAC 204.810 and 204.810(a), addresses the information that an applicant must include in a permit application if a determination of BACT is required for the requested permit to be issued. In this regard, they provide that:

> The owner or operator of a proposed major stationary source or major modification shall submit all information necessary to perform any analysis or make any determination required under this Part.
>
> a) With respect to a source or modification to which Sections 204.1100, 204.1110, 204.1130, and 204.1140 apply, such information shall include:
>
> …
>
> 3) A detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that BACT, as applicable, would be applied.

35 IAC 204.820, Source Obligation
Any owner or operator who constructs or operates a source or modification not in accordance with the application submitted under this Part or with the terms of any approval to construct (emphasis added), or any owner or operator of a source or modification subject to this Part [35 IAC Part 204] who begins actual construction after September 4, 2020 without applying for and receiving approval under this Part, shall be subject to appropriate enforcement action.

35 IAC 204.1100(c), Control Technology Review
This rule sets forth the BACT requirement for a project that is a major project for pollutant(s) for purposes of Part 204. It provides that:

> A major modification shall apply BACT for each regulated NSR pollutant for which it would result in a significant net emissions increase at the source. This requirement applies to each proposed emissions unit at which a net emissions increase in the pollutant would occur as a result of a physical change or change in the method of operation in the unit.

35 IAC 204.1110, Source Impact Analysis
This rule requires that the applicant for a permit for a project that is a major project for pollutant(s) for purposes of Part 204 demonstrate that the project would not cause or contribute to violation(s) of the relevant National Ambient Air Quality Standard (NAAQS). In this regard, this rule provides that:

> The owner or operator of the proposed source or modification shall demonstrate that allowable emission increases from the proposed source or modification, in conjunction with all other applicable emissions increases [emphasis added] or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of:
>
> a) Any NAAQS in any air quality control region; …

35 IAC 204.1130, Air Quality Analysis
This rule requires that an applicant for a permit for a project that is a major project for pollutant(s) for purposes of Part 204 address the ambient air quality in the area that the project would affect for those pollutant(s). In this regard, 35 IAC 204.1130(a)(1) addresses a "Preapplication Analysis," requiring that:

> 1) Any application for a permit under this Part [35 IAC Part 204] shall contain an analysis of ambient air quality in the area that the major stationary source or major modification would affect for each of the following pollutants:
>
> A) For the source, each pollutant that it would have the potential to emit in a significant amount;
>
> B) For the modification, each pollutant for which it would result in a significant net emissions increase.
>
> …
>
> 3) With respect to any such pollutant for which such a NAAQS does exist, the analysis shall contain continuous air quality monitoring data gathered for purposes of determining whether emissions of that pollutant would cause or contribute to a violation of the standard or any maximum allowable increase.
>
> 4) In general, the continuous air quality monitoring data that is required shall have been gathered over a period of at least one year and shall represent at least the year preceding receipt of the application. However, if the Agency determines that a

> complete and adequate analysis can be accomplished with monitoring data gathered over a period shorter than one year (but not less than four months), the data that is required shall have been gathered over at least that shorter period.
>
> …
>
> 35 IAC Part 270 Clean Air Act Permit Program Procedures

35 IAC 270.401(f), General Application Information (Certification)
This rule expands upon the certification that Clean Air Act Permit Program (CAAPP) applications must contain pursuant to Subsection 39.5(5)(f) of the Act, requiring that such certifications by a responsible official for the source must be based upon information and belief after reasonable inquiry. It provides that:

> A CAAPP application shall contain a certification by a responsible official that, based on information and belief formed by the responsible official after reasonable inquiry, the statements and information in the application are true, accurate, and complete. This certification shall be dated and signed by the responsible official.

Illinois Environmental Protection Agency

Notice of Intent to Deny
Revised Draft Denial Letter and New Public Comment Period
Application for a Revision to a Construction Permit/PSD Approval
US Steel Corporation in Granite City

United States Steel Corporation (US Steel), 1951 State Street, Granite City, has applied to the Illinois Environmental Protection Agency (Illinois EPA) for a revision to an air pollution control construction permit/PSD (Prevention of Significant Deterioration) approval that was originally issued in 1996 for a production increase project at its steel mill located in southeastern Granite City (the Granite City Works). This facility emits particulate, sulfur dioxide, lead, volatile organic material, nitrogen oxides (NOx), and carbon monoxide (CO). The application requests increases in permitted emissions of CO, which the original application understated. As the application requests increases in permitted CO emissions for which the project originally was a major modification subject to PSD, the current application must address compliance with Illinois' rules for PSD, 35 Illinois Administrative Code Part 204. The application also does not show that the requested increase in NOx emission would not make the project a major modification for NOx. Based on its review of the application, the Illinois EPA has made a preliminary determination that the current application does not comply with the applicable air pollution control regulations.

As the application requests revisions to provisions of the permit that would relate to PSD, the Illinois EPA must prepare a draft permit denial letter for public review and comment. A draft permit denial letter was previously made available beginning in July 2023. By this notice, the Illinois EPA, is announcing that it has prepared a revised draft permit denial and is now making this "revised draft denial letter" available for public review and comment. In response to certain comment that were received on the initial draft denial letter, this revised draft denial letter more clearly sets forth the sections of the Illinois Environmental Protection Act, the provision(s) of Title 35 Subtitle B: Air Pollution of the Illinois Administrative Code, and the reasons that would be the basis for the Illinois EPA's proposed denial of this application.

The Illinois EPA is accepting comments prior to making a final decision on this application. **Comments must be postmarked by 11:59 pm, January 8, 2024.** All persons, including the applicant, shall raise all reasonably ascertainable issues and submit all reasonably available arguments supporting their position by the close of the public comment period.

If sufficient interest is expressed in this matter, a hearing or other informational meeting may be held. Comments, questions and requests for information should be directed to

Brad Frost, Office of Community Relations, Illinois EPA, PO Box 19506, Springfield, IL 62794-9506, phone 217/782-7027, TDD 866/273-5488, brad.frost@illinois.gov.

Persons wanting more information may view the draft permit denial letter and project summary at https://epa.illinois.gov/public-notices/boa-notices.html The repository for these documents and the application is located at the Illinois EPA's offices at 1101 Eastport Plaza Drive, Suite 100, Collinsville, 618/346-5120 and 1021 N. Grand Ave. East, Springfield, 217/782-7027. (Please call ahead to assure that someone will be available to assist you). Copies of the documents will be made available upon request to the contact listed above.

The facility is located in a potential Environmental Justice area. More information concerning Environmental Justice may be found at https://epa.illinois.gov/topics/environmental-justice.html

December 2023

Project Summary for the Proposed Denial of an Application* from United States Steel Corporation – Granite City Works for Revisions to a Construction Permit/PSD Approval Issued for a Production Increase Project at its Mill in Granite City

Note : This Project Summary has been prepared to accompany the public comment period that the Illinois EPA is holding on a Revised Draft Denial Letter, which has been prepared in response to certain comments that were received on the initial Draft Denial Letter.

Site Identification No.: 119813AAI
Permit/Application No.: 95010001

Illinois EPA Contacts:
Review Engineers: Minesh Patel, Christopher Romaine and Jason Schnepp
Community Relations Coordinator: Brad Frost

Schedule for Public Comment Period:
Comment Period Begins: December 8, 2023
Comment Period Scheduled to Close: January 8, 2024

*. In its application, U. S. Steel asks that the requested revisions of Permit 95010001 be processed by the Illinois EPA with "Integrated Processing," as is allowed by Section 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act. Integrated Processing of the revised permit would allow changes to the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, as would be set forth in the revised permit, to subsequently be made by means of an Administrative Amendment of the CAAPP permit. Integrated Processing would require that the revision of the permit provide for compliance requirements that are substantially equivalent to those that are required in CAAPP permits. The processing of the permit must also be subject to procedural requirements that are substantially equivalent to those that apply for issuance CAAPP permits, including an opportunity for USEPA to review and comment upon a proposed version of the revised permit following completion of a public comment period on the draft of the revised permit.

1. Introduction

United States Steel - Granite City Works (US Steel) has applied to the Illinois EPA for revisions to an air pollution control construction permit (Permit 95010001) for a project at its Granite City Works, the steel mill in Granite City. This project (the "Project") involved increases in the permitted production of iron and steel by this facility. As this facility is a source of emissions, Permit 95010001 provided approval for the Project under both Illinois' construction permit programs for sources of emissions and the Prevention of Significant Deterioration (PSD) program under the federal Clean Air Act. This permit was originally issued in January 1996 to National Steel and was transferred to US Steel after it became the owner of the facility. This proposed denial involves the US Steel's revised application submitted in October 2022 (the "2022 application").

A key reason why revisions to Permit 95010001 are needed is that emission testing conducted in 2014 on the two basic oxygen furnaces (BOFs), in which steel is produced, showed their emissions of nitrogen oxides (NOx), as well as volatile organic material (VOM), are higher than is allowed by this permit. This is because the original application understated the NOx and VOM emissions of the BOFs and the emission limits in this permit were based on information in the original application.

US Steel has worked to prepare an application for revisions to Permit 9501001 that would allow more emissions of NOx and VOM from the BOFs. The 2022 application also addresses other issues that are now posed by the manner in which the Project was originally permitted and subsequent changes that have occurred at the facility. Notably, the emissions of carbon monoxide (CO) of certain units have also been found to be higher than stated in the original application. A baghouse control system has been installed for the BOFs to improve control of particulate emissions from charging and tapping of these furnaces. The byproduct coke oven batteries formerly at the facility were shut down in 2015. A brief description of some of the revisions to Permit 95010001 that US Steel has requested is provided at the back of this document in Appendix 1. The requested revisions do not include increases in the permitted iron and steel production of the facility as allowed by this permit as issued in 1996.

The Illinois EPA has made a preliminary determination that the 2022 application should be denied. The reasons for this are now set forth in the revised draft of the proposed denial that has been prepared. Brief descriptions of the reasons why the Illinois EPA has determined that the 2022 application should be denied are provided in Appendix 2 of this document. For some requested revisions to Permit 95010001, the application should be denied because it does not show that they would comply with the relevant regulatory requirements and USEPA policy that apply to this permit. For other requested revisions, the application does not include the information needed to support those revisions or enable those revisions to be made as a practical matter. In addition, the application should be denied because it would not allow for processing of a revised permit with Integrated Processing, as has been requested. If the Illinois EPA's final decision is to deny this application, it is expected that Permit 95010001 would continue in effect as it now exists until and unless action is taken on a subsequent application.

As required by the PSD program, the Illinois EPA **must** hold a public comment period on its preliminary determination that the 2022 application should be denied and the draft denial letter that has been prepared. This will allow for the public to consider and comment on this planned action

and the draft of the denial letter that the Illinois EPA has prepared. The Illinois EPA previously prepared a draft of its proposed denial letter and made it available for a public comment period that began in July 2023. The Illinois EPA has now prepared a revised draft of its proposed denial letter and is again making it available for public review and comment. This revised draft of the proposed denial letter more clearly sets forth the sections of the Illinois Environmental Protection Act, the provision(s) of Title 35 Subtitle B: Air Pollution of the Illinois Administrative Code, and the reasons that would be the basis for the Illinois EPA's proposed denial on the 2022 application. For this purpose, for each denial point, Attachment 1 of the revised draft denial letter now includes an overview of the laws, rules and reasons that would be the basis for the Illinois EPA's proposed denial of this application. This is followed by the explanation and discussion that were provided in the initial draft denial letter with, as specifically denoted, corrections to certain numerical emission data and a date in the initial draft denial letter. The revised permit denial letter also has two appendices. Appendix A lists the various sections of the Act that are cited in Attachment 1 as the statutory basis for this denial letter, with description and, in some cases, general explanation why the section might be violated if Permit 95010001 were to be revised as requested by this application. Appendix B lists the various provisions in Subtitle B of Title 35 of the Illinois Administrative Code that are cited as the regulatory basis for this denial letter, with description and, in some cases, general explanation why the provision might be violated if Permit 95010001 were to be revised as requested by this application.

This project summary for the revised draft of the proposed denial letter is identical to the initial project summary except as it explains that a revised draft denial letter has now been prepared and is being made available for public review and comment and this project summary now also makes corrections to certain details in the project summary that accompanied the initial draft denial letter.

2. Background on the Granite City Works

The Granite City Works are an integrated steel mill, making both iron and steel. It has two blast furnaces to make iron from iron ore and an associated casthouse located between them in which tapping of iron and slag from the furnaces take place . Two basic oxygen furnaces (BOFs) are used to process iron from the blast furnaces, together with scrap metal, into steel. Before molten iron from the blast furnaces is charged to a BOF vessel, the iron undergoes "desulfurization" with a reagent to remove sulfur from the iron. Ladles of molten steel produced in the BOFs are transferred to "ladle metallurgy" where with the final additions of alloying materials are made to the molten steel. The two basic oxygen furnaces, the iron desulfurization operation, and the ladle metallurgy operations are all located in the basic oxygen furnace shop (BOF shop). From ladle metallurgy, the ladles of molten steel are transferred to the continuous casters in an adjoining building. The solid steel slabs from continuous casting are processed in rolling mills at the source, which make long, thin strips of steel that are wound in coils. Steel slabs from the casters also go to other plants to be made into finished steel.

Other operations at the Granite City Works include raw material handling and storage, steam boilers, and fuel-burning process equipment. The raw material handling and storage operations handle raw materials, such as iron ore pellets, limestone and other fluxing agents, coke, and alloy materials, for the iron and steel making operations. The steam boilers can burn both natural gas and blast furnace gas (BFG). BFG is a low heat content gaseous byproduct from the blast furnaces. BFG is the principal fuel for the blast furnace stoves in which the blast air supply for these furnaces is

heated. Other fuel-burning process equipment at the source burns natural gas. Vehicle traffic on roads and parking lots at the Granite City Works also is a source of emissions of fugitive dust.

The Granite City Works formerly included two by-product recovery coke oven batteries and associated by-product processing plant. These operations were permanently shut down in February 2015. The primary source for coke used in the blast furnaces is now two heat recovery coke oven batteries in Granite City that are operated by Gateway Energy. With the shutdown of the by-product recovery coke oven batteries, coke oven gas is no longer produced and available for use in the blast furnace stoves, boilers and other fuel-burning equipment at the Granite City Works that previously used coke oven gas to provide a portion of their fuel.

Granite City is located in Madison County, which is part of the S. Louis Major Metropolitan Area. Madison County is designated nonattainment under the federal Clean Air Act for the National Ambient Air Quality Standard (NAAQS) for ozone.[1] For other pollutants for which there are NAAQS, i.e., carbon monoxide (CO), lead, nitrogen dioxide (NO_2), particulate matter$_{10}$ (PM_{10}), particulate matter$_{2.5}$ ($PM_{2.5}$) and sulfur dioxide (SO_2), Madison County is designated attainment or unclassifiable. USEPA maintains information about current ambient air quality for ozone and particulate on the internet at AirNow (airnow.gov). The Illinois EPA prepares annual reports for ambient air quality as measured by its network of air monitoring stations around the states. These reports are also available on the internet (epa.illinois.gov/topics/air-quality-reports).

The Granite City Works are in an area that is of concern for Environmental Justice. As such, any proposed permit actions involving this facility are subject to the Illinois EPA's "Environmental Justice Policy." As addressed in this policy, the Illinois EPA is committed to protecting the environment and the health of the residents of Illinois, and to promoting equity in the administration of its environmental programs.

3. The Production Increase Project or the "Project"

In January 1996, National Steel, the former owner of the Granite City Works was issued Construction Permit 95010001 for increases in the allowable production of iron and steel by the Granite City Works, also referred to as the "Production Increase Project" or the "Project." As explained at that time, the increases in production would in part involve continuing improvements in the operation and maintenance of equipment, which is something that normally occur over the course of time. These would involve things such as the availability and use of ore pellets with higher yield, the availability and use of better refractories linings for furnaces, and ongoing improvements in maintenance practices that would reduce the frequency and duration of furnace outages for maintenance. However, the Project also involved certain physical changes to emission units to enable increased production of iron, i.e., changes to the blast furnace stove blowers to increase their air flow capacity. As such, the Project entailed a modification to the Granite City Works for which an air pollution control construction permit was needed.

[1] Air quality designations are adopted by USEPA. The designations for Illinois are found at 40 Code of Federal Regulations (CFR) 81.314.

National Steel's application for a construction permit for the Project addressed its implications for emissions of the iron and steel making operations and other operations at the Granite City Works that would be affected. The application showed that the increases in emissions from the Project would be significant so that the Project was a major modification for sulfur dioxide (SO_2)and carbon monoxide (CO) under the federal rules for Prevention of Significant Deterioration (PSD), 40 CFR 52.21, as governed in 1996.[2] In this regard, in 1996, Granite City was located in areas that were designated attainment for the NAAQS for SO_2 and CO. The application submitted by National Steel addressed the substantive requirements of the PSD rules, as they applied to the Project for SO_2 and CO. For example, the application addressed the use of Best Available Control Technology (BACT) for the casthouse at the blast furnaces as it was identified as emitting SO_2 and the blast furnace stoves as they were identified as emitting SO_2 and CO. The Illinois EPA found that emissions of these pollutants from these units would be appropriately controlled with measures that reflected BACT.

National Steel's application showed that Project was not a major modification for other pollutants. For lead, the application showed that the increase in lead emissions would not be significant. For particulate matter (PM),[3] particulate matter$_{10,}$[4] nitrogen oxides (NOx) and volatile organic material (VOM), the application showed that the net increases in emissions from the Project, considering contemporaneous decreases and increases in emissions, would not be significant. For example, the shutdown of ingot casting and the associated blooming mill at the Granite City Works provided emission decreases that were contemporaneous with the emission increases from the Project. Accordingly, for lead, PM, PM_{10}, NOx and VOM, the permitting of the Project did not address the substantive requirements of PSD or Illinois's rules for Major Stationary Sources Construction and Modification (MSSCAM), 35 IAC Part 203 (more generally referred to as Nonattainment New Source Review or "NaNSR").

In this regard, in 1996, Granite City was located in areas that were attainment for PM and NO_2.[5] National City's application showed that the net increases in emissions of these pollutant from the Project (i.e., the increases in emissions after considering contemporaneous increases and decreases in emissions) would be below the rates that would be considered to be significant under PSD (25 and 40 tons/year for PM and NOx , respectively). In 1996, Granite City was located in areas that

[2] In 1996, the Illinois EPA administered the USEPA's PSD rules at 40 CFR 52.21 under a delegation agreement with USEPA. The Illinois EPA now implements the PSD program through states regulation at 35 IAC Part 204, which have been approved by USEPA as part of Illinois' State Implementation Plan.

[3] Particulate matter (PM), as addressed by the application and relevant USEPA and Illinois rules, only includes filterable particulate and not condensable particulate. Relevant rules provide that measurements of PM emissions are to be made by test methods that are designed to only measure filterable particulate.

[4] For particulate matter$_{10}$, the application only addressed filterable emissions and not condensable emissions. As subsequently addressed in USEPA rules, emissions of condensable particulate were not regulated as a constituent of particulate matter$_{10}$ before January 1, 2011 [40 CFR 51 Appendix S, Emission Offset Interpretative Ruling, Part II, (A)(31)(ii)(*a*)].
In Illinois' rules, filterable particulate matter$_{10}$ is referred to as "PM-10;" condensable particulate as "condensible PM-10." This usage is confirmed in 35 IAC 212.108(a) and (b) by the methods that are specified for emissions testing.

[5] For purposes of PSD and MSSCAM, NOx was initially regulated as a precursor to the formation of nitrogen dioxide (NO_2) in the atmosphere. As addressed in the Clean Air Act as amended in 1990, NOx also became also regulated as a precursor to the formation of ozone. Finally, NOx is now also regulated as it is a precursor to $PM_{2.5}$.

were designated nonattainment for NAAQS for ozone and PM_{10}. Madison County was and continues to be nonattainment for ozone. The part of Madison County that was nonattainment for PM_{10} included Granite City. For VOM and NOx, as they are regulated as precursors to ozone in the atmosphere, National City's application showed that the net increases in emissions from the Project would be below the rates that would be significant under MSSCAM (40 tons/year for both VOM and NOx). For PM_{10},the application showed that the net increase in PM_{10} emissions from the project would also be below the rate that would be significant under MSSCAM (15 tons/year).

When issuing Permit 95010001 for the Project in 1996, the Illinois EPA included various limits to hold National Steel to the representations made in the application and make those representations enforceable. The future annual production of iron by the blast furnaces and steel by the BOFs were limited to the maximum production levels requested by National Steel in the application. The future annual emissions of different pollutants from the various process units affected by the Project were limited. For the BOFs, whose particulate emissions were only controlled by an electrostatic precipitator (ESP) add-on control system in 1996, separate emission limits were set for the emissions from ESP and the uncaptured emissions from open roof monitor above the BOFs. For fuel-burning units, e.g., the blast furnace stoves and boilers, emissions limits for different pollutants were set collectively for the group of such units, rather than individually. However, separate limits were set for the emissions from burning BFG, natural gas and fuel oil.[6] The annual emission limits for different pollutant were accompanied by "emission factor limits" that addressed emissions in pounds per ton of iron or steel produced or handled, or for the fuel-burning units, emissions in pounds per volume of fuel burned. The permit required emission testing to be conducted for certain units following issuance of the permit to verify compliance with the requirements of the permit. [7, 8]

The Illinois EPA also included certain requirements in Permit 95010001 for the BOFs that were more stringent than those that had previously applied.[9] The opacity of emissions from the roof

[6] For fuel burning units, the permit did not set limits for emissions from the burning of coke oven gas (COG). The operation of the by-product coke oven batteries at the Granite City Works and the associated production of COG was considered to be unaffected by the increased production of iron by the blast furnaces. As a matter of good practice, coke oven batteries are operated at a stable production rate that is consistent with the design and conditions of the batteries. To the extent that the amount of coke produced at a source is more or less than is needed by the source, surplus coke can readily be shipped to other sources, or the deficit made up with coke shipped in from other sources.

[7] For the blast furnaces, emission testing was required for the baghouse that controls particulate emissions of the casthouse, i.e., the structure that encloses the area where molten iron and slag are periodically tapped from the bottoms of the blast furnaces, with testing required PM, VOM, SO_2 and NOx, as well as for opacity. For the BOFs, testing was required for the ESP control system for emissions of PM, CO and lead, as well as for opacity. Testing for emissions of PM was also required for the baghouse that control iron molten iron desulfurization operation that precedes the BOFs and from a representative steam boiler while burning BFG.

[8] The permit stated that the BACT requirement of the PSD rules would be met for SO_2 and CO. However, the permit did not identify specific emission limits or practices that were determined to be BACT for the BACT-subject units. For CO, the specific limits or practice that would be considered to be BACT would be addressed with the proposed revisions to this permit. For CO. US Steel has identified the existence of emissions and higher levels of emissions from the blast furnace casthouse and stoves, respectively. As such, for these unit, BACT for CO must be reevaluated. For SO_2, US Steel has not requested increases in permitted annual emissions. Therefore, BACT for SO_2 does not need to be reevaluated. It would nevertheless be reasonable in the revised permit to identify requirements that are considered to be BACT for SO_2.

[9] The PM-10 emissions of the Granite City Works with the Project were of singular concern to the Illinois EPA. In 1996, an area that included Granite City was designated as nonattainment for PM_{10} air quality. The

monitor was limited to 20 percent on a 3-minute average, from 30 percent on a 6-minute average. Specific practices that were required to be used to reduce particulate emissions of the BOFs. For example, use of flame suppression was required during tapping of a BOF, when molten steel and slag are poured from a BOF into a ladle. Minimum values were set for the air flow through the hoods that capture the particulate emissions of the BOFs for control by the ESP, with different values set for the charging, refining, and tapping steps in the operation of a BOF. A housekeeping program was required for the area below the ESP where collected particulate is transferred from hoppers on the bottom of the ESP into fabric containers for transport off-site. For roadways at the Granite City Works, the permit set specific requirements for the frequency of treatment of different road segment to reduce emissions of fugitive dust due to vehicle traffic on the roadway. These requirements were accompanied by requirements for daily recordkeeping for the treatment of roadways and the implementation of the cleaning program for these roads. The permit also required periodic treatment of certain public roads that serve the source to their reduce emissions.

4. <u>Improved Control of Particulate Emissions of the BOFs (the New Baghouse)</u>

The version of Permit 95010001 that is the subject of US Steel's 2022 application is the revised permit issued on December 17, 2012. In this regard, in 2010, US Steel agreed to install a baghouse control system with fabric filter that would operate along with the existing ESP system to improve control of particulate emissions of the BOFs from charging and tapping. The commitment to the additional control system was made in an agreement between US Steel and the Illinois EPA[10] for several measures to reduce particulate emissions from steelmaking.[11] For the BOFs, installation of a baghouse system was required to improve control of emissions from tapping, when steel and slag are poured from a BOF vessel into a ladle. US Steel was also required to evaluate whether the new baghouse system could be designed to also improve the control of emissions from charging, when iron and scrap metal are poured and unloaded into a BOF vessel. US Steel determined that the new

---

Illinois EPA performed computerized dispersion modeling for the future PM_{10} air quality of the Granite City area with the Project. The modeling analysis showed that the National Ambient Air Quality Standards (NAAQS) for PM_{10} would be met with PM-10 emissions from the Project-affected units at the Granite City Works at the maximum rates in reflected by the application. In May of 1998, the USEPA redesignated the area in which Granite City is located to attainment for PM_{10}.

Incidentally, the Granite City area is now also designated attainment for the NAAQS for $PM_{2.5,}$ The NAAQS for $PM_{2.5}$ were initially adopted by USEPA in 2006, with the NAAQS on an annual average subsequently being lowered in 2012. The ambient air monitoring stations conducted in Granite City by the Illinois EPA continue to show attainment of the NAAQS for PM_{10} and $PM_{2.5}$.

[10] "United States Steel Corporation Granite City Works and IEPA Memorandum of Understanding," signed by US Steel on June 30, 2010, and by the Illinois EPA on July 1, 2010 (the Agreement).

[11] In addition to the new baghouse system for the BOFs, the Agreement also provided for use of "steam rings." In a BOF, oxygen is used during the refining step to remove carbon and silica from the molten iron by oxidation. The oxygen lances are inserted into the BOF through openings in the hood over the BOF. Steam rings inject steam in the annular areas between the lances and the openings for the lances. This interferes with outward flow through the openings in the hood improving capture of particulate. by the hood.

The Agreement also provided for limits for emissions of particulate matter, in grains per dry standard cubic foot (gr/dscf), that were more stringent than the emission standards that were applicable under state rules. and 40 CFR 63 Subpart FFFFF:

Baghouses for iron desulfurization, slag skimming and ladle metallurgy: 0.005 gr/dscf (compared to 0.01 gr/dscf)

ESP for the BOFs: 0.01 gr/dscf (compared to 0.02 gr/dscf)

New baghouse for the BOFs: 0.005 gr/dscf (compared to 0.01 gr/dscf).

baghouse system could be designed to improve control of emissions from both charging and tapping. As such, once the new baghouse system began operation, the existing ESP system continued to control emissions for the BOFs from refining; the emissions from charging and tapping began to be controlled by a combination of the ESP system and the new baghouse system.

The new baghouse system for the BOFs was initially addressed by Construction Permit 11050006, as issued on August 31, 2011. For purposes of PSD and MSSCAM, this permit was based on the new system being a project that would reduce the emissions of particulate and lead from these furnaces AND NOT increase any emissions. US Steel subsequently applied for a revision of this permit, which was issued on April 1, 2013. In the application for revision of this permit, US Steel formally requested Integrated Processing so as to allow certain related changes to the CAAPP permit for the Granite City Works, Permit 96030056, to be made by means of an administrative amendment. This would assure that the baghouse system could be used in compliance with requirements in the CAAPP permit, which did not address the possibility that a baghouse might be added for the BOFs. For example, for tapping of a BOF, flame suppression was required by the CAAPP permit reduce particulate emissions. However, this would not be appropriate with the new baghouse system.[12]

It was not possible to simply revise Permit 11050006 with Integrated Processing to enable the revisions to the CAAPP permit that were needed to facilitate the installation and use of this system. It was first necessary to revise Permit 95010001, the permit that is now the subject of the 2022 application.[13] This is because the requirements in the CAAPP permit that were impediments to moving forward with the baghouse system were actually established by Permit 95010001.[14] For example, Condition 11 of Permit 95010001 required the use of flame suppression for tapping; the CAAPP permit merely restated this requirement. Accordingly, Permit 95010001 was revised to provide that this requirement, as well as similar operational requirements that would be inconsistent with the use of the new baghouse system would cease to apply when the new system began to be operated.[15] In their place, US Steel was broadly required to operate and maintain the BOFs and

[12] In flame suppression, the use of natural gas burners reduces generation of particulate by depleting the amount of oxygen in the air that comes in contact with molten metal. To improve control of emissions from tapping, the new baghouse system includes local hoods specifically to capture emissions from tapping, as well as local hoods to capture emissions from charging. With local capture hoods for tapping, the continued use of flame suppression would be unsafe, posing hazards both to personnel and equipment, as well as being of uncertain effectiveness to reduce emissions. The high levels of draft provided by the local capture hoods are incompatible with flame suppression as they can act to interfere with the stability and orientation of the flame and pose risks of blowing out the flame.

[13] The revision of Permit 95010001 was completed several months before the revision of Permit 11050006, the permit for the baghouse system. As a PSD permit issued pursuant to 40 CFR 52.21, the revision to Permit 95010001 did not take effect on December 13, 2012, when it was issued. It became effective later in January 2013 after the date for filing an appeal of the revised permit with USEPA's Environmental Appeals Board had passed without any appeal. With the effectiveness of revised Permit 95010001, the revision to Permit 11050006 with Integrated Processing could then be completed.

[14] If Permit 95010001 had not been revised to remove operational requirements that precluded the use of the new baghouse system, these requirements could not have been removed from the CAAPP permit by means of Integrated Processing of a revision to Permit 11050006. These operational requirements would still have been applicable since these requirements would have continued to be present in Permit 95010001.

[15] To address the period before the new baghouse system was operational, the revision to Permit 95010001 provided that the use of flame suppression for tapping and other measures that would obstruct the use of the

associated emissions capture and control systems in accordance with the applicable requirements of the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Facilities, 40 CFR 63 Subpart FFFFF.[16]

In the revision to Permit 95010001, operational requirements for the BOFs and the ESP system that were considered to be obsolete or outdated with the new requirements of the NESHAP, 40 CFR 63 Subpart FFFFF, were also removed. The operational requirements of this NESHAP were determined to better address proper operation of emission control systems for BOFs. For example, as related to capture of secondary emissions,[17] the NESHAP addresses the operation of the capture hoods and the air flow entering the control device(s), rather than the aggregate air flow at the stack of the control device(s).[18] Likewise, the compliance procedures of the NESHAP (e.g., requirements for emission testing and operational monitoring) were determined to be more appropriate for the BOFs and their control systems than the requirements in Permit 95010001.[19]

In summary, the previous revisions to Permit 95010001 were narrowly focused on enabling the installation of the new baghouse system. This was done by removing specific requirements that were inconsistent with the use of this system and, more generally, by removing requirements that were no longer appropriate because of applicable requirements in 40 CFR 63 Subpart FFFFF. The revisions to Permit 95010001 did not extend to other requirements, such as the emissions limits set by this permit for the BOFs. Likewise, the changes to the CAAPP permit that were authorized by means of the Integrated Processing of the revision of Permit 11050006 were focused on enabling the future operation of new baghouse system, including the related changes that had been made in the December 2012 revision to Permit 95010001.[20] The changes authorized to the CAAPP permit

---

new baghouse system cease to apply when US Steel began operation of the new system. [Revised Permit 95010001, Condition 11(b).]

[16] US Steel became subject to the requirements of this NESHAP, which applies to the BOFs and certain other operations at the Granite City Works, beginning May 22, 2006. This is because the facility is considered an existing source under 40 CFR 63 Subpart FFFFF.

[17] In common usage, the particulate emissions of BOFs from refining are often referred to as the "primary emissions;" the emissions from charging and tapping are referred to as "secondary emissions." However, in the NESHAP, 40 CFR 63.7852, the primary particulate emissions of a BOF are defined as the emissions that are captured for control by the primary emission control system; the secondary emissions are the emissions that are not captured for control by the primary emission control system. As such, the Granite City Works, the ESP control system is the primary control device for the BOFs under the NESHAP. All emissions that are captured by this system, including emissions from charging, refining and tapping, are primary emissions.

[18] The NESHAP also places the burden for establishing the specific measures that will be implemented to ensure proper operation of the capture systems and control devices for BOFs on the source rather than on the permitting authority. The measures that are required to be used are the ones that were present when performance testing for particulate matter emissions shows compliance with the applicable standard.

In light of the applicable requirements of the NESHAP, the operating procedures and requirements in Attachment A, as formerly addressed by Condition 10, were also considered overly prescriptive. For example, Attachment A set out actions that were to be to be taken by employees, e.g., the emission control foreman and operator, rather than practices that the Permittee was required to implement.

[19] A practical concern also existed because certain operational requirements of Permit 95010001 were similar to but different than those of the NESHAP. Given the requirements of the NESHAP, which were newer and developed through rulemaking, the continuing implementation and oversight of the older requirements in Permit 95010001 was not considered to be an appropriate or effective use of resources.

[20] The 2012 revision of Permit 11050056 provided that the changes to the CAAPP permit for the facility that were authorized by means of Integrated Processing could only happen or take effect after the new baghouse

also included relevant requirements for the ongoing operation of the baghouse system that were actually set in Permit 11050006 and would appropriately be restated in the CAAPP permit. However, changes were not authorized to the emissions limits in the CAAPP permit for the BOFs and various other emission units as those limits were still present in Permit 95010001.[21]

5. US Steel's Current Application for Revisions to Permit 95010001

US Steel's current application (the "2022 application" or "application") requests a number of revisions to Permit 95010001. A key reason why revisions to Permit 95010001 are needed is that emission testing for the two basic oxygen furnaces (BOFs) shows their emissions of nitrogen oxides (NOx), as well as their emissions of volatile organic material (VOM), are higher than is allowed by this permit.[22] This is because the original application understated the NOx and VOM emissions of the BOFs and the emission limits in this permit reflected information in the application. US Steel has also determined that emissions of carbon monoxide (CO) of the casthouse on the blast furnaces and certain Projected-affected fuel burning units are higher than are addressed by the permit. This is because original application did not address CO emissions from the casthouse and understated CO emissions from Project-affected fuel burning units

Accordingly, the 2022 application requests revisions to Permit 9501001 to allow more emissions of NOx and VOM from the BOFs, which the original application understated. In particular, the application requests that the permitted NOx emissions of the casthouse and the BOFs be increased by 19.4 and 220.2 tons/year, respectively. To support these increases in emissions, the application includes revised netting analyses that attempt to show that the Project would not be a major modification for purposes of either PSD or MSSCAM with the requested increases in emissions.

US Steel also requests that the revised permit address CO emissions from the casthouse and allow more CO emissions from fuel burning units.[23] For CO, the application attempts to show that the

---

system for the BOFs began operation (Permit 11050056, issued April 1, 2013, page 16). US Steel has not yet applied to the Illinois EPA to initiate issuance of an administrative amendment to the CAAPP permit that would reflect the changes to this permit authorized by Permit 11050056.

[21] US Steel filed an appeal of revised Permit 11050056 with the Illinois Pollution Control Board (Board), PCB 13-62. Similar to the appeal of CAAPP permit for the facility (PCD-53), Permit 11050056 was appealed because it also provided for the emission limits for the BOFs and other units in the BOF shop set by Permit 95010001 to again be restated in the CAAPP permit. In this regard, to address the changes to the CAAPP permit that would be needed for use of the new baghouse system, Permit 11050006 provides for the complete replacement of Section 7.5 of the CAAPP permit, which addresses the basic oxygen furnace shop, including the basic oxygen furnaces, with a new, revised Section that addresses the basic oxygen furnace shop with the new baghouse system. As an appeal was filed, the provision of Permit 11050056 that would have restated those limits have been stayed pending resolution of the appeal.

[22] This emissions testing of the BOFs for NOx and VOM was first conducted in 2014, with further testing conducted in 2018 and 2021.

[23] The 2022 application requests that Permit 95010001 be revised to address an additional 25,334 tons/year of CO. This would include emissions of 320 tons/year of CO from the casthouse, for which CO emissions were not identified and addressed in the original permitting for the project. This would also include an additional 25,014 ton/year from Project-affected fuel burning units, other than ten boilers that are now retired. For the fuel burning units, US Steel has determined that the emission factors for CO utilized in the original permitting of the Project, particularly the emission factor for blast furnace gas (BFG) used in the blast furnaces stoves, understated CO emissions.

Project would still comply with the substantive requirements of PSD, which are applicable as the Project originally was a major modification for CO under the PSD program. The application includes an evaluation of BACT for CO for the casthouse and blast furnace stoves, i.e., the units that are or would become subject to the BACT requirement of the PSD program.[24] The application also includes a new air quality impact analysis for CO that would address the Project with the increases in CO emissions as are requested.

This 2022 application also addresses other issues that are now posed by the manner in which the Project was originally permitted. For PM, PM_{10}, NOx and VOM (i.e., pollutants other than CO, sulfur dioxide (SO_2),and lead), the application requests that the revised permit not include the provisions in Permit 95010001 that would address emissions of individual "processes" in pounds/ton of production or throughput. (For convenience, these provisions in the permit that address emissions in pounds/ton of production or throughput or, for lead, in pounds per hour, are generally referred to by the Illinois EPA as "emission factor limits." The Illinois EPA set the emission factor limits and limits on annual emissions in Permit 95010001to ensure that the Project would not be a major modification for purposes of PSD or MSSCAM.[25] With regard to the current limits for the annual emissions of PM, PM_{10}, NOx and VOM of individual processes or emission points, the application requests "group limits" for the annual emissions of groups of related emission units.[26] For emission units for which routine emission testing is feasible, the emissions contributed by units towards the group limits would be determined using emissions rates that reflect the results of emission testing. For certain emissions units or their uncaptured emissions (e.g., the uncaptured particulate emissions of the BOFs), for which routine emission testing is not feasible, the application requests that the revised permit set "prescribed emission factors." For these units or emission points, the prescribed emission factors would effectively replace the provisions currently

[24] The BOFs were not physically modified as part of the Project. Accordingly, they would not become subject to requirements for BACT or LAER even if the Project were a major modification for a pollutant.

[25] The removal from Permit 95010001 of the "emission factor limits" would facilitate resolution of two permit appeals filed by US Steel with the Illinois Pollution Control Board (PCB), PCB 2013-53 and PCB 2013-62, as these appeals address PM, PM_{10} and NOx and VOM emissions. Both appeals indirectly address the emission factor limits in Permit 95010001. PCB 2013-53 concerns the revised Clean Air Act Permit Program (CAAPP) permit for the facility (Permit 96030056) issued in 2013. US Steel appealed this permit as it repeats the emission factor limits as originally set by Permit 95010001. PCB 2013-62 concerns the construction permit for the addition of the baghouse system to improve control of particulate emissions from charging and tapping of the BOFs, Permit 11050006, as reissued in 2013. For the BOFs, this permit also repeats the emission factors limits for the BOFs set by Permit 95010001. US Steel appealed the subject emission factor limits in these permits because, before issuing the revised CAAPP permit for the facility in 2013, the Illinois EPA had explicitly explained that the provisions in the permit containing "emission factors" were considered to constitute enforceable limits on emissions.

[26] For example, the application requests that the revised permit limit the overall emissions of a group of units that includes the casthouse for the blast furnaces and other, ancillary units involved in production of iron. The permit currently sets separate limits for the emissions of the casthouse, the emissions from charging the blast furnaces, and the emissions from slag pit activities. Unlike the current limits for annual emissions, which apply on a calendar year basis, the proposed new limits for annual emissions would be rolled monthly, restricting emissions over each consecutive 12 month period.

in Permit 95010001 for process units that currently restrict emissions in pounds/ton of input or production or in pounds/hour.[27]

Lastly, the application also recognizes subsequent changes at the facility, which occurred after the Project, that were not contemplated in 1996 and not provided for when Permit 95010001 was originally issued. The changes at the facility include the addition of a baghouse control system for the BOFs to improve control of their particulate emissions. The changes also include the shutdown of the by-product coke oven batteries that were formerly at the facility, which eliminated emissions from these operations. In this regard, the application requests revisions to Permit 95010001 to provide for increased use of natural gas by Project-affected fuel burning units. The application explains that this is necessary with the shutdown of the by-product coke oven batteries because COG is no longer available and more natural gas may need to be used.

The Illinois EPA has reviewed the 2022 application to determine whether the application shows compliance with applicable regulatory requirements and would support issuance of a revision to Permit 95010001 as requested by US Steel. The Illinois EPA has also considered whether the application would support issuance of such a revised permit with Integrated Processing, as has also been requested, so that related revisions to the CAAPP permit for the Granite City Works may be made by administrative amendment. The Illinois EPA has made a preliminary determination that the 2022 application should be denied. The reasons for this determination are set forth in the draft of the proposed denial letter that has been prepared.[28] As discussed in further detail below, for some of the revisions requested to Permit 95010001, the application does not show that they would comply with the relevant regulatory requirements and USEPA policy that apply for this permit. For other requested revisions, the application does not include the information needed to support those revisions or enable those revisions to be made as a practical matter. In addition, the application would not allow for processing of a revised permit with Integrated Processing, as has been requested. If the Illinois EPA's final decision is to deny this application, it is expected that Permit 95010001 would continue in effect as it now exists until and unless action is taken on a subsequent application.

6. Discussion of Key Reasons for the Planned Denial of the Application

6.1. The Revised Netting Analysis for the Project for NOx

A. Overview

The revised netting analysis for NOx submitted for the Project with additional NOx emissions as requested does not show that the Project would not become a major modification for NOx. Accordingly, a revised permit cannot be issued as requested because, for emissions of NOx, the 2022 application does not address or show fulfillment of the substantive requirements of the rules for Prevention of Significant Deterioration (PSD) and Major Stationary Sources Construction and

[27] Unlike the emission factor limits in Permit 95010001, which the Illinois EPA considers to be directly enforceable against US Steel, prescribed emissions factors established in a revision to Permit 95010001 would instead be specific values for emission rates that US Steel would have to use for normal operation when determining compliance with the limits on annual emissions set by the revised permit.

[28] Brief descriptions of the reasons why the Illinois EPA's preliminary determination for this application is that it should be denied are provided in Appendix 2 of this document.

Modification related to impacts on air quality, i.e., air quality analysis for impacts on NO_2 air quality per 35 IAC 204.1130 and emission offsets for NOx per 35 IAC 203.302. For the blast furnaces and blast furnace stoves, i.e., the emission units that underwent physical modifications with the Project, the application also does not show fulfillment of the BACT and LAER requirements, respectively of PSD (35 IAC 204.1100) and MSSCAM (35 IAC 203.301) for NOx. This showing is necessary because Permit 95010001 is currently based on the net increase in NOx emissions from the Project not being significant so that the Project is not a major modification for NOx. The application requests that the Project be permitted for additional NOx emissions but does not show that the Project would still not be a major modification for NOx if the permit were revised as requested. As the Project would become a major modification for NOx with the requested revisions to Permit 95010001, the application must show for NOx that the relevant substantive requirements of PSD and MSSCAM are fulfilled for the Project. It would not be appropriate for a revised permit to be issued with increases in permitted NOx emissions as requested by the current application if this application does not also show that the applicable substantive requirements of PSD and MSSCAM would be met for the Project for NOx.

The revised netting analysis for the Project for NOx in the 2022 application suggests that this increase would be accompanied by decreases in the NOx emissions of certain other units. With these accompanying decreases, the net increase in NOx emissions from the Project with the requested revised permit would continue to not be significant.[29] However, the application does not identify the specific decreases in NOx emissions that occurred at different groups of Project-affected fuel burning units. Instead, the application simply indicates that the future NOx emissions of the Project-affected fuel burning units, overall, would be such that the Project would not be a major modification for NOx.

This netting analysis for NOx in the 2022 application cannot be relied upon for issuance of a revised permit for the Project as requested by US Steel. The application does not include relevant information showing that additional decreases in NOx emissions that would now be proposed to be relied upon would be contemporaneous and creditable for permitting of the Project. For emission decreases to be relied on for a netting analysis, 35 IAC 204.550 and 203.208 provide that the decreases must be contemporaneous and creditable. This necessitates information for how the additional decreases in NOx emissions addressed in the revised netting analysis for NOx were created and how the amounts of the decrease were quantified. Most significantly, the application does not show that certain decreases in NOx emissions that it would rely upon should be considered contemporaneous with the Project. A revised permit cannot be issued for the Project that relies upon "post-project" emissions decreases, which occurred after the Project, to show that the Project with the requested increases in NOx emissions of the furnaces, should still not be considered a major modification. This is critical because changes that are unrelated to the Project have occurred at

[29] When a netting analysis that showed a project would not be a major modification is found to have understated emissions of certain new or modified emission units, the next step is usually to examine whether the project should still not be considered a major modification. The revised netting analysis for this purpose may consider adjustments such as reductions in the permitted emissions of other new or modified units involved in the project. It may also consider additional emission decreases that were not relied upon by the original netting analysis but could have been as they are contemporaneous and creditable. As this reexamination of a project shows that it still would not be considered a major modification with appropriate adjustments to the netting analysis, an appropriately revised construction permit may be issued that is based on the project continuing to not be a major modification.

certain fuel burning units after the initial issuance of Permit 95010001. The application proposes to rely upon the decreases in NOx emissions due to these changes, which were not and could not have been relied upon by the original permit for the Project. These decreases in emissions would be relied upon by the revised netting analysis as it does not account for and exclude the emissions decreases from these changes from the analysis. (In addition, as will be addressed below, the application does not include appropriate support for certain units for the quantification of NOx emissions in the revised netting analysis.)

B. The Analysis Relies on Emission Decreases That Are Not Contemporaneous

As related to the requirement of the NSR rules that decreases in emissions relied upon for netting be contemporaneous, the 2022 application relies on decreases in emissions that occurred long after 1996. This includes decreases from the shutdown of ten of the twelve boilers at the facility that were originally addressed by Permit 95010001 in 1996. The shutdown of Boilers 1 through 10 was required by Construction Permit 06070023, which was originally issued in July 2006 for construction of a cogeneration boiler that would burn blast furnace gas (BFG) and natural gas. The application does not show that NOx emissions of these ten boilers, as existed in the period prior to 2009, were considered in the "future" NOx emissions with the Project from the Project-affected fuel burning units. In addition, with regard to the two remaining old boilers at the facility, Boilers 11 and 12, that continue in operation, flue gas recirculation systems have been installed pursuant to Construction Permit 10080022, issued in January 2011. These systems were installed to reduce NOx emissions to facilitate compliance with 35 IAC 217.164. The application does not show that the revised netting analysis for NOx does not rely on the lower NOx emissions from these boilers that are now being achieved with the new systems, rather than the NOx emissions as previously existed with the Project in the period before these systems were installed.

The application also indicates baseline NOx emissions from use of coke oven gas (COG) in the blast furnace stoves and Boilers 11 and 12. In 2015, US Steel shut down the two by-product recovery coke oven batteries at the Granite City Works. COG ceased to be available for use in the stoves or Boilers 11 and 12. However, COG was available for use in the stoves and these boilers in 1996. As related to the Project, the application does not show that the revised netting analysis for NOx would not rely upon decreases in the NOx emissions of the stoves and boilers due to the elimination of COG, which did not occur until 2015.[30]

In summary, for purposes of applicability of NSR, the NOx emissions allowed from the Project in 1996 that would be permitted with the requested revisions to the permit could be substantially higher than indicated in the 2022 application. This application does not show that this would not be the case such that the Project would not become a major modification for NOx with the requested increases in the permitted emissions of the blast furnaces and the BOFs. The timing of actions that have resulted in decreases in NOx emissions of fuel burning units after 1996 is critical when considering applicability of NSR to the Project with the requested revisions to Permit 95010001. As the decreases in NOx emissions from certain actions cannot be considered or would be smaller, the net increase in NOx emissions of the Project would be greater. In this regard, it must be assumed that the "future NOx emissions" indicated in the application reflect maximum actual NOx emissions

[30] The revised netting analysis does address increased use of natural gas by Project-affected fuel burning units because COG is no longer available and more natural gas may need to be used to make up for this.

beginning in 2023, with the requested revisions to Permit 95010001. The application does not suggest that these future NOx emissions are the emissions that should have been allowed by the permit back in 1996 when the permit was issued and the Project commenced.[31]

C. Insufficient Information to Independently Confirm the Revised Baseline NOx Emissions

The revised determination of baseline NOx emissions of Project-affected fuel burning units that is part of the revised netting analysis is not accompanied by information that would allow it to be independently verified. In this regard, the application does not show that all Project-affected fuel burning units have been addressed. For units that are addressed, the application does not show that appropriate emission factors and operating data have been used to estimate emissions. As specific concerns exist with the determination of baseline NOx emissions for certain emission units, concerns exist with the determination of the overall baseline NOx emissions for the Project. In particular, this application does not include supporting documentation or explanation for the baseline usage of COG utilized in the revised netting analysis. The application utilizes a NOx emission factor for Boilers 11 and 12 for use of COG that the application states is based on emission testing conducted on the stack for underfiring of one of the coke batteries, rather than testing on one of these boilers or other similar boiler. For burning of natural gas, the application does not show the emission factor that is utilized for boilers would also be appropriate for ladle preheaters and casting operations.

D. Supporting Date Is Not Provided For Future NOx Emissions of Fuel-Burning Units

The 2022 application proposes a future amount for the NOx emissions of Project-affected fuel burning units of 706 tons/year. The application does not explain why actual NOx emissions of the subject units would not exceed this amount going forward if the permit were revised, much less demonstrate that actual emissions have not exceeded this amount historically. The application does not include a demonstration that the actual NOx emissions of Project-affected fuel burning units would not have exceeded the "future amount" or post-project emissions indicated in the revised netting analysis for the Project for NOx since Construction Permit 95010001 was issued if the production of iron and steel by the source was at the levels allowed by this permit.

6.2. The Application Does Not Address the Potential for Uncaptured Emissions of NOx, VOM and CO Through the Roof Monitor of the BOF Shop

The application is deficient in its approach to the uncaptured emissions of NOx, VOM and CO emissions of the BOFs. For the BOFs, consistent with the original permitting of the Project, the application only quantifies stack emissions of NOx, VOM and CO. Moreover, the revised netting analyses for NOx and VOM assume that all emissions of these pollutants from the BOFs are now captured. That is, with the new baghouse system to improve control of particulate emissions, all

[31] Indeed, with the requested revisions of Permit 95010001, it is unclear how the "future NOx emissions" of affected fuel burning units indicated in the application are emissions that could have been allowed by this permit in 1996. The future NOx emissions of these units indicated in the application are less than their baseline NOx emissions. As the Project did not include any elements that would lower the NOx emissions of fuel burning units, the production of more iron and steel would have been accompanied by increased utilization of the blast furnace stoves and boilers so that in 1996 the NOx emissions of fuel burning units allowed by Permit 95010001 must necessarily be more than the baseline emissions. (Use of COG was not expected to be affected by the Project because production of COG was constrained by the design and operation of the existing coke oven batteries, which were not being modified as part of the Project.).

NOx and VOM emissions of the BOFs that originally were not captured and were emitted through the roof monitor are now captured and emitted through the stack on the baghouse system.

This assumption is not appropriate. At a fundamental level, the application does not include any support for this assumption. A rigorous analysis for and quantification of the uncaptured emissions of NOx and VOM from these furnaces is warranted as these emissions were not addressed in the original permitting for the Project, likely because they were considered negligible. Then, the data for NOx and VOM emissions from the baghouse stack, which is now available from testing of the baghouse, does not support this assumption and, if anything, shows that this assumption is unsound. This is because this testing shows that there are emissions of these pollutants from charging and tapping and, as such, data for the uncaptured emissions of these pollutants is also appropriate. In this regard, the results of emission testing for the NOx and VOM emissions from the new baghouse system on these furnaces, as cited by the application, indicate more than negligible levels of emissions. Finally, the assumption that all NOx and VOM emissions of these furnaces is now captured is inconsistent with the approach taken in the application to the particulate and lead emissions of these furnaces, which assumes that there are uncaptured emissions that still occur through the roof monitor. By way of contrast, the 2022 application requests that the revised permit establish prescribed emission factors for the particulate emissions of the BOFs that occur through the roof monitor.

The fact that there are emissions of NOx and VOM from the BOFs that now occur from the stack of the new baghouse system but were previously not captured and were not originally quantified raises concern that similar circumstances are present for emissions of CO. In this regard, the application requests various revisions to Permit 95010001 to correct issues that are posed for the original permitting of the Project with respect to CO emissions. However, the application does not propose any such revisions for the BOFs or explain why such revisions are not needed. For example, the application also does not explain why it would not be inappropriate for any revised permit to set a limit for the annual emissions of CO from the BOFs through the stacks of the control systems, with associated requirements for periodic emission testing.

6.3. The Inventory Used in the Air Quality Analysis for CO Omits Certain Emissions

The results of the analysis of the impacts of the Project on ambient air quality for CO cannot be relied upon because the inventory for the CO emissions of the facility with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered. The application includes an air quality analysis for CO because the Project was originally permitted as a major modification for CO under the PSD program and the application requests revisions to Permit 95010001 to increase the CO emissions for which the Project is permitted. To support this request, an air quality analysis for CO must be part of the application pursuant to 35 IAC 204.1130, since this request involves revisions to the provisions in Permit 95010001 that involve the Project as it is a major modification for CO under the PSD program. In this regard, the air quality analysis in the 2022 application does not address uncaptured CO emissions of the casthouse. As discussed earlier, the application does not address uncaptured emissions from these furnaces or does not explain why uncaptured emissions would not be present. In this regard, the application does not show 100 percent capture of the particulate emissions of these furnaces by the control systems for particulate. The application also does not explain why the

air quality analysis in the application should not consider the CO emissions of the former by-product coke oven batteries at the facility. These batteries were in operation when the Project was originally permitted in 1996 and did not cease operation until 2015. Accordingly, the analysis does not address CO ambient air quality with the Project as would have been predicted by the original air quality analysis for the Project if it had addressed the additional CO emissions now being requested for the Project. In addition, the air quality analysis uses a value for CO background air quality on an 8-hour average that is based on ambient air quality data collected for a three year period consisting of 2016, 2017 and 2018. As such the value used for background air quality is not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted.

6.4. The Proposed Scope of Proposed Group Emission Limits Is Overly Broad

The application does not show that the proposed collections of emission units for the requested group limits for annual emissions of particulate, NOx and VOM are appropriate. In particular, the application does not propose limits that would only apply to the annual emissions of the casthouse on the blast furnaces and to the annual emissions of the two BOFs. These are principal emission units at this facility. It would be reasonable and appropriate for both the annual emissions of the casthouse and the annual emissions of the two BOFs to be directly limited separately from the emissions of any other units. The construction permits issued by permitting authorities in other jurisdictions cited in the application as support for emission limits that apply to groups of emission units do not show that the annual emissions of the casthouse and the BOFs should not both continue to be limited individually.

In this regard, the application points to USEPA policy and practice concerning how the potential emissions of a source may be restricted. The application shows that USEPA has found that construction permits may be issued that restrict potential emissions by means of limits on annual emissions that are practically enforceable. Accordingly, the current provisions in Permit 95010001 that limit emissions of process units in pounds/ton of production of throughput, which apply on a short-term rather than annual or long-term basis, are not essential to restrict potential emissions. In addition, the application points to several construction permits issued outside of Illinois since 2000 for which the permitting authority determined that annual emission limits that apply to groups of emission units that are practically enforceable were determined to be sufficient to restrict potential emissions without need for accompanying limits that address emissions on a short-term basis.[32] However, the application does not show that the specific circumstances of the Project are such that the current limits for annual emissions of the principal emission units should be replaced with group limits that apply to the combined emissions of the principal emission units and other lesser emission

[32] The application cites two decisions by the USEPA's Environmental Appeals Board (EAB):

- The 2012 decision of the EAB for an Outer Continental Shelf (OCS) Permit to Construct and Title V Air Quality Operating Permit issued by Region 10 of USEPA to Shell Offshore, Inc. (USEPA, EAB, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2012).
- The 2018 decision of the EAB for a PSD permit issued by the Department of Environmental Quality for Pima County, Arizona, to Tucson Electric Power (USEPA, EAB, *In Re Tucson Electric Power*, PSD Appeal No. 18-02, Order Denying Review, Decided December 3, 2018).

units.[33] The circumstances of the Granite City Works are not the same as those presented by the cited permits. The Granite City Works are a manufacturing facility at which iron is produced from iron ore and then converted into steel in BOFs. The processes that generate emissions at the Granite City Works are different than the oil-fired engines that are generally addressed by the permit for Shell Offshore and the natural gas-fired engines addressed by the permit for Tucson Electric. The permit for Shell Offshore, Inc., addresses a marine drilling unit, the "Kulluk," and an associated fleet of support vessels that may be used during July through November of each year to conduct exploratory drilling operations in areas of the Beaufort Sea north of Alaska. The permit for Tucson Electric Power addressed a new peaking electrical generating facility with ten engine-generating units at Tucson Electric's Irvington Station.

6.5. Inadequate Justification for Elimination of Current Limits for Project-Affected Fuel Burning Units

The justification provided in the application for revisions to Permit 95010001 to eliminate limits on usage of fuel and, presumably, emission by Project-affected fuel burning units is not adequate. Although this application indicates that the revised permit should not contain the limits for usage of natural gas and blast furnace gas currently set by Permit 95010001, it does not propose any new limits in their place. This rationale is deficient because it does not consider that the application also requests that the revised permit address an increase in the usage of natural gas at the facility as a consequence of the shutdown of the by-product coke oven batteries. While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed above, this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the application does not show that new limits for fuel usage would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shut down. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown.

6.6. The Application Does Not Show That the Emission Factors Proposed As Prescribed Factors for Certain Units Would Be Representative

A. <u>Introduction</u>

To calculate baseline emissions for certain emission units for which emission testing is not feasible or practical, the 2022 application necessarily relies on use of emission factors that are not based on

[33] For the casthouse, Permit 95010001 currently sets separate limits for the emissions of various pollutants from the main baghouse for the casthouse, the iron spout baghouse, and the roof monitor (uncaptured emissions). If Permit 95010001 were to be revised, it would be reasonable for each pollutant for which emissions are limited for the permit to restrict the overall emissions of pollutants other than CO from the casthouse, rather than to individually limit the stack emissions of each control system and the uncaptured emissions. (As the Project is subject to BACT for CO, the limit could only apply to stack emissions.)
The circumstances of the BOF are similar, as the current permit separately addresses emissions of particulate and lead from the ESP stack and the roof monitor. It would also be reasonable in a revised permit to set limits for different pollutants for the overall emissions of each pollutant from the BOFs.

source-specific emissions testing. Likewise, for the ongoing determination of the emissions of these units, the application requests that revised Permit 95010001 "prescribe" or specify the emission factors that are to be used. As explained in the application, where a permit relies on a limit on annual emissions or an "annual emission cap" to restrict potential emissions, USEPA policy and precedent provide that:

> Where the permit prescribes an emission factor to be used in conjunction with operational data in demonstrating compliance [with an annual emission cap], the permitting authority should describe the basis for its determination that the emission factor is representative.
>
> 2022 application, Section 3, p. 3.

For the Granite City Works, the USEPA specifically addressed the use of emission factors for determining compliance with emission limits in an order of December 3, 2012. Relative to prescribing emission factors, the USEPA's finding, as is provided below, should be considered *dicta* since the permit that was the subject of the appeal did not actually provide for use of prescribed emission factors. As the order addresses the possibility of using prescribed emission factors in terms of the actions that the Illinois EPA would need to take when issuing a permit that prescribed emission factors, the order serves to identify the underlying information that a permit applicant must provide in an application if it seeks a permit that would provide for use of prescribed emission factors. The Illinois EPA would then be responsible for assuring that the emission factors that are prescribed would be appropriate and sufficient for compliance or noncompliance with the associated emission limits to be reasonably determined.

> …IEPA [Illinois EPA] must include in the permit itself the monitoring methodology for determining compliance with these limits [emission factor limits and annual emission limits]. If using emission factors, IEPA must propose the actual emission factors in the permit or supporting permit record, and provide supporting documentation for the accuracy and appropriateness of these emission factors, such as historical source test data or other available information. If source test data are not readily available for a specific emission unit, as IEPA asserts, other sources of emission factors (including published literature and material and energy balances) must be reviewed and cited for acceptable emission factors before issuing the permit.
>
> USEPA, Order Responding to Petitioner's Request that the Administrator Object to Issuance of State Operating Permit, Petition Number V-2011-2, *In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056*, Petition Number V-2011-2, dated December 3, 2012, p. 12.

B. Particulate Emissions of the BOFs Through the Roof Monitor

The application does not include support for the particulate emission factors that are proposed as prescribed factors for the roof monitor on the BOF shop (i.e., the uncaptured emissions from the BOFs). In this regard, the permitting of the Project in 1996 relied upon various changes that were made to improve capture and control of emissions of particulate from the BOFs. As capture and control for particulate improved, the factor for future uncaptured emissions would be different and lower (better) than the factor for baseline uncaptured emissions.

C. Continuous Casting Lines

For the caster mold, slab ripping and slab ripping processes on the continuous casting lines, prescribed emission factors that are proposed reflect emission factors from a report prepared by the Illinois EPA in 1991, i.e., "Illinois EPA 1991 EIS PM/PM_{10}." This is not sufficient to show that the emission factors that are proposed as prescribed factors are representative.

D. Particulate Emissions of the Casthouse Through the Roof Monitor

For the casthouse roof monitor (uncaptured emissions particulate emissions of the casthouse), the application only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency. Further support is needed for a prescribed emission factor for uncaptured emissions of the casthouse that is based on achievement of this level of capture.

E. Emissions of the Slag Pits and Iron Pellet Screen

For the slag pits and the iron pellet screen, the application does not provide support for the background information or inputs that were used to adjust the published factors for the operating conditions or circumstances of these units at the facility. Absent this information, the Illinois EPA cannot assess whether the prescribed emission factors proposed for these units should be considered representative.

F. Current Provisions of the CAAPP Permit Requiring Use of Appropriate Emission Factors

The application is also deficient as it simply requests revisions to Permit 95010001 to require use of prescribed emission factors for certain units. The application does not address the fact that the CAAPP permit currently does not accommodate the use of prescribed emission factors to calculate emissions but instead requires use of "appropriate emission factors." To facilitate the use of prescribed emission factors, the application also needs to propose or request revisions to general provisions in Permit 95010001 so as to also enable subsequent revisions to be made by administrative amendment to the CAAPP permit for the facility, Permit 96030056, to allow prescribed emission factors to actually be used to determine ongoing emissions of certain units.[34]

6.7. Requested Changes for Consistency with the Grouping of Units in the CAAPP Permit

In the 2022 application, US Steel generally requests changes to the organization of Permit 95010001 because the areas or sections of the CAAPP permit in which certain units are addressed are different than those in Permit 95010001. Most notably, in Permit 95010001, discrete material handling and processing operations are addressed with either the blast furnace operations, operations in the basic oxygen furnace shop or the continuous casting operations, based upon the area with which they were considered to be associated. In the CAAPP permit, these discrete

[34] The CAAPP permit currently provides that "appropriate emission factors" shall be used when determining emissions to evaluate compliance with the emission limits for process units set by Permit 95010001. These procedures do not provide for the use of prescribed emission factors. Rather, US Steel is generally required to use "appropriate emission factors," i.e., factors that do not understate emissions, with the primary responsibility for the appropriateness of the factors that being are used resting on US Steel. The CAAPP permit also provides for recordkeeping and reporting by US Steel so that information about the factors that are being used is publicly available and the Illinois EPA, the USEPA and interested parties can review the factors that are in use.

material handling and processing operations are generally addressed in a separate section of the permit, Section 7.1, "Material Handling and Processing Operations." In addition, in the CAAPP permit, the "Argon Stirring Station and Material Handling Tripper" was addressed with units in the basic oxygen furnace shop in Section 7.5 of the CAAPP permit rather than with the continuous casting operations as in Permit 95010001.

While it is reasonable for there to be consistency in the groupings or categorization of emission units in Permit 95010001 and the CAAPP permit, as generally requested by US Steel, several concerns are posed by the specific changes to Permit 95010001 that have been requested. For example, US Steel requests that the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" now be addressed in Permit 95010001 with operations in the Basic Oxygen Furnace Shop and be identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." However, the application does not actually identify the specific units that would be addressed by the proposed new term.

On the other hand, the application does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS (Handling System). These emission units are currently addressed in Permit 95010001 with continuous casting operations. In the CAAPP permit, a "Steel Deslagging Station" is identified as one of the continuous casting operations. The application does not explain why this steel deslagging operation should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the basic oxygen furnace shop as it would constitute a "BOPF {basic oxygen process furnace] shop ancillary operation" for purpose of 40 CFR 63 Subpart FFFFF. US Steel does not explain why the current placement in Permit 95010001 of the steel deslagging station with continuous casting is appropriate and this station should not also be addressed with other BOPF shop ancillary operations.[35]

6.8 The Application Does Not Address the Amendment to the CAAPP Permit Previously Authorized Pursuant to Construction Permit 11050006

The 2022 application does not identify the version of the CAAPP permit for the Granite City Works, Permit 96030056, that would be eligible for administrative amendment pursuant to the Integrated Processing of the revisions to Permit 95010001 that are requested. This is relevant because the Illinois EPA has already issued a construction permit with Integrated Processing, i.e., Permit 11050006, issued April 1, 2013, for the addition of a baghouse system to improve control of particulate emissions of the BOFs. However, US Steel has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006.[36]

[35] For Ladle Drying/Preheating, the application also does not request any changes to Permit 95010001 to maintain consistency with the approach taken in the CAAPP permit. In Permit 95010001, these emission units are addressed with other Project-affected fuel burning units. In the CAAPP permit, these units are addressed in Section 7.5 as "Basic Oxygen Processes" with other units in the BOF Shop, as well as elsewhere in the permit with other Project-affected fuel burning units. In addition, the CAAPP permit sets a limit for the total NOx emissions of the BOF Shop.

[36] The 2022 application does address the addition of the baghouse control system for the BOFs as related to the emission of the furnaces. US Steel does not propose separate limits set for the individual emission points

Accordingly, in the absence of a formal request from US Steel to the Illinois EPA to initiate the administrative amendment of the CAAPP permit contemplated by Permit 11050006, the application can only request Integrated Processing to allow administrative amendments of the current CAAPP permit, as has actually been physically issued by the Illinois EPA.[37]

6.9. The Application Does Not Address Changes to the CAAPP Permit That Are Needed Due to Revisions To 40 CFR 63 Subpart FFFFF

The application does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020. Among other revisions to 40 CFR 63 Subpart FFFFF, USEPA acted to remove exemptions from the emission and opacity limits in this NESHAP for periods of startup, shutdown and malfunction (SSM). Accordingly, effective January 12, 2022, the emission and opacity limits of this NESHAP became applicable at all times. The requirements of this NESHAP that formerly dealt with SSM ceased to be applicable. Notably, subject sources would no longer be required to keep startup, shutdown and malfunction plans detailing the procedures for operating and maintaining subject emission unit(s) during periods of SSM, as had been required by 40 CFR 63 Subpart FFFFF as it had applied 40 CFR 63.6(e)(3) in the general provisions of the NESHAP regulations to subject sources. These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the BOFs and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate.

6.10. Changes to the CAAPP Permit That Have Resulted from Shutdown of Emission Units

The application is deficient as it does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emission units, as generally addressed by Condition 9.11 of the CAAPP permit.

> Condition 9.11 Permanent Shutdown
> This permit only covers emission units and control equipment while physically present at the indicated source location(s). Unless this permit specifically provides for equipment relocation, this permit is void for the operation or activity of any item of equipment on the date it is removed from the permitted location(s) or permanently shutdown. …

for these furnaces. Instead, the application requests that the revised permit set overall limits for the emissions from the control systems of the BOFs.

[37] Concerns are posed by certain conditions in existing Permit 11050006 and the related amendments to CAAPP Permit 96030056 that it authorizes. The application is not accompanied by a request for changes to Permit 11050006 or a proposal for how to address these concerns so that they would not be perpetuated in the amended CAAPP permit.

While the 2022 application acknowledges that the by-product coke ovens at the Granite City Works have been shut down, this application does not separately address the consequences for the current CAAPP permit. The shutdown of these batteries was accompanied by the shutdown of coal and coke handling operations, the coke by-products plant, the handling of coke by-products, and possibly certain wastewater treatment processes. In addition, although not shut down, Boilers 11 and 12, Ladle Dryer/Preheaters and Slab Reheat Furnaces are no longer able to use COG as fuel since COG is no longer produced at the facility. As such, provisions in the CAAPP permit that identify or address the use of COG in these units are no longer necessary. It would be improper for the revised version of the CAAPP permit authorized by means of the Integrated Processing of a revision to Permit 95010001 to still physically include provisions that should no longer be present in the revised CAAPP permit given the permanent shutdown of the emission units that were subject to those provisions.

6.11. The Evaluation of BACT for CO in the Application Is Not Sufficient

The evaluation of BACT for CO in the application lacks necessary information to support US Steel's proposal for BACT for CO for the emissions units for which this must be determined or redetermined under the PSD program as a consequence of the requested revisions to Permit 95010001. The evaluation addresses BACT for CO for the casthouse for which BACT must now be determined as it is now recognized that the casthouse emits CO. It also addresses BACT for CO for the blast furnace stoves as the application requests that the revision of Permit 95010001 allows for more emissions of CO from these units.

A. <u>The Scope of the Evaluation of Available Control Options</u>

As provided in the definition of BACT in Section 169(3) of the Clean Air Act and as confirmed by USEPA guidance, a determination of BACT must consider options to control or reduce emissions of an emission unit besides add-on control devices. For the casthouse, when identifying control options, the BACT evaluation only identifies end-of-pipe or "add-on control" control options. The evaluation does not identify other process-related control options such as work practices. In contrast, for the blast furnace stoves, the evaluation identifies both add-on control options and a process-related control option. i.e., "Work Practice Standards, including good combustion practices." The evaluation does not explain why process-related control options are not available for the casthouse.

B. <u>Documentations for the Investigation into Available Control Options</u>

For both the casthouse and the blast furnace stoves, the BACT evaluation in the application is not accompanied by supporting documentation for the investigation that was conducted into available control options. Instead, the evaluation simply states that a review of available control options was conducted. This is not sufficient for the Illinois EPA, the USEPA and interested parties to confirm that the review of available control options for the BACT evaluation was thorough and can be relied upon to have reasonably identified potentially available control options for BACT.

C. <u>Support for Not Setting Numerical BACT Limits for the Blast Furnace Stoves</u>

For the blast furnace stoves, the BACT evaluation for CO in the application is not accompanied by supporting documentation to support the claim that it is infeasible to measure their CO emissions so that BACT should not be set as a numerical emission standard. Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While

certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

6.12. Inconsistency of the Application with a Pending 2008 Application & Pending Appeals

A. Pending 2008 Application

On February 4, 2008,[38] the Illinois EPA received an application from US Steel applied for revisions to Permit 95010001 to increase permit limits for the sulfur content of blast furnace gas (BFG) and the SO_2 emissions resulting from the combustion of BFG. The 2022 application is inconsistent with and conflicts with that prior application (the "2008 application"). As such, these two applications, as they currently exist, cannot be processed by the Illinois EPA absent appropriate action by US Steel on one or both of these applications, e.g., changes to the 2022 application so that it requests the same revisions to SO_2 emission limits for use of BFG as the 2008 application. In this regard, the 2022 application "… does not request any changes to the emission limits for SO_2 and lead emissions established in the Construction Permit 95010001." The 2008 application does request changes to the provisions of the permit for SO_2, as it is an "Application to modify to correct the emission factors used to develop the original application and permit in light of newly identified information on emissions and emission factors."

B. Pending Board Appeals

The application does not request any changes to the emissions limits for SO_2 and lead currently set by Permit 95010001. For CO, the application does request that the revised permit address emissions of CO from the casthouse and raise the limits for CO emissions of Project-affected fuel burning units.[39] However, the application does not request revisions to the emission limits currently in Permit 95010001 for the CO emissions of the BOFs, i.e., the limits in pounds per ton of steel produced and in tons per year for the CO emissions of these furnaces through the ESP stack. As such, the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62, as it does not propose revisions to current permit limits for emissions of SO_2, CO and lead. In these appeals, US Steel challenged all emission factor limits set by Permit

[38] Several things interfered with work on the 2008 application. These include the amount of effort needed by the Illinois EPA to issue the initial CAAPP permit for the Granite City Works. The first two CAAPP permits issued for this facility had to be enhanced and reissued to address certain deficiencies identified by USEPA in Orders responding to petitions requesting the USEPA object to the permits that had been issued. Then, additional revisions to Permit 95010001, as US Steel has tried to address with the 2022 application, were found to be necessary because the NOx and VOM emissions of the basic oxygen furnaces exceed or may exceed the limits established in this permit. Work on the current application for revisions to this permit was also disrupted by an interruption in the iron and steel production of the facility that began in December 2015. This interruption, which ultimately lasted for over two years, meant that it was uncertain that the facility would resume production of iron and steel.

[39] As already discussed, in the original application for Permit 95010001, the casthouse was not identified as a source of CO and information for CO emissions was not provided. The application also requests updates to the limits for CO emissions from use of BFG and natural gas in Project-affected fuel burning units to reflect new information for the CO emissions from burning these fuels.

95010001 for individual process operations. US Steel has not amended these appeals so that they only address emission factor limits for PM, PM_{10}, NOx and VOM and no longer address the emission factor limits that are set for SO_2, CO and lead. In addition, in the application, US Steel does not explain why the emission factor limits in Permit 95010001 for SO_2, CO and lead that were appealed are no longer considered to be objectionable. That is, US Steel would not again challenge those limits as it has already done in PCB 0013-53 and PCB 0013-62 if a revision to Permit 95010001 were issued that continued to include the current emission factor limits.

With regard to the CO emissions of the BOFs, the application also does not request revisions to Permit 95010001 as the current permit only addresses CO emissions from the "BOF ESP Stack." The application does not request that these limits be revised so that they address all stack emissions of the BOFs, e.g., CO emissions from both the stack of the new baghouse system and the stack of the ESP system.

6.13. Other Deficiencies in the Application

There are also a number of other lesser reasons why the Illinois EPA determined that the application should be denied, as are set forth in the draft of the denial letter. For example, this application does not include a signed certification for its truth, accuracy and completeness. While this deficiency could be remedied with a supplement to the application that provides both this certification and corrections to the errors in the application that have been noted, this would not be sufficient for a revised permit to be issued given more substantial deficiencies in the application that have been identified..

7. Request for Comments

It is the Illinois EPA's preliminary determination that US Steel's 2022 application for revisions to Permit 95010001 should be denied. The Illinois EPA has prepared a draft of the denial letter that it proposes to issue for the 2022 application. The draft denial letter details the reasons why the Illinois EPA has determined that this application should be denied.

The Illinois EPA is providing the public with an opportunity to review and comment on this proposed denial of this application and the reasons for such action identified by the Illinois EPA as set forth in the draft of the denial letter.

Appendix 1

Brief Descriptions of the Revisions to Permit 95010001 Requested By US Steel

- Raise permitted NOx and VOM emissions of the basic oxygen furnaces (steel production) to correct for data in the original application that understated emissions. This revision would facilitate resolution of two appeals to Illinois' Pollution Control Board (PCB), PCB 2013-053 and PCB 2013-062 as they address NOx and VOM emissions of the BOFs. The first appeal addresses the Clean Air Act Permit Program (CAAPP) permit for the facility (Permit 96030056) as issued in 2013 as it repeats emission limits set by Permit 95010001. The second appeal addresses Construction Permit 11050006, a construction permit issued in 2013 for improvements to the particulate control for the BOFs, as this permit also refers to emission limits set by Permit 95010001.

- Eliminate limits set by the permit for individual process operations for emissions of particulate matter and particulate matter$_{10}$ (collectively particulate), NOx and VOM. These limits, which are in pounds/ton of throughput and tons/year, were set for purposes of New Source Review (NSR). In place of these limits, set "group limits" for the annual emissions of groups of related operations, e.g., limits for the overall emissions of the casthouse for the blast furnaces and other units involved in production of iron. This would also facilitate resolution of the two appeals to the PCB as they both challenge the limits in pounds/ton of throughput. These requested revisions would make the permit less stringent. Any "overage" of emissions by certain unit(s) in a group could potentially be balanced by lower levels of emissions by other units in the group. Group limits have been allowed by USEPA for purposes of PSD in certain construction permits issued outside of Illinois.

- Address the CO emissions of the casthouse for the blast furnaces, which were not identified in the original application and are not currently addressed by the permit.

- Provide for an increase in usage of natural gas by Project-affected fuel burning units because coke oven gas is no longer available with the shutdown in 2015 of the byproduct coke oven batteries at the facility.

- Update the construction permit to be consistent with the grouping of units in the CAAPP permit for the facility, including addressing discrete material handling operations as a group of units.

- Process the revised construction permit with "Integrated Processing" so that appropriate revisions can be made to the CAAPP permit for the facility by Administrative Amendment rather than by a separate proceeding for a major modification of the CAAPP permit.

- Update Permit 95010001 with a number of minor revisions as requested to US Steel.

Appendix 2:

Brief Descriptions of Deficiencies in the Application Identified in the Draft Denial Letter

- The revised netting analysis for the Production Increase Project (the "Project") for NOx in the 2022 application attempts to show that the Project would still not be a major modification for purposes of Prevention of Significant Deterioration (PSD) or Major Stationary Source Construction and Modification (MSSCAM) with higher permitted emissions of nitrogen oxides (NOx) from the basic oxygen furnaces, as are being requested. However, the revised netting analysis for NOx does not fulfill relevant requirements of the rules governing netting analyses. As a result, the revised analysis does not show that the Project would still not be a major modification for purposes of PSD and MSSCAM with the requested increases in NOx emissions to correct erroneous data in the original application. In addition, for NOx, the application does not address applicable requirements of the PSD and MSSCAM programs that would become applicable as the Project would now be a major modification. As related to the effect of the Project on air quality, these include an air quality impact analysis for nitrogen dioxide (NO_2) under the PSD program and emission offsets for NOx under MSSCAM. As related to control of NOx emissions, this entails use of appropriate control measures for the NOx emissions of the casthouse on the blast furnaces and the stoves associated with the blast furnaces. This is because the Project included physical modifications to the blast furnaces so that the control measures for NOx must reflect Best Available Control Technology (BACT) under PSD and the Lowest Achievable Emission Rate (LAER) under MSSCAM.

  In particular, the application relies on decreases in NOx emissions due to actions at the facility that occurred after 1996, i.e., the shutdown of ten older boilers in 2010 and the shutdown of the by-product coke oven batteries in 2015. These actions are not contemporaneous with the Project, which occurred in 1996. As such, the accompanying decreases in NOx emissions cannot be relied upon to show that the Project should still be considered non-major.

- Certain emissions data underlying the revised netting analysis cannot be independently confirmed by the Illinois EPA.

- The application lacks detailed supporting information for the contribution of various Project-affected fuel burning units to the actual annual NOx emissions under the requested revised permit.

- The application does not show that the proposed groups of operations for the requested "group limits" for annual emissions are appropriate. In this regard, the 2022 application requests that emission limits currently set by Permit 95010001 that apply to emissions of various pollutants from individual emission units or points of emissions from the casthouse on the blast furnaces and the BOFs, which have both captured/controlled emissions and uncaptured emissions, be replaced with limits that apply to the emissions of groups of related emission units. This would not provide for emission limits that only apply to the blast furnaces casthouse and the two BOFs. These are principal emission units at this facility and their emissions should be directly limited separate from the emissions of other units. The construction permits issued by other jurisdictions cited in the application as support for setting group limits do not eliminate the need

for the Illinois EPA to exercise its technical judgment when deciding whether and to what extent to set group limits.

- The 2022 application does not show that certain emission factors that the application requests be prescribed by the revised permit should be considered representative and acceptable. In this regard, the application requests that for certain emission units, the revised permit specify or prescribe the emission factors that are to be used on an ongoing basis for purposes of assessing compliance with limits on emissions set by the permit.

- As related to sulfur dioxide (SO_2) emissions from burning blast furnace gas, a fuel byproduct from the blast furnaces, the 2022 application is inconsistent with an earlier application for revisions to Permit 95010001. This earlier application was submitted in 2008 pursuant to a state consent decree (*People of the State of Illinois v. US Steel Corporation, Inc.*, Madison County Circuit Court No. 05-CH-750 (December 18, 2007)). This earlier application is still pending. It requests revisions to Permit 95010001 to allow more emissions of SO_2 from burning blast furnace gas, both in pounds of SO_2 per million cubic feet of gas burned and in tons per year. However, the current application does not request any such changes and instead states that the limits for SO_2 emissions from blast furnace gas should not be changed.

- The application does not include information to facilitate Integrated Processing of a revised permit, as requested by US Steel. Most significantly, the application does not provide information to support removal of provisions in the CAAPP permit for the now shutdown coke oven batteries and for use of coke oven gas that should not be included in any amended CAAPP permit.

- US Steel has not taken necessary action to enable Integrated Processing of the requested revised permit. This is because it has not initiated the amendment of the CAAPP permit authorized by Permit 11050006, as issued in 2013, which is an earlier construction permit that was subject to Integrated Processing. That permit addresses the addition of the baghouse control system to the BOFs to improve control of particulate emissions from charging and tapping of these furnaces. Prior to installation of the baghouse system, the particulate emissions from charging and tapping were only controlled with the electrostatic precipitator (ESP) control system.

- There are also a number of other lesser deficiencies in the 2022 application that also warrant the denial of this application.

Re: Comment Letter
United States Steel Corporation – Granite City Works
Notice of Intent to Deny Application for Revision to
Construction Permit/PSD Approval (Permit/Application No. 95010001)
ID No. 119813AAI

Dear Mr. Frost:

This letter is written on behalf of my client, United States Steel Corporation ("USSC"). Attached to this letter are comments prepared by USSC in response to the Illinois Environmental Protection Agency's ("Illinois EPA") Notice of Intent to Deny Application for Revision to Construction Permit/PSD Approval for the USSC Granite City Works. The Notice was posted on Illinois EPA's Public Notice website on July 21, 2023 and had an original deadline of August 21, 2023 for submittal of comments. On August 17, 2023, USSC submitted a request for an extension of the comment period. On August 18, 2023, Illinois EPA granted that request and extended the deadline for submitting comments to September 11, 2023. The comments attached to this letter are therefore timely submitted.

We appreciate the opportunity to submit comments on the Notice of Intent, as well as Illinois EPA's careful consideration of our comments.

Sincerely,

N. LaDonna Driver

Enclosure

Comments of the United States Steel Corporation - Granite City Works

Notice of the Intent to Deny Application for Revision to Construction Permit/PSD Approval (Permit/Application No. 95010001

While it is with great disappointment that U. S. Steel received Illinois EPA's notice of intent to deny the pending permit application, we respectfully request that the Agency reconsider its preliminary decision and work with U. S. Steel on resolving any outstanding issues. We also request to meet with Illinois EPA in the interest of reaching resolution considering many of the reasons that Illinois EPA raises in its proposed denial were not known to U. S. Steel until it received the notice (or very shortly beforehand) notwithstanding the parties met several times to discuss the permit application. U. S. Steel also notes that Illinois EPA did not notify U. S. Steel of any deficiency in the application or information submitted in such application pursuant to 35 Ill. Admin. Code 201.158 and 204.1300 or 415 ILCS 5/39.5(5). We are greatly disappointed that the Agency took this path, when many of the issues, as explained herein, could have been efficiently resolved if the Illinois EPA raised them during the years while the permit application was pending as is customary. U. S. Steel also notes that the permit application is for a revision to a previously issued PSD permit (as issued to National Steel Corporation in 1996) to a source that has been and continues to operate; and is not a request for a new major modification – and, therefore, the scope of the review is more limited and the process is substantially different than when compared to a major modification or a revision to a PSD permit for a source that has yet to operate.

In Section I below, U. S. Steel addresses Illinois EPA's stated reasons for its proposed denial of the pending permit application, as required by Section 39 of the Illinois Environmental Protection Act and as summarized in the draft denial letter. In Sections II through XIII below, U. S. Steel addresses the denial points listed in Attachment 1 to the draft denial letter.

I. U. S. STEEL DISAGREES WITH ILLINOIS EPA REGARDING WHETHER ISSUANCE OF THE REQUESTED PERMIT REVISION WOULD VIOLATE PROVISIONS OF THE ILLINOIS ENVIRONMENTAL PROTECTION ACT OR THE REGULATIONS OF THE POLLUTION CONTROL BOARD

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that Section 9.1 of the Illinois Environmental Protection Act *might be violated.* Neither Attachment 1 to the draft denial letter nor the accompanying Project Summary makes any mention of Section 9.1 or provides any indication as to how issuance of the requested permit revision *might violate* this provision. Because the notice is unclear as to what precisely "might be violated," U. S. Steel cannot substantively respond to this assertion. The ambiguity in the stated reason for the proposed denial violates due process. In addition, this assertion inappropriately shifts the burden on U. S. Steel to prove the negative; as Illinois EPA has not shown how or what would be violated. That being said, U. S. Steel is willing to discuss Illinois EPA's assertion such that meaningful discussions can potentially lead to resolution of the issue.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that Section 39 of the Illinois Environmental Protection Act might be

violated. Neither Attachment 1 to the draft denial letter nor the accompanying Project Summary makes any mention of Section 39. Section 39(a) states that "it shall be the duty of the Agency to issue …a permit upon proof by the applicant that the facility, equipment, vehicle, vessel, or aircraft will not cause a violation of this Act or of regulations hereunder." As set forth further herein, U. S. Steel maintains that its application demonstrates that the facility and equipment at issue in the application will not cause a violation of the Illinois Environmental Protection Act or the regulations thereunder. Therefore, it is Illinois EPA's duty, under the statute, to proceed with permit issuance. Section 39(a) further provides:

> If the Agency denies any permit under this Section, the Agency shall transmit to the applicant within the time limitations of this Section specific, detailed statements as to the reasons the permit application was denied. Such statements shall include, but not be limited to, the following:
>
> (i) the Sections of this Act which may be violated if the permit were granted;
>
> (ii) the provision of the regulations, promulgated under this Act, which may be violated if the permit were granted;
>
> (iii) the specific type of information, if any, which the Agency deems the applicant did not provide the Agency; and
>
> (iv) a statement of specific reasons why the Act and the regulations might not be met if the permit were granted.

For the various reasons set forth herein, U. S. Steel maintains that the draft permit denial does not satisfy the above requirements. To summarize the matters discussed in this comment: the Illinois EPA has not clearly specified how certain provisions of the Act and regulations might not be met if the permit were granted; for those areas where certain provisions of the Act and regulations are specified, Illinois EPA is incorrect that those provisions would be violated if the permit were granted; and where the Illinois EPA has asserted that information was not provided to the Agency, U. S. Steel is providing that information here, is directing the Illinois EPA to the information in the application, or describes why such information is not pertinent to the issues at hand. Accordingly, Illinois EPA should not issue the proposed permit denial. As stated herein, U. S. Steel stands ready to work with Illinois EPA to resolve any remaining concerns for permit issuance.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that subsections 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act, pertaining to administrative amendments of Clean Air Act Permit Program ("CAAPP") permits, might be violated. Neither Attachment 1 to the draft denial letter nor the accompanying Project Summary provides any indication as to how issuance of the requested permit revision might violate these provisions; indeed, the only discussion of these provisions in Attachment 1 is a determination by Illinois EPA that the administrative amendment process can be used only to amend "the current CAAPP permit." U. S. Steel agrees with this determination. U. S. Steel further notes that, because the listed subsections of the Illinois Environmental Protection Act relate only to the CAAPP, it would be inappropriate to deny the application for a revision of the construction permit

and PSD approval based on a failure to satisfy these statutory provisions, as discussed in Section XIII.A herein.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that subsections 39.5(5)(c) and 39.5(10)(a)(i) of the Illinois Environmental Protection Act might be violated. Neither Attachment 1 to the draft denial letter nor the accompanying Project Summary makes any mention of subsections 39.5(5)(c) or 39.5(10)(a)(i) or provides any indication as to how issuance of the requested permit revision might violate these provisions. The draft denial letter states that the application does not satisfy the requirement for a certification of truth, accuracy, and completeness in subsection 39.5(5)(e); this is not a valid basis for denial of the permit application for the reasons discussed in Section III herein.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that 35 Ill. Adm. Code Sections 203.128 and 204.560 might be violated. The cited rule provisions are definitions, not affirmative requirements, and cannot be violated.

Illinois EPA also proposes to deny the permit application, at least in part, because Section 201.142 and Section 201.160 might be violated. However, the Illinois EPA's basis for this assertion is unclear as it simply states that these sections "might be violated" with no supporting information. Nowhere in the letter or in Attachment 1 does Illinois EPA discuss and provide any explanation of this proposition. For this reason, U. S. Steel is unable to respond to the ambiguous claim. Furthermore, simply stating that something might be violated without providing supporting information cannot be used as the basis to deny a permit application.

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that 35 Ill. Adm. Code Sections 203.601, 203.602, 204.1100, 204.1110, 204.1120 and 204.1130 might be violated. These claims, which relate to the Prevention of Significant Deterioration ("PSD") and Nonattainment New Source Review ("NNSR") programs under the federal Clean Air Act, are without merit for the reasons discussed in Sections VI through VIII below.

II. THE PERMIT APPLICATION SATISFIES 35 ILL. ADM. CODE SECTION 201.159

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the pending permit application "does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022, as required by 35 IAC 201.159" and that "the 2022 application includes a photocopy of an earlier certification, dated February 25, 2022, which was submitted with a prior application." These assertions are incorrect in several respects.

First, the agency misrepresents the requirements of the cited rule provision, which are as follows. There is no requirement for a certification of truth, accuracy, and completeness.

> All applications and supplements thereto shall be signed by the owner and operator of the source, or their authorized agent, and shall be accompanied by evidence of authority to sign the application.

Second, the application that the agency refers to as the "2022 application" is actually a construction permit application submitted on March 2, 2020. This permit application includes a completed 199-CAAPP form, with a certification signed and dated February 25, 2020, and a completed 197-FEE and form, with a check for the application fee of $23,000 and a certification signed and dated February 25, 2020.

A supplement to the permit application was submitted in October 2022. As required by 35 Ill. Adm. Code Section 201.159, the supplement was signed by Michael Patton, the General Manager of the Granite City Works. No application fee was provided, as is appropriate for a supplement to a pending application for a construction permit.

The list of statutory and regulatory requirements presented in the draft denial letter does not include any reference to 35 Ill. Adm. Code Section 201.159, so it is unclear whether these assertions in Attachment 1 to the draft denial letter are intended to support Illinois EPA's proposed denial of the application. If these assertions are so intended, U. S. Steel disagrees that this is a valid basis for denial of the application for the reasons described above.

Furthermore, U. S. Steel notes that, while Illinois EPA had the permit application supplement for months, and virtually met with U. S. Steel to discuss the pending permit application and the supplement, the Agency never requested such a new certification.

III. A SIGNED CERTIFICATION OF TRUTH, ACCURACY, AND COMPLETENESS IS PROVIDED HEREWITH

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the pending permit application "does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022" and that such a certification is required by Section 39.5(5)(e) of the Illinois Environmental Protection Act. This is not a valid basis for denial of the permit application for the following reasons.

As noted in Section II above, the agency mischaracterizes the October 2022 submittal as a new or separate permit application, as it is merely a supplement to the permit application submitted in March 2020. In the transmittal letter for the supplement, and for administrative convenience U. S. Steel suggested that Illinois EPA refer to the supplement rather than to the initial submittal from March 2020 because, as requested by Illinois EPA staff following review of the initial permit application submittal, the sections of the permit application were reordered.[1] The cited provision of the Illinois Environmental Protection Act requires that each submitted permit application include a certification, but it does not expressly require a separate certification for each supplement to a permit application.

Nonetheless, and without waiving any rights or defenses, U. S. Steel is providing a new certification of the truth, accuracy and completeness of the supplement that was submitted in October 2022 as Exhibit 1 with these comments. Accordingly, even if Illinois EPA's interpretation of Section 39.5(5)(e) of the Illinois Environmental Protection Act is correct and a separate certification is

[1] For example, the sections summarizing changes to CO emissions and presenting proposed Best Available Control Technology ("BACT") determinations for CO emissions were sections 3 and 4 of the initial permit application and were sections 4 and 8 of the supplement, and these sections were cross-referenced in sections 1 and 2 of each submittal.

required for each supplement to a pending permit application, that requirement is now satisfied and this claimed deficiency is no longer a valid basis for denial of the permit application. Furthermore, this issue could easily have been avoided if IEPA simply made a request to certify the supplement. U. S. Steel has worked collaboratively with Illinois EPA in responding to inquiries and requests.

IV. PURPORTED FAILURE TO BE CONSISTENT WITH PENDING BOARD APPEALS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the application must be denied because it does not individually address all items that are currently under appeal with the Illinois Pollution Control Board. In particular, Illinois EPA claims, "the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62." Quite strikingly, Illinois EPA cites to no Board order or regulatory or statutory citation to support its assertion. This is for good reason, as there is none. The assertion is without merit. Although it is logical that Illinois EPA might inquire about contested provisions in the appeals before the Board that may appear to be absent in the application, the absence of such mention is not grounds for denying the permit application. Furthermore, the permit application submitted in March 2020 and supplemented in October 2022 has been pending for more than three years, during which time Illinois EPA and U. S. Steel met in person and virtually on several occasions to discuss the PSD permit revisions, yet only in the proposal to deny the permit application did U. S. Steel learn of Illinois EPA's apparent contention that U. S. Steel was obligated to address individually in its permit application all items that are currently under appeal with the Illinois Pollution Control Board. U. S. Steel's understanding from these discussions was that, with satisfactory issuance of the revised permit, the pending appeals could be dismissed in their entirety. U. S. Steel would be pleased to discuss Illinois EPA's concerns in the context of the appeal before the Board, but the Agency cannot claim these differences as a basis to deny the permit application.

V. PURPORTED INCONSISTENCY BETWEEN THIS PERMIT APPLICATION AND THE PERMIT APPLICATION SUBMITTED IN 2008 REQUESTING REVISIONS RELATING TO SO_2 EMISSIONS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the application must be denied because it "is inconsistent with" a separate permit application submitted in 2008.

Unfortunately, the Illinois EPA has not acted on the 2008 application. That application was submitted in accordance with the Consent Decree between U. S. Steel and the Illinois EPA. (*See, People of the State of Illinois v. United States Steel Corporation,* No. 05-CH-750, Third Judicial Circuit, Madison County.) The 2008 application was submitted based on limited information that was available at the time, and subsequent information indicates that when averaged over the year, the emission factor in the existing permit is appropriate. This topic was discussed with the Illinois EPA as the permit application submitted in 2020 was pending; and the Illinois EPA did not object to this development at the time. To now claim that this discrepancy serves as a basis to deny the PSD application is disingenuous. U. S. Steel cannot simply withdraw the 2008 permit application at this time but would do so following issuance of the revised PSD permit, pursuant to the permit application submitted in 2020 and supplemented in 2022, and termination of the Consent Decree. U. S. Steel has indicated it would work with Illinois EPA on that process and remains committed and willing to do so.

VI. THE PERMIT APPLICATION IS SUFFICIENT AS TO THE PSD AIR QUALITY IMPACTS ANALYSIS FOR CARBON MONOXIDE

The Production Increase Project was a major modification under the preconstruction PSD permitting program because it involved physical and operational changes that would result in a significant net increase in emissions of carbon monoxide (CO). National Steel Corporation, then the owner and operator of Granite City Works, submitted a PSD permit application for this project in 1995. Illinois EPA determined that this PSD permit application included all necessary information and granted PSD approval for the project in conjunction with issuance of Permit No. 95010001 on Jan. 25, 1996. One of the key requirements of the preconstruction PSD permitting program, which Illinois EPA determined had been satisfied by National Steel Corporation's 1995 permit application, is an air quality impact analysis—a demonstration by the applicant that the project will not cause or contribute to a violation of any national ambient air quality standard for CO. 40 CFR § 52.21(k).

As explained in the permit application submitted by U. S. Steel in March 2020 and supplemented in October 2022, recent information suggests that some of the emissions data relied upon by Illinois EPA in issuing Permit No. 95010001 in 1996 is not representative. Therefore, during informal discussions between Illinois EPA and U. S. Steel, the parties agreed that corrective updates to these data and to the CO air quality impact analysis is appropriate. The pending permit application includes such updated analysis.

In Attachment 1 to the draft denial letter, Illinois EPA indicates that a basis for the denial of the permit application is that the updated CO air quality impact analysis "cannot be relied upon because the inventory for the CO emissions of the source with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered." In particular, Illinois EPA indicates it has "concern" there may be some CO emissions from the Basic Oxygen Furnace Shop Roof Monitor which are not reflected in the air quality impact analysis and also suggests that the analysis should "consider the CO emissions of the former by-product coke oven batteries at the source." In addition, Illinois EPA asserts that the ambient background CO concentration data used by U. S. Steel, gathered by Illinois EPA during the period of three calendar years from 2016 through 2018, are "not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted."

None of the concerns listed by Illinois EPA are deficiencies warranting denial of the permit application. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a request for revision of a PSD approval include any of the listed information, nor does the agency point to even an application form or guidance document suggesting that such information be provided. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[2] but that was not done here.

[2] *See, e.g.,* 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

As it relates to the possibility of CO emissions from the Basic Oxygen Furnace Shop Roof Monitor, U. S. Steel responds further as follows: Illinois EPA's prior determination that the Production Increase Project would not cause or contribute to a violation of any national ambient air quality standard for CO was based on the agency's assumption that there are no CO emissions from this point. In the pending permit application, U. S. Steel did not request any changes to existing permit terms relating to this emission point. Illinois EPA has neither requested that U. S. Steel's updated CO air quality impacts analysis include any emissions from this emission point, nor has the agency provided a quantitative estimate of those emissions. In the absence of such a request, U. S. Steel had no reasonable basis to conclude that the agency had reconsidered its prior determination as relating to CO emissions from the Basic Oxygen Furnace Shop Roof Monitor; it was therefore reasonable for U. S. Steel to conclude that its updated CO air quality impacts analysis, with revisions to the CO emission rates only for those emission points where the parties agreed that National Steel Corporation's modeled rates should be corrected, was sufficient for the purpose of requesting revisions to the permitted CO emissions from certain combustion units burning blast furnace gas and/or natural gas and affected by Production Increase Project.

As it relates to historical CO emissions from the by-product coke oven batteries that were operated by National Steel Corporation at the time the PSD approval was granted by Illinois EPA in 1996, U. S. Steel responds further as follows: It is unclear to U. S. Steel whether this observation relates to the demonstration that was approved by Illinois EPA in 1996 or to the demonstration submitted by U. S. Steel in March 2020 and supplemented in October 2022. If the former, then U. S. Steel notes that those emissions were, in fact, included.[3] If the latter, then U. S. Steel notes that it is not requesting PSD approval or other authorization for CO emissions from by-product coke oven batteries and that there is no basis for considering emissions under a counterfactual scenario in evaluating whether a requested change will cause or contribute to a violation of any national ambient air quality standard.

Finally, as it relates to the use of 2016-2018 background CO concentration data, U. S. Steel responds further as follows: These data were the most current quality-assured data available at the time of U. S. Steel's submittal of the pending permit application in March 2020 and use of these data was approved by Illinois EPA following its review of U. S. Steel's dispersion modeling protocol in February 2020. U. S. Steel agrees that the 2016-2018 background CO concentration data are less current now than they were at the time of permit application submittal. Currentness of air quality data is one aspect of the permit application review process that is ensured by compliance with the procedural requirements relating to timely processing of permit applications.[4]

VII. THE PERMIT APPLICATION IS SUFFICIENT AS TO BEST AVAILABLE CONTROL TECHNOLOGY

A. Introduction

The pertinent provision of the PSD rule governing the required contents of the permit application pertaining to establishment of Best Available Control Technology ("BACT") is a requirement to include in the application:

[3] *See, e.g.,* permit application supplement submitted by National Steel Corporation Jan. 16, 1996, at Table 5-8.
[4] *See,* 35 Ill. Adm. Code Section 201.158 (providing that a permit application shall be deemed to have been filed 30 days after submittal if Illinois EPA has not notified the applicant that it is incomplete) and 42 U.S.C. § 7475(c) (requiring final action on a PSD permit application not later than one year after filing).

> A detailed description as to what system of continuous emission reduction is planned for the source or modification, emission estimates, and any other information necessary to determine that best available control technology would be applied. 40 CFR § 52.21(n)(1)(iii).[5]

It is undisputed that the permit application includes estimates of the CO emissions from the casthouse and the blast furnace stoves as well as a detailed description of the systems of continuous emission reduction that U. S. Steel plans to use to control these emissions.

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the application "lacks necessary information" for the agency to make BACT determinations for the casthouse and the blast furnace stoves.

B. CO Emissions from Blast Furnace Casthouse

For the casthouse, as discussed in Section 8.2.3 of the permit application, the only control options identified by U. S. Steel for potential consideration in a BACT determination by Illinois EPA are add-on air pollution control equipment options—specifically, installation and use of a capture system and some type of incinerator. Illinois EPA asserts that this part of the permit application is deficient because it provides neither an explanation of "why process-related control options are not available" nor, with respect to the literature search conducted by U. S. Steel that did not identify any process-related control options for CO emissions from blast furnace casthouses, "documentary support for the review of available control options that was conducted." It is unclear to U. S. Steel how it would be helpful to Illinois EPA's BACT determination to have copies of reports that contain no pertinent information, and it is even more unclear how U. S. Steel might be expected to know, without receiving from Illinois EPA a request for specific additional information, which reports containing no pertinent information would be most valuable for this purpose. As to the first of the purported deficiencies listed by Illinois EPA—the failure to explain why no process-related control options are available for controlling CO emissions from the blast furnace casthouse—U. S. Steel notes that Illinois EPA is familiar with the chemical reaction that is intentionally forced to occur in the casthouse as an inherent part of the ironmaking process.[6] Having not received from Illinois EPA a request for specific additional information, U. S. Steel had no way to know that it was necessary to explain in the permit application that the partial combustion of coke inevitably yields carbon monoxide as a reaction product.

U. S. Steel also notes that, as it pertains to CO emissions from the casthouse, U. S. Steel has not requested any changes to its current permits and is currently subject neither to any numeric emission limitations nor to any work practice requirements other than those in 40 CFR part 63, subpart FFFFF. U. S. Steel did not include any information pertaining to BACT for CO emissions from the casthouse in the initial permit application submitted in March 2020; at the request of Illinois EPA, although

[5] *See, also,* the current PSD rule at 35 Ill. Adm. Code Section 204.810(a)(3).

[6] *See, e.g.,* "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 4 ("The charge materials (iron ore, coke, limestone and other flux material) are fed into the furnace at the top through a double-bell lock system. Heated air is blown into the furnace through nozzles or tuyeres near the bottom of the furnaces. In the furnaces, the coke undergoes partial combustion to carbon monoxide providing the heat to melt the charge as well as reducing the iron ore to elemental iron.")

under no obligation to do so,[7] U. S. Steel voluntarily provided a proposed BACT analysis for CO emissions from the casthouse in the permit application supplement submitted in October 2022. Illinois EPA's proposed denial of the permit application will simply ensure the status quo is maintained, *i.e.*, that U. S. Steel is not subject to any limitations on CO emissions from the casthouse.

C. CO Emissions from Blast Furnace Stoves

In the permit application it submitted in 1995, National Steel Corporation made the following proposal:

> Therefore the BACT recommendation for control of CO emissions from the blast furnace stoves is the maintenance of good combustion practices.[8]

As described in Section 8.1 of the permit application, Illinois EPA reviewed this proposal and agreed with it, determining that work practices constitute BACT for CO emissions from the blast furnace stoves at Granite City Works.

As discussed in Section 8.2.1.1 of the permit application, this determination is consistent with the PSD rule requirements, which expressly provides for a PSD permit to prescribe work practices to satisfy the BACT requirement where the permitting authority "determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible." 40 CFR § 52.21(b)(12).[9]

In 2013, when issuing the CAAPP permit for the Granite City Works, Illinois EPA again determined that work practices suffice for purposes of demonstrating compliance with the applicable requirements of Permit No. 95010001.[10]

In Section 8.2.2.6 of the permit application, in the discussion of step 5 of the proposed BACT analysis for CO emissions from the blast furnace stoves, U. S. Steel stated as follows:

> USS Granite City is proposing work practice requirements rather than numeric limits as BACT. Numeric emission limitations are not proposed because direct measurement of emissions—*i.e.*, use of U.S. EPA reference test methods—is not feasible for any of the fuel emissions units subject to the BACT requirements for CO emissions. In particular, for the stack serving the blast furnace A stoves, there is no sampling port,[45] and for the stack serving the blast furnace B stoves there is no sampling port satisfying the location requirement in U.S. EPA Reference Method 1.[46] Each stack is refractory lined and is believed to be approximately one hundred years old.
>
> For the reasons presented above, numeric CO emission standards are not feasible for the blast

[7] *See, e.g., U.S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677 (N.D. Ill. 2011)(holding that source owner's obligations with respect to BACT are limited to those imposed in a PSD permit).
[8] *See*, permit application supplement submitted by National Steel Corporation Oct. 30, 1995, at p. 4-11.
[9] *See, also*, the current PSD rule at 35 Ill. Adm. Code Section 204.280.
[10] *See*, CAAPP Permit No. 96030056 at Condition 7.4.12.b, stipulating that compliance with all applicable requirements for the stoves and certain other processes are demonstrated by meeting "the work practices, testing, monitoring, recordkeeping, and reporting requirements in Sections 7.4 and 5 of this permit;" note that the permit does not include any testing, monitoring, recordkeeping, or reporting requirements specific to the blast furnace stoves.

> furnace stoves.

Footnote 45. For the one-time exhaust gas sampling event discussed in footnote 19 of this permit application, USS Granite City inserted a sampling probe into the stack through a pipe used to inject steam into the stack.

Footnote 46. Appendix A-1 to 40 CFR part 60.

In Attachment 1 to the draft denial letter, Illinois EPA makes the following assertion:

> Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. For example, the application does not include diagrams for the existing ductwork of the stoves to address whether the configuration of this ductwork would accommodate installation of test ports at a location that would satisfy USEPA Reference Method 1. The application also does not show how the refractory lining on the stacks or their age, approximately one hundred years old, would present significant technical challenges and costs so that the installation of test ports at a suitable location should be considered infeasible. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

With respect to both Illinois EPA's general suggestion that "further support" is needed and its list of specific examples, Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. Notably, the documentation provided in the permit application supplement submitted in October 2022 regarding infeasibility of emissions testing is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. U. S. Steel's permit application includes all information required by the applicable permitting rules—including the PSD rule—relating to BACT for CO emissions from the blast furnace stoves at Granite City Works. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[11] but that was not done here.

D. Emissions Associated with Combustion of Coke Oven Gas

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it "does not demonstrate that prior to February 2015, when the by-product recovery coke oven batteries at the Granite City Works were shut down and [coke oven gas] ceased to be available, BACT was being utilized for the SO_2 and CO emissions from use of [coke oven gas] in the stoves." U.

[11] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

S. Steel acknowledges that the BACT determination made by Illinois EPA in 1996, in response to the permit application submitted by National Steel Corporation in 1995, may have been deficient in this regard. Nonetheless, Illinois EPA's assertion that any such historical deficiency is relevant to U. S. Steel's pending permit application is entirely without merit.[12]

VIII. PSD AND NNSR APPLICABILITY WITH RESPECT TO NO_X EMISSIONS

A. Lack of Clarity in Illinois EPA's Claims

Attachment 1 to the draft denial letter at paragraph 1 suggests that the permit application is deficient because it does not include or otherwise address the substantive requirements of the PSD and NNSR programs with respect to NO_X emissions. However, in its evaluation of whether the Production Increase Project is or would become a major modification, Illinois EPA appears to take into account emissions and emissions increases that were authorized by Illinois EPA at the time Permit No. 95010001 was issued to National Steel Corporation.[13] In addition, in summarizing its review of the updated net emissions increase ("netting") analysis provided in the permit application, Illinois EPA conspicuously avoids using the controlling language of the source obligation provisions, discussed in detail in Section VIII.B below, but rather states that the application "does not show that the Project would still not be a major modification for NO_X." In this regard, Illinois EPA's assertions regarding applicability of the substantive requirements of the PSD and NNSR programs with respect to NO_X emissions are ambiguous: U. S. Steel cannot determine from the draft denial letter and associated documents whether Illinois EPA is claiming that the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel Corporation prior to U. S. Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs or, instead, if Illinois EPA is claiming that the measures required by Permit No. 95010001 as issued to National Steel Corporation were sufficient to ensure the Production Increase Project would not be a major modification and that the project would become a major modification solely by virtue of the relaxations requested by U. S. Steel.

For purposes of these comments, U. S. Steel has assumed Illinois EPA's claims fall into the latter category, *i.e.*, that the Production Increase Project would become a major modification for NO_X solely by virtue of the requested relaxations.

---

[12] *See, e.g., U.S. v. Midwest Generation, LLC*, 781 F. Supp. 2d 677 (N.D. Ill. 2011)(holding that source owner's obligations with respect to BACT are limited to those imposed in a PSD permit).

[13] *See, e.g.,* Attachment 1 at p. 4, suggesting that the updated applicability analysis should include "'future' NO_X emissions" from Boilers 1 through 10 based on the configuration of those boilers as they existed at the time the Production Increase Project was implemented by National Steel and at the time U. S. Steel purchased the assets in 2003, notwithstanding the fact that those boilers are prohibited from operating currently and in the future; Attachment 1 at p. 4, suggesting that the updated applicability analysis should include greater NO_X emission rates from Boilers 11 and 12 based on the configuration of those boilers as they existed at the time the Production Increase Project was implemented by National Steel and at the time U. S. Steel purchased the assets in 2003, notwithstanding the fact that the Boilers are prohibited from operating at those emission rates currently and in the future; Attachment 1 at p. 4, suggesting that the updated applicability analysis should include greater NO_X emission rates from Boilers 11 and 12 and from the blast furnace stoves based on the use of coke oven gas as fuel in those units at the time the Production Increase Project was implemented by National Steel and at the time U. S. Steel purchased the assets in 2003, notwithstanding the fact that coke oven gas is not an available fuel at the facility currently or in the future.

B. Source Obligation

Under the PSD and NNSR programs as in effect at the time of the Production Increase Project, where the project involved changes to existing emissions units that are so significant that the emissions unit was deemed not to have begun normal operation, the post-change actual emissions of that unit are assumed equal to its potential to emit. 40 CFR § 52.21(b)(21).[14] The major modification applicability test was therefore based on a comparison of the pre-project actual emissions and the post-project potential to emit of the emissions unit or group of units. 40 CFR §§ 52.21(b)(2)-(3). An emissions unit's potential to emit is its maximum capacity to emit a pollutant under its physical and operational design. 40 CFR § 52.21(b)(4). Limitations on the capacity to emit a pollutant are treated as part of the design of an emissions unit or group of units if the limitation or the effect it would have on emissions is legally enforceable and enforceable as a practical matter. Where the potential to emit of a unit or group of units is governed by enforceable limitations rather than by the unrestricted physical capacity of that unit or those units, and where those limitations were necessary to a determination that a project was not a major modification, the term "synthetic minor" is commonly used to describe the project and the associated limitations.

As explained in detail in Section 2.2.4 of the permit application, the PSD and NNSR rules provide that after-the-fact PSD or NNSR permitting is required when a project becomes a major modification "solely by virtue of a relaxation in" a synthetic minor limitation. 40 CFR § 52.21(r)(4).[15] These "source obligation" provisions effectively require updated PSD and NNSR applicability analyses in situations where the applicant proposes to relax a synthetic minor limitation in a permit.

Applicability analyses performed in order to determine whether the source obligation provisions apply in conjunction with a requested relaxation are prospective, not retrospective. All of the facts as they will exist at the time of the requested relaxation are considered in the updated emissions increase calculations; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.[16]

The updated NO_X emissions increase calculations presented in the permit application fully conform to and satisfy the source obligation provisions of the PSD and NNSR rules. U. S. Steel's prospective calculation of potential NO_X emissions from the certain fuel combustion units affected by the Production Increase Project includes zero emissions from Boilers 1 through 10, which accurately represents the future potential to emit of those boilers because they no longer exist; does not include

[14] Except as noted, all citations to the applicable PSD rules herein are to the federal PSD rule as codified and in effect at the time of issuance of Permit No. 95010001 in 1996; where the corresponding provision of the then-effective NNSR rule is equivalent, separate citations are not provided.

[15] *See, also,* the current PSD rule at 35 Ill. Adm. Code Section 204.850.

[16] *See, e.g.*, letter from S.C. Riva, U.S. EPA, to R. Frontanes, Pfizer Pharmaceuticals LLC (Sept. 23, 2015), conveying U.S. EPA's non-applicability determination for proposed relaxation of synthetic minor limitations that had been imposed in 1994 in order to establish synthetic minor status with respect to NO_X emissions from a project that involved installation of five diesel generators and two boilers. The synthetic minor limitations imposed in 1994 established the combined potential to emit NO_X from the seven new units at 56 tons per year; if the combined potential to emit had been 65 tons per year or more, the project would have been a major modification. U.S. EPA's 2015 applicability determination allowed relaxation of the limitations such that the new potential to emit would be 90 tons per year; the agency's source obligation analysis relied on the fact that other facts had changed during the intervening time period and it gave no consideration to the fact that, had the combined potential to emit been 90 tons per year historically, the project would have been a major modification.

the greater NO_X emission rates of Boilers 11 and 12 prior to the required retrofit of flue gas recirculation in those boilers; and includes zero emissions from combustion of coke oven gas as fuel, which accurately represents the future emissions of units that previously burned coke oven gas because coke oven gas is no longer an available fuel at the facility. As discussed further in Sections VIII.C and VIII.D below, if Illinois EPA revises Permit No. 95010001 with the requested relaxations and other changes to the limitations in the permit currently in effect, the Production Increase Project will not become a major modification solely due to those relaxations.

C. Project Emissions Increases and Net Emissions Increases

By definition, the net emissions increase from a project is the sum of two values: The increase in actual emissions from the project and "[a]ny other increases and decreases in actual emissions at the source that are contemporaneous with the particular change and are otherwise creditable." 40 CFR § 52.21(b)(3)(i).

Illinois EPA proposes to deny the permit application, at least in part, because Illinois EPA preliminarily determined that "additional decreases in NO_X emissions that would now be proposed to be relied upon" by U. S. Steel are not contemporaneous and otherwise creditable.[17] This preliminary determination is erroneous for three reasons.

First, to the extent that Illinois EPA's analysis includes separate calculations of increases and decreases based on specific fuels and changes in fuels, those calculations are inconsistent with the PSD and NNSR rule requirements. As described previously, the major modification applicability test requires a comparison of the pre-project actual emissions of the emissions unit or group of units with the post-project actual emissions (or potential to emit) of that emissions unit or group of units; the applicable definition of actual emissions does not provide for a calculation that considers only some portions of the units' emissions. For the certain fuel combustion units affected by the Production Increase Project, the change in actual NO_X emissions is properly calculated as the total post-project actual NO_X emissions, regardless of the fuel or fuels being burned to generate those emissions, minus the total pre-project actual NO_X emissions, regardless of the fuel or fuels that were burned to generate those emissions. This is the basis for the values shown in Table 6-8 of the permit application.

Second, the emissions changes at issue are at certain fuel combustion units affected by the Production Increase Project. Emissions changes at these emissions units must be included in the calculation of the emissions increase that will occur as a result of the project, under the first clause in the definition of the term "net emissions increase."[18] Therefore, it was proper to include the emissions changes at the certain fuel combustion units affected by the Production Increase Project in the updated calculation of the NO_X emissions increase from the project, -10.7 tons per year, as calculated in Table 6-8 of the permit application and as shown in Table 6-9 of the permit application.

Third, even if the contribution of the certain fuel combustion units affected by the Production Increase Project were properly considered as among the other decreases under the second clause of the

[17] Attachment 1 at p. 3.

[18] Contrast this with the emissions changes at the blooming mill and galvanizing line shown in Table 6-9. Because these are emissions units not affected by the Production Increase Project, increases and decreases in actual emissions at these units are among the other changes that are considered under the second clause in the definition.

definition rather than a contribution to the emissions increase from the project under the first clause of the definition, it is not relied upon for the non-applicability determination. The net NO_X emissions increase from the project as presented in Table 6-9 of the permit application is -237.3 tons per year; even if the decrease of 250.3 tons per year as calculated by Illinois EPA is omitted from the calculation, the net emissions increase is 13 tons per year (-237.3+250.3), which is less than the significant level of 40 tons per year and therefore sufficient to demonstrate that the Production Increase Project would not become a major modification solely by virtue of the relaxations requested by U. S. Steel.

D. Substantive Requirements of the PSD and NNSR Programs Are Not Applicable with Respect to NO_X Emissions

Because the Production Increase Project would not become a major modification with respect to NO_X emissions solely by virtue of the relaxations requested by U. S. Steel, the substantive requirements of the PSD and NNSR programs[19] are not required elements of the permit application and the fact that these requirements are not addressed in the permit application is not a valid basis for application denial.

IX. THE PERMIT APPLICATION INCLUDES ALL REQUIRED INFORMATION PERTAINING TO PRE-PROJECT (BASELINE) NO_X EMISSIONS CALCULATIONS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient in that it omits certain information that is purportedly necessary for Illinois EPA to validate the PSD/NNSR non-applicability determinations. As explained below, these assertions are without merit.

A. Volume of Coke Oven Gas Combusted During the Pre-Project Baseline Period

In Attachment 1 to the draft denial letter, Illinois EPA states that the updated calculations of the NO_X emissions change resulting from the Production Increase Project include the difference between the pre-project and post-project actual emissions from certain combustion units and that the calculation of pre-project actual NO_X emissions rates for some of these combustion units includes consideration of NO_X formed from combustion of coke oven gas, among other fuels. These statements are correct.

Illinois EPA then asserts that the pre-project coke oven gas usage rates used in calculating these emission contributions "are not accompanied by any documentation or explanation," suggesting that it is not enough to identify the quantity of coke oven gas consumed in each type of affected combustion unit. With respect to an "explanation," this assertion is incorrect. The permit application includes extensive discussion of the use of coke oven gas as fuel during the pre-project baseline period.[20]

With respect to additional documentation or further explanation, Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular documentation or explanation in conjunction with a historical operational rate or emissions rate, nor do they point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. Notably, the

[19] 35 Ill. Adm. Code Sections 203.601, 203.602, 204.1100, 204.1110, 204.1120 and 204.1130.
[20] *See, e.g.*, pp. 2-4, 4-2, 5-5, and 11-2 of the body of the permit application. Additional information is provided in the appendices to the application.

documentation provided for coke oven gas in the permit application supplement submitted in October 2022 is indistinguishable from the documentation provided with respect to other fuels, both in the permit application supplement submitted in October 2022 and in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. In all cases, what was provided was a table of usage values, with no primary source documents such as strip charts, because it is neither required nor customary to provide such documents. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[21] but that was not done here.

B. NO_X Emission Factor for Use of COG in Boilers 11 and 12:

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that Table 6-4 in the permit application indicates the emission factor used in calculating the amount of NO_X formed from combustion of coke oven gas in the boilers during the pre-project baseline period is based on emissions testing performed at a coke oven battery.

The emission factor basis listed in Table 6-4 of the permit application is a scrivener's error. The error was pointed out to U. S. Steel by Illinois EPA's permit application reviewer by telephone in January 2023. The factor is actually based on emission testing performed at Boiler #12, which is one of the boilers that is the subject of the calculation. This fact was conveyed to Illinois EPA's permit application reviewer by telephone in January 2023.

C. Emission Factor for Use of Natural Gas in Ladle Preheaters

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the calculations presented in the permit application in support of the pre-project actual NO_X emissions from certain fuel combustion units affected by the Production Increase Project, U. S. Steel used a single emission factor for all such units, including ladle preheaters. This statement is correct.

Illinois EPA then asserts that the permit application "does not show that it is appropriate to utilize this emissions factor for ladle preheaters." Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular documentation or justification for the emission factors used to estimate historical emissions, nor do they point to even an application form or guidance document suggesting that such documentation or justification be provided. Notably, for a period of nearly thirty years, the emission factor at issue has been used consistently for all purposes pertaining to the permitting of the Production Increase Project and has been both accepted and prescribed by Illinois EPA for that purpose.[22] In light of Illinois EPA's repeated acceptance of and reliance on this emission factor for

[21] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[22] *See, e.g.*, "Calculation Sheet" prepared by Jim Ross of Illinois EPA, Dec. 5, 1995 (summarizing Illinois EPA's review of the construction permit application submitted by National Steel Corporation and received by Illinois EPA on Jan. 3, 1995) at p. 12; permit application supplement submitted by National Steel Corporation Jan. 16, 1996, at p. 3-2; Construction Permit No. 95010001 as issued Jan. 25, 1996, at Table 4 (prescribing use of this factor for ladle preheaters and certain other combustion units); Construction Permit No. 95010001 as revised Dec. 17, 2012, at Table 4 (same).

calculating NO_X emissions from combustion of natural gas in ladle preheaters in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application submitted in March 2020 and supplemented in October 2022.

D. Emissions from Use of Natural Gas on the Continuous Casting Lines:

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the calculations presented in the permit application in support of the pre-project actual NO_X emissions from emissions units affected by the Production Increase Project, U. S. Steel indicated there is no NO_X formation from the continuous casting operation other than from combustion of natural gas and, because all natural gas consumption in the continuous casting operation is accounted for elsewhere, U. S. Steel did not account for any additional pre-project actual NO_X emissions from the continuous casting operation. Illinois EPA's statements in this regard are correct.

Illinois EPA then asserts that U. S. Steel's failure to double-count the pre-project actual NO_X emissions from the continuous casting operation is "problematic." This assertion is incorrect. U. S. Steel's election not to overstate the pre-project actual NO_X emissions from emissions units affected by the Production Increase Project is the correct and appropriate approach, as it best represents the increases in actual emissions resulting from the project, consistent with the requirements of the PSD and NNSR rules. However, the manner in which U. S. Steel presented in the permit application the natural gas usage rates and associated NO_X emissions contributions during the pre-project baseline period gas is unclear, and that lack of clarity appears to have caused confusion on the part of Illinois EPA's reviewer. The lack of clarity and the correctness of the total pre-project actual NO_X emissions from natural gas consumption in certain fuel combustion units affected by the Production Increase Project is explained below.

Following are the natural gas usage rates during the pre-project baseline period as listed in Table 3-2 of the permit application submitted by National Steel Corporation in 1995[23] and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996.

Source Description	Emission Factor	Base Year Throughput	Actual Emission	Projected Throughput	Projected Emission
Boiler House 1 (Blrs 1-10) – NG	306 lb/MMcf	361 MMcf	55.23 tpy	included below	
Boiler #11 – NG	306 lb/MMcf	226 MMcf	34.58 tpy	included below	
Boiler #12 – NG	306 lb/MMcf	218 MMcf	33.35 tpy	included below	
BOF Preheaters/Dryers – NG	306 lb/MMcf	283 MMcf	43.30 tpy	included below	
Continuous Caster #1 & #2 – NG	306 lb/MMcf	57 MMcf	8.72 tpy	included below	
Natural gas usage	306 lb/MMcf	1,145 MMcf	inc. above	1,145 MMcf	175.19

[23] *See,* permit application supplement submitted by National Steel Corporation Jan. 16, 1996, at Table 3-2.

The total natural gas usage in the affected units during the pre-project baseline period is 1,145 million cubic feet per year, including 805 million cubic feet per year from the boilers and 340 million cubic feet per year from the BOF shop and the continuous casting operations. The total associated NO_X contribution during the pre-project baseline period is 175.19 tons per year, including 123.17 tons per year from the boilers and 52.02 tons per year from the BOF shop and the continuous casting operations. National Steel Corporation's projection of the total post-project natural gas usage in the affected units, including the continuous casting operations, was the same as the pre-project amount: 1,145 million cubic feet per year. The total NO_X emissions increase from the Production Increase Project as shown in Table 3-2 of the permit application submitted by National Steel Corporation in 1995 is 238.8 tons per year.

Illinois EPA included in Permit No. 95010001 a limit on total post-project natural gas usage and a limit on total post-project NO_X emissions contribution from this natural gas usage. The limits are 1,145 million cubic feet per year and 175.19 tons per year, respectively.[24] These limits precisely match the values that were presented in Table 3-2 of the permit application submitted by National Steel Corporation in 1995 and that included natural gas usage in the continuous casting operations. Illinois EPA also included in the permit a list of the fuel combustion units to which these limits apply.[25] Likely inadvertently, Illinois EPA omitted the continuous casting operations from this list of fuel combustion units. It is undisputed that Illinois EPA accepted and relied upon both the pre-project baseline information and the projections presented in Table 3-2 of the permit application submitted by National Steel Corporation in 1995: The total NO_X emissions increase authorized in the construction permit issued in 1996 is 238.8 tons per year,[26] which precisely matches the value presented in the 1995 permit application.

In the permit application submitted by U. S. Steel in March 2020 and in the supplement submitted in October 2022, the total natural gas usage in the affected units during the pre-project baseline period is documented as 1,145 million cubic feet per year, including 805 million cubic feet per year from the boilers and 340 million cubic feet per year from the BOF shop. The total associated NO_X contribution during the pre-project baseline period is documented as 175.19 tons per year, including 123.17 tons per year from the boilers and 52.02 tons per year from the BOF shop. Consistent with the approach taken by Illinois EPA in drafting Permit No. 95010001, and perpetuating what was likely an inadvertent error, U. S. Steel omitted the continuous casting operations from the list of fuel combustion units burning natural gas and contributing to the total associated NO_X contribution during the pre-project baseline period but included the contribution of the continuous casting operations. However, emissions associated with natural gas combustion in this operation were properly accounted for both in pre-project baseline and the post project emission for the project affected units.

X. THERE ARE NO QUANTIFIABLE FUGITIVE EMISSIONS OF NO_X OR VOM FROM THE BASIC OXYGEN FURNACES

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application "does not address uncaptured emissions" of NO_X and VOM from the basic oxygen furnaces and that the emissions calculations presented in the permit application reflect an assumption "that all emissions of

[24] *See, e.g.*, Construction Permit No. 95010001 as issued Jan. 25, 1996, at Special Condition 21 and Table 4.
[25] *Ibid* at Special Condition 21, Special Condition 35, and Table 4.
[26] *Ibid* at Special Condition 42.c and Table 6.

these pollutants from the basic oxygen furnaces are now captured" and routed to atmosphere through the electrostatic precipitator or baghouse. Illinois EPA also acknowledges that such uncaptured emissions, if they exist, are not significant and that, if estimated quantities of such uncaptured emissions were added to the calculations supporting the PSD/NNSR non-applicability demonstrations, would yield smaller (rather than greater) emissions increases.

With one minor exception, Illinois EPA's general statements characterizing the emissions increase calculations presented in the permit application, as summarized above, are correct. The minor exception is this: The permit application does not reflect an assumption that there are zero uncaptured emissions of NO_X and VOM from the basic oxygen furnaces but rather reflects the conclusion that, if there are any such uncaptured emissions, those emissions are fugitive emissions[27] and are not quantifiable. Fugitive emissions are counted for purposes of PSD and NNSR applicability determinations only to the extent that such emissions are quantifiable.[28]

Although Illinois EPA presents speculation regarding possible fugitive emissions of NO_X and VOM from the basic oxygen furnaces, that speculation is not a sufficient basis to determine that such emissions exist and are quantifiable. U. S. Steel nor Illinois EPA has not identified any evidence of such quantifiable emissions in the literature or in the permitting records of other iron and steel mills.

The fact that there are fugitive particulate matter emissions from basic oxygen furnaces is not indicative of the formation of NO_X or VOM emissions. The capture system serving the secondary baghouse at Granite City Works is a large ventilation system that is generally evacuating the space around the basic oxygen furnace vessels during the charging, refining, and tapping operations. The primary mechanism for formation of particulate matter during charging and tapping is the oxidation of molten metal. This formation mechanism cannot be expected to result in the formation of NO_X or VOM.

XI. THE PERMIT APPLICATION INCLUDES ALL REQUIRED INFORMATION PERTAINING TO PRE-PROJECT (BASELINE) PARTICULATE MATTER EMISSIONS CALCULATIONS

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient for the following reason:

> With regard to baseline particulate emissions, the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be

[27] Fugitive emissions are "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." 40 CFR § 52.21(b)(20). The emissions capture systems serving the basic oxygen furnaces satisfy the stringent requirements of 40 CFR part 63, subpart FFFFF, which reflects U.S. EPA's determination of the maximum degree of reduction in emissions that is achievable for these operations. 42 U.S.C. § 7412(d)(2). It is indisputable that these capture systems reflect the state of the art and that, to the extent there are any uncaptured emissions of NO_X or VOM, those emissions could not reasonably be captured or controlled and thus are fugitive emissions.

[28] *See, e.g.*, 40 CFR § 52.21(i)(4)(vii)(exempting a project from PSD permitting requirements if it would be major "only if fugitive emissions, to the extent quantifiable, are considered" and it would occur at a source that is not in a listed source category); *see, also*, 45 *Fed. Reg.* 52676 at 52692 (Aug. 7, 1980)(EPA explains that it is declining to extend the exemption the exemption at § 52.21(i)(4)(vii) to the listed source categories, such as iron and steel mills, but stated, "EPA emphasizes, however, that fugitive emissions from a source in one of the listed categories will only be included in threshold calculations 'to the extent quantifiable'").

> independently confirmed. In this regard, the 2022 application does not provide needed supporting information for the "corrected" determinations of baseline particulate emissions of these operations as it is not accompanied by detailed calculations for the emissions from handling each material.

The assertion regarding a deficiency in the permit application is, for two reasons, without merit. First, Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Second, Illinois EPA's characterization of these pre-project (baseline) emission rates as "corrected" is erroneous: These are the values presented in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. U. S. Steel made no change to these values and is not in possession of information that would allow such change. In light of Illinois EPA's acceptance of and reliance on these values during that prior permitting action, which preceded U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the present permit application. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[29] but that was not done here.

XII. THE PERMIT APPLICATION INCLUDES ALL REQUIRED INFORMATION RELATING TO POST-PROJECT ACTUAL EMISSIONS OF PM, PM_{10}, NO_X, AND VOM AND TO ENFORCEABLE LIMITATIONS ON POTENTIAL TO EMIT THESE POLLUTANTS

A. It Is Feasible to Establish Enforceable Emission Caps for Groups of Emissions Units and Emission Points as Proposed in the Permit Application

As correctly described by Illinois EPA in Attachment 1 to the draft denial letter, U. S. Steel's permit application proposes that PM, PM_{10}, NO_X, and VOM emissions be subject to annual emission caps covering groups of related emissions units and emission points. For the blast furnace operations and the BOF shop, the proposed groupings include emission points with significant emissions, such as the BOF electrostatic precipitator stack, and minor emission points such as the iron spout baghouse stack. U. S. Steel's permit application also proposes approaches to making these emission caps enforceable as a practical matter, as would be required if these emission caps were to serve as synthetic minor limitations.[30]

In Attachment 1 to the draft denial letter, Illinois EPA asserts that there may be alternative groupings of emissions units and emission points that could be subjected to enforceable emission caps or other limitations:

> It would be reasonable and appropriate for both the annual emissions of the casthouse and the

[29] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[30] See discussion of synthetic minor limitations in Section VIII.B herein.

> annual emissions of the two basic oxygen furnaces to be directly limited separately from the emissions of any other units.
> *
> *
> Alternatively, limits specifically for the emissions of the casthouse for the blast furnaces and the basic oxygen furnaces, i.e., the principal units at the facility for iron and steel production, could be accompanied by group limits for the overall emissions of these principal units and the other, "non- principal" units in these areas of the facility. For example, limits could be set for both emissions of the casthouse and for the emissions of the casthouse, charging of the blast furnaces, and the slag pits. Attachment 1 at 18-19.

U. S. Steel agrees with Illinois EPA generally that there are potentially suitable groupings other than those proposed in U. S. Steel's permit application and that the approach suggested by Illinois EPA in Attachment 1 is likely permissible under the applicable permitting rules.

It is unclear whether Illinois EPA's discussion of other potentially suitable groupings of other emissions units and emission points is intended to explain Illinois EPA's proposed denial of the permit application.[31] If it is so intended, U. S. Steel disagrees that this represents a valid basis for such denial. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

B. Particulate Matter Emissions Associated with a Facility Configuration No Longer Authorized Are Immaterial to the "Source Obligation" Demonstration

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application does not include information associated with emissions from the handling of coal and coke at the by-product coke oven batteries that were permanently shut down in 2015. This statement is correct.

Illinois EPA then asserts that this omission represents a deficiency in the permit application because these emissions should be included in the total post-project actual emissions quantity as used in determining whether PSD and NNSR permitting requirements apply. This assertion is without merit. Although this information may be relevant to an evaluation of whether the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel Corporation prior to U. S. Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs, it is not relevant to the "source obligation" analysis and demonstration that are required here. As discussed in Section VIII.B above, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.

[31] Notably, Illinois EPA has not claimed that the groupings and approaches proposed by Illinois EPA would result in permit conditions that are not enforceable as a practical matter or that are otherwise impermissible under the applicable rules.

C. The Permit Application Includes All Required Information Relating to Quantifying Emissions of NO_X and VOM from the Blast Furnace Casthouse Roof Monitor

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed NO_X and VOM emission caps, U. S. Steel proposed that emissions of these pollutants from the Blast Furnace Casthouse Roof Monitor be calculated as 5.3% of the measured emission rate from the Blast Furnace Casthouse Baghouse. (This value reflects the assumption that the emissions from the baghouse represent 95.0% of the total emissions from the casthouse and the uncaptured and unmeasured emissions represent 5.0% of the total: 5% ÷ 95% = 5.3%.)

Illinois EPA then asserts that U. S. Steel's permit application does not demonstrate that the proposed methodology would yield calculated emission rates that are representative of actual emissions from the Blast Furnace Casthouse Roof Monitor under all conditions; in particular, Illinois EPA asserts, the proposed methodology might underestimate actual emissions if the capture efficiency is less than the assumed 95%. Finally, Illinois EPA suggests that prescribing specific emission rates for NO_X and VOM in the permit can reasonably be expected to be more representative than the ratio approach proposed by U. S. Steel.

It is unclear whether these assertions in Attachment 1 to the draft denial letter are intended to support Illinois EPA's proposed denial of the application. If these assertions are so intended, U. S. Steel disagrees that this is a valid basis for denial of the application. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

U. S. Steel agrees that the potential problem identified and discussed by Illinois EPA—that an actual capture efficiency of less than 95% would not be reflected in the calculation methodology proposed by U. S. Steel—exists as a theoretical matter. U. S. Steel contends that this scenario is effectively prohibited, as operation of the blast furnace casthouse capture system is subject to stringent requirements under 40 CFR part 63, subpart FFFFF, particularly § 63.7790(b). Thus, if it were left to U. S. Steel to decide on appropriate compliance demonstration methods for inclusion in the revised construction permit, the proposed 5.3% ratio approach would be used. However, U. S. Steel recognizes that this decision is within the judgment and discretion of Illinois EPA.

D. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Blast Furnace Casthouse Roof Monitor

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Blast Furnace Casthouse Roof Monitor be calculated using prescribed emission factors of 0.030 lb per ton of iron and 0.0153 lb per ton of iron, respectively. Each of these proposed emission factors is derived

from the pre-control PM emission factor of 0.6 lb per ton of iron published by U.S. EPA.[32] Specifically, the PM emission factor is based on an assumed 95% capture efficiency (*i.e.*, 5% of the pre-control emissions are emitted to atmosphere through the roof monitor; 5% × 0.6 = 0.030). The PM_{10} emission factor is based on an assumed particle size distribution where the PM_{10} emission rate is equal to 51% of the PM emission rate (51% × 0.030 = 0.0153), again based on data published by U.S. EPA.[33]

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to these emission factors because the application "does not include relevant supporting information," "only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency," and therefore does not demonstrate that the proposed emission factors would yield calculated emission rates that are representative of actual emissions from the Blast Furnace Casthouse Roof Monitor.

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the permit application regarding the emission factors at issue is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. The assumption of 95% capture efficiency for the blast furnace casthouse at Granite City Works has been consistently applied by Illinois EPA for many years.[34]

A brief recap of the history of U. S. Steel's approach with respect to this issue is in order. In the construction permit application submitted in March 2020, U. S. Steel proposed PM and PM_{10} emission factors of 0.031 lb per ton of iron and 0.0155 lb per ton of iron, respectively. These emission factors have been prescribed by Illinois EPA for this purpose for decades.[35] Among Illinois EPA's informal comments regarding that permit application submittal, Illinois EPA's permit application reviewer correctly pointed out that these historically assumed emission factors are slightly higher than the values that would result from correctly calculating the emission factors using Illinois EPA's historic assumptions of 0.6 lb per ton pre-control, 95% capture efficiency, and 51% PM_{10}:PM ratio. Illinois EPA's permit application reviewer also stated that the agency's records do not appear to contain an explanation for this discrepancy. Accordingly, the permit application reviewer suggested

[32] *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 4th Ed. U.S. EPA, Research Triangle Park, NC. Section 7.5, "Iron and Steel Production," Table 7.5-2, "Particulate Emission Factors for Iron and Steel Mills," May 1983.
[33] *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 5th Ed. U.S. EPA, Research Triangle Park, NC. Section 7.5, "Iron and Steel Production," Table 7.5-2, "Size Specific Emission Factors," January 1995.
[34] *See, e.g.*, "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 41.
[35] *See, e.g.*, Construction Permit No. 95090167 issued Sept. 15, 1995; Construction Permit No. 95010001 issued Jan. 25, 1996.

that U. S. Steel use the revised and corrected emission factors in the permit application supplement submitted in October 2022, which U. S. Steel did.

In light of Illinois EPA's repeated acceptance of and reliance on the assumption of 95% capture efficiency in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, and in light of the informal suggestion by Illinois EPA's permit application reviewer to correct the emission factor calculations in the manner described above, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[36] but that was not done here.

Alternatively, if Illinois EPA now believes there are insufficient data to quantify the capture efficiency of the state-of-the-art capture system employed at the blast furnace casthouse at Granite City Works, and that the fugitive emissions[37] from the Blast Furnace Casthouse Roof Monitor are therefore not quantifiable, then those emissions should be omitted from the analyses performed by Illinois EPA to determine whether the source obligation provisions apply in conjunction with the permit revisions requested by Illinois EPA. Fugitive emissions are counted for purposes of PSD and NNSR applicability determinations only to the extent that such emissions are quantifiable.[38]

E. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Slag Pits

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Slag Pits be calculated using a prescribed emission factor of 0.00417 lb per ton of hot metal.

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to this emission factor because the application "does not include relevant supporting information" and therefore does not demonstrate that the proposed emission factor would yield calculated emission rates that are representative of actual emissions from the Slag Pits.

---

[36] *See, e.g.,* 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[37] Fugitive emissions are "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." 40 CFR § 52.21(b)(20). The emissions capture systems serving the blast furnace casthouse satisfy the stringent requirements of 40 CFR part 63, subpart FFFFF, which reflects U.S. EPA's determination of the maximum degree of reduction in emissions that is achievable for these operations. 42 U.S.C. § 7412(d)(2). It is indisputable that these capture systems reflect the state of the art and that, to the extent there are any uncaptured emissions of PM_{10} or PM, those emissions could not reasonably be captured or controlled and thus are fugitive emissions.

[38] *See, e.g.,* 40 CFR § 52.21(i)(4)(vii)(exempting a project from PSD permitting requirements if it would be major "only if fugitive emissions, to the extent quantifiable, are considered" and it would occur at a source that is not in a listed source category); *see, also,* 45 *Fed. Reg.* 52676 at 52692 (Aug. 7, 1980)(EPA explains that it is declining to extend the exemption the exemption at § 52.21(i)(4)(vii) to the listed source categories, such as iron and steel mills, but stated, "EPA emphasizes, however, that fugitive emissions from a source in one of the listed categories will only be included in threshold calculations 'to the extent quantifiable'").

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the permit application regarding the emission factor at issue is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. The emission factor of 0.00417 lb per ton for the Slag Pits at Granite City Works has been consistently applied by Illinois EPA for decades.[39] The summary of the derivation of that factor as provided by U. S. Steel in the permit application is simply a paraphrasing of Illinois EPA's description.[40]

In light of Illinois EPA's repeated acceptance of and reliance on this emission factor in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[41] but that was not done here.

F. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Continuous Casting Operation

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Caster Mold, Slab Cutoff, and Slab Ripping operations be calculated using prescribed emission factors.

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to these emission factors because the application does not supporting information "sufficient to show that the emission factors that are proposed as prescribed factors are representative."

---

[39] *See, e.g.,* Construction Permit No. 95090167 issued Sept. 15, 1995; Construction Permit No. 95010001 issued Jan. 25, 1996.

[40] *See, e.g.,* "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 42, stating as follows:

> Emission Factor: 0.00417 lbs/ton of iron
> Origin of EF: Calculated from EPA Assessment of Atmospheric Emissions from Quenching of Blast Furnace Slag. Also, AP-42, Table 13.2.4-4, Fugitive Uncontrolled emissions.
> Summation of the following emission factors:
> a. Slag Quenching = 0.0026 lbs/ton iron,
> b. Slag Digging = 0.00157 lbs/ton iron.

[41] *See, e.g.,* 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any particular supporting information, nor does the agency point to even an application form or guidance document suggesting that such documentation or additional explanation be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. Notably, the supporting information provided in the permit application regarding the emission factors at issue is more extensive than the documentation provided in the permit application submitted by National Steel Corporation in 1995 and accepted by Illinois EPA when issuing Permit No. 95010001 in 1996. These PM/PM_{10} emission factors for the continuous casting operation at Granite City Works have been consistently prescribed by Illinois EPA for this purpose for many years.[42]

In light of Illinois EPA's repeated acceptance of and reliance on these emission factors in numerous permitting actions over a period of nearly thirty years, including several permitting actions occurring prior to U. S. Steel's ownership of the facility, U. S. Steel reasonably concluded that no further justification was needed as part of the permit application submitted in March 2020 or the permit application supplement submitted in October 2022. Of course, Illinois EPA retains authority to request additional information in conjunction with a construction permit application,[43] but that was not done here.

G. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Iron Pellet Screen

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Iron Pellet Screen be calculated using a prescribed emission factor of 0.00131 lb per ton of material. As explained in the permit application, the proposed emission factor is derived from the PM_{10} emission factor of 0.0087 lb per ton of material published by U.S. EPA for crushed stone screening,[44] with application of an 85% control efficiency. Specifically, the PM emission factor is based on an assumed 95% capture efficiency (*i.e.*, 5% of the pre-control emissions are emitted to atmosphere through the roof monitor; 5% × 0.6 = 0.030).

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to this emission factor because the application "does not include relevant supporting information," particularly with

[42] *See, e.g.*, "Statement of Basis for the Planned Issuance of a Revised Clean Air Act Permit Program (CAAPP) Permit for: United States Steel Corporation, Granite City Works," Illinois EPA (Feb. 4, 2013) at 47; Construction Permit No. 95090167 issued Sept. 15, 1995; Construction Permit No. 95010001 issued Jan. 25, 1996.

[43] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

[44] *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources (AP-42)*, 5th Ed. U.S. EPA, Research Triangle Park, NC. Section 11.19.2, "Crushed Stone Processing and Pulverized Mineral Processing," Table 11.19.2-2, "Emission Factors for Crushed Stone Processing Operations," updated Aug. 2004. A control efficiency of 85% was applied for this operation 7.5, "Iron and Steel Production," Table 7.5-2, "Particulate Emission Factors for Iron and Steel Mills," May 1983.

respect to the proposal to use an emission factor for PM derived from an emission factor published by U.S. EPA for PM_{10}, and therefore does not demonstrate that the proposed emission factor would yield calculated emission rates that are representative of actual emissions from the Iron Pellet Screen.

The listing of the PM_{10}-derived emission factor as the proposed, prescribed factor for PM emissions was a scrivener's error in the permit application; U. S. Steel's intent was to propose that Illinois EPA prescribe use of the corresponding PM emission factor of 0.00375 lb per ton of material as shown in Table 5-5 of the permit application supplement submitted in October 2022. Nonetheless, the assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any proposed emission quantification methods for fugitive emissions, nor does the agency point to even an application form or guidance document suggesting that such a proposal be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate, including recordkeeping requirements and other compliance demonstration methods; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

H. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Mag Lime Silo

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that U. S. Steel proposed in the permit application that emissions of PM and PM_{10} from the Mag Lime Silo be included in the permit conditions relating to demonstration of compliance with the proposed PM and PM_{10} emission caps, and further proposed that emissions of these pollutants from the Mag Lime Silo be calculated using a prescribed emission rate of 0.009 lb per hour.

Illinois EPA then asserts that U. S. Steel's permit application is deficient as relating to this emission factor because the application does not include supporting information demonstrating that the proposed emission rate of 0.009 lb per hour is representative of actual emissions from the Mag Lime Silo.

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a permit application include any proposed compliance demonstration methods, nor does the agency point to even an application form or guidance document suggesting that such a proposal be provided. U. S. Steel's permit application includes all information required by the applicable permitting rules. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate, including recordkeeping requirements and other compliance demonstration methods; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters. Here, it is noteworthy that U. S. Steel voluntarily proposed that emissions from the Mag Lime Silo be subject to limits where it had no obligation to do so. Illinois EPA's proposed denial of the permit application will simply ensure the status quo is maintained, *i.e.*, that U. S. Steel is not subject to any limitations on emissions from this emissions unit.

I. The Permit Application Includes All Required Information Relating to Quantifying Emissions of Particulate Matter from the Basic Oxygen Furnace Shop Roof Monitor

In Attachment 1 to the draft denial letter, Illinois EPA correctly states that, among the procedures proposed by U. S. Steel in the permit application for demonstration of compliance with the proposed PM and PM_{10} emission caps, U. S. Steel proposed that emissions of these pollutants from the Basic Oxygen Furnace Shop Roof Monitor be calculated using prescribed emission factors that are lower than the emission factors used by National Steel Corporation in the permit application submitted in 1995 and by Illinois EPA in the permit issued in 1996. Illinois EPA characterizes U. S. Steel's proposal as follows:

> For PM, an emission factor of 0.01986 pounds/ton is proposed as a prescribed factor, compared to the current emission factor limit of 0.0987 pounds/ton; for filterable PM_{10}, an emission factor of 0.0296 pounds/ton is proposed, compared to the current emission factor limit of 0.06614 pounds/ton.

This misstates U. S. Steel's proposal as presented in Section 5.5.2.2 of the permit application:

> For BOF Shop Roof Monitor, use PM emission factor of 0.0296 lb/ton and filterable PM10 emission factor of 0.0198 lb/ton.

Illinois EPA's mischaracterization of U. S. Steel's proposed emission factors for the Basic Oxygen Furnace Shop Roof Monitor is likely a scrivener's error in Attachment 1 to the draft denial letter.

Illinois EPA acknowledges in Attachment 1 to the draft denial letter that the emission factors proposed by U. S. Steel are representative of the current configuration of the Basic Oxygen Furnace Shop, but then asserts that U. S. Steel's permit application is deficient as relating to these emission factors because "those prescribed factors would not be representative of emissions before the new baghouse system was installed" and further asserts that "particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}."

These assertions are without merit. Although this information may be relevant to an evaluation of whether the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel Corporation prior to U. S. Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs, it is not relevant to the "source obligation" analysis and demonstration that are required here. As discussed in Section VIII.B above, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time.

J. The Permit Application Includes Adequate Explanation of Projected Post-Project Actual Emissions from Fuel Combustion Units and Does Not Diminish Illinois EPA's Authority to Impose Enforceable Limits

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application represents the maximum total post-project actual NO_X emissions from certain fuel combustion units affected by the

Production Increase Project will be 706 tpy and that the application also requests elimination of the gaseous fuel usage limits for these units. These statements are correct.

Illinois EPA then asserts that the permit application is deficient because it "does not explain why actual NO_X emissions of the subject units would not exceed this amount going forward if the permit were revised" as proposed. This assertion is without merit. The explanation is provided in Table 6-7 of the permit application supplement submitted in October 2022: The maximum potential emissions of the affected fuel combustion units are less than 706 tons NO_X per year.

Illinois EPA further asserts as follows:

> While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed above, this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the 2022 application does not show that new limits for fuel usage and emissions would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shutdown. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown. (Internal footnote omitted.)

A brief recap of the history of U. S. Steel's approach with respect to this issue is in order. In the construction permit application submitted in March 2020, U. S. Steel expressly requested enforceable emission caps for emissions of NO_X and other pollutants from the fuel combustion units affected by the Production Increase Project and provided emission calculations supporting these proposed emission caps. Among Illinois EPA's informal comments regarding that permit application submittal, Illinois EPA's permit application reviewer correctly pointed out that enforceable emission caps are superfluous and unnecessary where the maximum potential emissions of the affected unit or units is less than or equal to the emission caps under consideration. Accordingly, in the permit application supplement submitted in October 2022, U. S. Steel omitted the express request for enforceable emission caps for the affected fuel combustion units.

Notwithstanding this history, it remains the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. If Illinois EPA is not persuaded that the future actual emissions from the fuel combustion units affected by the Production Increase Project will be less than or equal to the values represented in the permit application in the absence of enforceable limits on fuel usage in, or an enforceable emission caps for, these units, then the agency undisputedly has the discretion and authority to impose such limits in the permit. The permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters. That should be especially true where, as here, the agency conveys its preliminary judgment, the applicant revises its permit application to be consistent with that representation, and then the agency vacillates.

With regard to Illinois EPA's suggestion that the limits the agency is now considering may need to "address fuel burning units other than the Project-affected units currently addressed by the permit," such as the slab reheat furnaces and cogeneration boiler at the Granite City Works, U. S. Steel disagrees that such limits would be appropriate. As these emissions units were not among the units affected by the Production Increase Project, the emissions from these units are not relevant to the "source obligation" analysis and demonstration that are required here, as discussed in Section VIII.B above.

K. NO_X Emissions Associated with a Facility Configuration No Longer Authorized or Under a Counterfactual Hypothetical Are Immaterial to the "Source Obligation" Demonstration

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application represents the maximum total post-project actual NO_X emissions from certain fuel combustion units affected by the Production Increase Project will be 706 tpy. This statement is correct.

Illinois EPA then asserts that the permit application is deficient because it does not "demonstrate that actual emissions have not exceeded this amount historically" nor does it demonstrate that actual emissions would not have exceeded this amount at any point in time since Permit No. 95010001 was issued in 1996 under the hypothetical scenario where "production of iron and steel by the source was at the levels allowed by this permit."

This assertion is without merit. The purportedly missing information relating to historical actual emission levels may be relevant to an evaluation of whether the Production Increase Project as authorized by Illinois EPA and as implemented by National Steel Corporation prior to U. S. Steel's ownership was a major modification subject to the substantive requirements of the PSD and NNSR programs, but it is not relevant to the "source obligation" analysis and demonstration that are required here. As discussed in Section VIII.B above, these analyses are prospective, not retrospective; there is no consideration of facts as they may have existed at some prior point in time and no "mixing" of facts from different points in time. The purportedly missing information relating to a hypothetical is not relevant to any demonstration or analysis that is a required element of the permit application submitted in 2020 and supplemented in 2022.

XIII. THE PERMIT APPLICATION INCLUDES ALL INFORMATION NECESSARY FOR INTEGRATED PROCESSING UNDER THE CAAPP OR, IN THE ALTERNATIVE, ANY DEFICIENCIES DO NOT FORM A BASIS FOR DENYING THE CONSTRUCTION PERMIT APPLICATION

A. Claimed Deficiencies in the Permit Application As Related to Integrated Processing Under the CAAPP Do Not Form a Basis for Denying the Construction Permit Application

As correctly noted by Illinois EPA in the draft denial letter, U. S. Steel requested that the revised construction permit be subjected to "integrated processing," as provided by subsections 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act, which would allow the changes to Permit No. 95010001 to be incorporated into the facility's CAAPP permit using the administrative amendment process.

Numerous purported deficiencies in the permit application listed by Illinois EPA in Attachment 1 to the draft denial letter are claimed to be deficient only because of the request for integrated processing. U. S. Steel generally does not agree with Illinois EPA regarding these claimed deficiencies, as discussed in Sections XIII.B through XIII.I below. In addition, U. S. Steel emphasizes that none of these issues would form a valid basis for denying the construction permit application; even if Illinois EPA were correct that these deficiencies would prevent the use of integrated processing, that would only provide a valid basis for denial of the request for integrated processing of the revised construction permit and associated revisions of the CAAPP permit.

B. The Permit Application Includes All Necessary Information Relating to General Provisions in the CAAPP Permit Governing Selection of Emission Factors

In Attachment 1 to the draft denial letter, Illinois EPA states that Permit No. 95010001 does not specify how emissions are to be quantified for purposes of demonstrating compliance with the permitted emission caps and that, in the absence of such compliance demonstration requirements, Illinois EPA imposed monitoring and recordkeeping requirements in the facility's CAAPP permit sufficient to assure compliance with applicable emission limits as required by subsection 39.5(7)(p) of the Illinois Environmental Protection Act. These statements are correct.

Illinois EPA then asserts that the pending permit application does not request revisions to Permit No. 95010001 "that would enable revisions to the CAAPP permit for the Granite City Works, Permit 96030056, to be made by administrative amendment." This assertion is incorrect. U. S. Steel requested that the construction permit be subjected to "integrated processing," which requires that Illinois EPA process the permit application and draft the permit using a program that "meets procedural and compliance requirements substantially equivalent to those" imposed in the CAAPP program. Although this request was stated generally, and the permit application did not specify with precision the monitoring and recordkeeping requirements to be imposed in the revised construction permit and the amended CAAPP permit, that approach is appropriate: It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate; the permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters. Inherently subsumed in a request for integrated processing is an implied request that Illinois EPA satisfy its mandate to draft a permit or permit revision that includes the minimum elements of a CAAPP permit—including monitoring, reporting, and recordkeeping requirements sufficient to assure compliance with applicable emission limits—and to remove or revise conflicting or redundant permit terms.

C. The Permit Application Includes All Required Information In Conjunction with the Request for Changes to Emission Point Naming

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the permit application, U. S. Steel requested that the emission point currently identified as "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" in Permit No. 95010001 be renamed and identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." This statement is correct.

Illinois EPA then asserts that, for the following reasons, the pending permit application is deficient.

> However, the application does not actually identify the specific units that would be addressed

> by the proposed new term. In this regard, the application is not accompanied by an itemized list of the equipment and activities that would be covered by this new term or a diagram that identifies this equipment and activities. US Steel's request also does not explain how the requested revision to Permit 95010001 would do what has generally been requested as the proposed new term would refer to a "Material Handling Tripper." As the 2022 application requests changes to terminology in Permit 95010001, the changes should act to better identify the emissions units that would be addressed, improving the specificity and clarity of the revised permit.[51, 52]
>
> [51] For example, the proposed new term would not make clear that the basic oxygen furnace shop actually has two ladle stirring stations and one ladle metallurgy furnace, all served by Baghouse 2.
>
> [52] The requested change to the terminology for these emissions unit(s) is also problematic as it would refer to a control device, Baghouse 2, rather than to the equipment or activities that generate emissions. Applied literally, the proposed term would only address captured emissions; it would not address the uncaptured emissions, which elude capture for control by the baghouse.

This assertion is without merit. As an initial matter, U. S. Steel has not characterized the listed item as an emissions unit, regardless of naming convention. It is an emission point, and that is how U. S. Steel correctly characterized it in the permit application. The only condition in Permit No. 95010001 that applies to this emission point is a particulate matter emission limit of 12.8 tons per year, which applies solely to the emission point and not separately to "the equipment or activities that generate emissions." Any uncaptured emissions from that equipment or activities are routed to atmosphere through the Basic Oxygen Furnace Shop Roof Monitor. Those emissions are subject to the separate emission limits for the item referenced as "BOF Roof Monitor." This is consistent with the overall structure of Permit No. 95010001, which was issued by Illinois EPA many years prior to U. S. Steel's ownership, in which the emission limits for non-fugitive emissions are applicable to emission points (e.g., "Casthouse Baghouse," "Iron Spout Baghouse," "BOF ESP Stack") rather than emissions units. A similar change to the item naming was effected by Illinois EPA in 2013 when issuing the CAAPP permit for the Granite City Works, where the agency referred to this emission point (i.e., the item to which the particulate matter emission limit of 12.8 tons per year is applicable) as "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)."[45]

The "list of the equipment and activities that would be covered by this new term" – *i.e.*, Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility – is precisely the same as the list of the equipment and activities that are currently covered by the term "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" as used in Permit No. 95010001 and by the term "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy Baghouse #2)" in the facility's CAAPP permit. U. S. Steel reasonably concluded that Illinois EPA would understand this fact because the permit application requested and enumerated only discrete changes to Permit No. 95010001, none of which related to reconfiguring the equipment and activities venting to this emission point. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that a straightforward request for revision of the name of an emission point be accompanied by a list of the equipment and activities venting to that emission point, nor does the

[45] *See,* CAAPP Permit No. 96030056 at Condition 7.5.6.g.

agency point to even an application form or guidance document suggesting that such information be provided. Of course, Illinois EPA retains authority to request additional documentation in conjunction with a construction permit application,[46] but that was not done here.

Notwithstanding all of the above, it remains the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate. If Illinois EPA wishes to revise the permit to "improv[e] the specificity and clarity of the revised permit better" or to "identify the emissions units that would be addressed" by a particular emission limit, Illinois EPA has the discretion and authority to make such revisions. The permit applicant has no obligation to reflect in the permit application a correct guess as to how the permitting authority will exercise its judgment regarding these matters.

D. The Permit Application Includes All Required Information Relating to the Steel Slag Removal Station and the Handling Operation for Raw Materials Used in Ladle Metallurgy

In Attachment 1 to the draft denial letter, Illinois EPA states that, in the permit application, U. S. Steel "does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS." Although U. S. Steel did not request any permit revisions with respect to this item that it considers to be substantive, the absolute statement is incorrect, as U. S. Steel indicated in the permit application that this item should be renamed as "Baghouse 1 for Material Handling." This revision was suggested by U. S. Steel for two reasons: First, renaming this item based on the emission point rather than the emitting activity is more consistent with the naming convention generally used in Permit No. 95010001, as discussed in Section XIII.C above. Second, the historical naming of this item is misleading, as this baghouse does not serve to control emissions from any slag removal operation; the steel slag removal station at Granite City Works is not served by any capture system or baghouse.

The requested renaming is consistent with the approach taken by Illinois EPA in Attachment 3 of the CAAPP for the facility, which refers to this item as "Baghouse #1."

Illinois EPA then asserts that the pending permit application is deficient in two respects relating to the steel slag removal station (i.e., the activity identified as "deslagging station" in historical permitting documents). This assertion is without merit as discussed below.

First, Illinois EPA states that the permit application "does not explain why this steel deslagging operation should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the basic oxygen furnace shop." U. S. Steel has claimed neither that the steel slag removal station should not appropriately be categorized as slag skimming nor that it should not be addressed with the other slag skimming operations in the basic oxygen furnace shop. Plainly, U. S. Steel was under no obligation to offer, as part of the permit application or otherwise, a justification for a claim that it was not making.

[46] *See, e.g.*, 35 Ill. Adm. Code Section 201.152 ("The Agency may adopt procedures that require data and information in addition to and in amplification of the matters specified in the first sentence of this Section, that are reasonably designed to determine compliance with this Chapter and ambient air quality standards, or that set forth the format by which all data and information shall be submitted.").

Second, Illinois EPA states that the permit application "does not request revisions to Permit 95010001 to facilitate amendment of the CAAPP permit to appropriately address the emissions of this deslagging station and the associated material handling system." Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, include a request for revisions "to facilitate amendment of the CAAPP permit" for the facility. It is the responsibility of Illinois EPA to draft both a construction permit and a CAAPP permit with conditions it judges to be suitable and appropriate. The permit applicant has no obligation to reflect in the permit application a correct guess as to what revisions to one permit would be viewed by the permitting authority as facilitating revisions to another permit.

E. The Permit Application Includes All Required Information Relating to the Ladle Drying Preheaters

In Attachment 1 to the draft denial letter, with respect to the Ladle Drying Preheaters, Illinois EPA states that the permit application is deficient because U. S. Steel "does not request any changes to Permit 95010001 to maintain consistency with the approach to these units in the CAAPP permit."

This assertion is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, include a request for revisions "to maintain consistency with the approach to these units in the CAAPP permit" for the facility. It is the responsibility of Illinois EPA to draft both a construction permit and a CAAPP permit with conditions it judges to be suitable and appropriate. The permit applicant has no obligation to reflect in the permit application a correct guess as to what revisions to one permit would be viewed by the permitting authority as maintaining consistency with another permit.

F. The Permit Application Includes All Required Information Relating to Identification of the CAAPP Permit to be Administratively Amended Following Integrated Processing of the Construction Permit Application

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application is deficient because it "does not identify the version of the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, Permit 96030056, that would be eligible for administrative amendment" under the integrated processing provisions. Relatedly, Illinois EPA asserts that U. S. Steel "has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006."

These assertions are without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, specify the "version" of the CAAPP permit for the facility that should be amended. It is solely the responsibility of Illinois EPA to make revisions and amendments to CAAPP permits in conformance with applicable rules and laws.

Regarding whether U. S. Steel has initiated the process of incorporating the provisions of Permit No. 11050006 into the facility's CAAPP permit, U. S. Steel responds further as follows: In November

2013, U. S. Steel submitted an application to renew the CAAPP permit for Granite City Works. In this permit application, U. S. Steel expressly requested that Illinois EPA incorporate the conditions of Permit No. 11050006 into the CAAPP permit and noted that "the Basic Oxygen Furnace process described in the CAAPP permit condition 7.5 needs to be updated with the new secondary baghouse added as part of the Emission Reduction Project (Construction Permit No. 11050006)."[47] That application was deemed complete by operation of law in January 2014.[48] Illinois EPA retains authority to request additional information in conjunction with a CAAPP permit application,[49] but the agency has not done so.

G. The Permit Application Includes All Required Information Relating to the Relationship Between Fugitive Dust Control Measures Required by Permit No. 95010001 and Requirements of 35 Ill. Adm. Code Part 212

In Attachment 1 to the draft denial letter, Illinois EPA states that the permit application is deficient because it "does not make clear the relationship between these requirements established by permit [relating to emissions of fugitive dust from roadways, parking areas, and open access areas] and state regulatory requirements for fugitive emissions in 35 IAC Part 212 Subpart K."

This assertion is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, specify the relationship between existing permit terms and applicable rule requirements. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws.

H. The Permit Application Includes All Required Information Relating to Applicable Provisions of 40 CFR Part 63 Subpart FFFFF

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it "does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020." Relatedly, in Attachment 1, Illinois EPA makes the observation:

> These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the 2022 application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the basic oxygen furnaces and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate.

[47] *See,* CAAPP permit renewal application at pp. 2-1 and 4-1.
[48] *See,* subsection 39.5(5)(f) of the Illinois Environmental Protection Act ("Unless the Agency notifies the applicant of incompleteness, within 60 days of receipt of the CAAPP application, the application shall be deemed complete.").
[49] *See,* subsection 39.5(5)(g) of the Illinois Environmental Protection Act ("If after the determination of completeness the Agency finds that additional information is necessary to evaluate or take final action on the CAAPP application, the Agency may request in writing such information from the source with a reasonable deadline for response.").

The assertion regarding a deficiency in the permit application is without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, include suggested bases upon which Illinois EPA might reopen the facility's CAAPP permit. It is solely the responsibility of Illinois EPA to reopen the CAAPP permit where the agency determines that the permit must be revised or revoked to assure compliance with all applicable requirements.[50]

U. S. Steel generally agrees with Illinois EPA's observation regarding the relevance of the NESHAP requirements and responds further as follows: The applicable requirements of the NESHAP as currently codified are legally enforceable, and the monitoring, testing, recordkeeping, and work practice requirements of that rule provide a sound technical basis for demonstration of compliance with particulate matter emission limits, regardless of whether Illinois EPA satisfies the mandate to reopen the CAAPP permit where such reopening is required to assure compliance with all regulatory requirements.

I. The Permit Application Includes All Required Information Relating to Equipment that is Listed in the CAAPP Permit and Has Been Permanently Shut Down

In Attachment 1 to the draft denial letter, Illinois EPA asserts that the permit application is deficient because it "does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emissions units" and further asserts that "[t]he responsibility to identify provisions in the CAAPP permit that should not be carried forward initially falls on US Steel as it is the CAAPP Permittee for the Granite City Works."

These assertions are without merit. Illinois EPA does not identify any provision of the Illinois Environmental Protection Act or the Illinois Administrative Code requiring that any application for a construction permit revision, even one for which integrated processing is requested, request changes to the facility's CAAPP permit other than those directly resulting from the requested revisions of the underlying construction permit. It is the responsibility of Illinois EPA to draft a permit with conditions it judges to be suitable and appropriate and in conformance with applicable rules and laws.

The pending permit application was submitted for the narrow and specific purpose of addressing the outstanding appeal items and the underlying PSD and NNSR applicability evaluations relating to the Production Increase Project implemented by National Steel Corporation. This application was not intended to address changes that are not directly relevant to that purpose.

In November 2013, U. S. Steel submitted an application to renew the CAAPP permit for Granite City Works. That application was deemed complete by operation of law in January 2014.[51] Illinois EPA

[50] *See,* subsection 39.5(15)(a)(iv) of the Illinois Environmental Protection Act.
[51] *See,* subsection 39.5(5)(f) of the Illinois Environmental Protection Act ("Unless the Agency notifies the applicant of incompleteness, within 60 days of receipt of the CAAPP application, the application shall be deemed complete.").

retains authority to request additional information in conjunction with the CAAPP permit application,[52] but the agency has not done so.

[52] *See*, subsection 39.5(5)(g) of the Illinois Environmental Protection Act ("If after the determination of completeness the Agency finds that additional information is necessary to evaluate or take final action on the CAAPP application, the Agency may request in writing such information from the source with a reasonable deadline for response.").

Construction Permit Application for a Proposed Project at a CAAPP Source	For Illinois EPA use only
	ID No.:
	Appl. No.:
	Date Rec'd:
	Chk No./Amt:

This form is to be used to supply general information to obtain a construction permit for a proposed project involving a Clean Air Act Permit Program (CAAPP) source, including construction of a new CAAPP source. Detailed information about the project must also be included in a construction permit application, as addressed in the "General Instructions For Permit Applications," Form APC-201.

Proposed Project

1. Working Name of Proposed Project:
1996 Construction Permit Revision

2. Is the project occurring at a source that already has a permit from the Bureau of Air (BOA)?
☐ No ☒ Yes If Yes, provide BOA ID Number: 119813AAI

3. Does this application request a revision to an existing construction permit issued by the BOA?
☐ No ☒ Yes If Yes, provide Permit Number: 95010001

4. Brief Description of Proposed Project:
This application proposes revisions to certain emission limits and other requirements in the 1996 Construction Permit for the U.S. Steel Granite City facility.

Source Information

1. Source name:* United States Steel Corporation - Granite City Works

2. Source street address:* 1951 State Street

3. City: Granite City	4. County: Madison	5. Zip code:* 62040

ONLY COMPLETE THE FOLLOWING FOR A SOURCE WITHOUT AN ID NUMBER.

6. Is the source located within city limits? ☐ Yes ☐ No
If no, provide Township Name:

7. Description of source and product(s) produced:	8. Primary Classification Code of source: SIC: _____ or NAICS: _____
9. Latitude (DD:MM:SS.SSSS):	10. Longitude (DD:MM:SS.SSSS):

* Is information different than previous information? ☐ Yes ☐ No
If yes, then complete Form CAAPP 273 to apply for an Administrative Change to the CAAPP Permit for the source.

Identification of Permit Applicant

1. Who is the applicant? ☒ Owner ☐ Operator	2. All correspondence to: (check one) ☒ Source ☐ Owner ☐ Operator
3. Applicant's FEIN: 25-1897152	4. Attention name and/or title for written correspondence: Krista Armentrout - Environmental Manager

This Agency is authorized to require and you must disclose this information under 415 ILCS 5/39. Failure to do so could result in the application being denied and penalties under 415 ILCS 5 et seq. It is not necessary to use this form in providing this information. This form has been approved by the forms management center.

Review Of Contents of the Application	
NOTE: ANSWERING "NO" TO THESE ITEMS MAY RESULT IN THE APPLICATION BEING DEEMED INCOMPLETE	
1. Does the application include a narrative description of the proposed project?	☒ Yes ☐ No
2. Does the application clearly identify the emission units and air pollution control equipment that are part of the project?	☒ Yes ☐ No
3. Does the application include process flow diagram(s) for the project showing new and modified emission units and control equipment, along with associated existing equipment and their relationships?	☒ Yes ☐ No
4. Does the application include a general description of the source, a plot plan for the source and a site map for its location?	☐ Yes ☐ No ☒ N/A* * Material previously provided
5. Does the application include relevant technical information for the proposed project as requested on CAAPP application forms (or otherwise contain all relevant technical information)?	☒ Yes ☐ No
6. Does the application include relevant supporting data and information for the proposed project as provided on CAAPP forms?	☒ Yes ☐ No
7. Does the application identify and address all applicable emission standards for the proposed project, including: State emission standards (35 IAC Chapter I, Subtitle B); Federal New Source Performance Standards (40 CFR Part 60)?	☒ Yes ☐ No
8. Does the application address whether the project would be a major project for Prevention of Significant Deterioration, 40 CFR 52.21?	☒ Yes ☐ No ☐ N/A
9. Does the application address whether the project would be a major project for "Nonattainment New Source Review," 35 IAC Part 203?	☒ Yes ☐ No ☐ N/A
10. Does the application address whether the proposed project would potentially be subject to federal regulations for Hazardous Air Pollutants (40 CFR Part 63) and address any emissions standards for hazardous air pollutants that would be applicable?	☒ Yes ☐ No ☐ N/A* * Source not major ☐ Project not major ☐
11. Does the application include a summary of annual emission data for different pollutants for the proposed project (tons/year), including: 1) The requested permitted emissions for individual new, modified and affected existing units*, 2) The past actual emissions and change in emissions for individual modified units* and affected existing units*, and 3) Total emissions consequences of the proposed project? (* Or groups of related units)	☒ Yes ☐ No ☐ N/A * The project does not involve an increase in emissions from new or modified emission units.
12. Does the application include a summary of the current and requested potential emissions of the source (tons/year)?	☒ Yes ☐ No ☐ N/A* * Applicability of PSD, NA NSR or 40 CFR 63 to the project is not related to the source's emissions.
13. Does the application address the relationships and implications of the proposed project on the CAAPP Permit for the source?	☒ Yes ☐ No ☐ N/A* * CAAPP Permit not issued
14. If the application contains information that is considered a TRADE SECRET, has it been properly marked and claimed and all requirements to properly support the claim pursuant to 35 IAC Part 130 been met? Note: "Claimed" information will not be legally protected from disclosure to the public if it is not properly claimed or does not qualify as trade secret information.	☐ Yes ☐ No ☒ N/A* * No information in the application is claimed to be a TRADE SECRET
15. Are the correct number of copies of the application provided? (See Instructions for Permit Applications, Form 201)	☒ Yes ☐ No
16. Does the application include a completed "FEE DETERMINATION FOR CONSTRUCTION PERMIT APPLICATION," Form 197-FEE, a check in the amount indicated on this form, and any supporting material needed to explain how the fee was determined?	☒ Yes ☐ No

Extension of the Public Comment Period in the Matter of the Intent to Deny an Application to Revise a Construction Permit/PSD Approval US Steel Corporation in Granite City

The comment period in this matter has been extended to September 11, 2023. All persons, including the applicant, shall raise all reasonably ascertainable issues and submit all reasonably available arguments supporting their position by the close of the public comment period. Persons wanting more information may view the draft permit denial letter and project summary at https://epa.illinois.gov/public-notices/boa-notices.html All comments should be received no later than September 11, 2023 and sent to:

Mr. Brad Frost
Office of Community Relations
Illinois EPA
P.O. Box 19506
Springfield, IL 62794-9506

Dear Mr. Frost:

Re: *United States Steel Corporation – Granite City Works*
Request for Extension of Comment Period
Illinois EPA Notice of Intent to Deny Application for
Revision to Construction Permit/PSD Approval – Permit/Application No. 95010001
ID No. 119813AAI

United States Steel Corporation (U. S. Steel) respectfully requests an extension of at least 21-days to the comment period to allow U. S. Steel to properly consider the Illinois EPA's proposed denial of the above referenced permit application. This additional time is necessary to allow a thorough evaluation of the numerous, complex issues raised in the Illinois EPA's proposed denial. With this additional time, U. S. Steel can provide more meaningful comments to assist Illinois EPA in its continued review of the application and its supporting materials. As the Illinois EPA is aware, U. S. Steel worked diligently in preparing the application and meeting with the Illinois EPA – and we desire to continue to work in a collaborative manner with Illinois EPA during this process. We believe the additional time will be beneficial to that process. We appreciate the Illinois EPA's careful consideration of this request.

If you have any questions, please contact me at dwhacker@uss.com or (412) 433-2919.

Kind Regards,

cc: K. Jones, Esq. (USS)
L. Driver, Esq. (Hepler Broom)

CERTIFIED MAIL

DENIAL OF AN APPLICATION FOR REVISIONS TO A CONSTRUCTION PERMIT/PSD APPROVAL[1] (DRAFT)

(Draft July 2023)

U.S. Steel Granite City
Attn: Krista Armentrout – Environmental Manager
1951 State Street
Granite City, Illinois 62040

Permit/Application No.: 95010001 I. D. No.: 119813AAI
Date Permit Originally Issued: January 25, 1996
Date Application for Revisions Received: October 7, 2022
Subject of Permit: Production Increase
Location: Granite City Works, Southeastern Granite City

The Illinois EPA has reviewed your above application for revisions to the above-referenced construction permit/Prevention of Significant Deterioration (PSD) approval issued for the above referenced project. The permit application is DENIED because Sections 9.1, 39, 39.5(5)(c), 39.5(10)(a)(i) and 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act (Act) and Sections 201.142,201.160, 203.128, 203.601, 203.602, 204.560, 204.1100, 204.1110, 204.1120 and 204.1130 of Title 35 of the Illinois Administrative Code (IAC) might be violated.

The specific reasons why provisions of the Act and State regulations may not be met if this permit were revised as requested by this application are detailed in the Listing of Denial Points, Attachment 1 of this permit denial.

Before taking action to deny the above-referenced application, the Illinois EPA held a public comment permit on a draft of a proposed permit denial letter in accordance with 35 IAC Part 252, as provided for by 35 IAC 252.105(b).

If you have any questions on the denial of this application, please call Minesh Patel at 217/785-1705.

William D. Marr
Manager, Permit Section
Bureau of Air

WDM:mvp:tan

[1]. In this application, US Steel request that the revision of this permit be processed with "Integrated Processing," as is provided for by Section 39.5(13)(a) and (c)(v) of the Act. Integrated Processing would allow changes to the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, as would be set forth in the revised permit, to subsequently be made by means of an Administrative Amendment of the CAAPP permit.

U.S. Steel Granite City (I. D. No. 119813AAI)
Permit/Application No. 95010001
Application for Revisions to the Permit Received on October 7, 2022
Draft of Permit Denial Letter July 2023

ATTACHMENT 1: LISTING OF DENIAL POINTS

1. THE REVISED NETTING ANALYSIS FOR THE PROJECT FOR NITROGEN OXIDES (NOx) DOES NOT FULFILL RELEVANT REQUIREMENTS OF NEW SOURCE REVIEW (NSR) FOR SUCH ANALYSES

Overview

For NOx emissions, the 2022 application for revisions to the Construction Permit 95010001 for the Production Increase Project (Project)[1] does not address or show fulfillment of the substantive requirements of the Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NaNSR) programs related to impacts on air quality, i.e., air quality analysis for impacts on NO_2 air quality per 35 IAC 204.1130 and emission offsets for NOx per 35 IAC 203.302. For the blast furnaces and blast furnace stoves, i.e., the emission units that underwent physical modifications with the Project, the 2022 application also does not show fulfillment of the BACT and LAER requirements, respectively of PSD (35 IAC 204.1100) and NaNSR (35 IAC 203.301) for NOx emissions.[2, 3] This showing is necessary because Permit 95010001 is currently based on the net increase in NOx emissions from the Project not being significant so that the Project is not a major modification for NOx.[4] The 2022 application requests that the Project be permitted for additional NOx emissions but does not show that the Project would still not be a major modification for NOx if the permit were revised as requested. As the Project

[1] Permit 95010001 was initially issued in January 1996 for a "Production Increase" at the Granites City Works. It provides for increases in the allowable production rates of iron from 2,372,500 to 3,165,000 tons per year and of steel from 2,774,000 to 3,580,000 tons per year. This permit was preceded by Construction Permit 9209014, a permit for increases in production issued in September 1992. That permit provided for increases in the permitted production rate on a monthly average basis for iron from 5,600 to 6,500 tons per day (equivalent to production of 2,372,500 tons per year) and for steel from 6,900 to 7,600 tons per day (equivalent to production of 2,774,000 tons per year).

[2] The basic oxygen furnaces, at which the largest increase in permitted NOx emissions is requested, were not physically modified and would not become subject to requirements for BACT or LAER for NOx even if the Project were a major modification.

[3] The 2022 application also does not include an analysis of alternatives. This analysis would have been required to be included in the original application for the Project if it had been recognized in 1996 that the Project was a major modification for NOx. It is beyond the scope of the revisions of Permit 95010001 that are now requested to address the fact that such an analysis was not originally part of the construction permit application for the Project.

[4] Under the PSD program, the significant emission rate for NOx is 40 tons/year; under NaNSR, since Granite City is not in an area that is classified as serious, severe or extreme nonattainment for ozone air quality, the significant emissions rate for NOx is also 40 tons/year. An increase in NOx emissions or, if the source elects to evaluate the net increase in emissions, a net increase in NOx emissions from a project that is equal to or greater than this rate is considered significant. (35 IAC 204.660 and 35 IAC 203.209.)

would become a major modification for NOx with the requested revisions to Permit 95010001, the 2022 application must show for NOx that the relevant substantive requirements of PSD and NaNSR are fulfilled for the Project. It would not be appropriate for a revised permit to be issued with increases in permitted NOx emissions as requested by the current application if this application does not also show that the applicable substantive requirements of PSD and NaNSR would be met for the Project for NOx.

In this regard, the 2022 application requests that the permitted NOx emissions of the casthouse on the blast furnaces and the basic oxygen furnaces be increased by 19.4 and 220.2 tons/year, respectively, for an overall increase of 239.6 tons/year. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.)[5] The revised netting analysis for the Project for NOx in the 2022 application suggests that this increase would be accompanied by decreases in the NOx emissions of certain other units. With these accompanying decreases, the net increase in NOx emissions from the Project with the requested revised permit would continue to not be significant.[6] The requested increase in the permitted NOx emissions of the blast furnaces and basic oxygen furnaces, 239.6 ton/year combined, would not result in the Project becoming a major modification for NOx. For this purpose, the 2022 application indicates that the overall decrease in NOx emissions from Project-affected fuel burning units would now be 250.3 tons/year, comparing their revised baseline NOx emissions of 956.3 tons/year and future NOx emissions of 706 tons/year. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) However, the 2022 application does not identify the specific decreases in NOx emissions that occurred at different groups of Project-affected fuel burning units. Instead, the 2022 application simply indicates that the future NOx emissions of the Project-affected fuel burning units, overall, would not exceed 706.0 tons/year.

This netting analysis for NOx in the 2022 application cannot be relied upon for issuance of a revised permit for the Project as requested by US Steel. The application does not include relevant information showing that additional decreases in NOx emissions that would now be proposed to be relied upon would be contemporaneous and creditable for permitting of the Project. For

[5] In the 2022 application, the increases in the NOx emissions of the blast and basic oxygen furnaces reflect proposed corrections to baseline emissions, as well as increases in the permitted emissions with the project. For the blast furnaces, the application indicates that baseline NOx emissions should be lowered from 15.6 to 4.6 tons/year. For the basic oxygen furnaces, baseline NOx emissions should be raised from 46.94 to 179.8 tons/year. (2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units.")

[6] When a netting analysis that showed a project would not be a major modification is found to have understated emissions of certain new or modified emission units, the next step is usually to examine whether the project should still not be considered a major modification. The revised netting analysis for this purpose may consider adjustments such as reductions in the permitted emissions of other new or modified units involved in the project. It may also consider additional emission decreases that were not relied upon by the original netting analysis but could have been as they are contemporaneous and creditable. As this reexamination of a project shows that it still would not be considered a major modification with appropriate adjustments to the netting analysis, an appropriately revised construction permit may be issued that is based on the project continuing to not be a major modification.

emission decreases to be relied on for the purpose of a netting analysis, 35 IAC 204.550 and 203.208 provide that the decreases must be contemporaneous and creditable. This necessitates information for how the additional decreases in NOx emissions addressed in the revised netting analysis for NOx were created and how the amounts of the decrease were quantified. Most significantly, the 2022 application does not show that certain decreases in NOx emissions that it would rely upon should be considered contemporaneous with the Project. A revised permit cannot be issued for the Project that relies upon "post-project" emissions decreases, which occurred after the Project, to show that the Project with the requested increases in NOx emissions of the furnaces, should still not be considered a major modification. This is critical because changes that are unrelated to the Project have occurred at certain fuel burning units after the initial issuance of Permit 95010001. The 2022 application proposes to rely upon the decreases in NOx emissions due to these changes, which decreases were not and could not have been relied upon by the original permit for the Project. These decreases in emissions would be relied upon by the revised netting analysis as the analysis does not account for and exclude the emissions decreases from these changes from the analysis. (In addition, as will be addressed separately below, the 2022 application does not include appropriate support for certain units for the quantification of NOx emissions in the revised netting analysis.)

Application Relies on Emission Decreases That Are Not Contemporaneous

As related to the requirement of the NSR rules that decreases in emissions relied upon for netting be contemporaneous, the 2022 application indicates baseline NOx emissions of 131.8 and 123.2 tons/year from the use of blast furnace gas (BFG) and natural gas, respectively, in Boilers 1 through 12. (2022 application, Appendix B - Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) Boilers 1 through 12 are the twelve boilers at the source in 1996 that were addressed by Permit 95010001. Ten of these boilers, Boilers 1 through 10, were shut down in 2009.[7] The 2022 application does not show that NOx emissions of these ten boilers, as existed in the period prior to 2009, were considered in the "future" NOx emissions with the Project of at most 706 tons/year from the Project-affected fuel burning units. In addition, with regard to Boilers 11 and 12, the two remaining old boilers at the source that continue in operation, flue gas recirculation systems have

[7] The shutdown of Boilers 1 through 10 was required by Condition 2.6(a) of Construction Permit 06070023, which was originally issued in July 2006. This permit addresses construction of a cogeneration boiler at the facility that would be designed to produce both high-pressure steam to generate electricity and lower pressure process steam. This boiler has been constructed and is in operation. The permitting of this new boiler relied upon contemporaneous decreases in NOx emissions from several actions, most notably, a decrease of 558.9 tons/year from addition of low NOx burners to four reheat furnaces. The permitting of the new cogeneration boiler also relied on a 33.41 tons/year decrease in NOx emissions from the shutdown of Boilers 1 through 10 as this eliminated use of natural gas by these boilers. The related application for emissions decreases that were contemporaneous with the new boiler did not rely on any decreases in the NOx emissions of these boilers from use of COG and BFG. This is because "…the boilers shutdowns will not result in any change in the amount of BFG and COG combusted at the Facility." (Application 06070022, Section 3.3.1. "Boilers 1 through 10 Shutdown Emission Calculations," p. 3-7.) The reliance of Permit 06070023 on emission decreases from the shutdown of these boilers is a further impediment to reliance on these decreases in a revised netting analysis for the Project.

been installed on these boilers pursuant to Construction Permit 10080022, issued in January 2011. These systems were installed to control NOx emissions to facilitate compliance with 35 IAC 217.164. The 2022 application does not show that the revised netting analysis for NOx does not rely on the lower NOx emissions from Boilers 11 and 12 that are now being achieved with the new control systems, rather than their NOx emissions as previously existed with the Project in the period before these control systems were installed.

The application also indicates baseline NOx emissions of 461 tons/year from use of coke oven gas (COG) in the blast furnace stoves and Boilers 11 and 12.[8] In 2015, US Steel shut down the two by-product recovery coke oven batteries at the Granite City Works. COG ceased to be available for use in the stoves or Boilers 11 and 12. However, COG was available for use in the stoves and these boilers in 1996. As related to the Project, the 2022 application does not show that the revised netting analysis for NOx would not rely upon decreases in the NOx emissions of the stoves and boilers due to the elimination of COG, which did not occur until 2015.[9]

In summary, for purposes of applicability of NSR, the NOx emissions allowed from the Project in 1996 that would be permitted with the requested revisions to the permit could be substantially higher than indicated in the 2022 application.[10] This application does not show that this would not be the case such that the Project would not become a major modification for NOx with the

[8] For Project-affected boilers, the 2022 application indicates that baseline NOx emissions from usage of COG are addressed only for Boilers 11 and 12. (2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units.") This is likely erroneous since the application for Permit 06070022 indicates that Boilers 1 through 10 also had the ability to use COG.

[9] The 2022 application does reflect increased use of natural gas by Project-affected fuel burning units. The application explains that with the shutdown of the by-product coke oven batteries, COG is no longer available and more natural gas may need to be used (e.g., 2022 application, Section 6.3, Post-Project NOx Emissions Limitations"). Permit 95010001 currently limits annual use of natural gas by the Project-affected fuel burning units to 1,346 million cubic feet. The revised netting analyses in the 2022 application are based on a post-project annual natural gas usage of up to 1,980 million cubic feet (e.g., Tables 5-7, 6-6 and 7-3).

The decreases in NOx emissions that resulted from the shutdown of the coke oven batteries and elimination of COG in 2015 are contemporaneous with any increases in NOx emissions due to the accompanying use of more natural gas. However, these emissions decreases are not contemporaneous relative to the Project, which was undertaken in 1996. In addition, an application for revisions to Permit 95010001 is not an appropriate venue to address the use of more natural gas due to the shutdown of the coke oven batteries. The Project involved increases in production of iron and steel. The Project-affected fuel burning units do not include four slab furnaces that also used COG and now must use more natural gas. Lastly, the consequences of the shutdown of the coke oven batteries on the facility's NOx emissions, including the consequences for the slab reheat furnaces, are the subject of a separate construction permit application, Application 15030001, received March 5, 2015, which application is still pending.

[10] It should be noted that for purposes of applicability of NSR, for the same reasons that the 2022 application understates the net increase in emissions of NOx from Project-affected fuel burning units, the application also understates the increases or net increases in emissions of the Project for purposes of NSR for particulate matter (PM), particulate matter$_{10}$ (PM_{10}) and volatile organic material (VOM), i.e., pollutants other than NOx for which the requested revised permit for the Project would rely upon the increase or net increase in emissions not being significant.

requested increases in the permitted emissions of the blast furnaces and the basic oxygen furnaces. The timing of actions that have resulted in decreases in NOx emissions of fuel burning units after 1996 is critical when considering applicability of NSR to the Project with the requested revisions to Permit 95010001. As the decreases in NOx emissions from certain actions cannot be considered or would be smaller, the net increase in NOx emissions of the Project would be greater. In this regard, it must be assumed that the "future NOx emissions" indicated in the 2022 application reflect maximum actual NOx emissions beginning in 2023, with the requested revisions to Permit 95010001. The application does not suggest that these future NOx emissions are the emissions that should have been allowed by the permit back in 1996 when the permit was issued and the Project commenced.[11]

[11] With the requested revisions of Permit 95010001, it is unclear how, , the "future NOx emissions" of fuel burning units indicated in the 2022 application are NOx emissions that could have been allowed by this permit in 1996. The future NOx emissions of affected fuel burning units indicated in the 2022 application are less than the baseline NOx emissions, i.e., proposed future emissions of 706 tons/year compared to the claimed baseline of 956 tons/year. However, the Project did not include any elements that would lower the NOx emissions of fuel burning units. Rather, the production of more iron and steel would be accompanied by increased utilization of the blast furnace stoves and boilers as more blast air and steam are generally needed for blast furnaces to produce more iron. Accordingly, in 1996, the NOx emissions of fuel burning units allowed by Permit 95010001 must necessarily be more than the baseline emissions, as this permit addresses a project that involves use of more BFG and natural gas by Project-affected fuel burning units. (Use of COG was not expected to be affected by the Project because production of COG was constrained by the design and operation of the existing coke oven batteries, which were not being modified as part of the Project.)

Indeed, the future NOx emissions of the fuel burning units for purposes of any revised netting analysis should be expected to be substantially greater than their baseline emissions. If one assumes that the increases in emissions would be proportional to the permitted increase in iron production, future NOx emissions of the fuel burning units would be expected to increase by roughly 40 percent. If the baseline emissions of these units should have been 956 tons/year, as indicated in the 2022 application, this suggests future emissions of these units with the Project should be about 1,340 tons/year (956 tons/year x 1.4 = 1.338 ~ 1,340 tons/year). Alternatively, absent any decreases in NOx emissions from the twelve boilers and the discontinuation of COG, and disregarding increased use of natural gas in place of COG, the NOx emissions from the Project-affected fuel burning units for purposes of NSR applicability, as of 1996, would be on the order of 1,420 tons/year (Proposed future emissions of 706 tons/year + 131.8 tons/year attributable to use of BFG by the boilers + 123.2 tons/year attributable to use of natural gas by the boilers + 461 tons/year from the discontinuation of the use of COG in the stoves and Boilers 11 and 12 ~ 1,420 tons/year). If so, the calculated change in NOx emissions from Project-affected fuel burning units for purposes of NSR applicability would be a net increase on the order of 460 tons/year (1,420 – 956 = 464), rather than a net decrease of about 250 tons/year.

2. THE DETERMINATION OF BASELINE NOx EMISSIONS IN THE REVISED NETTING ANALYSIS CANNOT BE INDEPENDENTLY CONFIRMED

The new determination of baseline NOx emissions of Project-affected fuel burning units provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not show that all Project-affected fuel burning units have been addressed. For units that are addressed, the application does not show that appropriate emission factors and operating data have been used to estimate emissions. As specific concerns exist with the determination of baseline NOx emissions for certain emission units, as discussed below, concerns exist with the determination of the overall baseline NOx emissions for the Project.

Baseline Usage of Coke Oven Gas (COG)

As already discussed, the use of coke oven gas (COG) in Project-affected fuel burning units is introduced in the 2022 application for revisions to Permit 95010001.[12] This application does not include supporting documentation or explanation for the baseline usage of COG utilized in the revised netting analysis. The annual usage of COG in the blast furnace stoves (374 million cubic feet/year) and in boilers (2,211 million cubic feet/year) is simply presented in the revised netting analysis for NOx. (2022 application, Appendix B - Emission Calculations, USS Granite City - 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis). The indicated usages of COG are not accompanied by any documentation or explanation.

Emission Factor for Use of COG in Boilers 11 and 12:

For COG, the 2022 application utilizes a NOx emission factor for Boilers 11 and 12[13] of 404 pounds/million cubic feet of COG.[14] The application states that this factor is based on emission testing conducted on the stack of A Coke Battery (2022 application, Table 6-4. "NOx Emission

[12] It should be noted that the introduction in the revised netting analysis for the Project of NOx emissions from use of COG in Project-affected fuel burning units is not acknowledged in the section of the 2022 application in which historical production and operating rates are discussed. Section 6.2.1 of the application, "Historical Throughput Rates," states that "The pre-project actual emissions were calculated using the same production and operating rates as the 1995 Application shown in Table 6-3 [Pre-Project Production and Operating Rates for NOx]." This statement is clearly not accurate as the usage of and NOx emissions from COG were not quantified in the 1995 application. Moreover, Table 6-3 does not include information for the historical or baseline usage of COG.

[13] In the 2022 application, there is an inconsistency in the information for the baseline NOx emissions of boilers. In Table 6-5, "Pre-project Actual Emissions and Summary of Changes to Pre-Project NOx Emissions Factors for Affected Emissions Units," baseline NOx emissions of Boilers 1 through 10 do not appear to be addressed since this table shows that baseline emissions are provided for B11 and B12 (Boilers 11 and 12). In Appendix B, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis, baseline NOx emissions appear to be provided for all boilers, as information is shown as being for "boilers."

[14] For the stoves, the revised netting analysis utilizes a lower NOx emission factor of 80 pounds/million cubic feet of COG. The application states that this factor is based on an emission test for which the date is unknown (2022 application, Table 6-4, p. 6-3). As this factor is identical to the NOx emission factor in USEPA's WebFIRE data base for burning of COG in industrial boilers, this factor can be considered appropriate. (USEPA, Clearinghouse for Inventories & Emission Factors, Emission Factors & AP 42, WebFIRE, Search WebFIRE, with search conducted using the term "coke oven gas" in the field under Select options under Source Classification Code.)

Factors for Fuel Burning"). The application does not show that it is appropriate to utilize an emission factor developed from the results of emission testing on the combustion stack of a coke oven battery to calculate emissions of a boiler. There are significant differences between combustion of COG as occurs at coke ovens and combustion of fuel in a boiler. At a fundamental level, a combustion stack emits the products of combustion from the heating of coke ovens to the high temperature needed to convert coal into coke. Regenerative heat exchangers are utilized to efficiently achieve this temperature. Boilers 11 and 12 emit the products of combustion from burning fuel to achieve the temperature needed convert water into process steam.[15]

Emission Factor for Use of Natural Gas in Ladle Preheaters:

For use of natural gas, the 2022 application utilizes a single emission factor for NOx emissions from all Project-affected fuel burning units. This factor, 306 pounds/million cubic feet of natural gas reflects the results of emission testing conducted on Boiler 12 when using natural gas. The application does not show that it is appropriate to utilize this emissions factor for ladle preheaters, which are different types of emissions units than boilers. Moreover, the revised netting analysis for NOx in the application erroneously indicates that the estimated baseline NOx emissions of ladle preheaters were "Revised to use current AP-42 emission factor." (2022 application, Appendix B, Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase Analysis.) The current AP-42 NOx emission factor for small boilers (<100 million Btu/hour heat input) without low NOx burners or flue gas recirculation is only 100 pounds/million cubic feet of natural gas. (USEPA, *Compilation of Air Pollutant Emission Factors*, AP-42, Table 1.4-1.)

Emissions from Use of Natural Gas on the Continuous Casting Lines:

Unlike the original application, the 2022 application does not directly address NOx emissions associated with use of natural gas in continuous casting operations.[16] In this regard, this application states

> The pre-project actual emissions for the Continuous Caster Mold – Caster #1 and Caster 2 process, as presented by National Steel Corporation in the 1995 Application listed NOx emissions from this operation. USS Granite City evaluated this analysis and determined that there is no NOx formation from this operation. Any NOx emissions from this operation are due to combustion of natural gas and are already accounted for under the gaseous fuel burning activities listed above [Section 6.2.2.1, Fuel Burning Emissions Units

[15] Application 15030001, the pending application for a construction permit for use of more natural gas with the shutdown of the by-product coke oven batteries, utilizes an emission factor for use of COG of 80 pounds/million cubic feet for baseline NOx emissions of Boiler 12. This is the NOx emission factor in FIRE for use of COG in boilers. This factor is much lower than 404 pounds/million cubic feet, the factor for COG used in the 2022 application for the baseline emissions of Boilers 11 and 12.

It should be noted that Application 15030001 does not include a NOx emission factor for Boiler 11 for COG. This is likely because Boiler 11 did not use COG in the baseline period used for Boilers 11 and 12 (January 2013 through December 2014) for the net increase analysis in this application.

[16] As reflected in Permit 95010001, the original permitting of the Project accounted for NOx emissions of 89.5 tons/year from Caster Molds – Casting but did not account for any NOx emissions from Slab Cut-Off and Slab Ripping, for which only particulate emissions were addressed.

> Emissions (Revised)]. Therefore, in the revised analysis, NOx emissions are not included from this operation.
>
> 2022 application, Section 6.2.2.7, "Continuous Caster Mold Process Emissions (Revised)."

This is problematic for several reasons. First, the 2022 application does not address the NOx emissions of the natural gas-oxygen torches used in the slab cutting and slab ripping processes, which are part of the continuous casting lines.[17] Second, as the application indicates that NOx emissions are present from the mold processes on the casting lines, the application does not show that the same NOx emission factor is appropriate for this use of natural gas as utilized for ladle preheaters or, alternatively, separately account for the NOx emissions from use of natural gas in the casting process. Lastly, the 2022 application does not identify either the caster processes or the torches as units whose use of natural gas and resulting NOx emissions would be addressed with the emissions of other Project-affected fuel burning units (e.g., 2022 application, Table 6-5, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-project NOx Emission Factors for Affected Emissions Units").

[17] Alternatively, if NOx is not formed by the torches given they are supplied with oxygen, the application does not confirm that usage of natural gas by the torches was not considered when the baseline NOx emissions from use of natural gas in Project-affected fuel burning units were determined.

3. THE APPLICATION LACKS INFORMATION FOR THE ACTUAL NOx EMISSIONS OF PROJECT-AFFECTED FUEL BURNING UNITS

The 2022 application proposes a future amount for the NOx emissions of Project-affected fuel burning units of 706 tons/year. The 2022 application does not explain why actual NOx emissions of the subject units would not exceed this amount going forward if the permit were revised, much less demonstrate that actual emissions have not exceeded this amount historically.

The 2022 application does not include a demonstration that the actual NOx emissions of Project-affected fuel burning units would not have exceeded the "future amount" or post-project emissions indicated in the revised netting analysis for the Project for NOx since Construction Permit 95010001 was issued if the production of iron and steel by the source was at the levels allowed by this permit.

4. FOR THE BASIC OXYGEN FURNACES, THE 2022 APPLICATION DOES NOT ADDRESS THE POTENTIAL FOR UNCAPTURED EMISSIONS OF NOx, VOM AND CO THROUGH THE ROOF MONITOR FOR THESE FURNACES

For the basic oxygen furnaces, consistent with the original permitting of the Project, the 2022 application only quantifies stack emissions of NOx, VOM and CO. For these furnaces, the application does not address uncaptured emissions of these pollutants. (For these furnaces, the 2022 application does address uncaptured emissions of particulate and lead[18] for which Permit 95010001 limits emissions of these pollutants from the "BOF [Basic Oxygen Furnace] Roof Monitor," (Permit 95010001, Condition 18 and Table 2, Item 2)).

The revised netting analyses for NOx and VOM in the 2022 application assume that all emissions of these pollutants from the basic oxygen furnaces are now captured. That is, with the installation of the new baghouse control system on the furnaces to improve control of particulate emissions from the charging and tapping processes, all NOx and VOM emissions of these furnaces that originally were not captured and were emitted through the roof monitor now are captured and are emitted through the stack on the baghouse system. For example, as related to emissions of NOx, the application explains,[19, 20]

> At the time of the 1995 Application, the BOF Shop did not include a baghouse to capture secondary emissions. Secondary emissions were released to the atmosphere through the BOF Shop roof monitor. No information was available at the time about the NOx emissions from the BOF Shop roof monitor. Since then, the BOF Shop includes a capture system for secondary emissions that are routed to a baghouse. NOx emissions testing for the BOF Shop

[18] The uncaptured lead emissions of the basic oxygen furnaces are summarily addressed by the 2022 application. In Section 2.2, this application states that changes to the current limits for lead emissions set by Permit 95010001 are not requested. As such, this application acknowledges the current limits for lead emissions in Permit 95010001, including the limits for uncaptured emissions from these furnaces that are emitted through the roof monitor (Permit 95010001 Condition 18 and Table 2, Item 2). Revisions to these limits are not requested.

[19] The 2022 application addresses uncaptured emission of VOM of the basic oxygen furnaces in a similar manner in Part 7 of the application. Refer to the second Section 7.2.2.1 in the application on p. 6-4, "BOF Baghouse – Secondary Emissions (New)."

[20] As reflected in this excerpt, the 2022 application refers to the NOx and VOM emissions of the baghouse system as "secondary emissions." This is inconsistent with the meaning of this term under the NESHAP for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, which only restricts this term to emissions of particulate matter. It is also misleading as it does not distinguish between captured and uncaptured emissions and suggests that capture of these emissions with a baghouse is sufficient to eliminate concerns for the existence of uncaptured emissions.

In this regard, as defined at 40 CFR 63.7852, "*Secondary emissions* mean **particulate matter** emissions (emphasis added) that are not controlled by a primary emissions control system, including emissions that escape from open and closed hoods, lance hole openings, and gaps or tears in the primary emission control system." For secondary emissions, 40 CFR 63 Subpart FFFFF recognizes the existence of both captured or stack emissions and uncaptured emissions, as would occur through a roof monitor. For basic oxygen furnaces, as well as setting emission limits for particulate emissions from primary control systems, this NESHAP also sets separate emission limits for 1) the particulate matter emissions from a control device used for the collection of secondary emissions, and 2) the opacity of secondary emissions that exit any opening in the furnace shop or other building housing a basic oxygen furnace.

> baghouse completed in the 2019-2020 time frame shows an average NOx rate of 0.0075 lb/ton for the BOF Shop Baghouse Stack. USS Granite City added the BOF Shop secondary NOx emission baseline based on the result of the stack test for the BOF Shop Baghouse stack.
>
> 2022 application, Section 6.2.2.6. "BOF Baghouse – Secondary Emissions (New)."

This assumption made by the 2022 application for uncaptured emissions of NOx and VOM of the basic oxygen furnaces, i.e., that all emissions that were formerly uncaptured are now emitted through the baghouse system, is not appropriate. At a fundamental level, the application does not include any support for this assumption. A rigorous analysis for and quantification of the uncaptured emissions of NOx and VOM from these furnaces is warranted as these emissions were overlooked in the original permitting for the Project.[21]

Then, the data for NOx and VOM emissions from the baghouse stack, which is now available from testing of the baghouse, does not support this assumption and, if anything, shows that this assumption is unsound. This is because this testing does not address the level of capture being achieved by the baghouse system. Rather it shows that there are emissions of these pollutants from charging and tapping and, as such, data for the uncaptured emissions of these pollutants is also appropriate. In this regard, the results of emission testing for the NOx and VOM emissions from the new baghouse system on these furnaces, as cited by the application, indicate more than negligible levels of emissions. (2022 application, Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised NOx PSD Net Emissions Increase

[21] In the original permitting of the Project, the uncaptured emissions of NOx and VOM from the basic oxygen furnaces appear to have been considered negligible. This was likely because the emissions of NOx and VOM of the furnaces were all attributed to the refining process, rather than to charging and tapping. During the refining step in a basic oxygen furnace, oxygen is injected into the molten iron charged to a furnace, which removes carbon from the iron by oxidation, converting the iron into steel. The oxidation of the carbon also provides heat to facilitate the melting of the scrap metal that is also charged to the furnace, so molten metal in the appropriate temperature range can be tapped from the furnace.

In 1996, the basic oxygen furnaces were only controlled by the electrostatic precipitator (ESP) system. While the ESP system only reduces or controls emissions of particulate and not emissions of NOx or VOM, the ESP system does capture NOx and VOM from these furnaces. As the capture efficiency for particulate emissions from refining is assumed to be at least 99.9 percent, it was also reasonable to assume that the ESP system also would achieve at least 99 percent capture for NOx and VOM. With these assumptions, i.e., that NOx and VOM are only generated during the refining step and at least 99.9 percent capture of these emissions is achieved by the ESP system, given the limits on emissions of NOx and VOM from the stack of the ESP set by Permit 95010001, i.e., 69.63 and 10.74 tons/year, respectively, the uncaptured emissions of NOx and VOM from these furnaces would have been projected to be no more than 0.07 and 0.01 tons/year, respectively,. (For example, for NOx, 69.63 tons/year ÷ (99.9 ÷ 100.0) x (100.0 – 99.9) ÷ 100.0 = 0.07 tons/year.) For purposes of determining applicability of NSR to the Project. the increases in NOx and VOM emissions of the furnaces with the Project would be less because these calculations for uncaptured emissions address all emissions of the furnaces, both baseline emissions and the increases in emissions from the Project.

Even with the correction to the emission data for the basic oxygen furnaces indicated in the 2022 application, <u>if</u> all NOx and VOM emissions of these furnaces were actually attributable to the refining step, uncaptured NOx and VOM emissions would still be very small. For example, the potential NOx emissions from the stack of the ESP are now shown to be 380.0 tons/year. With capture of at least 99.9 percent of the NOx by the ESP system, the potential uncaptured NOx emissions from these furnaces would still only be an additional 0.38 tons/year.

Analysis and Revised VOM PSD Net Emissions Increase Analysis.) For NOx, the application indicates baseline captured emissions of 179.8 tons/year, of which, based on the measured emissions from the new baghouse system, as much as 5.1 percent, i.e., 9.1 tons/year, would have been uncaptured in 1996; captured VOM emissions are 26.6 tons/year, of which as much as 15.8 percent, i.e., 4.2 tons/year, would have been uncaptured emissions in 1996. However, instead of assuming that all NOx and VOM emissions are now captured, it would not be unreasonable to assume that the new baghouse system improved capture of the emissions from charging and tapping such that the levels of captured emissions from the baghouse stack and the uncaptured emissions through the roof monitor are now identical.[22, 23]

Finally, the assumption that all NOx and VOM emissions of these furnaces is now captured is inconsistent with the approach taken in the 2022 application to the particulate and lead emissions of these furnaces, for which it is assumed that there are uncaptured emissions that still occur through the roof monitor. In particular, the 2022 application requests that the revised permit establish prescribed emission factors for the particulate emissions of the basic oxygen furnaces

[22] It is reasonable to assume that the new baghouse that was installed to improve control of particulate emissions from charging and tapping of the basic oxygen furnaces reduced these emissions to less than half of their previous amounts. For example, the nominal control efficiency for charging and tapping went from 95 percent with only the ESP control system to 97.5 percent with the addition of the baghouse system. With this assumption, the potential NOx and VOM emissions from the baghouse stack from charging and tapping would be estimated to be about the same as the potential uncaptured emissions from charging and tapping that still occur through the roof monitor, with both being about 2.5 percent of the total emissions from the furnaces. The remainder of the NOx and VOM emissions from charging and tapping continue to occur through the ESP stack (95 percent of the total emissions of the furnaces).

[23] With this assumption, the potential NOx emissions of the basic oxygen furnaces with the Project would become 420.4 tons/year, rather than 400.0 tons/year (400.0 tons/year x (100% + 5.1%) ÷ 100% = 420.4 tons/year. The potential VOM emissions of these furnaces with the Project would become 52.1 tons/year, rather than 45.0 tons/year (45.0 tons/year x (100% + 15.8%) ÷ 100% = 52.1 tons/year.

that occur through the roof monitor.[24] For example, for pre-project actual emissions of the roof monitor, Section 5.2.2.7 of the application explains the following, [25]

> Prescribed emissions factors consistent with the approach described in Section 3 [Discussion of Permit Conditions Used to Restrict PTE] are provided herein. USS Granite City is proposing prescribed emission factors for the BOF Shop Roof Monitor for which emissions testing is not feasible.[Footnote 33] For BOF Roof Shop Monitor, use PM emissions factor of 0.0296 lb/ton and filterable PM_{10} emission factor of 0.0198 lb/ton.
>
> Footnote 33: PM and PM_{10} emissions factors are appropriately determined from the results of emission testing per 40 CFR 63 Subpart FFFFF to determine PM and PM_{10} emission rates for the BOF ESP and baghouse, Desulf/Soda Ash and Hot Metal Charging Baghouse, Slag Skimming Baghouse, and Baghouse 2 for Argon Stirring and Ladle Metallurgy.
>
> 2022 application, Section 5.5.2.2. "Prescribed Emission Factors for Certain BOF Shop Operations."

---

[24] The 2022 application requests that Permit 95010001 be revised to set "prescribed emission factors" for the emissions of certain emissions units or their uncaptured emissions (e.g., the uncaptured particulate emissions of the basic oxygen furnaces, which are also referred to as the emissions through the roof monitor of the basic oxygen furnace shop). For those units or emission points, the prescribed emission factors would effectively replace the provisions currently in Permit 95010001 that address emissions in pounds/ton of input or production or in pounds/hour. For convenience, these provisions in the permit are generally referred to as "emission factor limits." The usage of this term extends to the provisions of the permit that address emission of lead that are in pounds per hour. In this regard, in Permit 95010001, Table 2, these limits for lead emissions are listed under the heading of "Emission Factor," along with the limits in pounds per ton of production for emissions of other pollutants.

Unlike the emission factor limits currently in Permit 95010001, which the Illinois EPA considers to be directly enforceable against US Steel, prescribed emissions factors that would be established in a revision to Permit 95010001 would not be enforceable. Instead, prescribed emission factors would be specific values for emission rates that US Steel would have to use for normal operation when determining compliance with the limits on annual emissions set by the revised permit. The appropriateness of the various prescribed emissions factors that are selected would be a matter that would be considered during the processing of the revisions to Permit 95010001. Given the role of prescribed emission factors in determining compliance with annual emission limits set by the permit, it is expected that prescribed emission factors would only be set for units for which emissions testing is not feasible or is not warranted given the low levels of annual emissions predicted by engineering analysis and calculations. It is also expected that, as it is practical to do so, prescribed emission factors would be conservative, reflecting the maximum rates of emissions that could occur during the routine, compliant operation of emissions units.

[25] For pre-project actual emissions of particulate matter of the basic oxygen furnace through the roof monitor, Section 5.2.2.7 of the 2022 application explains the following,

> The BOF roof monitor actual emissions were calculated using the information from AP-42 Chapter 12.5 and AIRS (Aerometric Information Retrieval System) database. For pre-change actual PM and PM_{10} emissions, National Steel used 90% capture efficiency during the charging and tapping steps and 99% capture efficiency during the refining step for BOP operations. A detailed description of the baseline roof monitor PM and PM_{10} emission factors is provided in Appendix C of the 1995 Application. For the BOF operations, per particle size distribution in AP-42 Table 12.5-2, 67% of PM is PM_{10}. No changes are necessary for this emission factor.
>
> 2022 application, Section 5.2.7.7, BOF Roof Monitor Emissions (No Change)

The fact that there are emissions of NOx and VOM from the basic oxygen furnaces that now occur from the stack of the new baghouse system but were previously not captured and were not originally quantified raises concern that similar circumstances are present for emissions of CO. [26] In this regard, the 2022 application requests various revisions to Permit 95010001 to correct issues that are posed for the original permitting of the Project with respect to CO emissions, but the application does not propose any such revisions for the basic oxygen furnaces or explain why such revisions are not needed.[27]

[26] For the basic oxygen furnaces, uncaptured emissions of CO should generally be expected to be much greater than the uncaptured emissions of NOx or VOM because the permitted stack emissions of CO of these furnaces are much greater. In this regard, Permit 95010001 limits the CO emissions from the stack of the ESP system for these furnaces to 16,097 tons/year. (The 2022 application does not request an increase in this limit.) If only 99.9 percent capture of CO is assumed by the ESP system, the potential uncaptured CO emissions of these furnaces would be 16.1 tons/year. (16,097 tons/year ÷ {99.9 ÷ 100.0} x {100.0 – 99.9} ÷ 100.0 = 16.1 tons/year CO.) Of course, the capture efficiency of the ESP system for CO could be higher than the efficiency for NOx or VOM if CO is only formed during the refining step when oxygen is actually being injected into the furnace and not during the entire refining step. However, one approach to the revision of Permit 95010001 would be to conservatively assume that the capture efficiency of the ESP system for CO is the same as its capture efficiency for particulate.

[27] The application also does not suggest that it would be inappropriate for any revised permit to simply limit the stack emissions of CO from the basic oxygen furnaces, addressing the combined stack emissions of the ESP and the new baghouse, to the current limits for the CO emissions of the furnaces in Permit 95010001, which limits currently apply only to emissions from the stack of the ESP.

5. THE EMISSION INVENTORY FOR THE SOURCE USED IN THE AIR QUALITY ANALYSIS FOR CARBON MONOXIDE (CO) OMITS CERTAIN CO EMISSIONS

The results of the analysis of the impacts of the Project on ambient air quality for carbon monoxide (CO) cannot be relied upon because the inventory for the CO emissions of the source with the Project does not address all CO emissions or otherwise explain why the CO emissions of certain units need not be considered. The 2022 application includes an air quality analysis because the Project was originally permitted as a major modification for CO under the Prevention of Significant Deterioration (PSD) program and the application requests revisions to Permit 95010001 to increase the CO emissions for which the Project is permitted.[28] To support this request, an air quality analysis for CO must be part of the application pursuant to Illinois' PSD rules, 35 IAC 204.1130, Air Quality Analysis, since the request involves revisions to the provisions in Permit 95010001 that involve the Project as it is a major modification for CO under the PSD program.

Uncaptured Emissions from the Casthouse on the Blast Furnaces

The air quality analysis in the 2022 application does not address the uncaptured emissions of the casthouse (2022 application, Appendix C – Air Quality Modeling Report, Table for "US Steel Granite City Volume Source Inputs"). The application indicates potential CO emissions of 13.6 tons/year from the roof monitor on the casthouse (2022 application, Section 4.4). These "uncaptured" CO emissions from the casthouse, which are not captured by the baghouse systems on the casthouse, must be addressed in the air quality analysis submitted to support revisions of Permit 95010001 to provide for more CO emissions from the Project.

Uncaptured Emissions from the Basic Oxygen Furnaces

The air quality analysis in the 2022 application does not address uncaptured emissions of the basic oxygen furnaces. (2022 application, Appendix C – Air Quality Modeling Report, Table for "US Steel Granite City Volume Source Inputs.") As discussed earlier, the 2022 application does not address uncaptured emissions from these furnaces. The application also does not explain why uncaptured emissions would not be present as the application does not show 100 percent capture of the emissions of these furnaces by the control systems for emissions of particulate. As there are uncaptured CO emissions from these furnaces, these emissions must also be addressed in the air quality analysis submitted to support revisions of Permit 95010001 to accommodate additional CO emissions from the Project.

By-product Coke Oven Batteries

[28] The 2022 application requests that Permit 95010001 be revised to address an additional 25,334 tons/year of CO. This would include emissions of 320 tons/year of CO from the casthouse on the blast furnaces, for which CO was not addressed in the original permitting for the project (2022 application, Section 4.4, p. 4-4) . This would also include an additional 25,014 ton/year from Project-affected fuel burning units, other than Boilers 1 through 10, which are now retired (2022 application, Sections 4.2 and 4.3, pp. 4-2 and 4-3). For the fuel burning units, US Steel has determined that the emission factors for CO utilized in the original permitting of the Project, particularly the emission factor for blast furnace gas used in the blast furnaces stoves, understated CO emissions.

The 2022 application does not explain why the air quality analysis in the application should not consider the CO emissions of the former by-product coke oven batteries at the source. These batteries were in operation when the Project was originally permitted in 1996 and did not cease operation until 2015. Accordingly, the analysis does not address CO ambient air quality with the Project as would have been predicted by the original air quality analysis for the Project if it had addressed the additional CO emissions now being requested for the Project. On the other hand, the analysis addresses CO emissions of emission units that did not exist in 1996, as this analysis addresses the emissions of the heat recovery coke ovens adjacent to the Granite City Works, which were built and are now operated by Gateway Energy & Coke. [29]

In addition, the air quality analysis in the application uses a value for CO background air quality on an 8-hour average that is based on ambient air quality data collected for a three year period consisting of 2016, 2017 and 2018. As such the value used for background air quality is not necessarily appropriate as a representation of either current ambient air quality or the historic air quality at the time that the Project was originally permitted.[30]

---

[29] The modelling in the air quality analysis did address the CO emissions of the new coke oven batteries adjacent to the Granite City Works that are owned and operated by Gateway Energy & Coke. However, modeling of the CO emissions of new units would only compensate for the CO emissions of existing units if the new batteries were direct, in-kind replacements of the shutdown units, which is not the case. This is not the case. The batteries that were shut down by US Steel were by-product recovery batteries. They recovered chemicals from the off-gas from the coking process (e.g., benzene, toluene and naphthalene, with the gas then used as fuel for heating the coke ovens and in certain other units at the source. Gateway's batteries are heat recovery batteries, in which the off-gas from coking is combusted in the ovens and the heat is used to make steam and generate electricity. Moreover, the new batteries and the old batteries both operated for a period of several years before US Steel shut down its batteries.

[30] Under the PSD program, the air quality analysis for a project whose modelled maximum impact(s) by itself on air quality for a pollutant are above certain specified concentration(s) or "significant impacts levels" under the PSD program must also consider "background air quality." This accounts for the contribution to ambient air quality of mobile sources (e.g., cars, trucks and buses) and of other sources (e.g., residential and commercial heating), which contribution cannot be determined as part of the computerized dispersion modelling for discrete emission units performed as part of the analysis. The air quality analysis in the 2022 application shows that the maximum air quality impact of the Project with the requested increases in CO emissions would continue to be above the significant impact level for CO on an 8-hour average. (In the original air quality analysis, the Project's impacts were significant for CO on both a 1-hour and an 8-hours average.) The value for background in the current air quality analysis is based on data collected at an ambient air monitoring station in East St. Louis operated by the Illinois EPA. If US Steel shows that the air quality analysis for the revision to Permit 95010001 should address current ambient air quality for CO, the value for background air quality in the analysis should be updated. Since the Illinois EPA discontinued ambient monitoring for CO at its East St. Louis monitoring station in 2020, the new value for background would likely need to be based on data collected at an appropriate monitoring station in Missouri operated by the Missouri Department of Natural Resources.

It should be noted that the values for background used in the original air quality analysis were likely conservative, as they were based on data from a now retired monitoring station in Granite City that was less than a third of a mile from the Granite City Works. Given the location of that station, the ambient air quality data collected at that station may have included the contribution to air quality of units for which modelling was also conducted, so that the original analysis effectively counted the impacts of those units twice. Thus, it is reasonable for the current air quality analysis to use value(s) for background air quality based on data collected at a monitoring station other than the one that was originally used.

6. SCOPE OF PROPOSED GROUP EMISSION LIMITS

The application does not show that the proposed collections of emission units for the requested group limits for annual emissions of particulate, NOx and VOM are appropriate.[31, 32] In particular, the application does not propose limits that would only apply to the annual emissions of the casthouse on the blast furnaces and to the annual emissions of the two basic oxygen furnaces. These are principal emission units at this facility. It would be reasonable and appropriate for both the annual emissions of the casthouse and the annual emissions of the two basic oxygen furnaces

[31] For PM, PM_{10}, NOx and VOM (i.e., pollutants other than sulfur dioxide (SO_2), carbon monoxide (CO) and lead), the 2022 application requests that the revised permit not include the provisions in Permit 95010001 that the Illinois EPA considers would limit emissions of individual "processes" in pounds/ton of production or throughput and in tons/year. These provisions were set to ensure that the Project would not be a major modification for purposes of New Source Review (NSR). The removal from Permit 95010001 of the "emission factor limits" which limit emissions of various process operations relative to their production or throughput, would facilitate resolution of two permit appeals filed by US Steel with the Illinois Pollution Control Board (PCB), PCB 2013-53 and PCB 2013-62. Both appeals indirectly address the emission factor limits in Permit 95010001. PCB 2013-53 concerns the revised Clean Air Act Permit Program (CAAPP) permit for the facility (Permit 96030056) issued in 2013. US Steel appealed this permit as it repeats the emission factor limits as originally set by Permit 95010001. PCB 2013-62 concerns the construction permit for the addition of the baghouse system to improve control of particulate emissions from charging and tapping of the BOFs, Permit 11050006, as reissued in 2013. For the BOFs, this permit also repeats the emission factors limits for the BOFs set by Permit 95010001. US Steel appealed the subject emission factor limits in these permits because, prior to issuing the revised CAAPP permit for the facility in 2013, the Illinois EPA had explicitly explained that the provisions in the permit containing emission factors were considered to constitute enforceable limits on emissions. This was done in the Illinois EPA's "Statement of Basis for a Planned Revision of the Clean Air Act Permit Program (CAAPP) Permit for: U. S. Steel Corporation, Granite City Works, 20th and State Streets, Granite City, Illinois," of March 2011, pages 20 through 26. That these provisions set enforceable limits was then recognized by the USEPA in the Administrator's subsequent order of December 3, 2012, "In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056," Petition Number V-2011-2, pages 7 through 9).

[32] With regard to the current limits for the annual emissions of PM, PM_{10}, NOx and VOM of individual processes, the 2022 application requests "group limits" for the annual emissions of groups of related emission units. For example, the application requests that the revised permit limit the overall emissions of a group of units that includes the casthouse for the blast furnaces and other, ancillary units involved in production of iron. The permit currently sets separate limits for the emissions of the casthouse, the emissions from charging the blast furnaces, and the emissions from slag pit activities. Unlike the current limits for annual emissions, which apply on a calendar year basis, the proposed new limits for annual emissions would be rolled monthly, restricting emissions over each consecutive 12 month period. The requested limits would theoretically be less stringent than the current limits as US Steel could potentially compensate for any "overage" of emissions by unit(s) in a group of units with lower levels of emissions from other units in the group.

Incidentally, in these appeals, US Steel only challenges the emission factor limits for "processes," such as the casthouse, the basic oxygen furnaces, continuous casting operations, and discrete material handling operations. These appeals do not challenge the emission factor limits for fuel burning units affected by the Project. Those limits do not restrict the emissions of individual units or groups of similar units. Instead, they separately restrict the emissions from use of different fuels, i.e., blast furnace gas, natural gas and oil.

to be directly limited separately from the emissions of any other units. The construction permits issued by permitting authorities in other jurisdictions cited in the application as support for emission limits that apply to groups of emission units do not show that the annual emissions of the casthouse and the basic oxygen furnaces should not both continue to be limited individually.[33]

In this regard, the 2022 application points to USEPA policy and practice concerning how the potential emissions of a source may be restricted (2022 application, Section 3, "Discussion of Permit Conditions used to Restrict PTE [Potential to Emit]). The application shows that USEPA has found that construction permits may be issued that restrict potential emissions by means of limits on annual emissions that are practically enforceable. Accordingly, the current provisions in Permit 95010001 that limit emissions of process units in pounds/ton of production of throughput, which apply on a short-term rather than annual or long-term basis, are not essential to restrict potential emissions. In addition, the application points to several construction permits issued outside of Illinois since 2000 for which the permitting authority determined that annual emission limits that apply to groups of emission units that are practically enforceable were determined to be sufficient to restrict potential emissions without need for accompanying limits that address emissions on a short-term basis.[34, 35] However, the 2022 application does not show that the

[33] In light of the construction permits issued by other permit authorities cited by the application as support for group limits, it would seem acceptable for a revised permit to set group limits for the emissions units or operations that do not qualify as principal units. For example, for the production of iron, a revised permit could set limits for the overall emissions from charging the blast furnaces and the slag pits. Alternatively, limits specifically for the emissions of the casthouse for the blast furnaces and the basic oxygen furnaces, i.e., the principal units at the facility for iron and steel production, could be accompanied by group limits for the overall emissions of these principal units and the other, "non-principal" units in these areas of the facility. For example, limits could be set for both emissions of the casthouse and for the emissions of the casthouse, charging of the blast furnaces, and the slag pits.

[34] The 2022 application, Appendix E - "Copies of EPA Determinations," contains two decisions by the USEPA's Environmental Appeals Board (EAB):

- The 2012 decision of the EAB for an Outer Continental Shelf (OCS) Permit to Construct and Title V Air Quality Operating Permit issued by Region 10 of USEPA to Shell Offshore, Inc. (USEPA, EAB, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2012).
- The 2018 decision of the EAB for a PSD permit issued by the Department of Environmental Quality for Pima County, Arizona, to Tucson Electric Power (USEPA, EAB, *In Re Tucson Electric Power*, PSD Appeal No. 18-02, Order Denying Review, Decided December 3, 2018).

[35] In a footnote, the 2022 application also refers to the USEPA's order responding to a petition to object to a Title V permit issued for a facility in Middletown, New York proposed by Masada (USEPA, Order, May 2, 2001, *In the Matter of Orange Recycling and Ethanol Production Facility, Pencor-Masada Oxynol, LLC*, Permit ID: 3-3309-00101/00001, Issued by the New York State Department of Environmental Conservation, Petition No.: II-2000-07.) As explained by US Steel in the application, in this order, the USEPA upheld the,

> …use of annual emission caps with a rolling cumulative total methodology and rejected petitioners' "concerns that the permit appears to rely on after-the-fact monitoring, rather than engineering practices, test data or vendor guarantees" to establish restrictions on PTE. U. S. EPA based its findings on the fact that "[i]f the source has no room to operate under the PTE emission limiting cap, it must cease operation or face a violation" and that "all PTE limits rely on after the fact monitoring of some kind."

specific circumstances of the Project are such that the current limits for annual emission of the principal emission units should be replaced with group limits that apply to the combined emissions of principal emission units and other lesser emission units.[36] The circumstances of the Granite City Works are not the same as those presented by the cited permits. US Steel's Granite City Works is a manufacturing facility at which iron is produced from iron ore in blast furnaces and steel is produced from molten iron and scrap metal in basic oxygen furnaces. The processes that generate emissions at the Granite City Works are different than the oil-fired engines that are generally addressed by the permit for Shell Offshore and the natural gas-fired engines addressed by the permit for Tucson Electric. The permit for Shell Offshore, Inc., addresses a marine drilling unit, the "Kulluk," and an associated fleet of support vessels that may be used during July through November of each year to conduct exploratory drilling operations in areas of the Beaufort Sea north of Alaska. The permit for Tucson Electric Power addressed a new peaking electrical generating facility with ten engine-generating units at Tucson Electric's Irvington Station. The utilization of the individual generating units in the new facility would vary from day to day and season to season as the use of the units would be tied to the inability of other electrical generating facilities to meet the demand for electricity.[37]

2022 application, Footnote 11.

[36] For the casthouse on the blast furnaces, Permit 95010001 currently sets separate limits for the emissions of various pollutants from the casthouse baghouse (i.e., the main baghouse for the casthouse), the iron spout baghouse, and the roof monitor (uncaptured emissions). If Permit 95010001 were to be revised, it would be reasonable for each pollutant for which emissions are limited, other than CO, for the permit to restrict the overall emissions of the pollutant from the casthouse, rather than to individually limit the stack emissions of each control system and the uncaptured emissions. The application also does not suggest that it would be inappropriate for any revised permit to simply limit the stack emissions of CO from the BOFs.

For the basic oxygen furnaces, the current permit separately addresses emissions of particulate and lead from the stack of the ESP and the roof monitor (uncaptured emissions.) For these furnaces, it would also be reasonable in a revised permit to set limits for different pollutants for the overall emissions of the pollutant from these furnaces. In particular, the revised permit would not set limits specifically for the emissions of the new baghouse system that was installed to improve control of particulate emissions from charging and tapping of these furnaces. Instead, the revised permit would address emissions that occur from this baghouse with limits for different pollutants for the overall emissions of these furnaces.

[37] At the Shell Off-Shore and Masada facilities, variability of utilization or operation of different emission units was a consideration in the permitting of these facilities. In its response to comments on the draft permit for Shell Offshore, USEPA Region 10 explains,

> The commenters are correct that EPA guidance does express a general preference for shorter time periods rather than 12-month rolling limits. See 1989 PTE Guidance at 9. As the commenter acknowledges, however, EPA has also recognized that longer rolling limits are appropriate for sources with substantial and unpredictable variations in emissions, as well as for those sources that curtail operation during part of a year on a regular seasonal cycle. Id. at 9 – 10. Such is the case here. Shell's planned exploratory operations are atypical as compared to other sources because emission units consist of multiple engines and generators with variable emission on the Kulluk and a fleet of numerous support vessels. Operations will vary from hour-to-hour, day-to-day month-to-month, and season-to-season based on factors such as the number of wells drilled, the activity being undertaken (drilling mud cellar lines, other drilling activity, or activity that does not involve drilling), the depth of wells drilled, whether emergency engines are being run for testing, and ice conditions. Given the variability in operations, and thus emissions expected from the source, and after considering a full

range of options for limiting the source's potential to emit, Region 10 determined that it was appropriate to establish longer-term rolling limits.

USEPA, Region 10, "Response for Comments for Outer Continental Shelf Permit to Construct and Title V Air Quality Operating Permit: Conical Drilling Unit Kulluk," October 2011, p. 26.

In the USEPA's order for Masada of April 8, 2002, USEPA observes that,

Masada's operations will have significant fluctuations due [sic] the variability of the processed waste, making an operating parameter-based PTE limit less appropriate. The emissions-based PTE limit discussed below recognizes this fact and provides Masada with operational flexibility accordingly. Moreover, Masada will be measuring its emissions on a real-time basis using CEMS [continuous emissions monitoring systems], obviating the need to limit and monitor operating parameters as a surrogate for emissions.[Footnote 6] Thus the petitioners have not demonstrated that it was inappropriate for the NYSDEC [New York State Department of Environmental Conservation] to restrict Masada's emissions directly, rather than its operation or production.

Although it is generally preferable that PTE limitations be as short-term as possible (e.g., not to exceed one month), EPA guidance [USEPA, "Guidance on Limiting Potential to Emit in New Source Permitting," June 13, 1989] also allows permits to be written with longer term limits if they are rolled (meaning recalculated periodically with updated data) on a frequent basis (e.g., daily or monthly). The 1989 guidance recognizes that such longer rolling limits may be appropriate for sources with 'substantial and unpredictable annual variation in production." 1989 Guidance at 9.

Footnote 6. This is consistent with prior EPA practice in appropriate circumstances. See e.g., Memorandum entitled "3M Tape Manufacturing Division Plant, St. Paul, Minnesota," from John Rasnic to David Kee, dated July 14, 1992 ("a federally enforceable emission limit may be used …to limit the potential to emit as long as a continuous emissions monitor (CEM) or an acceptable alternative is used."); and Memorandum entitled "Policy Determination on Limiting Potential to Emit for Koch Refining Company Clean Fuels Project," from John Rasnic to David Kee, dated March 13, 1992 ("Use of an emission limit to restrict potential to emit …is acceptable provided that emissions can be and are required to be readily determined or calculated.")

USEPA, Order, April 8, 2002, "*In the Matter of Orange Recycling and Ethanol Production Facility, Pencor-Masada Oxynol, LLC*, Permit ID: 3-3309-00101/00003, Issued by the New York State Department of Environmental Conservation," Petition No.: II-2001-05, p. 6)

7. INADEQUATE JUSTIFICATION FOR ELIMINATION OR REVISION OF CURRENT LIMITS FOR PROJECT-AFFECTED FUEL BURNING UNITS

The justification provided in the 2022 application for revisions to Permit 95010001 to eliminate or revise limits on usage of fuel and, presumably, emissions by Project-affected fuel burning units is not adequate. Although this application indicates that the revised permit should not contain the limits for usage of natural gas and BFG currently set by Permit 95010001, it does not propose any new limits in their place.

> USS Granite City is also requesting revision/elimination of gaseous fuel usage limits for project-affected combustion units. In 2015, USS Granite City shutdown its by-product coke oven batteries. This eliminated the ability to use coke oven gas ("COG") as a fuel at the mill. In addition, ten of the twelve boilers at the time of the Project in 1996 have been retired. These actions have greatly reduced the emissions from fuel combustion in project-affected emissions units and obviate the need to preserve limits to restrict PTE of the remaining units.
>
> 2022 application, Section 2.2.3, p. 2-4.

This rationale is deficient because it does not consider that the 2022 application also requests that the revised permit address an increase in the usage of natural gas at the facility as a consequence of the shutdown of the by-product coke oven batteries. While the limits for fuel usage and emissions currently in Permit 95010001 may no longer be relevant, as generally addressed above,[38] this does not mean that other limits for fuel usage and emissions are not appropriate. In this regard, the 2022 application does not show that new limits for fuel usage and emissions would not now be needed and those limits should address fuel burning units other than the Project-affected units currently addressed by the permit. In this regard, limits for usage of fuels and emissions should not extend to Boilers 1 through 10, as they are no longer in operation, having been shut down a number of years before the coke oven batteries were shutdown. As the four slab reheat furnaces at the facility were affected by the elimination of COG, new limits may be needed that also extend to these furnaces. It may also be appropriate for the cogeneration boiler to be addressed by the new limits as this boiler began operation several years before the by-product coke oven batteries at the facility were shutdown.

[38] It is noteworthy that the 2022 application does not address what an appropriate limit for usage of COG would have been in Permit 95010001 if the permit had originally addressed use of COG by Project-affected fuel burning units. In the absence of such information, it is unclear how the shutdown of the two by-product coke ovens at the facility and elimination of COG led to decreases in NOx emissions relative to the limits for NOx emissions of fuel-burning units set by Permit 95010001.

8. THE APPLICATION DOES NOT SHOW THAT EMISSION FACTORS THAT ARE PROPOSED AS PRESCRIBED FACTORS FOR CERTAIN UNITS WOULD BE REPRESENTATIVE

To calculate baseline emissions of certain emission units for which emission testing is not feasible or practical, the 2022 application necessarily relies on use of emission factors that are not based on source-specific emissions testing. Likewise, for the ongoing determination of the emissions of these units, the application requests that revised Permit 95010001 "prescribe" or specify the emission factors that are to be used. As explained in the 2022 application, where a permit relies on a limit on annual emissions or an "annual emission cap" to restrict potential emissions, USEPA policy and precedent provide that:

> Where the permit prescribes an emission factor to be used in conjunction with operational data in demonstrating compliance [with an annual emission cap], the permitting authority should describe the basis for its determination that the emission factor is representative.
>
> 2022 application, Section 3, p. 3

This summary of relevant USEPA policy in the 2022 application is consistent with the statements made by the EAB and the Administrator of USEPA in various orders responding to petitions that request it object to Title V permits or, in Illinois, CAAPP permits), issued by a permitting authority. In its decision in *Shell Offshore, Inc.*, the EAB also considered the use of prescribed emission factors in the permit that was appealed. The EAB did not object to this practice. It found that the use of prescribed emission factors may be appropriate for a permit to prescribe use of specific emission factors published by USEPA in its *Compilation of Air Pollutant Emission Factors* (AP-42) for certain emission units for the purpose of determining emissions for purposes of compliance with annual emission limits set by the permit.[39]

> The Region explained in the record its rationale, based on the Region's technical expertise and applied in certain limited circumstances, for supplementing source-specific emission factors derived for most of the emission units or groups of emission units with either AP-42 emission factors, or factors derived from source test data Shell submitted to the Region in support of two separate, previously OCS [Outer Continental Shelf] PSD permits authorizing Shell to conduct exploratory activities in the Chukchi and Beaufort Seas using the *Discover* drillship.
>
> USEPA, Environmental Appeals Board, *In Re Shell Offshore, Inc.*, OCS Appeals Nos. 11-05, 11-06 & 11-07, Order Denying Petitions for Review, Decided March 30, 2013.

[39] The EAB did observe that it is preferable that compliance with emission limits set by a permit be determined using source-specific emission factors, as would be developed by emissions testing required by the permit. The EAB did not address prescribed emission factors from sources other than AP-42 since the permit that was appealed only prescribed use of emission factor from AP-42. Given the general nature and limited scope of AP-42, the EAB's decision should not be interpreted to preclude use of emissions factors from source other than AP-42. There are emission units and pollutants for which use of prescribed emissions is appropriate for which emission factors are not present in AP-42 or better emission factors are available from other sources.

For US Steel, Granite City Works, the USEPA specifically addressed the use of emission factors for determining compliance with emission limits in an order of December 3, 2012. Note that relative to prescribed emission factors, the USEPA's finding, as is provided below, might be considered *dicta*. This is because the permit that was the subject of the appeal did not provide for use of prescribed emission factors. In addition, as the order addresses the possibility of using of prescribed emission factors in terms of the actions that the Illinois EPA would need to take when issuing a permit that prescribed emission factors, the order serves to identify the underlying information that a permit applicant must provide in an application if it seeks a permit that would provide for use of prescribed emission factors. The Illinois EPA would then be responsible for assuring that the emission factors that are prescribed would be appropriate and sufficient for compliance or noncompliance with the associated emission limits to be reasonably determined.[40,]

> …IEPA [Illinois EPA] must include in the permit itself the monitoring methodology for determining compliance with these limits [emission factor limits and annual emission limits]. If using emission factors, IEPA must propose the actual emission factors in the permit or supporting permit record, and provide supporting documentation for the accuracy and appropriateness of these emission factors, such as historical source test data or other available information. If source test data are not readily available for a specific emission unit, as IEPA asserts, other sources of emission factors (including published literature and material and energy balances) must be reviewed and cited for acceptable emission factors before issuing the permit.
>
> USEPA, Order Responding to Petitioner's Request that the Administrator Object to Issuance of State Operating Permit, Petition Number V-2011-2, *In the Matter of United States Steel Corporation – Granite City Works, CAAPP Permit No. 96030056*, Petition Number V-2011-2, dated December 3, 2012, p. 12.

<u>Roof Monitor on the Basic Oxygen Furnace Shop – Particulate Emissions:</u>

[40] In an order concerning a Title V permit issued by the Texas Commission on Environmental Quality (TCEQ), the Administrator of USEPA stated the following when addressing the use of emission factors in the permit:

> …Moreover, the justification provided by a permittee in a permit application should not substitute for the judgment of the permitting authority (TCEQ) with responsibility for ensuring that a Title V permit contains sufficient monitoring to ensure compliance. If TCEQ wishes to adopt and incorporate an applicant's technical justification for specific monitoring into the current Title V permit record, it must, at minimum, identify specifically where such a justification is to be found (just as it would be required to do it if [sic]wished to incorporate by reference a requirement located elsewhere.)
>
> USEPA, Administrator, Order Responding to Petition Requesting Objection to the Issuance of Title V Operating Permit, Petition No. VI-2017-6, *In the Matter of BP Amoco Chemical Company, Texas City Chemical Plant, Galveston County, Texas, Permit No. 01513*, dated July 20, 2021, p. 18.

The 2022 application does not include support for the particulate emission factors that are proposed as prescribed factors for the roof monitor on the basic oxygen furnace shop (i.e., the uncaptured emissions from these furnaces). The application does include support for the baseline particulate emission rates for the roof monitor on the basic oxygen furnace shop.[41, 42] However, the permitting of the Project in 1996 relied upon various changes that were made to improve capture and control of emissions of particulate from the basic oxygen furnaces and decrease the uncaptured emissions of particulate. For example, a fourth section was added to the ESP in 1995, increasing the volume of air that it could handle. As such, the baseline particulate emission rates of the Project are not representative of future emissions with the Project. Moreover, the emission factors actually proposed in Section 5.5.2.2 in the 2022 application are lower than emission factor limits now contained in Table 2 of Permit 95010001 for the roof monitor on the basic oxygen furnace shop. For PM, an emission factor of 0.01986 pounds/ton is proposed as a prescribed factor, compared to the current emission factor limit of 0.0987 pounds/ton; for filterable PM_{10}, an emission factor of 0.0296 pounds/ton is proposed, compared to the current emission factor limit of 0.06614 pounds/ton. The 2022 application does not show that the emission factors for the roof monitor on the basic oxygen furnace shop that are proposed as prescribed emission factors in Section 5.5.2.2 of the application are representative.[43]

Caster Mold, Slab Cutoff/Ripping Processes in Continuous Casting:

[41] The baseline emission rates for the roof monitor are based on emissions factors from AP-42 for uncontrolled emission with application of 90 and 99 percent capture efficiencies for the refining process and the charging and tapping processes, respectively, being provided by the ESP control system on the furnaces in the baseline period before 1996 (2022 application, Section 5.5.2.2). While the application cites to Appendix C in the original application for the Project as support for these values for capture efficiency, this appendix only uses these assumed values of capture efficiency when calculating baseline emission rates for the Project. This appendix does not actually provide technical support for these values for capture efficiency being representative of the levels of capture efficiency that were achieved for particulate emissions of the basic oxygen furnaces in the baseline period for the Project. Appendix C also does not provide support for the higher levels of capture efficiency (95% and 99.9%) that it uses for operation and emissions for the basic oxygen furnaces with the Project.

[42] It should generally be noted that the sections of the 2022 application that provide the explanation or basis for the emission factors used in the application are not the sections in which prescribed emission factors are proposed for certain units. The basis for the different emission factors is typically provided earlier in the application in the sections of the application where baseline emission rates are addressed. For example, the particulate emission rates or factors for the roof monitor on the blast furnace casthouse are discussed in Section 5.2.3.3 (2022 application, p. 5-3); the proposed prescribed emission factors for this emission point, which are the same numerically, are provided later in Section 5.5.1.2 without further discussion (2022 application, p. 5-14 and 5-15).

[43] The emission factors that the 2022 application proposes to be prescribed for particulate emissions from the roof monitor on the basic oxygen furnaces may be appropriate at the present time given the installation of a baghouse control system on these furnaces. Nonetheless, for a revised permit to be issued that prescribes emission factors for emission from the roof monitor, the application must show that those factors are representative with the emission control measures that are required by the permit. It must also be recognized that those prescribed factors would not be representative of emissions before the new baghouse system was installed and operation of this system was required. As such, particulate emissions factors that are representative of particulate emissions circa 1996, before installation of the baghouse system on the furnaces, should be used in the revised netting analyses for PM and PM_{10}.

For the caster mold, slab ripping and slab ripping processes on the continuous casting lines, prescribed emission factors are proposed in Section 5.5.3 of the 2022 application that are identical to the baseline particulate emission rates for these emission units as generally discussed in Section 5.2.2.11, 5.2.2.13 and 5.2.2.14 of the application. In these sections, the application explained that these emission factors reflect emission factors from a report prepared by the Illinois EPA in 1991, i.e., "Illinois EPA 1991 EIS PM/PM_{10}." This is not sufficient to show that the emission factors that are proposed as prescribed factors are representative. In this regard, the statement that these factors were taken from a historic report prepared by the Illinois EPA does not show that this report included information showing why these factors should be considered representative and can be prescribed by a revised permit.

Mag-Lime Silo:

For the Mag-Lime Silo, a prescribed emission rate of 0.009 pounds/hour is proposed (2022 application, Section 5.5.4.2). As explained in the application, this unit, which stores the reagent used in desulfurization of iron in the basic oxygen furnace shop, was overlooked in the original permitting of the Project (2022 application, Section 5.4.4 and Footnote 34, p. 5-16 and 5-17). US Steel elected not to address its baseline emissions in the revised netting analyses for PM and PM_{10} because emissions are low, i.e., potential annual emissions less than 0.1 tons. However, the application does not include calculations explaining how US Steel determined that potential particulate emissions of this unit are less than 0.1 tons/year, much less information showing that a prescribed emission rate of D0.009 pounds/hour should be considered representative of the emissions of this unit.[44]

[44] The application also does not explain how US Steel determined that the potential annual particulate emissions of the Mag-Lime Silo are less than 0.1 tons. In this regard, the application does not include calculations that identify any assumptions about operation of this unit or the control of its emissions made by US Steel when calculating the potential emissions of this unit. For example, for particulate matter, was the outlet emission rate of the filter that is part of this unit assumed to be less than the regulatory limit of 0.03 grains per dry standard cubic foot pursuant to 35 IAC 212.308 and 212.313?

9. FOR THE ROOF MONITOR OF THE CASTHOUSE, THE APPLICATION DOES NOT SHOW THAT THE METHODOLOGY THAT IS PROPOSED TO BE PRESCRIBED FOR THE DETERMINATION OF NOx AND VOM EMISSIONS WOULD BE REPRESENTATIVE

For the NOx and VOM emissions of the roof monitor on the casthouse on the blast furnaces (i.e., uncaptured emissions, which do not pass through a control device), the 2022 application proposes a prescribed emission calculation methodology that involves the results of emission testing for the main baghouse for the casthouse and an assumed capture efficiency of 95 percent.[45] For example, for NOx emissions from the roof monitor, the application requests that,

> Prescribed emissions factors consistent with the approach described in Section 3 [Discussion of Permit Conditions Used to Restrict PTE] are provided herein. USS Granite City is proposing a prescribed emissions calculation methodology for NOx emissions from the blast furnace casthouse roof monitor based on application of 95% capture emissions to the NOx stack test result for the blast furnace casthouse baghouse.
>
> 2022 application, Section 6.5.1.2, Prescribed Emission Factors for Blast Furnaces Operations, p 6-9.

The application does not show that the "proposed methodology" would result in NOx and VOM emissions rates for the roof monitor that would be representative. In this regard, the proposed methodology would yield emission rates for the roof monitor that would be related directly to the measured emissions of the main baghouse on the casthouse. However, it would not address the effect of variation in capture efficiency on emissions. That is, with the proposed methodology, if emissions from the baghouse measured by a particular test were "lower," the calculated emission rate of the roof monitor would also be lower. The methodology would not address a situation in which the emissions measured by testing are lower because the capture efficiency of the baghouse system during testing was also lower. In this situation, there would actually be more emissions through the roof monitor. As such, unlike specific emission rates for NOx and VOM that would be prescribed in a revised permit, the "proposed methodology" would not address the NOx and VOM emissions from the roof monitor in a way that can reasonably be considered to be representative on an ongoing basis.[46, 47]

---

[45] With the proposed methodology, the NOx or VOM emission rate for the uncaptured emissions of the casthouse would be derived from the emission rate of the main baghouse measured by periodic testing using the following formula:

[{Measured rate of the baghouse (lbs/ton) ÷ 0.95} x 0.05] = Calculated rate for the monitor (lbs/ton)

[46] This issue would not be present with an appropriate prescribed emission factor. As such, a factor would not change based on the results of periodic testing, the factor could be reviewed when processing the application to confirm that it was conservatively developed so as to be representative on an ongoing basis.

[47] Section 7.5.1.2 of the 2022 application, which addresses the proposed calculation methodology for the VOM emissions from the roof monitor on the casthouse, erroneously refers to the results of emissions testing of the main baghouse system on the casthouse for NOx rather than testing for VOM.

10. THE APPLICATION DOES NOT INCLUDE NECESSARY SUPPORT FOR THE EMISSION FACTORS THAT ARE PROPOSED AS PRESCRIBED FACTORS FOR CERTAIN UNITS.

The 2022 application does not include relevant supporting information for certain emission factors used in the application, as follows. Absent this information the Illinois EPA cannot assess whether the prescribed emission factors proposed for these units should be considered representative.

Blast Furnace Casthouse Roof Monitor:
The prescribed particulate emission factors proposed for the roof monitor on the casthouse (i.e., the uncaptured emissions from the casthouse) are identical to the baseline emission rates. These rates are based on emission factors from AP-42 for uncontrolled emissions with application of a 95 percent capture efficiency for the baghouse control systems on the casthouse. The application only references a single memorandum from 2019 by various USEPA staff and a consultant as support for achievement of 95 percent capture efficiency (2022 application, Section 5.2.3). Further support is needed for a prescribed emission factor based on achievement of 95 percent capture.

Slag Pits:
For particulate emissions from quenching of slag, the 2022 application does not include a copy of the "EPA assessment" that is the basis of the emission factors and material showing how the selected emission factors were derived from this assessment. For emissions from transfer of slag, the application does not include a copy of the calculations by which the emission factors were developed from the formulas provided in AP-42, Section 13.2.4. The application also does not address whether the emission factors rely on control by the application of water or the presence of residual moisture and, if so, the basis for the assumed levels of control efficiency. (2022 application, Section 5.2.2.5, p 5-4).

Iron Pellet Screen:
For the Iron Pellet Screen, the proposed prescribed emission factor for PM and PM_{10} emissions is identical to the baseline emission rates (2022 application, Section 5.2.2.16). While the emission factor for uncontrolled emissions for screening of crushed stone in Table 11-19.2-2 in AP-42 is identified as the basis of this emission rate, a control efficiency of 85 percent is applied, reducing the factor that is actually used to 15 percent of the cited AP-42 factor. The application does not describe the means by which the particulate emissions of this screen are controlled or reduced to show that 85 percent control of particulate emissions is achieved for the Iron Pellet Screen.[48] In addition, AP-42 lists two emission factors for screening of crushed stone, one for PM and one for PM_{10}. The emission factor for PM is about three times the factor for PM_{10} (0.025 pounds/ton ÷ 0.0087 pounds/ton = 2.87, ~ 3). The 2022 application does not show that for screening of iron ore pellets, an emission factor that was developed for PM_{10} is directly transferable to PM emissions.

[48] The CAAPP permit, Condition 7.4.2 indicates that the Iron Pellet Screen is not served by emission control equipment.

11. THE DETERMINATIONS OF PARTICULATE EMISSIONS FROM HANDLING OF COKE, IRON PELLETS AND LIMESTONE ARE NOT SUPPORTED AND CANNOT BE CONFIRMED

With regard to baseline particulate emissions, the determination of baseline emissions from handling of coke, iron pellets and limestone provided in the revised netting analysis cannot be independently confirmed. In this regard, the 2022 application does not provide needed supporting information for the "corrected" determinations of baseline particulate emissions of these operations as it is not accompanied by detailed calculations for the emissions from handling each material. (2022 application, Table 5-5. "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM Emissions Factors for Affected Emission Units" and Table 5-6, "Pre-project Actual Emissions and Summary of Proposed Changes to Pre-Project PM_{10} Emissions Factors for Affected Emission Units.")[49]

With regard to emissions with the Project, the 2022 application does not include information for particulate emissions from handling of coke, iron pellets and limestone. Since the by-product coke oven batteries were not shut down until 2015, emission information is needed for handling of coal for the period of operation with the Project before the batteries were shut down. Likewise for coke, emission information is needed to address handling of coke before US Steel constructed the conveyor system to receive coke directly from the heat recovery coke production facility built by Gateway.[50]

[49] Tables 5-5 and 5-6 do refer to "Table F-3 of the 1995 application" for these material handling operations. A copy of this table is provided in Appendix B of the 2022 application. However, this table only appears to address PM_{10} emissions, for which it provides annual emissions in tons/year. This table does not include calculations and background information showing how the annual emissions of PM_{10} were determined. Finally, the data for annual emissions of material handling operations appears to rely on the "PM10 SIP" requiring a 90 percent reduction from uncontrolled emissions without providing any support for this assumption.

[50] As this new conveystem was constructed as part of a different project, i.e., the construction of the Gateway facility, rather than the Production Increase Project, US Steel should not address emissions that are specifically associated with this new system.

12. THE REQUESTED CHANGES TO THE GROUPING OF UNITS IN THE PERMIT FOR CONSISTENCY WITH THE GROUPINGS OF UNITS IN THE CAAPP PERMIT WOULD NOT ADDRESS ALL DIFFERENCES IN THE GROUPINGS OF UNITS

As addressed in Section 2.2.2 of the 2022 application, US Steel generally requests changes to the organization of Permit 95010001 because the areas or sections of the CAAPP permit in which certain units are addressed are different than those in Permit 95010001. Most notably, in Permit 95010001, discrete material handling and processing operations are addressed with either the blast furnace operations, operations in the basic oxygen furnace shop or the continuous casting operations, based upon the area with which they were considered to be associated. In the CAAPP permit, these discrete material handling and processing operations are generally addressed in a separate section of the permit, Section 7.1, "Material Handling and Processing Operations." In addition, in the CAAPP permit, the "Argon Stirring Station and Material Handling Tripper" was addressed with units in the basic oxygen furnace shop in Section 7.5 of the CAAPP permit rather than with the continuous casting operations as in Permit 95010001.

While it is reasonable for there to be consistency in the groupings or categorization of emission units in Permit 95010001 and the CAAPP permit, as generally requested by US Steel, several concerns are posed, as discussed below, by the specific changes to Permit 95010001 that have been requested.

Requested Changes for the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)"**:**

As explained in Section 11.1.2 of the 2022 application, US Steel requests that the "Argon Stirring Station and Material Handling Tripper (Ladle Metallurgy)" now be addressed in Permit 950100001 with operations in the Basic Oxygen Furnace Shop. The application also requests that this unit be identified as "Baghouse 2 for Argon Stirring and Ladle Metallurgy Facility." However, the application does not actually identify the specific units that would be addressed by the proposed new term. In this regard, the application is not accompanied by an itemized list of the equipment and activities that would be covered by this new term or a diagram that identifies this equipment and activities. US Steel's request also does not explain how the requested revision to Permit 95010001 would do what has generally been requested as the proposed new term would refer to a "Material Handling Tripper." As the 2022 application requests changes to terminology in Permit 95010001, the changes should act to better identify the emission units that would be addressed, improving the specificity and clarity of the revised permit.[51, 52]

Absence of A Request for Revisions for the "Deslagging Station and Material HS"**:**

[51] For example, the proposed new term would not make clear that the basic oxygen furnace shop actually has two ladle stirring stations and one ladle metallurgy furnace, all served by Baghouse 2.

[52] The requested change to the terminology for these emission unit(s) is also problematic as it would refer to a control device, Baghouse 2, rather than to the equipment or activities that generate emissions. Applied literally, the proposed term would only address captured emissions; it would not address the uncaptured emissions, which elude capture for control by the baghouse.

The 2022 application does not request any revisions to Permit 95010001 with respect to the Deslagging Station and Material HS (Handling System).[53] These emission units are currently addressed in Permit 95010001 with continuous casting operations (Permit 95010001, Condition 20 and Table 3). In the CAAPP permit, a "Steel Deslagging Station" is identified as one of the continuous casting operations (CAAPP permit, Condition 7.6.2(a)).[54] The 2022 application does not explain why this steel deslagging operation should not appropriately be categorized as slag skimming and addressed with the other slag skimming operations in the basic oxygen furnace shop. In this regard, for the argon stirring station, US Steel does explain in Section 11.1.2 of the 2022 application that this station should be addressed with operations in the basic oxygen furnace shop rather than with continuous casting operations. This is because this station is a "BOPF shop ancillary operation" for purpose of the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF (2022 application, Section 11.1.2). US Steel does not explain why the current placement in Permit 95010001 of the steel deslagging station with continuous casting is appropriate and this station should not also be addressed with other BOPF shop ancillary operations. Alternatively, US Steel does not request that this station be addressed with other

[53] For example, in Section 5.2, the 2022 application does not identify any updates or revisions to the pre-project actual emissions of the steel deslagging station and associated material handling system. Likewise, Appendix B – Emission Calculations does not identify any changes from the 1996 netting analyses that involve these units (Appendix B – Emission Calculations, USS Granite City – 1996 Production Increase Project: Revised PM PSD Net Emissions Increase Analysis and Revised PM10 PSD Net Emissions Increase Analysis).

[54] The presence of a deslagging station that is physically located in the continuous casting building is indicated in the pending application for renewal of the CAAPP permit. This application indicates that the particulate emissions of this station are controlled.

> Deslagging Station:
> Molten steel from the BOF is transferred directly from the BOFs to the continuous casting building. The first operation carried out in this building is the skimming of slag from the surface of the molten steel. Slag removed by this operation is skimmed into slag pots for disposal. Baghouse #1 is used to control emissions from this process.
>
> CAAPP Renewal Application, Appendix D: Process Descriptions, Section 7.6 Continuous Casting, Deslagging Station, p. D-56.

BOPF shop ancillary operations.[55] Slag skimming is one of the operations that 40 CFR 63.7852 defines as being "Basic oxygen process furnace shop ancillary operations."[56, 57]

For the "Deslagging Station and Material HS," the 2022 application also does not request revisions to Permit 95010001 as the CAAPP permit currently limits particulate emissions of this operation twice, once as a continuous casting operation and again as a material handling operation. In this regard, the CAAPP permit limits the particulate emissions of a "Deslagging Station and associated Material Handling System (Condition 7.6.6(a). As indicated by a reference in this condition, the CAAPP permit also limits emissions of a "Material HS and Deslagging Station" (Condition 7.1.6(b)(i)) in Section 7.1 of the CAAPP permit, where discrete material handling and processing operations are addressed. The 2022 application does not request revisions to Permit 95010001 to facilitate amendment of the CAAPP permit to appropriately address the emissions of this deslagging station and the associated material handling system. In the absence of such revisions, the current CAAPP permit would suggest that the revised netting analyses for particulate should address the emissions of these units twice, once as deslagging and once as material handling. On the other hand, if Permit 95010001 would address emissions of these units in this way, the consolidated emission limits for continuous casting and discrete material handling operations would be inappropriate as emissions of the deslagging station and the associated material handling system would be accounted for twice.[58]

---

[55] The proper categorization of this steel deslagging station is important when considering US Steel's request for consolidation of the emission limits currently set by Permit 95010001. As a general matter, any new, "consolidated" limits set by a revised permit must be developed to apply to sensible groupings of units. The groupings of units should facilitate identification in the revised permit of the regulatory requirements that apply to various units. This is especially true as the consolidated limits would rely on certain applicable regulatory requirements, e.g., the work practices and operational monitoring requirements under 40 CFR 63 CFR Subpart FFFFF, to assure consistent operation of emission units so as to keep short-term emissions at or below the established emission rates for the units.

[56] For this steel deslagging station, there is a potential compliance issue relative to the NESHAP, 40 CFR 63 Subpart FFFFF. The CAAPP permit indicates that the emissions of this station are not controlled (CAAPP permit, Condition 7.6.2). On the other hand, if its emissions are controlled by Baghouse 2, the direct applicability of the NESHAP to this station becomes a minor matter. This is because Baghouse 2 is directly subject to requirements of 40 CFR 63 Subpart FFFFF as it controls emissions from "ladle metallurgy." Ladle metallurgy is defined by 40 CFR 63.7852 as "… a secondary steelmaking process that is performed typically in a ladle after initial refining in a basic oxygen furnace to adjust or amend the chemical and/or mechanical properties of steel. This definition does not include vacuum degassing."

[57] It is also noteworthy that as the steel deslagging station is identified as a continuous casting operation by Permit 95010001, the permit applies 35 IAC 212.458(b)(8), which sets a limit of 5 percent, 6-minute average, for the opacity of emissions from the various continuous casting operations (Permit 95010001, Condition 19). However, Permit 95010001 omits the introductory language for this standard that provides that it does not apply to fugitive emissions. The introductory language is present in the CAAPP permit, which addresses the standards that apply to both fugitive and non-fugitive emissions of continuous casting operations (Permit 96030056, Conditions 7.6.3((b), (b)(ii) and (c)).

[58] If there was not actually a material handling system associated with the steel deslagging station, this could be readily addressed in the application for revisions of Permit 95010001. The application could acknowledge the error in the original application, as reflected in the permit that was issued, accompanied by an accurate diagram for the deslagging station as it existed in 1995 and as it now exists. In this regard,

For "Ladle Drying/Preheating," Absence of Any Request for Changes**:**
For "Ladle Drying/Preheating," the 2022 application does not request any changes to Permit 95010001 to maintain consistency with the approach to these units in the CAAPP permit. In Permit 95010001, these emission units are addressed with other Project-affected fuel burning units (Permit 95010001, Table 4, Certain Fuel Combustion Units). In the CAAPP permit, these units are addressed in Section 7.5 as "Basic Oxygen Processes" with other units in the Basic Oxygen Furnace Shop, as well as elsewhere in the permit with other Project-affected fuel burning units (e.g., Conditions 5.6.2((ii) and (iii)). In addition, the CAAPP permit sets a limit for the total NOx emissions of the BOF Shop (Condition 7.5.6(b)). In the absence of appropriate changes to the CAAPP permit, since the ladle drying/preheating takes place in the basic oxygen furnace shop, the limit for the NOx emissions of the basic oxygen furnace shop would apply to the sum of the NOx emissions of the basic oxygen furnaces and the ladle dryers/preheaters.

it is perhaps noteworthy that Permit 95010001 does not identify the material(s) that are handled by the material handling operations associated with the steel deslagging station.

13. THE 2022 APPLICATION DOES NOT REQUEST REVISIONS TO PERMIT 95010001 AND, INDIRECTLY, TO THE CAAPP PERMIT THAT WOULD ALSO BE NECESSARY AS THIS APPLICATION REQUESTS THAT THE REVISED PERMIT PRESCRIBE EMISSION FACTORS FOR CERTAIN UNITS

The 2022 application does not request revisions to general provisions in Permit 95010001 that would enable revisions to the CAAPP permit for the Granite City Works, Permit 96030056, to be made by administrative amendment to allow prescribed emission factors to be used to determine ongoing emissions of certain emission units. In this regard, the CAAPP permit currently provides that "appropriate emission factors" shall be used when determining emissions to evaluate compliance with the emission limits for process units set by Permit 95010001. Permit 95010001 does not specify how emissions are to be determined for this purpose, much less specify that, for certain emission units and pollutants, prescribed emission factors are to be used.[59] Accordingly, the procedures to determine compliance with the emission limits set by Permit 95010001 were established in the CAAPP permit for the Granite City Works. This was necessary because the emission limits set by Permit 95010001 are applicable requirements under the CAAPP. The procedures that were established in the current CAAPP permit do not provide for the use of prescribed emission factors. Rather, the CAAPP permit generally requires US Steel to use "appropriate emission factors," i.e., emission factors that do not understate emissions, with the primary responsibility for the appropriateness of the factors that are used placed on US Steel.[60] The CAAPP permit also provides for recordkeeping and reporting by US Steel so that the Illinois EPA and interested parties can know and may review for the emission factors that are being used. However, the 2022 application simply requests revisions to Permit 95010001 to require use of prescribed emission factors for certain units. The application does not address the fact that the CAAPP permit currently does not accommodate the use of prescribed emission factors to calculate emissions but instead requires use of "appropriate emission factors."[61]

[59] Condition 39(a) of Permit 95010001 did require "one-time testing" for various pollutant for certain emission units within 270 days of the date that this permit was initially issued. Additional time was subsequently provided to complete testing for the particulate emissions of a boiler when burning blast furnace gas. Unfortunately, the permit did not require testing of the NOx and VOM emissions of the BOFs. That testing was subsequently required by the CAAPP permit issued for the facility.

[60] This approach is consistent with a basic principle of the Title V permit program, as reflected in the CAAPP, that the responsibility for showing compliance with applicable air pollution control requirements for a facility lies with the source or Permittee for the facility, and not with the permitting authority.

[61] It should also be noted that in PCB 2013-53, the appeal that is pending before the Pollution Control Board for CAAPP permit 96030056, US Steel challenged Condition 5.13, General Procedures for Certain Permit Limits on Emissions. Condition 5.13 is relevant to the requested revisions of Permit 95010001 as it specifies procedures by which compliance is to be generally determined with the emission factor limits and annual emission limits set by Permit 95010001for process units. In addition to not proposing revisions to Permit 95010001 to accommodate use of prescribed emissions factors, the 2022 application does not address related revisions to Condition 5.13 of Permit 96030056 to potentially facilitate resolution of PCB 2013-53 as Condition 5.13 is challenged in this appeal.

14. THE 2022 APPLICATION DOES NOT ADDRESS THE AMENDMENT TO THE CAAPP PERMIT AUTHORIZED BY CONSTRUCTION PERMIT 11050006, AS IS RELEVANT FOR THE REQUESTED INTEGRATED PROCESSING OF THE REVISION TO PERMIT 95010001

The 2022 application does not identify the version of the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, Permit 96030056, that would be eligible for administrative amendment pursuant to the Integrated Processing of the revisions to Permit 95010001 that are requested. This is relevant because the Illinois EPA has already issued a construction permit with Integrated Processing, i.e., Construction Permit 11050006, issued April 1, 2013. This permit addresses the addition of a baghouse system to improve control of particulate emissions of the basic oxygen furnaces from charging and tapping of the furnaces. With the addition of this new system, the furnaces have three points of emissions, i.e., the new baghouse, the historic ESP, and the roof monitor on the furnace shop.[62] Certain work practices that were required by Permit 95010001 for control of particulate emissions of the furnaces with only an ESP system conflicted with the use of the baghouse system or would no longer be appropriate when emissions were also controlled with the new system. To address the fact that these work practices were also present in the CAAPP permit for the facility, Construction Permit 11050006 was subject to Integrated Processing and allowed certain changes to be made to the CAAPP permit by administrative amendment.[63] This was intended to enable use of the new baghouse system for improved control of particulate emissions in compliance with the CAAPP permit without the need for a subsequent permit proceeding to modify the CAAPP permit. However, US Steel has not initiated action for the Illinois EPA to actually issue an amended CAAPP permit with changes as authorized by Permit 11050006.[64]

Section 39.5(13)(a) of the Illinois Environmental Protection Act provides that "The Agency shall take final action **on a request** for an administrative permit amendment within 60 days after **the**

[62] The new baghouse system required a construction permit because this system would affect the requirements that then existed for control of particulate emissions of the basic oxygen furnaces, including their emissions of lead. For purposes of NSR, the construction permit was issued based on the new baghouse system being a project that would reduce the emissions of particulate and lead from these furnaces rather than increase these emissions. The permit was also based on this new system not increasing the emissions of other pollutants from these furnaces. As such, the construction permit for the new baghouse system, Permit 11050006, did not set limits for emissions from the baghouse system. This permit also did not lower the existing limits for the emissions of the basic oxygen furnaces

[63] To address the changes to the CAAPP permit that would be needed for use of the new baghouse system, Permit 11050006 provides for replacement of Section 7.5 of the CAAPP permit, which addresses the basic oxygen furnace shop, including the basic oxygen furnaces, in its entirety. The new version of Section 7.5 addresses the basic oxygen furnace shop with the new baghouse system. Given the extent of the changes to Section 7.5 that were needed to accommodate addition of a baghouse to the particulate control system for the basic oxygen furnaces, this approach was taken to Permit 11050006 to provide accuracy, clarity and simplicity in the revisions to the CAAPP permit that were being authorized.

[64] The 2022 application does address the addition of the baghouse control system for the basic oxygen furnaces as related to the emission of the furnaces. US Steel does not propose separate limits set for the individual emission points for these furnaces. Instead, the application requests that the revised permit set overall limits for the emissions from the control systems of the basic oxygen furnaces.

receipt of the request." (Emphasis added.) Accordingly, in the absence of a formal request from US Steel to the Illinois EPA to initiate the administrative amendment of the CAAPP permit contemplated by Permit 11050006, the 2022 application can only request Integrated Processing to allow administrative amendments of the current CAAPP permit, as has actually been physically issued by the Illinois EPA.[65, 66]

[65] The timing of the physical issuance of a revised CAAPP permit by the Illinois EPA is critical as a procedural matter because it starts the period within which the Permittee may appeal such action to the Pollution Control Board. Moreover, in PCB 2013-62, US Steel has already appealed certain elements of the changes to the CAAPP permit that are addressed by the administrative amendment to the CAAPP permit authorized pursuant to Permit 11050006.

Given this appeal, the Illinois EPA would not "reinstate" those provisions when issuing the amended CAAPP permit. Instead, it is expected that the amended CAAPP permit would contain notes that explain that the appealed provisions continue to be present in the that existing CAAPP permit as they were appealed. Nevertheless, it is possible that US Steel would appeal those notes in the amended permit as they would acknowledge the continued existence of the appealed provisions.

[66] Concerns are posed by certain conditions in existing Construction Permit 11050006 and the related amendments to CAAPP Permit 96030056 that it authorizes. The 2022 application is not accompanied by a request for changes to Permit 11050006 or a proposal for how to address these concerns so that they would not be perpetuated in the amended CAAPP permit. One concern is that the deadlines in Permit 11050006 for performing emission testing on the new baghouse and completing certain other actions were based on the basic oxygen furnaces being in routine use once the construction of the new baghouse system was completed. The permit did not contemplate the over two yearlong interruption in production that began in December 2015. US Steel undertook this interruption in production in response to the poor markets for domestic steel at that time. As such, although failures to meet certain deadlines in Permit 11050006 likely were reasonable, it is not clear that they would be excused as being due to *force majeur* (i.e., event(s) that could not reasonably be anticipated or controlled by the source).

The other concern with existing Construction Permit 11050006 and the related amendments to CAAPP Permit 96030056 is that they overlook the role of the existing ESP control system in controlling particulate emissions from charging and tapping of the basic oxygen furnaces. Instead, Permit 11050006 incorrectly indicates that the new baghouse system will control emissions from charging and tapping of the furnaces and the existing ESP system will control emissions from the refining process. In fact, the new baghouse system was constructed to improve control of emissions from charging and tapping, with capture hoods to collect particulate emissions that are not captured by the hoods that serve the ESP system. This is perhaps most clearly shown in the 2010 Memorandum of Understanding between US Steel and the Illinois EPA (MOU) as this MOU addresses improvement in the control of emissions from charging of the furnaces. Section 4(d) of the MOU acknowledges the presence of the existing control for charging with the ESP. It also indicates that control of emissions from charging could be improved by ducting either some or all of these emissions to a new baghouse system. In any case, the errors in the description of the new baghouse system for the basic oxygen furnaces in Permit 11050006 should also be corrected so that erroneous information is not perpetuated in the amendments to the CAAPP permit.

15. THE 2022 APPLICATION WOULD NOT CLARIFY THE RELATIONSHIP BETWEEN FUGITIVE DUST CONTROL MEASURES REQUIRED BY PERMIT 95010001 AND MEASURES REQUIRED BY 35 IAC PART 212 SUBPART K

For roadways, parking areas, and open access areas, Conditions 23, 24, 26, 27, 28, 29 and 30 of Permit 95010001 require implementation of control measures for emissions of fugitive dust. The 2022 application does not make clear the relationship between these requirements established by permit and state regulatory requirements for fugitive emissions in 35 IAC Part 212 Subpart K.[67] In particular, Condition 29 requires daily recordkeeping for the implementation of required measures for on-site dust control. However, it does not address the relationship between these permit-mandated records and the recordkeeping required by 35 IAC 212.316(e)(2).[68] At the same time, Permit 95010001 does address one requirement of 35 IAC Part 212 Subpart K as Condition 25 restates the requirement of 35 IAC 212.316(e)(1), which provides that the opacity of fugitive particulate matter emissions from any roadway or parking area at the Granite City Works shall not exceed 5 percent.[69] That Permit 95010001 does not currently deal with regulatory requirements for fugitive dust is an issue as Integrated Processing of a revision of this this permit requires that the compliance procedures in the revised revised be consistent with those required by the CAAPP.

---

[67] Incidentally, the CAAPP permit for the Granite City Works appears to erroneously apply the requirements of 35 IAC Part 212 Subpart K, to the requirements for off-site dust control in Permit 95010001. These regulatory requirements, including that subject sources must be operated under the provisions of an operating program designed to significantly reduce fugitive particulate matter emissions, are applicable to US Steel for sources of fugitive dust at the Granite City Works. However, 35 IAC 212.302 appears to provide that the various emission standards and control requirements in 35 IAC Part 212 Subpart K, other than the general standard for the opacity of fugitive emissions in 35 IAC 212.301, apply for emission units for fugitive dust at certain types of facilities, including manufacturing facilities. Accordingly, these regulatory requirements would not apply to off-site roadways and the compliance procedures for the control measures for off-site roadways should instead be established by permit.

[68] For example, for roadways and parking areas at a steel mill in Granite City (i.e., the Granite City Works), 35 IAC 212.316(g)(2) requires the owner or operator to keep the following detailed records related to the application of control measures for these units:

> 35 IAC 212.316(g)(2) …
>
> D) For each application of water or chemical solution to roadways by truck: the name and location of the roadway controlled, application rate of each truck, frequency of each application, width of each application, identification of each truck used, total quantity of water or chemical used for each application and, for each application of chemical solution, the concentration and identity of the chemical;
> E) For application of physical or chemical control agents: the name of the agent, application rate and frequency, and total quantity of agent, and, if diluted, percent of concentration, used each day;
> F) A log recording incidents when control measures were not used and a statement of explanation.

[69] In Condition 31, Permit 95010001 also refers to 35 IAC Part 212 Subpart U, which also addresses fugitive emissions. For certain facilities, including the Granite City Works, it requires that the owner or operator prepare a contingency measure plan for reductions in particulate emissions that could be implemented in the event of an exceedance of the NAAQS for PM_{10}, 24-hour average. Incidentally, Illinois has never needed to implement the contingency plans required by 35 IAC Part 212 Subpart U.

16. THE 2022 APPLICATION DOES NOT ADDRESS CHANGES TO THE CAAPP PERMIT THAT ARE NEEDED DUE TO REVISIONS TO 40 CFR 63 SUBPART FFFFF, AS COULD BE EXPEDITED BY INTEGRATED PROCESSING OF PERMIT 95010001

The 2022 application does not address revisions to the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Integrated Iron and Steel Manufacturing Facilities, 40 CFR 63 Subpart FFFFF, made by USEPA in July 2020. (85 Federal Register, pages 42,074 – 42,130, July 13, 2020). Among other revisions to 40 CFR 63 Subpart FFFFF, USEPA acted to remove exemptions from the emission and opacity limits in this NESHAP for periods of startup, shutdown and malfunction (SSM). Accordingly, effective January 12, 2022, the emission and opacity limits of this NESHAP became applicable at all times. The requirements of this NESHAP that formerly dealt with SSM ceased to be applicable. Notably, subject sources would no longer be required to keep startup, shutdown and malfunction plans detailing the procedures for operating and maintaining subject emission unit(s) during periods of SSM, as had been required by 40 CFR 63 Subpart FFFFF as it had applied 40 CFR 63.6(e)(3) in the general provisions of the NESHAP regulations to subject sources,

These revisions to 40 CFR 63 Subpart FFFFF are relevant for Permit 95010001 and the revisions to this permit requested by the 2022 application. This is because Permit 95010001 relies on the applicable compliance procedures of 40 CFR 63 Subpart FFFFF (i.e., requirements for emission testing, opacity observations operational monitoring and recordkeeping), to verify consistent operation of the casthouse, the basic oxygen furnaces and other NESHAP-subject units and their emission controls, for the purposes of assuring compliance with the emission limits set by this permit for their emissions of particulate. This reliance occurs as the emission limits that are set or would be set by a revised permit would be restated in the CAAPP permit for the Granite City Works, Permit 96030056. The provision currently in CAAPP Permit 96030056 that reflect the exceptions to the requirements of 40 CFR 63 Subpart FFFFF for SSM create a break or interruption in this reliance on the NESHAP for purposes of enforceability of permit limits for emissions, even if the actual nature and effect of this break or interruption is uncertain. Any concern over such interruptions would be eliminated if the former provisions of the NESHAP regulations, which USEPA acted to strike in July 2020, were also no longer present in the CAAPP permit.[70]

[70] From a legal and practical perspective, the continued presence of the former provisions of 40 CFR 63 Subpart FFFFF in the CAAPP permit would be problematic. Would US Steel have to maintain startup, shutdown and malfunction plans as related to particulate emissions of NESHAP-subject units relative to permit limits for particulate emissions? Would the continued presence of these provisions in the CAAPP permit throw Integrated Processing of Permit 95010001 into question as the compliance procedures that would accompany the limits for particulate emissions in revised Permit 95010001 would not be consistent with the procedures required by the CAAPP? Would US Steel and the Illinois EPA have to delineate and then implement a secondary version of the compliance procedures that would deal with emissions of particulate from NESHAP-subject units during SSM events?

17. THE 2022 APPLICATION DOES NOT ADDRESS CHANGES TO THE CAAPP PERMIT THAT HAVE RESULTED FROM SHUTDOWN OF EMISSION UNITS, AS IS RELEVANT FOR THE REQUESTED INTEGRATED PROCESSING OF THE REVISION TO PERMIT 95010001

The 2022 application does not identify changes to the CAAPP permit for the Granite City Works, Permit 96030056, that are a consequence of permanent shut down of emission units, as generally addressed by Condition 9.11 of the CAAPP permit.

> Condition 9.11 Permanent Shutdown
> This permit only covers emission units and control equipment while physically present at the indicated source location(s). Unless this permit specifically provides for equipment relocation, this permit is void for the operation or activity of any item of equipment on the date it is removed from the permitted location(s) or permanently shutdown. …

While the 2022 application acknowledges that the by-product coke ovens at the Granite City Works have been shut down, this application does not separately address the consequences for the current CAAPP permit. The shutdown of these batteries was accompanied by the shutdown of coal and coke handling operations, the coke by-products plant, the handling of coke by-products, and possibly certain wastewater treatment processes.[71, 72] In addition, although not shut down, Boilers 11 and 12, Ladle Dryer/Preheaters and Slab Reheat Furnaces are no longer able to use COG as fuel since COG is no longer produced at the facility. As such, provisions in the CAAPP permit that identify or address the use of COG in these units are no longer necessary.[73] It

---

[71] The elimination of COG also affected the applicability of emission standards to certain units. For example, 35 IAC 212.458(b)(23) is no longer applicable to ladle dryers/preheaters, contrary to what is stated in Condition 7.5.3-1 of the CAAPP permit.

[72] US Steel's current application for renewal of CAAPP Permit 96030056, which was received by the Illinois EPA on December 3, 2013, also does not address shut down of the by-product coke oven batteries and other related operations at the facility. This application only acknowledges that changes to the CAAPP permit will be needed in the future to address the addition of the baghouse to the particulate control system for the basic oxygen furnaces when construction of the baghouse is complete.

> The existing equipment descriptions for the individual processes at GCW (Granite City Works) in the CAAPP permit sections 7.1 to 7.4 and 7.6 to 7.13 are generally accurate. However, the Basic Oxygen Furnace process described in the CAAPP permit condition 7.5 will eventually need to be updated with the new secondary baghouse added as part of the Emission Reduction Project (Construction Permit No. 11050006) once construction is complete.
>
> Application for Renewal of CAAPP Permit 95030056, Section 2.2.2, "Process Changes."

[73] Irrespective of whether certain provisions in the CAAPP permit related to use of COG are still necessary, Condition 5.6 of the CAAPP permit limits the SO_2 emissions of these units from use of COG. (This condition restates limits from Federally Enforceable State Operating Permit 94120017, originally issued December 12, 1994.) The absence of COG does not act to excuse US Steel from required recordkeeping and periodic reporting for emissions of SO_2 and PM_{10} from these units from use of COG (CAAPP permit, Conditions 5.9(e) and 5.10.3). It also does not excuse US Steel from required operational monitoring for the use and sulfur content of COG (CAAPP permit, Conditions 5.6(a) and

would be improper for the revised version of the CAAPP permit authorized by means of the Integrated Processing of a revision to Permit 95010001 to still physically include provisions that should no longer be present in the revised CAAPP permit given the permanent shutdown of the emission units that were subject to those provisions.[74] The responsibility to identify provisions in the CAAPP permit that should not be carried forward initially falls on US Steel as it is the CAAPP Permittee for the Granite City Works.[75] Moreover, as the 2022 application requests Integrated Processing of the requested revisions to Permit 95010001, the subsequent revisions to the CAAPP permit that would be authorized by the revisions to Permit 95010001 must fulfill the requirement that a CAAPP permit issued for a source accurately identify or address the emission units that constitute the source is being permitted.

7.3.9(f)). In this regard, the emission units addressed by CAAPP Condition 5.6, which are addressed by these requirements for operational monitoring, recordkeeping and reporting, have not been shut down.

[74] A fundamental requirement of the CAAPP is that applications for CAAPP permits must be truthful, accurate and complete. In this regard, Section 39.5(5)(e) of the Environmental Protection Act provides that "Each submitted CAAPP application shall be certified for truth, accuracy, and completeness by a responsible official in accordance with applicable regulations." Section 10(a)(i) of the Act provides that one of the standards of issuance for a CAAPP permit by the Illinois EPA is that "… the applicant has submitted a complete and certified application for a permit, permit modification, or permit renewal consistent with subsection 5 and 14 of this Section [Section 39.5 of the Act], as applicable, and applicable regulations." The requirement for an application to be truthful, accurate and complete is applicable to US Steel's current request for revisions to Permit 95010001 as it includes a request for Administrative Amendment to the CAAPP permit for the Granite City Works by means of Integrated Processing under the CAAPP. The scope of this requirement's applicability is not limited to only certain types of CAAPP applications, such as applications for initial CAAPP permits or renewals of CAAPP permits.

[75] As US Steel is the Permittee for a CAAPP source, it must periodically report compliance or noncompliance with each of the requirements set forth in the CAAPP permit. If US Steel believes that it is "in compliance" with regard to certain requirements in the CAAPP permit because those requirements have been affected by Condition 9.11 of the CAAPP Permit, it is appropriate for US Steel to request appropriate changes to the CAAPP permit by means of an appropriate application for amendment or modification of the CAAPP permit. This is especially true as certain requirements in the CAAPP permit that relate to use of COG apply to emission units that have not been shut down.

18. THE EVALUATION OF BEST AVAILABLE CONTROL TECHNOLOGY (BACT) IN THE 2022 APPLICATION FOR CARBON MONOXIDE (CO) IS NOT SUFFICIENT AND DOES NOT ADEQUATELY SUPPORT US STEEL'S PROPOSAL FOR BACT

The evaluation of Best Available Control Technology (BACT) for CO in Section 8 of the 2022 application lacks necessary information to support US Steel's proposal for BACT for CO for the emissions units for which this must be determined or redetermined under the PSD program as a consequence of the requested revisions to Permit 95010001. The evaluation addresses BACT for CO for the casthouse for which BACT must now be determined as it is now recognized that the casthouse emits CO. It also addresses BACT for CO for the blast furnace stoves as the 2022 application requests that the revision of Permit 95010001 allow for more emissions of CO from these units.

The Scope of the Evaluation

As explained in the 2022 application, consistent with the definition of BACT in Section 169(3) of the Clean Air Act (42 US Code Section 7479(3)) and as confirmed by USEPA guidance, a determination of BACT must consider options to control or reduce emissions of an emission unit besides add-on control devices.

> In the BACT analyses herein, the term "available" is used, consistent with U.S. EPA guidance to refer to any control strategy that is potentially applicable to the source type in question (i.e., a technology or control option that has a practical potential for application to the source category in general). These may include fuel cleaning, inherently lower polluting processes, and end of pipe control devices. All identified control strategies that are not inconsistent with the fundamental purpose and basic design of the proposed [sic] facility are listed in this step.
>
> 2022 application, Section 8.2.1.4, "Available Control Options," p. 8-4.

For the casthouse, when identifying control options, the BACT evaluation only identifies end-of-pipe or "add-on control" control options. The evaluation does not identify other process-related control options such as work practices (2022 application, Section 8.2.3.3). In contrast, for the blast furnace stoves, the evaluation identifies both add-on control options and a process-related control option. i.e., "Work Practice Standards, including good combustion practices" (2022 application, Section 8.2.2.3). The evaluation does not explain why process-related control options are not available for the casthouse.[76]

[76] Incidentally, with regard to the blast furnace stoves, the evaluation does not explain why "good combustion practices" are considered to be a type of work practice standard rather than a separate control option. In Section 8.2.2.6 "Step 5 - Establish CO BACT," the evaluation proposes operational monitoring for temperature and oxygen levels to confirm operation of the stoves for efficient combustion of fuel, thereby maintaining CO emissions within the level that is achievable given the nature of the physical and operational design of the stoves. The evaluation also separately proposes the less prescriptive practices that are more often considered to constitute good combustion practices. For example, Section 8.2.2.6 also

Support Provided for the Scope of the BACT Evaluation

For both the casthouse and the blast furnace stoves, the BACT evaluation in the 2022 application is not accompanied by supporting documentation for the investigation that was conducted into available control options. Instead, the evaluation simply states that a review of available control options was conducted. For example, for the casthouse, the evaluation states:

> Based on a review for BACT determinations in U.S. EPA's RBLC (RACT/BACT/LAER Clearinghouse) database and other literature, the control options that are potentially available to control CO emissions from the blast furnace casthouse are:
>
> - Capture system and thermal incineration and
> - Capture system and catalytic incineration.
>
> 2022 application, Section 8.2.3.3, p. 8-8.

When a BACT evaluation is submitted, it may be appropriate or necessary[77] for the application to also include documentary support for the review of available control options that was conducted. In this regard, BACT evaluations commonly include copies of information from the RBLC that is potentially relevant to the determination of BACT that must be made. Further explanation is also provided if some of that information is not considered applicable to the units that are the subject of the BACT determination. Likewise, as there is relevant information in the literature, especially as it is addresses available control options for the subject pollutant, copies of that information should be included in a BACT evaluation. This information enables the Illinois EPA, the USEPA and interested parties to confirm that the review of available control options for a BACT evaluation was thorough and can be relied upon to have reasonably identified potentially available control options for BACT.

Support Provided for Work Practices As BACT for the Blast Furnace Stoves

For the blast furnace stoves, the BACT evaluation for CO in the 2022 application is not accompanied by supporting documentation to support the claim that it is infeasible to measure their CO emissions so that BACT should not be set as a numerical emission standard.[78]

---

proposes to, "Conduct annual adjustment and tune-up to include, **at a minimum**, inspecting, adjusting, cleaning, or replacing instrumentation and operational control system components and inspecting the air-to-fuel ratio control system and adjusting as **appropriate** for **proper** operation." [Emphasis added.] Moreover, this statement of what would constitute "good combustion practices" for the stoves would be problematic as it would not be enforceable given the various qualifications, as highlighted, on the actions that are required actions to be taken.

[77] For the 2022 application, this information is considered necessary. BACT determinations for the CO emissions of casthouses for blast furnaces and blast furnace stoves are uncommon. The Illinois EPA does not have the ability based simply on its own experience and knowledge to confirm that the potential control options for CO BACT were reasonably identified in the BACT evaluations in the application.

[78] The definition of BACT at 35 IAC 204.280 provides that:

> USS Granite City is proposing work practice requirements rather than numeric limits as BACT. Numeric emission limitations are not proposed because direct measurement of emissions --*i.e.*, use of U.S. EPA reference test methods—is not feasible for any of the fuel emissions units subject to the BACT requirements for CO emissions. In particular, for the stack serving the blast furnace A stoves, there is no sampling port,[45] and for the stack serving the blast furnace B stoves there is no sampling port satisfying the location requirement in U.S. EPA Reference Method 1.[46] Each stack is refractory lined and is believed to be approximately one hundred years old.
>
> For the reasons presented above, numeric CO emission standards are not feasible for the blast furnace stoves.
>
> Footnote 45. For the one-time exhaust gas sampling event discussed in footnote 19 of this permit application, USS Granite City inserted a sampling probe into the stack through a pipe used to inject steam into the stack.
> Footnote 46. Appendix A-1 to 40 CFR part 60.
>
> 2022 application, Section 8.2.2.6, "Step 5 – Establish CO BACT," p. 8-7.

Further support is needed for the claim that measurement or testing of emissions of the blast furnace stoves is infeasible. While certain information about the stoves is provided, the application does not directly address the technological issues or costs that would be entailed to install suitable ports for testing on one or both sets of blast furnace stoves. For example, the application does not include diagrams for the existing ductwork of the stoves to address whether the configuration of this ductwork would accommodate installation of test ports at a location that would satisfy USEPA Reference Method 1. The application also does not show how the refractory lining on the stacks or their age, approximately one hundred years old, would present significant technical challenges and costs so that the installation of test ports at a suitable location should be considered infeasible. The application also does not show that there are other challenges that would need to be addressed or issues that should be considered, such as requirements of the Occupational Safety and Health Administration (OSHA), that would affect the technical feasibility and cost of installing suitable test ports on the stoves.

> If the Agency [Illinois EPA] determines that technological or economic limitations on the application of measurement methodology to a particular emission units would make the imposition of an emission standard infeasible, a design, equipment, work practice, operational standard or combination thereof, may be prescribed instead to satisfy the requirement for the application of BACT. Such standard shall, to the degree possible, set further the emission reduction achievable by implementation of such design, equipment, work practice or operation, and shall provide for compliance by means that achieve equivalent results.

19. THE APPLICATION DOES NOT ADDRESS BACT FOR SO_2 AND CO FROM USE OF COKE OVEN GAS (COG) IN THE BLAST FURNACE STOVES

The 2022 application does not demonstrate that Best Available Control Technology (BACT) was utilized as an aspect of the Project for the SO_2 and CO emissions of the blast furnace stoves, as required under the PSD program (e.g., 35 IAC 204.1100(c)). In this regard, unlike the original application, the 2022 application addresses emissions from use of coke oven gas (COG) as fuel in certain Project-affected units. (Refer to the revised netting analyses for the Project for particulate, NOx and VOM and in the 2022 application.) As the 2022 application now addresses emissions of certain pollutants from burning of COG in fuel-burning units, including the blast furnace stoves, this application must also address the related consequence for emissions of SO_2 and CO under the PSD program from burning COG in the stoves. SO_2 and CO are pollutants for which the Project is a major modification subject to PSD. However, the 2022 application does not address BACT for SO_2 and CO as applied to use of COG in the stoves. As such, the 2022 application does not demonstrate that prior to February 2015, when the by-product recovery coke oven batteries at the Granite City Works were shut down and COG ceased to be available, BACT was being utilized for the SO_2 and CO emissions from use of COG in the stoves.

With respect to CO, it is relevant that the BACT demonstration in the 2022 application focuses on CO emissions from burning of fuels other than COG. For fuel burning units, the 2022 application states that "CO emissions of these units result primarily from incomplete combustion during the firing of BFG and natural gas." This ignores the historic contribution of COG to the CO emissions of the stoves prior to February 2015. The 2022 application also does not state that, as of February 2015, it was no longer necessary to address CO emissions from use of COG because COG was no longer produced and available for use.

20. AS RELATED TO SO_2 EMISSIONS FROM USE OF BFG, THE 2022 APPLICATION IS INCONSISTENT WITH A PENDING 2008 APPLICATION

In 2008, US Steel applied for revisions to Permit 95010001 to increase permit limits for the sulfur content of BFG and the SO_2 emissions resulting from the use of BFG. That application (the 2008 application) was received on February 4, 2008. The 2022 application is inconsistent with and conflicts with the 2008 application. As such, these applications, as they currently exist, cannot be processed by the Illinois EPA absent appropriate action by US Steel on one or both of these applications, e.g., changes to the 2022 application so that it requests the same revisions to SO_2 emission limits for use of BFG as the 2008 application. In this regard, the 2022 application "… does not request any changes to the emission limits for SO_2 and lead emissions established in the Construction Permit 95010001." (2022 application, p. 2-2.) The 2008 application does request changes to the provisions of the permit for SO_2 as it is an "Application to modify to correct the emission factors used to develop the original application and permit in light of newly identified information on emissions and emission factors." (October 2008 application, p. 1-1.)

In particular, in the 2008 application:

> …US Steel seeks to revise the Production Increase Permit (95010001) to account for US Steel's revised method for calculating the SO_2 emissions from BFG combustion. This will increase the total allowable SO_2 emissions on an annual basis from combustion of BFG in the Production Increase Permit.
>
> 2008 application, pp. 2-2 and 2-3

The 2008 application specifically requests that the SO_2 emission factor limit for BFG be increased from 6.65 to 16.00 pounds/million cubic feet of gas burned. With the revised emission factor, the permitted SO_2 emissions from use of the 185,030 million cubic feet of BFG per year, as allowed by the permit, would increase from 615.22 to 1480.24 tons/year. However, the 2022 application provides that the limits for SO_2 for use of BFG should be unchanged. As such, the 2022 application indicates that for use of BFG the requested revised permit should continue to limit SO_2 emission to 6.65 pounds/million cubic feet burned and 615.22 tons/year.

Moreover, the existence of the 2008 application suggests that the revisions to SO_2 emission limits that it requested were needed at the time of that application. The 2022 application does not show that this was not the case, as it does not address historic SO_2 emissions from use of BFG to show that an SO_2 emission factor of 6.65 pounds/million cubic feet was appropriate when Permit 95010001 was originally issued in 1996 and that annual SO_2 emissions have never exceeded 615.22 tons/year.

21. AS RELATED TO EMISSION LIMITS FOR SO_2, LEAD AND CO, THE 2022 APPLICATION IS INCONSISTENT WITH PENDING BOARD APPEALS

As already mentioned, the 2022 application does not request any changes to the emissions limits for SO_2 and lead currently set by Permit 95010001. The application states, "This permit application also does not request any changes to the SO_2 and lead emission limits in Construction Permit No. 950100001, so SO_2 and lead emissions will not be discussed further." [2022 application, Section 2.2, "General Description of Requested Permit Revisions." p. 2-2.][79, 80, 81] For CO, the 2022 application does request that the revised permit address emissions of CO from the casthouse and raise the limits for CO emissions of Project-affected fuel burning units.[82]

---

[79] In Section 3 of the application, in which support for elimination of emission factor limits and use of group limits is generally provided, the application only addresses limits for particulate, NOx and VOM. For example, the application states that,

> The approach proposed by USS Granite City with respect to the PM, PM_{10}, NOx and VOM emissions caps to be used in any revised Construction Permit No. 95010001, including the proposed revisions to certain emission limitations, compliance demonstration requirements, and other permit conditions as discussed in detail in Sections 5 through 7 of the permit application ["Proposed Changes to Permit Terms for PM and PM_{10} Emissions Increases Analyses," "Proposed Changes to Permit Terms for NOx Emission Increases Analysis, and "Proposed Changes to Permit Terms for VOM Emission Increases Analyses," respectively] is consistent with policy and precedent and will improve the enforceability of the PTE limitations in Construction Permit No, 95010001. In particular, USS Granite City emphasizes that removal of certain conditions and provisions addressing emissions individual emission units or emission points, including both limits on annual emissions and provisions emission addressing emissions factors will not result in impairment of the enforceability of the PTE limitations.
>
> 2022 application, Section 3, "Discussion of Permit Conditions Used to Restrict PTE [Potential to Emit]," 3-3.]

[80] For process operations, Permit 95010001 currently limits SO_2 emissions from the casthouse and slag pits associated with the blast furnaces in pounds per ton of iron produced and tons per year. For the casthouse, the SO_2 emissions of the main baghouse for the casthouse, the baghouse for the iron spouts at the casthouse, and the uncaptured emissions from the casthouse are limited, respectively, to 0.2006, 0.0073, and 0.0104 pounds per ton of iron produced. The SO_2 emissions of the slag pits are limited to 0.0100 pounds per ton of iron produced. (Permit 95010001, Condition 5 and Table 1.)

Although the emission factor limits for the SO_2 emissions of the casthouse are not identified as Best Available Control Technology (BACT) by Permit 95010001, these limits are considered to be the determination of BACT for SO_2 and should have been identified as such in this permit. BACT is required for the casthouse for SO_2 because the Project was a major modification for SO_2 under the PSD program, as is stated in this permit. Accordingly, as Project included physical changes to the blast furnaces to increase their production capability, BACT is required for the SO_2 emissions of the casthouse.

[81] For operations in the basic oxygen furnace shop, Permit 95010001 currently limits lead emissions in pounds per hour and tons per year. For the basic oxygen furnaces, the lead emissions from the ESP stack and roof monitor are limited to 0.01934 and 0.0129 pounds per hour, respectively. The lead emissions from desulfurization and hot metal transfer are limited to 0.0133 pounds per hour. (Permit 95010001, Condition 18 and Table 2.) The permit does not address the lead emissions of the basic oxygen furnaces that are now captured and controlled by the new baghouse system nor does the 2022 application request any revisions to the permit to address the lead emissions of these furnaces that now occur from the stack of the baghouse.

[82] In the original application for Permit 95010001, the casthouse was not identified as a source of CO and information for CO emissions was not provided. The application also requests certain updates to the

However, the application does not request revisions to the emission limits currently in Permit 95010001 for the CO emissions of the basic oxygen furnaces, i.e., the limits in pounds per ton of steel produced and in tons per year for the CO emissions of these furnaces through the ESP stack.[83,] As such, the application is not consistent with two pending permit appeals before the Board, PCB 0013-53 and PCB 0013-62, as it does not propose revisions to current permit limits for emissions of SO_2, CO and lead. As previously discussed, in these appeals, US Steel challenged all emission factor limits set by Permit 95010001 for individual process operations. US Steel has not amended these appeals so that they only address emission factor limits for PM, PM_{10}, NOx and VOM and no longer address the t emission factor limits that are set for SO_2, CO and lead. In addition, in the 2022 application, US Steel does not explain why the emission factor limits in Permit 95010001 for SO_2, CO and lead that were appealed are no longer considered to be objectionable. That is, US Steel would not again challenge those limits as it has already done in PCB 0013-53 and PCB 0013-62 if a revision to Permit 95010001 were issued that continued to include the current emission factor limits.[84]

With regard to the CO emissions of the basic oxygen furnaces, the 2022 application also does not request revisions to Permit 95010001 as the current permit only addresses CO emissions from the "BOF ESP Stack." The application does not request that these limits be revised so that they address all stack emissions of the basic oxygen furnaces, e.g., CO emissions from both the stack of the new baghouse system and the stack of the ESP system. Moreover, as the 2022 application does not propose such revisions to the current limits for CO emissions of these furnaces, the application effectively requests a relaxation of the current limits. This is because the revised permit would not address the CO emissions of these furnaces that now occur through the baghouse stack. That is, the limits in the revised permit would not account for any CO emissions that are no longer being captured with the ESP system and are instead now being emitted from the baghouse system.[85]

---

limits for CO emissions from use of blast furnace gas and natural gas in Project-affected fuel burning units to reflect new information for the CO emissions from burning these fuels.

[83] Permit 95010001 currently limits CO emissions of the basic oxygen furnaces through the ESP stack to 8.993 pounds per ton of liquid steel produced and 16,097.47 tons/year. (Permit 95010001, Condition 18, Table 2, Section 1, BOF ESP Stack.) The permit does not address CO emissions that are now captured by the new baghouse system and emitted from its stack or any uncaptured CO emissions, which occur through the roof monitor.

[84] If the subject emission factor limits were included in a revised permit, the Illinois EPA could explain that, if these limits in the revised permit were stayed pursuant to an appeal to the Pollution Control Board, the limits would continue to be enforceable pursuant to Permit 95010001 as issued before the revision of the permit and any appeal of the revised permit to the Board.

[85] The 2022 application also does not request revisions to Permit 95010001 to address uncaptured CO emissions of the basic oxygen furnaces or otherwise address the uncaptured CO emissions of these furnaces. This is not consistent with the approach taken for the casthouse on the blast furnaces. For the casthouse, the application requests that the revised permit limit the overall emissions of CO from the stacks on the control systems serving the casthouse. The application also includes information for the overall CO emissions of the casthouse, including other captured emissions and uncaptured emissions.

> As discussed in Section 8.2.3.7 of this permit application [BACT Evaluation for Blast Furnace Casthouse], USS Granite City is proposing a CO BACT emission limit of 70 lb/hr based on total emissions of these two baghouses [main casthouse baghouse and iron spout baghouse], assuming

22. THE 2022 APPLICATION DOES NOT INCLUDE A SIGNED CERTIFICATION FOR THE ACCURACY AND COMPLETENESS OF THE APPLICATION

The 2022 application does not include a signed certification for the truth, accuracy and completeness of this application as it was actually submitted in October 2022, as required by 35 IAC 201.159 and Section 39.5(5)(e) of the Illinois Environmental Protection Act. In its place, the 2022 application includes a photocopy of an earlier certification, dated February 25, 2022, which was submitted with a prior application (2022 application, "Appendix A – Application Forms (Copies of Previously Submitted Versions)"). However, the 2022 application is a revision of the earlier application and US Steel intends the 2022 application to replace the earlier application submitted in March 2020 in its entirety (2022 application, Cover Letter). Accordingly, the 2022 application must include a new certification for its truth, accuracy and completeness.

95% capture efficiency for the capture system associated with the cast baghouse, as discussed in Section 5.2.3 of this permit application {A&B Blast Furnace Casthouse Roof Monitor Emissions PM_{10} Revised], the fugitive CO emissions from the casthouse roof monitor are 3.1 lb/hr. Total CO emissions from the casthouse roof monitor, including both baghouse and fugitive emissions are 73.1 lb/hr and 320 tons per year ("TPY").

2022 application, Section 4.4, "Updated CO Emissions Information for Blast Furnace Casthouse."

Illinois Environmental Protection Agency

Notice of Intent to Deny and Public Comment Period
Application for a Revision to a Construction Permit/PSD Approval
US Steel Corporation in Granite City

United States Steel Corporation (US Steel), 1951 State Street, Granite City, has applied to the Illinois Environmental Protection Agency (Illinois EPA) for a revision to an air pollution control construction permit/PSD (Prevention of Significant Deterioration) approval that was originally issued in 1996 for a production increase project at its steel mill located in southeastern Granite City (the Granite City Works). This facility emits particulate, sulfur dioxide, lead, volatile organic material, nitrogen oxides (NOx), and carbon monoxide (CO). The application requests increases in permitted emissions of CO, which the original application understated. As the application requests increases in permitted CO emissions for which the project originally was a major modification subject to PSD, the current application must address compliance with Illinois' rules for PSD, 35 Illinois Administrative Code Part 204. The application also does not show that the requested increase in NOx emission would not make the project a major modification for NOx. Based on its review of the application, the Illinois EPA has made a preliminary determination that the current application does not comply with the applicable air pollution control regulations. As the application requests revisions to provisions of the permit that would relate to PSD, the Illinois EPA has prepared a draft permit denial letter for public review and comment.

The Illinois EPA is accepting comments prior to making a final decision on this application. **Comments must be postmarked by 11:59 pm, August 21, 2023.** All persons, including the applicant, shall raise all reasonably ascertainable issues and submit all reasonably available arguments supporting their position by the close of the public comment period.

If sufficient interest is expressed in this matter, a hearing or other informational meeting may be held. Comments, questions and requests for information should be directed to Brad Frost, Office of Community Relations, Illinois EPA, PO Box 19506, Springfield, IL 62794-9506, phone 217/782-7027, TDD 866/273-5488, brad.frost@illinois.gov.

Persons wanting more information may view the draft permit denial letter and project summary at https://epa.illinois.gov/public-notices/boa-notices.html The repository for these documents and the application are located at the Illinois EPA's offices at 1101 Eastport Plaza Drive, Suite 100, Collinsville, 618/346-5120 and 1021 N. Grand Ave. East, Springfield, 217/782-7027. (Please call ahead to assure that someone will be available to assist you). Copies of the documents will be made available upon request to the contact listed above.

The facility is located in a potential Environmental Justice area. More information concerning Environmental Justice may be found at https://epa.illinois.gov/topics/environmental-justice.html

July 2023

Project Summary for the Proposed Denial of an Application* from United States Steel Corporation – Granite City Works for Revisions to a Construction Permit/PSD Approval Issued for a Production Increase Project at its Mill in Granite City

Site Identification No.: 119813AAI
Permit/Application No.: 95010001

Illinois EPA Contacts:
Review Engineers: Minesh Patel, Christopher Romaine and Jason Schnepp
Community Relations Coordinator: Brad Frost

Schedule for Public Comment Period:
Comment Period Begins: July 21, 2023
Comment Period Scheduled to Close: August 21, 2023

*. In its application, U. S. Steel asks that the requested revisions of Permit 95010001 be processed by the Illinois EPA with "Integrated Processing," as is allowed by Section 39.5(13)(a) and (c)(v) of the Illinois Environmental Protection Act. Integrated Processing of the revised permit would allow changes to the Clean Air Act Permit Program (CAAPP) permit for the Granite City Works, as would be set forth in the revised permit, to subsequently be made by means of an Administrative Amendment of the CAAPP permit. Integrated Processing would require that the revision of the permit provide for compliance requirements that are substantially equivalent to those that are required in CAAPP permits. The processing of the permit must also be subject to procedural requirements that are substantially equivalent to those that apply for issuance CAAPP permits, including an opportunity for USEPA to review and comment upon a proposed version of the revised permit following completion of a public comment period on the draft of the revised permit.

1. Introduction

United States Steel - Granite City Works (US Steel) has applied to the Illinois EPA for revisions to an air pollution control construction permit (Permit 95010001) for a project at its Granite City Works, the steel mill in Granite City. This project (the "Project") involved increases in the permitted production of iron and steel by this facility. As this facility is a source of emissions, Permit 95010001 provided approval for the Project under both Illinois' construction permit programs for sources of emissions and the Prevention of Significant Deterioration (PSD) program under the federal Clean Air Act. This permit was originally issued in January 1996 to National Steel and was transferred to US Steel after it became the owner of the facility. This proposed denial involves the US Steel's revised application submitted in October 2022 (the "2022 application").

A key reason why revisions to Permit 95010001 are needed is that emission testing conducted in 2014 on the two basic oxygen furnaces (BOFs), in which steel is produced, showed their emissions of nitrogen oxides (NOx), as well as volatile organic material (VOM), are higher than is allowed by this permit. This is because the original application understated the NOx and VOM emissions of the BOFs and the emission limits in this permit were based on information in the original application.

US Steel has worked to prepare an application for revisions to Permit 9501001 that would allow more emissions of NOx and VOM from the BOFs. The 2022 application also addresses other issues that are now posed by the manner in which the Project was originally permitted and subsequent changes that have occurred at the facility. Notably, the emissions of carbon monoxide (CO) of certain units have also been found to be higher than stated in the original application. A baghouse control system has been installed for the BOFs to improve control of particulate emissions from charging and tapping of these furnaces. The byproduct coke oven batteries formerly at the facility were shut down in 2015. A brief description of some of the revisions to Permit 95010001 that US Steel has requested is provided at the back of this document in Appendix 1. The requested revisions do not include increases in the permitted iron and steel production of the facility as allowed by this permit as issued in 1996.

The Illinois EPA has made a preliminary determination that the 2022 application should be denied. The reasons for this are set forth in the draft of the proposed denial that has been prepared. Brief descriptions of the reasons why the Illinois EPA has determined that the 2022 application should be denied are provided in Appendix 2 of this document. For some requested revisions to Permit 95010001, the application should be denied because it does not show that they would comply with the relevant regulatory requirements and USEPA policy that apply to this permit. For other requested revisions, the application does not include the information needed to support those revisions or enable those revisions to be made as a practical matter. In addition, the application should be denied because it would not allow for processing of a revised permit with Integrated Processing, as has been requested. If the Illinois EPA's final decision is to deny this application, it is expected that Permit 95010001 would continue in effect as it now exists until and unless action is taken on a subsequent application.

As required by the PSD program, the Illinois EPA is holding a public comment period on its preliminary determination that the 2022 application should be denied and the draft denial letter that

has been prepared. This will allow for the public to consider and comment on this planned action and the draft of the denial letter that the Illinois EPA has prepared.

2. Background on the Granite City Works

The Granite City Works are an integrated steel mill, making both iron and steel. It has two blast furnaces to make iron from iron ore and an associated casthouse located between them in which tapping of iron and slag from the furnaces take place . Two basic oxygen furnaces (BOFs) are used to process iron from the blast furnaces, together with scrap metal, into steel. Before molten iron from the blast furnaces is charged to a BOF vessel, the iron undergoes "desulfurization" with a reagent to remove sulfur from the iron. Ladles of molten steel produced in the BOFs are transferred to "ladle metallurgy" where with the final additions of alloying materials are made to the molten steel. The two basic oxygen furnaces, the iron desulfurization operation, and the ladle metallurgy operations are all located in the basic oxygen furnace shop (BOF shop). From ladle metallurgy, the ladles of molten steel are transferred to the continuous casters in an adjoining building. The solid steel slabs from continuous casting are processed in rolling mills at the source, which make long, thin strips of steel that are wound in coils. Steel slabs from the casters also go to other plants to be made into finished steel.

Other operations at the Granite City Works include raw material handling and storage, steam boilers, and fuel-burning process equipment. The raw material handling and storage operations handle raw materials, such as iron ore pellets, limestone and other fluxing agents, coke, and alloy materials, for the iron and steel making operations. The steam boilers can burn both natural gas and blast furnace gas (BFG). BFG is a low heat content gaseous byproduct from the blast furnaces. BFG is the principal fuel for the blast furnace stoves in which the blast air supply for these furnaces is heated. Other fuel-burning process equipment at the source burns natural gas. Vehicle traffic on roads and parking lots at the Granite City Works also is a source of emissions of fugitive dust.

The Granite City Works formerly included two by-product recovery coke oven batteries and associated by-product processing plant. These operations were permanently shut down in February 2015. The primary source for coke used in the blast furnaces is now two heat recovery coke oven batteries in Granite City that are operated by Gateway Energy. With the shutdown of the by-product recovery coke oven batteries, coke oven gas is no longer produced and available for use in the blast furnace stoves, boilers and other fuel-burning equipment at the Granite City Works that previously used coke oven gas to provide a portion of their fuel.

Granite City is located in Madison County, which is part of the S. Louis Major Metropolitan Area. Madison County is designated nonattainment under the federal Clean Air Act for the National Ambient Air Quality Standard (NAAQS) for ozone.[1] For other pollutants for which there are NAAQS, i.e., carbon monoxide (CO), lead, nitrogen dioxide (NO_2), particulate matter$_{10}$ (PM_{10}), particulate matter$_{2.5}$ ($PM_{2.5}$) and sulfur dioxide (SO_2), Madison County is designated attainment or unclassifiable. USEPA maintains information about current ambient air quality for ozone and particulate on the internet at AirNow (airnow.gov). The Illinois EPA prepares annual reports for

[1] Air quality designations are adopted by USEPA. The designations for Illinois are found at 40 Code of Federal Regulations (CFR) 81.314.

ambient air quality as measured by its network of air monitoring stations around the states. These reports are also available on the internet (epa.illinois.gov/topics/air-quality-reports).

The Granite City Works are in an area that is of concern for Environmental Justice. As such, any proposed permit actions involving this facility are subject to the Illinois EPA's "Environmental Justice Policy." As addressed in this policy, the Illinois EPA is committed to protecting the environment and the health of the residents of Illinois, and to promoting equity in the administration of its environmental programs.

3. The Production Increase Project or the "Project"

In January 1996, National Steel, the former owner of the Granite City Works was issued Construction Permit 95010001 for increases in the allowable production of iron and steel by the Granite City Works, also referred to as the "Production Increase Project" or the "Project." As explained at that time, the increases in production would in part involve continuing improvements in the operation and maintenance of equipment, which is something that normally occur over the course of time. These would involve things such as the availability and use of ore pellets with higher yield, the availability and use of better refractories linings for furnaces, and ongoing improvements in maintenance practices that would reduce the frequency and duration of furnace outages for maintenance. However, the Project also involved certain physical changes to emission units to enable increased production of iron, i.e., changes to the blast furnace stove blowers to increase their air flow capacity. As such, the Project entailed a modification to the Granite City Works for which an air pollution control construction permit was needed.
